Written Submission

for the
Royal Society for the Protection of Birds
and Suffolk Wildlife Trust

Submitted for Deadline 2
2 June 2021

Planning Act 2008 (as amended)

In the matter of:

Application by NNB Generation Company (SZC) Limited for an Order Granting Development Consent for

The Sizewell C Project

Planning Inspectorate Ref: EN010012
RSPB Registration Identification Ref: 20026628
Suffolk Wildlife Trust Registration Identification Ref: 20026359

Contents

1. INTRODUCTION 11

2. SUMMARY OF OUR CONCERNS 11

3. ENVIRONMENTAL CONCERNS 14

Land take from Sizewell Marshes SSSI (including impacts of the SSSI crossing) 14

Summary 14

The principle and justification for the proposed loss of part of Sizewell Marshes SSSI 15

Temporary land take from Sizewell Marshes SSSI 16

Adequacy of the proposed habitat compensation 16

Hydrological impacts on Sizewell Marshes SSSI 16

Introduction 16

The principle and justification for the proposed loss of part of Sizewell Marshes SSSI 17

Introduction 17

Legislation and Planning Policy 17

SSSI Crossing 18

Change to the SSSI crossing design to a single span bridge with embankments 19

Temporary land take from Sizewell Marshes SSSI 21

Adequacy of the proposed habitat compensation 22

Quantity, quality and timing of functionality of all the proposed habitat compensation 22

Fen meadow 22

Potential impacts from the proposed Pakenham Fen site on Pakenham Meadows SSSI 24

Potential impacts from the Benhall Fen Meadow site on the Abbey Farm compensation site 24

Wet woodland 25

Conclusions 26

Coastal Processes and RSPB Minsmere 27

Introduction 27

Sites and species of concern 29

International Importance 30

Summary of concerns relating to coastal processes 30

Summary of concerns relating to the assessment of coastal processes 34

Comments on implications of the changes to the application on coastal processes 36

Conclusions regarding impacts on coastal processes on protected sites and species 37

Mitigation and monitoring 37

Lack of detailed design 37

Mitigation activity in response to triggers 37

Mitigation activity and designated sites 38

Overall approach to Monitoring and Mitigation 39

Hydrology (surface water impacts) 40

Introduction 40

Minsmere RSPB Reserve 40

The relevance of water levels for the Ecology of RSPB Minsmere 42

Concerns regarding potential impacts on water levels of the Minsmere to Walberswick designated sites 44
Proposed Primary Mitigation to manage potential impacts 45
Approach to Monitoring and Mitigation 48
Potential impacts of water levels on the Minsmere to Walberswich SPA, Ramsar site and SSSI 50

Total small mammal numbers 90
Effect of water resource storage area and wetland habitats 93
Predictions of uplift in flight activity 93
Additional constraints on the functionality of the compensatory habitats 93
Additional visual disturbance constraints 93
Noise levels in compensation area 94
Additional stockpile 94
Water resource storage area and flood mitigation measures 94
Timing of functionality 95
Summary of constraints on the functionality of the marsh harrier compensation area 96
Conclusions regarding compensatory habitats proposed for loss of marsh harrier foraging resource 97
Be appropriate for the area and the loss caused by the Sizewell C Project 98
Be capable of protecting the overall coherence of the Natura 2000 network 98
Be capable of implementation 98
Be capable of ensuring that the Natura 2000 site is not irreversibly affected by the Sizewell C Project before the compensation is in place 98
Be directed in measurable proportions to the habitats and species negatively affected 98
Be related to the same biogeographical region (within the UK) 98
Serve functions that are comparable to those that motivated the original area's submission for designation 99
Be clearly defined, with implementation goals and managed so that the compensatory measures can achieve the goal of maintaining or improving the overall coherence of the National Sites Network (formerly known as the Natura 2000 network) 99
Overall conclusion in relation to requirements of EN-6 99
Impacts of Increased Recreational Pressure on Protected Sites and Species 99

1. INTRODUCTION

The RSPB

1.1 The Royal Society for the Protection of Birds (the RSPB) was set up in 1889. It is a registered charity incorporated by Royal Charter and is Europe's largest wildlife conservation organisation, with a membership of more than 1.1 million. The RSPB manages 220 nature reserves in the UK covering an area of over 158,725 hectares. The Society attaches great importance to the conservation of the 'Natura 2000' network (made up of Special Protection Areas (SPAs) and Special Areas of Conservation (SACs)), and the national network of Sites of Special Scientific Interest (SSSIs) notified by Natural England.

Suffolk Wildlife Trust

1.2 Suffolk Wildlife Trust has led local nature conservation efforts in Suffolk for five decades and has saved some of the county's most important wildlife sites as nature reserves. In the past eight years the Trust has spent over £7 million buying land for wildlife and currently cares for nearly 8000 acres of some of Suffolk's most inspiring wild places.

2. SUMMARY OF OUR CONCERNS

2.1 The Suffolk Coast is a network of coastal, estuarine and freshwater wetlands with shingle beaches, areas of Sandlings heathland, many of these areas designated for their conservation value. The area around Sizewell is particularly valuable, being next to Sizewell Marshes, a nationally protected site with irreplaceable habitats and species, and adjacent to Minsmere, the RSPB's flagship reserve and part of a wider site designated at the highest levels for its conservation value. The proposals for the development of Sizewell C pose significant risks to both these sites, and nature conservation more widely on the Suffolk Coast. Here we summarise the overall potential impacts.

2.2 Minsmere has a unique place in the history of nature conservation in the UK, being the place where the avocet, an iconic species previously lost from the UK, returned to breed and from where it began its recolonisation of the UK's wetlands. Likewise, the marsh harrier, now a familiar sight drifting over reedbeds on the Suffolk Coast and beyond, was reduced to a single pair but made its comeback from here. As well as its bird life, the reserve is important for a range of other species of plants, invertebrates, bats, amphibians and reptiles and has a known (but constantly growing) list of well over 6000 species. This is due to the range of habitats Minsmere contains, including reedbed, open water and scrape, wet grassland, ditches, coastal shingle, woodland, heather heathland and acid grassland.

2.3 Sizewell Marshes is a nationally designated nature conservation site, important for its lowland wet meadows, fens, reedbeds and wet woodlands. It holds populations of breeding wildfowl, rare invertebrates and plants. Important populations of bats also breed, hibernate and forage here, including nationally significant population of rare barbastelle.

2.4 The proposals for Sizewell C incorporate part of Sizewell Marshes, meaning that over 6ha of this SSSI is proposed to be lost entirely and a further 3ha damaged. The loss of nearly 10% of a nationally protected site is of serious concern to us, especially as some of the habitats lost are very hard, if not impossible, to recreate. The proposals for Sizewell C do include habitat compensation sites to try to recreate the habitats lost, but whilst reedbed has been created at Aldhurst Farm, the likelihood of success in recreating fen meadow is still not known and we still do not believe the proposals for fen meadow and wet woodland are adequate to ensure the re-establishment of the specialist plants and invertebrates lost from these habitats.

2.5 The Sizewell C proposals have the potential to significantly affect the habitats and species of Minsmere and Sizewell Marshes, mainly because of the proximity of the planned development to these sites. The construction area would be directly adjacent to the Minsmere South Levels and to Sizewell Marshes, containing important areas of wet grassland and pools for breeding and wintering wildfowl and for foraging marsh harriers. The significant levels of noise and visual disturbance from the construction area and the length of time over which these impacts would be expected (10-12 years) means that any displacement of these species could have a significant effect on their populations. For marsh harriers, from Minsmere foraging on the South Levels to further afield on Sizewell Marshes and the surrounding farmland, this means that they will effectively lose significant parts of their regular hunting grounds, which could affect their ability to provide food for their chicks. Over a period of years, this could affect Minsmere's marsh harrier population numbers. Waders and wildfowl on the South Levels and Sizewell Marshes may also be displaced by construction disturbance, and with significant proportions of Minsmere's populations of these species using these areas, this again could affect population levels in the medium term. We are also concerned that for some elements of the construction, timing is key to avoid impacts – if the timing of the construction of one of the water storage areas in the northern part of the construction area slips into the spring, the noise disturbance from this could affect breeding birds in Minsmere's reedbeds, home to specialists such as the bittern, marsh harrier and bearded tit.

2.6 Bats, including the rare barbastelle, would also be disturbed and displaced by construction – by the presence of lighting, noise and human activity, and the loss of some of the important connecting and feeding habitats between Minsmere and Sizewell as a result of the construction area. Roosting and hibernation sites for barbastelle may also be significantly impacted and it is likely that many unrecorded roosting sites will be lost.

2.7 The wetland areas of Minsmere and Sizewell Marshes are also at risk from changes to their hydrology. The movement of ground and surface water is crucial to maintaining the function of specialist habitats and the species they support. This is why we are so concerned about any potential impacts on Minsmere Sluice – a key structure which controls the drainage of Minsmere and much of the surrounding area. The combination of waterways entering the Sluice means that impacts on one of these waterways has the potential to have much wider effects. During the construction of Sizewell C, the discharge of water to one of these waterways, Leiston Drain, is expected to increase. The amount of water entering the Sluice from this source may mean that it is more difficult for water from the other waterways to drain at the same rate as previously. This could mean that it is not possible to drain Minsmere quickly when spring flooding occurs, meaning that nests of species such as lapwing, redshank, avocet and bittern are flooded out and habitats take longer to recover.

2.8 The Sluice also allows some entry of seawater into Minsmere to help maintain some of the specialist brackish habitats in the ditches and on the scrape. This means that these habitats are vulnerable to any contaminants entering by this route. Sizewell C would discharge hydrazine, a toxic chemical used as an anti-foulant in the cooling water system, during the later stages of construction and throughout its operation. At certain states of the tide it is possible that low levels of hydrazine would enter Minsmere via the Sluice. As yet, we do not know what the long-term impacts of this would be on the habitats and species of the scrape and ditches.

2.9 As the construction site for the power plant currently consists of soft, wet soils, the site will need to be drained and a hydrological cut-off wall constructed to stop water draining back into the site. This cut-off wall will affect the way water moves through the ground all around the site. Two ditches which run through the proposed development site will also need to be combined and rerouted. The changes to water movement could mean that parts of Sizewell Marshes become wetter and some southern parts of the Minsmere South Levels become slightly drier. In the long

term this could lead to changes to habitats in these areas, and changes to the species they support.

2.10 A small population of the rare natterjack toad is also found close to Sizewell, between the South Levels and Sizewell Marshes. The field where their breeding pond is found is currently proposed to become a water management zone during the construction of Sizewell C. Whilst it appears that the breeding pond and hibernation site within the nearly rabbit warren will be avoided, there will still be a significant loss of foraging habitat for the natterjacks. The proposals do not include enough mitigation to enhance connectivity to excellent habitat within Minsmere to the north.

2.11 The proposals for Sizewell C include large amounts of marine infrastructure, including intakes, outfalls, landing facilities and coastal defences. The new structures all have the potential to affect the way coastal processes along the Minsmere and Sizewell frontage work. The coastline in this area is highly dynamic, with climate change and sea level rise adding to the vulnerability of this frontage. We are concerned that some of these structures, particularly the coastal defences, could exacerbate coastal changes in the medium to long term which could affect the future frontage of Minsmere. At present we are concerned that it is not clear what the impacts of this will be.

2.12 The marine environment of the Greater Sizewell Bay is part of a wider marine protected site, important for red-throated divers in winter and for providing foraging areas for Sandwich, common and little tern colonies at Minsmere and other sites nearby. All these species are heavily dependent on their fish prey, and anything which affects the abundance or distribution of their prey species could have knock-on effects on their populations and breeding success. The construction of Sizewell C could affect fish through underwater noise and vibration, increasing suspended sediment though dredging and through discharges of chemicals such as hydrazine during the commissioning stages. During the operation of the power plant, large numbers of fish would be abstracted by the cooling water system. While some of these will be collected and returned to the sea, many of these will already be dead or dying by this point, leading to changes to water quality in the area. This impact could be significantly reduced by the use of an acoustic fish deterrent, in line with best practice and the advice of the Environment Agency, but this is not currently proposed at Sizewell. The return of the cooling water to the sea will also lead to the formation of a thermal plume, which will also contain chemicals such as hydrazine and compounds derived from the chlorine added to the cooling water system. The effects of these on birds and their fish prey is unclear, but of concern, particularly when considered alongside the other impacts affecting the marine environment. The number of vessels required to bring in deliveries to the site is also a cause for concern, particularly in relation to the internationally important red-throated diver population. These birds are highly sensitive to disturbance, with vessel traffic known to cause them to move away from and avoid busy areas.

2.13 The beaches at Sizewell and Minsmere support internationally important vegetated shingle habitats and rare beach nesting birds such as ringed plover. These birds and plants are very vulnerable to human activity on the beaches; the ringed plover are easily flushed from the nests and may abandon them if disturbed significantly or repeatedly by people or dogs while the specialist plants can be easily damaged by trampling. With parts of the footpath network in the Sizewell area being either closed, diverted or just unattractive to users due to the construction works, we are concerned that people are likely to use the neighbouring areas more heavily during the construction period, meaning that sensitive beach wildlife may be affected. In addition, whilst the main visitor areas of the Minsmere reserve have infrastructure designed to allow large numbers of people to visit without disturbing the wildlife, the outer parts of Minsmere are more sensitive and usually much less heavily visited. We are concerned that these areas, particularly the heathlands where the vulnerable stone curlew, woodlark and nightjar nest, may be very attractive to those displaced from the Sizewell area. Without careful management of the impacts

of additional visitors, these heathlands could be damaged by trampling, dog waste and disturbance.

2.14 In summary, we do not believe it will be possible to develop Sizewell C as proposed without significant effects on Minsmere, Sizewell Marshes, Greater Sizewell Bay and the wider nature conservation value of the Suffolk Coast. The proposals have the potential to damage highly protected wildlife sites and to impact nationally and internationally important populations of rare species, which are valued in their own right, by those that live on and visit the Suffolk Coast and all who care about nature conservation across the UK and beyond.

3. ENVIRONMENTAL CONCERNS

Land take from Sizewell Marshes SSSI (including impacts of the SSSI crossing)

Summary

3.1 Sizewell Marshes is designated as a Site of Special Scientific Interest which means it is of national importance and protected under the Wildlife and Countryside Act (1981) as amended.

3.2 The notification[1] for Sizewell Marshes SSSI includes that important for 'large area of lowland, unimproved wet meadows which support outstanding assemblages of invertebrates and breeding birds. Several nationally scarce plants are also present.'[2]

3.3 Sizewell Marshes SSSI is situated to the west of Sizewell nuclear power station and is a complex of marshes with a unique mix of geology and hydrology that has created nationally significant botanical and invertebrate diversity. The site has three main habitats; species rich grazing marsh, tall herb fen and wet alder carr woodland. The value of the SSSI is enhanced by its close proximity and connectivity to RSPB Minsmere.

3.4 Floristically, the grazing marshes and its network of dykes is one of the best examples of this habitat remaining in East Anglia. The dominant vegetation group is M22 *Juncus subnodulosus - Cirsium palustre* fen meadow, with intermediate areas between this dominated by MG10 *Holcus lanatus - Juncus effusus* rush pasture. The M22 *Juncus - Cirsium* communities are very species rich and contain a wide range of plants of conservation interest. The dyke system supports a wealth of plant species including the nationally scarce soft hornwort (*Ceratophyllum submersum*) and whorled water milfoil (*Myriophyllum verticillatum*). The wet woodland W6 *Alnus glutinosa- Urtica dioca* community comprises of chiefly alder and willow with some oak and supports a very high invertebrate diversity.

3.5 18 species of dragonfly have been recorded including rarities such as Norfolk hawker (*Aeshna isosceles*), hairy dragonfly (*Brachytron pratense*) and lesser red eyed damselfly (*Erythromma viridulum*). In total 236 moth species have been recorded since 1996 including *Senta flammea*, a nationally rare species. Further impressive counts include 12 species of grasshopper and cricket, including short winged conehead (*Tetrix subulata*) & Roesel's bush cricket (*Metrioptera roeselli*); a good range of spiders, including the nationally rare *Leiobunum rotundum*; and three nationally rare species of fly: *Odontomyia argentata, Oxycera morrisii* and *Odintomyia ornate.*

3.6 148 bird species have been recorded with a total of 80 breeding species including little egret, gadwall, kingfisher, barn owl & water rail and Cetti's warbler. Wintering birds include bittern, bearded tit and snipe. Mammals include otters, water voles, water shrews and harvest mouse as well as red deer. The SSSI is thought to hold an excellent bat community including barbastelle,

---

1 Sizewell Marshes SSSI notification

2 Please refer to [SSSI ecohydrology section] for more details on the nature and conservation value of the interest features within the SSSI.

Natterer's, all three pipistrelle species, brown long eared, noctule, serotine, and Daubenton's recorded annually. It is likely that nationally rare barbastelle and regionally scarce Natterer's bat breed on site.

3.7 Natural England has defined operations likely to damage the special interest[3] of Sizewell Marshes SSSI. Of these, the following are relevant to our concerns:

13a Drainage

13b Modification of the structure of watercourses

14 The changing of water levels and tables and water utilisation

3.8 Natural England views about management[4] for conservation and enhancement of the special conservation interest of wet grassland with breeding and wintering bird interest include the importance of managing water levels and minimising disturbance

- Wet grassland requires active management, traditionally by grazing, if it is to retain its conservation interest. [Periodic hay cutting which allows a breaking up of the thatch, is also important for botanical value.]
- Maintenance of a mosaic of shallow surface pools and un-flooded areas during the winter will provide roosting and feeding habitat for wintering wildfowl and waders
- From April onwards, the area of standing surface water should be reduced to increase the area available for nesting waders and also by concentrating aquatic invertebrates in small pools to provide suitable feeding areas for their young.
- Some shallow areas of flooding should be maintained until late June to provide patches of bare muddy ground on which the birds and their young can feed as raised sward height makes feeding on the drier areas more difficult.
- The birds using these features are directly vulnerable to disturbance, which can cause them to lose time spent feeding or drive them to areas with a poorer supply of food. Management should seek to minimise any harmful disturbance, especially at times when bird populations are under stress, such as severely cold conditions.

3.9 Our main concerns include:

The principle and justification for the proposed loss of part of Sizewell Marshes SSSI

3.10 Vol. 1 ES Addendum Ch. 2 Main Development Site[5] Table 2.38 notes the proposed development will result in the loss of 9.54ha of the SSSI (comprising 6.52ha permanent and 3.02ha 'temporary' loss).

3.11 We are concerned about the principle and scale of the proposed loss of part of Sizewell Marshes SSSI and its justification against the policy tests set out in the Overarching National Policy Statement for Energy (EN-1)[6].

3.12 In addition we are unconvinced about the Applicant's justification for the choice of an embankment and culvert (a single span 'bridge') rather than a triple span bridge to cross Sizewell Marshes SSSI, despite the higher land take from the SSSI. We are concerned that the loss of SSSI

---

3 Operations likely to damage the special interest of Sizewell Marshes, Suffolk

4 Views about management of Sizewell Marshes SSSI

5 Volume 1 Environmental Statement Addendum Chapter 2 Main Development Site (AS-181)

6 Department of Energy and Climate Change (2011) Overarching National Policy Statement for Energy (EN-1)

via the embankment/culvert option will lead to a much larger loss than the triple span bridge option, and this has not been adequately nor clearly justified.

3.13 Therefore, currently it is our view that the Application has not met the requirement in EN-1 paragraph 5.3.7, namely.

> "*As a general principle, and subject to the specific policies below, development should aim to avoid significant harm to biodiversity and geological conservation interests, including through mitigation and consideration of reasonable alternatives…; where significant harm cannot be avoided, then appropriate compensation measures should be sought*."

3.14 Due to our concerns over the principle of the proposed loss of part of Sizewell Marshes SSSI and its assessment against the tests set out in EN-1.

Temporary land take from Sizewell Marshes SSSI

3.15 We dispute the term 'temporary' damage[7] and we believe it is likely many of the construction activities that will take place (such as repeated tracking across the SSSI) will result in the permanent damage to nationally important fen habitat. We are also concerned about the designation of some loss as 'temporary'[8], which has not been supported by proposals for adequate restoration methods.

Adequacy of the proposed habitat compensation

3.16 Whilst we welcome the Applicant proposals to compensate for the losses of reedbeds and ditches, fen meadow and wet woodland by creating compensatory habitat, we are concerned that the quantity, quality and timing of functionality of all the proposed habitat compensation is inadequate to compensate for loss of all affected SSSI habitats.

Hydrological impacts on Sizewell Marshes SSSI

3.17 Our concerns relating to hydrological impacts on the retained habitats of Sizewell Marshes SSSI are detailed in the SSSI ecohydrology section below.

Introduction

3.18 We are grateful to the Applicant for all the pre-application and pre-examination engagement and discussions. We also engaged with the all consultations (including the Change Application[9]) and repeatedly made our concerns known.

3.19 Therefore it is disappointing to see so many of our concerns remaining. However we remain keen to work further with the Applicant during the Examination process especially on possible management, mitigation and compensation plans as new proposals are brought forward for example the wet woodland strategy[10] submitted at Deadline 1.

3.20 We outline our current position below (as set out in our relevant representations [RR-1059 (RSPB)[11] and RR-1180 (SWT)[12] and our Change Application responses).

The principle and justification for the proposed loss of part of Sizewell Marshes SSSI

Introduction

3.21 We are concerned about the principle and scale of the proposed loss of part of Sizewell Marshes SSSI and its justification against the policy tests set out in the Overarching National Policy Statement for Energy (EN-1)[13].

Legislation and Planning Policy

3.22 As set out above we do not agree that the requirement in EN-1[14] paragraph 5.3.7 'to avoid significant harm to biodiversity …through mitigation and the consideration of reasonable alternatives' has been met.

3.23 Although the National Planning Policy Framework[15] (NPPF) (2019) does not contain specific policies for nationally significant infrastructure projects it does note at para 175.

> *When determining planning applications, local planning authorities should apply the following principles: a) if significant harm to biodiversity resulting from a development cannot be avoided (through locating on an alternative site with less harmful impacts), adequately mitigated, or, as a last resort, compensated for, then planning permission should be refused;*
>
> *b) development on land within or outside a Site of Special Scientific Interest, and which is likely to have an adverse effect on it (either individually or in combination with other developments), should not normally be permitted. The only exception is where the benefits of the development in the location proposed clearly outweigh both its likely impact on the features of the site that make it of special scientific interest, and any broader impacts on the national network of Sites of Special Scientific Interest;*

3.24 and at para 170.

> *Planning policies and decisions should contribute to and enhance the natural and local environment by:*
>
> *d) minimising impacts on and providing net gains for biodiversity, including by establishing coherent ecological networks that are more resilient to current and future pressures;*

3.25 This clearly states development *likely to have an adverse effect* on a SSSI should not normally be permitted unless the benefits clearly outweigh its likely impact and that planning decisions should minimise impacts on and provide net gains for biodiversity.

3.26 It is the Applicant view that due to the location of the Application being in the National Policy Statement for Nuclear Power Generation, consideration of alternative locations is not required (ES Non-technical summary, section 3.2[16]).

3.27 The Planning Statement[17] section 8.3.39 notes

> *Therefore, taking into account the overall planning balance set out in Section 11 of this Planning Statement and with particular regard to the measures set out above it can be*

---

13 Department of Energy and Climate Change (2011) Overarching National Policy Statement for Energy (EN-1)
14 Department of Energy and Climate Change (2011) Overarching National Policy Statement for Energy (EN-1)
15 National Planning Policy Framework (2019)
16 Volume 1 6.1 Environmental Statement – Non Technical Summary (APP-159)
17 Planning Statement (APP-590)

concluded that the benefits of the development outweigh the harm and the Sizewell C power station is in accordance with paragraphs 5.3.11, 5.3.14, 5.3.15, 5.3.17 and 5.3.18 of EN-1.

3.28 However in our view, there is inadequate evidence provided to support the conclusion that the *benefits of the development outweigh the harm*. Therefore we consider that the Applicant must provide further evidence to justify its conclusion and that there is no need to consider alternatives.

3.29 EN-1[18] provides more on these important requirements, noting at paragraph 5.3.11.

> *Where a proposed development on land within or outside an SSSI is likely to have an adverse effect on an SSSI….development consent should not normally be granted. Where an adverse effect, after mitigation, on the site's notified special interest features is likely, an exception should only be made where the benefits (including need) of the development at this site, clearly outweigh both the impacts that it is likely to have on the features of the site that make it of special scientific interest and any broader impacts on the national network of SSSIs. … use* [of] *requirements and/or planning obligations* [should be made] *to mitigate the harmful aspects of the development and, where possible, to ensure the conservation and enhancement of the site's biodiversity or geological interest.*

3.30 With the National Policy Statement for Nuclear Power Generation (EN-6)[19] providing more clarity on considerations and requirements specifically in relation to the Application, paragraph C.8.63

> *The Appraisal of Sustainability identified the potential for the mitigation of biodiversity effects on sites of UK wide conservation importance (Sizewell Marshes SSSI), including the creation of replacement habitat. The Appraisal of Sustainability notes that developers could avoid or minimise losses and disturbance to protected species through careful site layout, design, routing, location of the development, associated infrastructure, and construction management and timings. The Appraisal of Sustainability finds that there is potential for habitat creation within the wider area in order to replace lost 'wet meadows' habitats of the Sizewell Marshes SSSI, but also finds that it may not be possible to fully compensate for losses of this habitat. The applicant will need to develop an ecological mitigation and management plan to minimise the impacts.*

SSSI Crossing

3.31 As mentioned above we are unconvinced about the Applicant's justification for the choice of an embankment and culvert rather than a triple span bridge to cross Sizewell Marshes SSSI, despite the higher land take from the SSSI. In addition we are concerned that this larger loss of the SSSI has not been adequately considered nor that the Applicant has minimised all possible impacts to the SSSI and its features.

3.32 The Sustainability Statement[20] submitted with the Application notes at paragraph 3.8.22

> *The crossing would be constructed at the narrowest point to minimise the land-take of the SSSI. The design of the SSSI crossing has evolved to minimise impacts on ecology*.

---

18 Department of Energy and Climate Change (2011) Overarching National Policy Statement for Energy (EN-1)

19 Department of Energy and Climate Change (2011) National Policy Statement for Nuclear Power Generation (EN-6) Volume II of II - Annexes

20 8.13 Sustainability Statement (APP-617)

3.33 ES Vol. 2 Ch. 6 Alternatives and Design Evolution[21] Table 6.1 compares the SSSI land take of the four SSSI crossing options presented at Stage 2 consultation

Option 1: Causeway over culvert (0.40ha)

Option 2: Single span bridge with vertical wing walls (0.22ha)

Option 3: Three span bridges (0.19ha)

Option 4: Causeway over culvert with adjacent short-term bridge (0.45ha)

3.34 Paragraph 6.2.39 states that the Option 1 causeway over culvert was selected for speed and ease of construction and operational flexibility even though the SSSI land take is considerably higher. APP-190 only assesses the impact of total SSSI loss with the causeway over culvert option selected and claims no residual impact following mitigation without presenting evidence to support this conclusion.

3.35 Nor are the potential impacts of the four SSSI crossing options individually assessed and compared. We consider the impact of all four options should be so assessed and compared to ensure that the right option is chosen to minimise potential effects and losses to the SSSI and its features.

3.36 Noting both the Sustainability Statement above and the Design and Access Statement overarching design principle 11 to

Minimise land take from the SSSI. In this way land take is minimised and where unavoidable, additional compensatory habitat is created. (Part 1[22] , section 6.3.10)

3.37 Along with the High Level Design Principle 10

the development will be designed with the aim of avoiding significant harm to biodiversity (habitats and species) particularly designated interest features of nationally and internationally designated sites, protected and priority species. (In Table 5.1)

3.38 The Application currently clearly does not meet these principles due to its choice of an embankment and culvert.

3.39 Natural England[23] also stated the Applicant would need to demonstrate that the proposals have been designed in a manner that minimises land take from Sizewell Marshes SSSI.

Change to the SSSI crossing design to a single span bridge with embankments

3.40 Whilst the proposed bridge to cross Sizewell Marshes SSSI in the Change Application (Vol. 1 ES Addendum Ch. 2 Main Development Site[24]) appears to be an improvement on the plans presented in the Application (ES Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[25]) (from an ecological standpoint), we still consider that the bridge should be designed more sensitively as a three span bridge to further reduce SSSI loss from the crossing and to provide greater connectivity for species/groups including invertebrates, water voles, otters and bats, thereby reducing the potential for fragmentation of populations.

---

21 ES Volume 2 Main Development Site Chapter 6 Description of Alternatives and Design Evolution (APP-190)
22 Main Development Site Design and Access Statement Part 1 (APP-585)
23 Natural England Relevant Representation [RR-0878] 103.
24 ES Volume 1 Environmental Statement Addendum Chapter 2 Main Development Site (AS-181)
25 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology (AS-033)

3.41 We note the commitment in Vol. 1 ES Addendum Ch. 2 Main Development Site[26] paragraph 2.2.138 to the provision of a ledge to allow otters to pass and the incorporation of bat roosts into the structure, however, detailed designs and full assessment of the potential impacts from the proposed bridge over the Sizewell Marshes SSSI are required.

3.42 We also note that whilst the revised design may improve connectivity for some species (e.g. otters) compared to the design in the Application, some species (in particular, certain species of invertebrates) will still be significantly negatively affected by the proposals. Again, our preference would be for a three-span bridge which would result in higher light levels reaching the watercourse below and hence greater connectivity for all affected species.

3.43 Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[27] paragraph 2.9.65 notes that the revised design will reduce land-take from Sizewell Marshes SSSI by 0.08ha. Whilst this intention is welcomed, the sections of SSSI remaining in the bridge section would be impacted during the construction period, potentially over a continuous period of a number of years and more evidence is required to demonstrate how potential harm can be minimised as well as potential for their restoration, despite being in such close proximity to the causeway structure (discussed further below).

3.44 A detailed design for the SSSI crossing has not been submitted to the Examination. ES Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[28] notes at paragraph 14.4.10

> *The final dimensions would be confirmed as the design progresses*.

3.45 This means the impacts of the crossing cannot be properly assessed or scrutinised by Interested Parties and the Examination Authority.

3.46 This does not comply with EN-1[29] which notes at paragraph 4.2.8

> *Where some details are still to be finalised the ES should set out, to the best of the applicant's knowledge, what the maximum extent of the proposed development may be in terms of site and plant specifications, and assess, on that basis, the effects which the project could have to ensure that the impacts of the project as it may be constructed have been properly assessed.*

3.47 EN-6[30] goes on to note, paragraph C2.51

> *The potential impacts of development on designated habitats will be taken into account in the project level assessments and considered by the* [PINs] *as part of the application for development consent.*

3.48 EN-6 notes at paragraph C.8.67

> *The* [PINs] *should also refer to the Appraisal of Sustainability … and consider whether the applicant's proposals have sufficiently taken into account the issues identified, where they are still relevant.*

3.49 We are concerned that the information before the Examination is inadequate for the Examining Authority to consider fully and robustly all possible effects on the SSSI and its features.

Temporary land take from Sizewell Marshes SSSI

3.50 ES Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[31] paragraph 14.7.125 notes temporary loss includes habitats that would be impacted temporarily during the construction phase and those where replacement habitat is proposed within the site. Table 14.10 shows the temporary land take from wet woodland, fen meadow, wet reedbed and ditches. 14.7.125 explains the area of temporary impact includes wet woodland and fen meadow located within the corridor which will be used to install overhead power lines and notes

> *The wet woodland would be coppiced to enable the cable to be laid out, prior to lifting and the fen meadow would be protected from damage using appropriate methods for spreading the weight of plant in wet ground.*

3.51 We dispute the term 'temporary' impact and we believe it is likely many of the activities that will take place (such as repeated tracking across the SSSI) will result in the permanent damage to nationally important fen habitat. The Applicant has not presented evidence to demonstrate how the fen meadow will be protected from damage and how the habitat will be able to be re-established after construction. In our view the Applicant should provide detailed evidence for scrutiny during the Examination.

3.52 Details to support the temporary loss of wet reedbed and ditches are missing and we request the Applicant provides evidence to support the assertion of temporary loss of those habitats.

3.53 We are also concerned about the designation of some loss as 'temporary', because it has not been supported by proposals for adequate restoration methods.

3.54 Vol. 1 ES Addendum Ch. 2 Main Development Site[32] Table 2.36: Revised Sizewell Marshes SSSI land take calculations show 0.61ha temporary and 0.46ha permanent loss of fen meadow and 2.23ha temporary and 3.06ha permanent loss of wet woodland.

3.55 We have significant concern that areas of 'temporary' fen meadow loss will suffer long term damage and hence there could be a total of 1.07ha of permanent loss and permanent damage. We request monitoring of the condition of the fen meadow subject to 'temporary' loss and if a significant effect is identified, further habitat creation would be required to compensate for this.

3.56 The 'temporary' loss is largely wet woodland which will take a long time to return to the habitat quality at the start of the 'temporary' land take.

3.57 Table 6.1 of the outline Landscape and Ecological Management Plan (oLEMP)[33] notes the proposed management for habitat reinstatement of Sizewell Marshes SSSI Marsh, Fen and Reedbed

> *The area of marsh, fen and reedbed habitats within the temporary construction area for the SSSI crossing in the Sizewell Marshes SSSI would be reinstated following construction completion. A detailed re-instatement plan would be included within the detailed LEMP.*

3.58 But it does not mention a re-instatement plan for temporary loss of wet woodland.

3.59 We request the Applicant submits a detailed habitat re-instatement plan for all habitats subject to 'temporary' loss for scrutiny during the Examination process.

---

31 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology (AS-033)

32 ES Volume 1 Environmental Statement Addendum Chapter 2 Main Development Site (AS-181)

33 8.2 Outline Landscape and Ecological Management Plan (oLEMP) (REP1-010)

Adequacy of the proposed habitat compensation

3.60 ES Vol 2 Ch 14 Terrestrial Ecology and Ornithology[34] Table 14.12 summarises the effects from the construction phase on Sizewell Marshes SSSI. It concludes a moderate adverse effect from direct land take resulting in habitat loss and fragmentation would be reduced to minor adverse (not significant) with additional mitigation. The additional mitigation proposed includes

> *Habitat monitoring to ensure habitat creation meets its objectives. Aim to create/ restore more fen meadow habitat than is being lost to allow for uncertainties in creation; use of two sites reduces risk Compensatory funding in the event of failure to deliver compensatory habitats at either location, to enable fen meadow creation at other sites. Wet woodland strategy to identify further wet woodland habitat opportunities*.

3.61 Vol. 1 ES Addendum Ch. 2 Main Development Site[35] submitted with the change Application concludes impacts to Sizewell Marshes SSSI are considered to remain as minor adverse (not significant).

3.62 The Applicant proposes to compensate for the losses of reedbeds and ditches, fen meadow and wet woodland by creating compensatory habitat. We request the Applicant provides a plan with all proposed compensation areas for all affected habitats clearly annotated.

Quantity, quality and timing of functionality of all the proposed habitat compensation

3.63 We are concerned that the quantity, quality and timing of functionality of all the proposed habitat compensation is inadequate to compensate for loss of all affected SSSI habitats.

3.64 For example Aldhurst Farm habitat creation[36] has been designed to compensate for the loss of reedbed and ditch habitat only. We are keen to see that any habitat creation is of the highest quality and achieves the best possible outcomes for wildlife (irrespective of whether this becomes an enhancement or compensation site). Currently we do not agree that it will compensate for the SSSI loss since this continues to be inadequately demonstrated.

3.65 We are also concerned about the lack of an attempt to address loss of fen meadow, wet woodland and specialist invertebrates. We therefore consider there will be residual impacts (other than reedbed) and we are not confident that compensation more recently proposed will fully address this.

3.66 Compensation habitat should be in place and functional before habitat loss occurs. The construction programme should follow the appropriate compensation work and not the other way around. We request the Applicant defines the seasons when the habitat creation work would need to take place. The timing of the construction programme needs to accommodate this.

Fen meadow

3.67 As stated above the revised Sizewell Marshes SSSI land take calculations in Vol. 1 ES Addendum Ch. 2 Main Development Site[37] show 0.61ha temporary and 0.46ha permanent loss of fen meadow.

---

34 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology (AS-033)
35 ES Volume 1 Environmental Statement Addendum Chapter 2 Main Development Site (AS-181) 2.9.52, 2.9.65, 2.9.86
36 ES Volume 1 Environmental Statement Addendum Chapter 2 Main Development Site (AS-181) 14.4.11
37 ES Volume 1 Environmental Statement Addendum Chapter 2 Main Development Site (AS-181)

3.68 The Fen Meadow Strategy (Vol. 3 Ch. 2 ES Addendum Terrestrial Ecology and Ornithology Appendices 2.9.A-2.9.D Part 2[38]) proposes creation of 4.5 ha of fen meadow at three sites (Benhall, Halesworth and Pakenham) to compensate for the permanent loss of approximately 0.5ha of fen meadow within the SSSI.

3.69 Whilst the provision of more SSSI compensatory habitat (paragraph 1.1.3) is welcome, the distance from the area of loss at Sizewell Marshes SSSI is of concern. Compensation sites should be as close to the lost habitats as possible and given the distance of Pakenham from Sizewell, there is a clear limitation of Pakenham in terms of compensation for the loss of the Sizewell Marshes SSSI. Consideration should be given to increasing the compensation ratio to take account of the distance of the compensation site from Sizewell Marshes SSSI.

3.70 Although the EC guidance on "Managing Natura 2000 sites" (EC, 2018)[39] is not directly relevant to SSSIs it does helpfully explain that the extent of compensation required is directly related to:

- the quantitative and qualitative aspects inherent to the elements of integrity likely to be impaired
- the estimated effectiveness of the measure(s) [section 5.5.4]

3.71 The EC Guidance (2018) also states that ratios are best set on a case-by case basis, but should generally be well above 1:1. Ratios of 1:1 or below should only be considered when it can be shown that measures will be fully effective in reinstating structure and functionality in a short period of time [section 5.5.4].

3.72 Paragraph 5.1.8 of the Strategy notes:

> *Once the land for the three fen meadow locations has been secured, either by agreement or by compulsory acquisition powers in the DCO as made, SZC Co will undertake the relevant 'Year 1 works' to be defined in the Fen Meadow Plan and as detailed below at 5.1.9 onwards, within a period to be defined within the plan and linked to the commencement of works in the DCO as made.*

3.73 The Strategy does not mention when the habitat creation works will commence in relation to the construction programme and SSSI land-take. Section 6 states the target is to establish at least 4.5ha of M22 fen meadow habitat across the three fen meadow sites within 10 years of commencing the habitat creation works. The Indicative Phasing Schedule shows fen meadow habitat creation during construction years 1 to 3. Compensation habitat should be in place and functional before habitat loss occurs. The construction programme should follow the appropriate compensation work and not the other way around. We request the Applicant defines the seasons when the habitat creation work would need to take place. The timing of the construction programme needs to accommodate this.

3.74 Due to potentially high nutrient levels found in the surface water, the newly proposed fen compensation sites may only support more generalist species, with a resulting overall loss of biodiversity. We have seen no evidence as yet regarding the technical feasibility of fen meadow creation on these sites.

---

[38] Volume 3 Chapter 2 Environmental Statement Addendum Terrestrial Ecology and Ornithology Appendices 2.9.A-2.9.D Part 2 (AS-209)

[39] European Commission (2018) Managing Natura 2000 sites. The provisions of Article 6 of the 'Habitats' Directive 92/43/EEC section 5.5.4

3.75 We request the Applicant provides peer-reviewed evidence from similar schemes to demonstrate it is feasible to successfully create M22 species-rich fen/fen meadow habitat. We also request clarification of the next steps if it is found that it is not feasible to create this habitat.

3.76 Paragraph 1.1.4 proposes that a 'Fen Meadow Plan' be prepared in accordance with the Fen Meadow Strategy and be subject to a DCO Requirement 14A.

3.77 We are concerned that the detailed surveys to inform the Fen Meadow Plan (4.1.9) will not be completed until after the close of the Examination. We are still awaiting the Fen Meadow Plan Report 1 which the fen meadow strategy (4.1.11) noted '*will be prepared for submission in Q1 2021, to provide the baseline reports for the sites and water data available to that period, timed to inform stakeholders and the commencement of the examination*'.

3.78 If the detailed surveys do not provide confidence that fen meadow establishment is achievable or there is a high degree of uncertainty, then other sites should be identified to deliver new fen meadow habitats.

3.79 Paragraph 4.1.11 also notes The Fen Meadow Plan Draft 1 to be submitted later in the examination process '*will provide further interim data and define in draft the management interventions required to create fen meadow habitats'*. We welcome the commitment to include draft monitoring and remedial measures to ensure SSSI quality fen meadow is delivered. The delivery of fen meadow compensation must be legally and financially secured via the S.106 Agreement with flexibility to take account of the fact that the Plan will be finalised after the close of the Examination.

3.80 With regard to the plans to transfer green hay to the Pakenham site discussed in paragraph 5.1.9 and 5.1.11, in terms of ecological best practice these transfers should be from the Pakenham Meadows SSSI.

3.81 We welcome the commitment to include surveys of existing fen meadow local to the compensation site, including Pakenham Meadows SSSI, to identify species (e.g. invertebrates) present locally and then target measures to encourage their colonisation of the newly created fen meadow habitat (4.1.10).

Potential impacts from the proposed Pakenham Fen site on Pakenham Meadows SSSI

3.82 The potential impacts from the proposed Pakenham Fen site on the features of the adjacent Pakenham Meadows SSSI need to be assessed. Ecological, groundwater and surface water surveys of the Pakenham Meadows SSSI should be undertaken to establish its condition before construction of the Pakenham compensation area. The SSSI should be monitored during and after construction to detect any potential impacts from groundwater and surface water changes on its features, allowing rapid deployment of mitigation measures should any changes occur.

Potential impacts from the Benhall Fen Meadow site on the Abbey Farm compensation site

3.83 We are concerned about potential impacts from the Benhall Fen Meadow site on the Abbey Farm compensation site that is providing compensatory habitat for expected losses of part of the coastal reedbeds to sea level rise and managed realignment[40] [41] – specifically to compensate for

---

[40] Suffolk Coastal District Council, Waveney District Council and the Environment Agency (2010) Anglian Region Habitat Creation Programme http://www.suffolksmp2.org.uk/publicdocuments/finalsmp2/Regional%20Habitats%20Creation%20Programme.doc Section 1.2, Table 1, Table 2, Table 3

[41] Shoreline Management Plan 7 (suffolksmp2.org.uk)

adverse effects on the Benacre to Easton Bavents Special Protection Area (SPA), and the Minsmere-Walberswick SPA and Ramsar site.

3.84 The Benhall Fen Meadow site is on the River Fromus catchment, upstream of the Abbey Farm compensation site, where the RSPB has been managing the compensatory habitat[42]. Abbey Farm is functioning as reedbed now and supports breeding bittern and marsh harrier. The site manager (pers. comms.) confirmed the site is currently vulnerable to water supply when river levels drop in the summer months.

3.85 If the Applicant needs to hold more water back upstream in the summer for the Benhall fen meadow compensation site this could exacerbate the issues downstream at the Abbey Farm compensation site.

3.86 In addition it is important to note that it is government policy) that sites identified, or required, as compensatory measures for *adverse effects* on protected sites (SPAs, SACs and Ramsar sites) should be given the same protection as those protected sites[43], with EC Guidance (2018) also requiring that they themselves become protected sites[44] . Therefore, consideration of potential effects of the proposed Benhall compensation site on the Abbey Farm compensation site should be undertaken and should *likely significant effect* be identified, an HRA carried out. We request the Applicant provides modelling and a thorough assessment of the potential impacts of the proposed Benhall compensation site on the Abbey Farm compensation site.

Wet woodland

3.87 The Wet Woodland Strategy[45] (paragraph 1.1.2) proposes creation of 3.06ha of wet woodland, with 0.7ha to be created on the EDF estate and 2.36ha created between the Benhall and Pakenham fen meadow compensation sites. Since compensation sites should be as close as possible to the lost habitats, we consider the compensation ratio should be increased to take account of the distance of the off-site compensation sites from Sizewell Marshes SSSI but without constraining the creation of fen meadow habitat.

3.88 Section 6 of the Strategy notes establishment of the wet woodland habitats would commence within 12 months of the commencement of development under the DCO and continue for 10 years. The test of success (paragraph 7.1.1 of the Strategy) is the establishment by Year 10, of at least 3.06ha of developing wet woodland habitat. Compensation habitat should be functional before habitat loss occurs. We are concerned it will not be functional for at least 10 years following loss of the SSSI habitat

3.89 Paragraph 5.1.10 of the Strategy also contains a proposal to create 0.7ha wet woodland habitat in a new wetland corridor within the marsh harrier habitat improvement area. We are concerned that the creation of wet woodland within the marsh harrier compensation area will result in a loss of habitat available for foraging marsh harriers (as discussed below) as the habitat is not likely to be functional by the time construction starts.

---

42 Suffolk Coastal District Council, Waveney District Council and the Environment Agency (2010) Anglian Region Habitat Creation Programme http://www.suffolksmp2.org.uk/publicdocuments/finalsmp2/Regional%20Habitats%20Creation%20Programme.doc Table 4 (Snape, Suffolk)

43 Ministry of Housing, Communities and Local Government (2019) National Planning Policy Framework (NPPF), paragraph 176

44 European Commission (2018) Managing Natura 2000 sites. The provisions of Article 6 of the 'Habitats' Directive 92/43/EEC section 5.5.5

45 9.8 Wet Woodland Strategy (REP1-020)

3.90 Para 8.1.2 of the Strategy refers to contingency approach to deliver the balance of wet woodland and any additional required to meet the total of 3.0ha on the EDF Energy estate at either Aldhurst Farm or on the new wetlands which would have been established on the marsh harrier compensatory habitat area in the north-east of the EDF Energy estate. We consider compensation at Aldhurst Farm should focus on reedbed and wet woodland should not be created there at the expense of reedbed.

3.91 Due to the many concerns above about adequacy, we strongly recommend that the need for contingency habitat is considered now and information submitted to the Examination, so that it can be taken account of by the ExA. Also, there will be a need to consider potential impacts on neighbouring habitats e.g. if waders are nesting nearby it is not ideal to introduce tree cover which provides perching for predators.

Conclusions

3.92 In conclusion, based on the information available at present, our key concerns are

- The principle and scale of the proposed loss of part of Sizewell Marshes SSSI and its justification against the policy tests set out in the Overarching National Policy Statement for Energy (EN-1)
- The choice of an embankment and culvert (a single span 'bridge') rather than a triple span bridge to cross Sizewell Marshes SSSI, despite the higher land take from the SSSI, has not been adequately and clearly justified
- We consider the Applicant should assess and compare the impact of all four options for the SSSI crossing and provide sufficient evidence for Natural England to advise the Examination on any effects on the special interest of the SSSI.
- A detailed design for the SSSI crossing has not been submitted to the Examination.
- We do not agree that the Application has met the requirement in EN-1 paragraph 5.3.7

  to avoid significant harm to biodiversity …through mitigation and the consideration of reasonable alternatives

- We dispute the term 'temporary' impact and we believe it is likely many of the activities that will take place will result in permanent damage to nationally important fen habitat
- The designation of some loss as 'temporary' has not been supported by a detailed habitat re-instatement plan for all habitats subject to 'temporary' loss
- The quantity, quality and timing of functionality of all the proposed habitat compensation is inadequate to compensate for loss of all affected SSSI habitats
- Compensation habitat should be in place and functional before habitat loss occurs. The construction programme should follow the appropriate compensation work and not the other way around. We request the Applicant defines the seasons when the habitat creation work would need to take place. The timing of the construction programme needs to accommodate this.
- We request the Applicant provides peer-reviewed evidence from similar schemes to demonstrate it is feasible to successfully create fen meadow habitat. We also request clarification of the next steps if it is found that it is not feasible to create this habitat.
- We request the Applicant provides modelling and a thorough assessment of the potential impacts of the proposed Benhall compensation site on the Abbey Farm compensation site.
- Due to the many concerns about adequacy of compensation habitat, we strongly recommend that the need for contingency habitat is considered now and information submitted to the Examination, so that it can be taken account of by the ExA.

3.93 More information and details are required now for these proposals to be fully considered and taken account of.

Coastal Processes and RSPB Minsmere

Introduction

3.94 The RSPB owns the coastal frontage running from the boundary with the EDF estate (just north of the Application red line boundary) to the boundary with National Trust, north of the Minsmere Sluice, where the Coney Hill cross bank/north wall meets the coast (at approximately OS Grid Ref TM478671).

RSPB Minsmere shoreline, looking north from Minsmere Sluice towards Dunwich Cliffs. Copyright Tormod Amundsen/Biotope

3.95 The coastal frontage forms part of the Minsmere to Walberswick SAC, SPA, Ramsar site and SSSI (the designated sites) and is particularly important for its vegetated shingle and coastal dune habitat, the former of international importance for the annual vegetation of driftlines[46] and perennial vegetation of stony banks[47] floral communities.

3.96 The annual vegetation of driftlines feature is a primary reason for site selection of the Minsmere – Walberswick SAC, represented on the Minsmere frontage by the presence of orache *Atriplex* spp and sea sandwort *Honckenya peploides.* The site is one of only two representative sites of this habitat on the east coast of England and one of only four known outstanding localities in the United Kingdom. This habitat is considered to be rare as its total extent in the UK is estimated to be less than 100ha. The Perennial vegetation of stony banks is a qualifying feature of the Minsmere – Walberswick SAC, represented on the Minsmere frontage by the presence of the yellow horned-poppy *Glaucium flavum* and the rare sea-kale *Crambe maritima* and sea pea *Lathyrus japonicus.* The last two species are also qualifying features of the Ramsar designation and all three species are cited in the SSSI designation.

46 Annual vegetation of drift lines (Annual vegetation of drift lines) - Special Areas of Conservation (jncc.gov.uk)

47 Coastal shingle vegetation outside the reach of waves (Perennial vegetation of stony banks) - Special Areas of Conservation (jncc.gov.uk)

3.97 A number of studies (eg Cadbury 199648, 200449, 201550) have confirmed the importance of the vegetation on this shingle frontage. The shingle and dune barrier also provide protection for the nationally and internationally important brackish and freshwater habitats on the landward side, which form valuable low-lying habitat in the Minsmere valley, part of the Minsmere to Walberswick SPA, SAC, Ramsar and SSSI sites and managed by the RSPB as part of Minsmere reserve.

3.98 This stretch of the coast is a dynamic system and it can be difficult to interpret or predict natural geomorphological change. However, Pye & Blott (2005)[51], in response to an Environment Agency consultation, concluded that there was no scientific basis to conclude that a major coastal realignment, involving virtual abandonment of the freshwater habitat interests at Minsmere, is required in the short to medium term (i.e in the next 50 years). This was also the conclusion of the Minsmere Flood Risk Management Study (Environment Agency 2009)[52], which concluded that the defences south of the Minsmere Sluice were less likely to be at risk of coastal erosion over the next 100 years. This study informed the Environment Agency's Minsmere Sea Defences project, completed in 2012, that afforded protection to freshwater habitats (Schofield & Ferguson 2014)[53].

3.99 Studies used to inform EA's project indicated that the enhancements to the Coney Hill cross bank and adjacent areas should allow the freshwater habitats to be maintained *in situ* for the next 50 years at least. The studies (Black & Veatch 2006[54]) proposed that the majority of the RSPB Minsmere frontage had a residual life of between 50 – 200 years. Therefore, but for the Application, there is no reason to believe additional defences will be needed in the medium term, nor that the designated sites and their features are at risk during this period also.

Sites and species of concern

3.100 As described in more detail above, the following are the protected sites, species and other protections relevant to this issue:

- Minsmere to Walberswick SAC, SPA, Ramsar, SSSI

- RSPB Minsmere Council of Europe Diploma site – in recognition of the maintenance of an exceptional European interest with exemplary management (Council of Europe[55] 1979 and 2019[56])[57]
- Annual vegetation of drift lines (Annex 1 SAC qualifying feature and primary reason for site designation)
- Perennial vegetation of stony banks (Annex 1 SAC qualifying feature)
- Wetland bird populations threatened by flooding of freshwater habitat (including shoveler, gadwall, bittern, marsh harrier, avocet & little tern)
- Breeding ringed plover
- Sizewell beach County Wildlife Site (identified in Doody & Randall 2003[58] as being an important site for coastal vegetated shingle)
- Heritage Coast[59]
- Invertebrate communities on shingle - the shingle invertebrate assemblage on the Minsmere frontage has not been systematically surveyed but is likely to support an important invertebrate community.

International Importance

3.101 Doody & Randall (2003) identify that Great Britain supports a significant proportion of European shingle shore structures and that vegetated shingle (comprised of Annual vegetation of driftlines and Perennial vegetation of stony banks) is recognised as an internationally important habitat, particularly as it is scarce in the rest of Europe with the UK supporting a high proportion of the European resource. Elsewhere globally, coastal shingle has few occurrences outside of Japan and New Zealand. The vegetated shingle on the Suffolk Coast is therefore of significant global importance and is one of the main reasons it is designated as a SAC and Ramsar site.

Summary of concerns relating to coastal processes

3.102 As described in ES *Vol. 2 Ch. 2 Description of Permanent Development*[60] and *ESVol. 2 Ch. 20 Coastal Geomorphology and Hydrodynamics*[61], various aspects of the proposed development have the potential to interfere with the coastal processes on the Minsmere frontage. These include:

---

55 Council of Europe (1979) Resolution (79)13. On the award of the European Diploma to the Minsmere nature reserve (United Kingdom)

56 Council of Europe (2019) Resolution CM/ResDip(2019)5 on the renewal of the European Diploma for Protected Areas awarded to the Minsmere Nature Reserve (United Kingdom)

57 The European Diploma for Protected Areas is a prestigious international award for **the efficient protection and management of landscapes, reserves or natural monuments and sites,** granted since 1965 by the Committee of Ministers of the Council of Europe. It recognises natural and semi-natural areas and landscapes of exceptional European importance for the preservation of biological, geological and landscape diversity which are managed in an exemplary way. Protected areas can receive the Diploma due to outstanding scientific, cultural or aesthetic qualities, but they must also have suitable conservation management. Since its creation in 1965, 74 protected areas, in 29 countries (both EU and non EU) have been granted the European Diploma. Minsmere is one of only five sites in the UK to have achieved this award.

59 The national policy framework and objectives for heritage coasts were developed by the Countryside Commission, a predecessor of Natural England, and ratified by government. Heritage coasts: definition, purpose and Natural England's role - GOV.UK (www.gov.uk) Heritage Coast is a definition to conserve the best stretches of undeveloped coast in England, established to conserve protect and enhance the natural beauty of the coastline; the terrestrial coastal and marine flora and fauna and their heritage features (see Natural England heritage coast definition and purpose – accessed 27 May 2021)

60 ES Volume 2 Main Development Site Chapter 2 Description of Permanent Development (APP-180)

61 ES Volume 2 Main Development Site Chapter 20 Coastal Geomorphology and Hydrodynamics (APP-311)

- The Hard Coastal Defence Feature (HCDF)[62]
- The Soft Coastal Defence Feature (SCDF) [63]
- The permanent beach landing facility (BLF) and temporary BLF, introduced in the Change Application)[64]
- Two Fish Return and Recovery Outfalls (FRR)[65] and Combined Drainage Outfall (CDO) [66]

3.103 The potential for these structures and associated activities to affect coastal processes on the shoreline have been identified in the Environmental Statement and HRA accompanying the Application.

3.104 Risk of potential impacts to the Minsmere – Walberswick designated SAC, SPA, Ramsar and SSSI sites include:

- Accelerated erosion which could:
  - Lead to the loss of habitat supporting SAC and SSSI designated flora
  - Accelerate a breach of the shingle and dune barrier bank, allowing saline incursion and flooding into the brackish and freshwater areas of RSPB Minsmere (affecting the SPA and Ramsar site species) and Sizewell Marshes SSSI and any breach of the barrier bank has the potential to impact on the visitor infrastructure on the RSPB Minsmere reserve
  - Affect access routes for the public, potentially increasing trampling and disturbance impacts on the SAC and SPA features due to alternative routes being sought
  - Affect nesting bird species e.g. little tern (SPA feature) and ringed plover through loss of habitat and/or increased disturbance

- Increased accretion
  - Leading to a change in coastal dynamics and coastal composition which could affect the SAC, Ramsar and SSSI designated flora
  - This could provide increased protection for the brackish and freshwater habitats and visitor infrastructure at RSPB Minsmere, but would require management that was sympathetic to the potential adverse impact[67]

3.105 Section 20.4 of ES*Vol. 2 Ch. 20 Coastal Geomorphology and Hydrodynamics* describes the baseline geomorphology of the Greater Sizewell Bay, including the shoreline, nearshore and offshore bars and Sizewell to Dunwich offshore bank.

3.106 Should the two FRR and CDO outfalls have an effect on the nearshore bars, this could affect sediment supply or lead to more storm damage to the adjacent sections of coast, potentially increasing erosion effects. Pye & Blott (2005)[68] amongst others have illustrated the apparent relationship between the nearshore and offshore bars and patterns of local erosion and accretion along the shoreline at Minsmere and surrounding areas and have highlighted that changes to the nearshore and offshore bars appear to be related to episodes of erosion or accretion along the shoreline.

62 As described within APP-180: section 2.4.57 to 2.4.60 pp16 & 17; APP311 section 2.5 pp29 – 32

63 As described within APP-180: section 2.4.58 p 17; APP311 section 2.5 pp29 – 32

64 As described within APP-180: section 2.4.66 to 2.4.75 pp17 & 18; APP311 section 2.5 pp29 – 32

65 The FRR outfalls enable larger organisms caught on the drum screens during the abstraction of the cooling water to be returned to the sea.

66 As described within APP-180: section 2.6.7 to 2.6.9 p 31; APP311 section 2.5 pp29 – 32

67 Increased deposition of sediment on the foreshore, which could happen as a consequence of the SZC offshore infrastructure influencing sediment transport, would cause an accumulation of sand and shingle, building the beach and providing increased protection to Minsmere

68 Pye, Prof. K. & Blott, Dr. S. (2005) Coastal Processes and Morphological Evolution of the Minsmere Reserve and Surrounding Area, Suffolk. *Unpubl. Report for RSPB*

3.107 Little tern (SPA feature) nested on the coastal shingle at Minsmere until 2008 and have nested on the coastal lagoons in more recent years. The species may return to nest on the coastal shingle in future years and needs to be considered as a potential breeding species. Suitable sand and shingle habitat, with reduced human disturbance is essential to attract this species to settle and breed successfully. Ringed plover (not a designated feature, but of local importance) continue to breed annually on the coastal shingle shoreline, including the area south of Minsmere Sluice and again rely on suitable sand and shingle habitat and limited disturbance.

3.108 Doody and Randall (2003)[69] highlight that vegetated coastal shingle in the UK is largely protected as SSSI, Heritage Coast, AONB and ownership by the RSPB and others, which should allow protection from damage by activities such as coastal defence works. They note that man's intervention in natural coastal processes represents one of the main long-term threats to vegetated shingle, with coast protection work changing the accretion rate of shingle to coastal areas. They acknowledge where coastal protection techniques involve a more integrated approach allowing natural processes to work where possible and relying more on 'soft' defences rather than 'hard' structures such as sea walls, there is an opportunity to create new, stable areas of shingle. Although they recognise that if new stable areas of shingle are created these could also create new areas of shingle vegetation, they note it does not always follow that this new area of shingle will restore the plant and animal assemblages of areas that have been lost.

3.109 ES *Vol. 2 Ch. 20 Coastal Geomorphology and Hydrodynamics* section 20.7.4 page 32 describes initial investigations suggesting shingle won from the excavation of the footings for the HCDF will be of suitable size and quality to be used as source material for construction of the SCDF.

3.110 However it is noted that this is subject to a further suitability assessment once excavations begin; otherwise sediments for the SCDF would be delivered to the site (from a licenced aggregate extraction site and/or using excavated material from the main development site) rather than reprofiling the beach. *Vol. 3: ES Addendum Appendices Ch. 2 Main Development Site Appendix 2.15.A Coastal Geomorphology and Hydrodynamics*[70] *section 6.5 page 33* confirms that mitigation methods for the SCDF would involve either moving existing beach sediment (bypassing or recycling) or introducing new material (recharge).

3.111 Doody and Randall (2003) note that ongoing beach recycling operations relating to the introduction of sea defence structures (e.g. sea walls) often involve activities which have a significant impact on shingle vegetation. The act of moving the beach material does have a profound impact on the vegetation and any invertebrates associated with stable or semi stable shingle structures. Problems can occur where long-term works are carried out as this will prevent any natural beach profiles (or reprofiling following disruption) being allowed to develop.

3.112 Beach recharge is often seen as a more environmentally friendly 'softer' option for coastal defence. However, the import of material foreign to the locality can bring with it its own pressures and issues. Imported marine-dredged shingle can cause nutrient enrichment (or possibly depletion) and adverse effects on local beaches can occur when shingle of unsuitable type/size is used.

3.113 Alternatively, beach recycling prevents the accretion of 'pioneer' shingle ridges[71], essential for the SAC Annex 1 annual vegetation of drift lines feature and a key component of the mosaic of

---

69 Doody, Dr P. & Randall, Dr R. (2003) *A Guide to the Management and Restoration of Coastal Vegetated Shingle.* English Nature report

70 Volume 3: Environmental Statement Addendum Appendices Chapter 2 Main Development Site Appendix 2.15.A Coastal Geomorphology and Hydrodynamics (AS-237)

71 Pioneer shingle ridges are new, naturally formed shingle ridges, created by natural coastal processes that in turn provide habitat for the vegetation communities

habitats for scarce invertebrates (part of the Ramsar site listing), due to the regular intervention to move beach material from one location to another. In summary, Doody and Randall (2003)[72] consider beach nourishment can be detrimental in increasing the amount of fine sediment within the shingle, hence changing the conditions required by pioneer species (such as *Atriplex* spp, sea kale and sea pea). They note that if the new or replenished beach is allowed to develop without interference through reprofiling and the material is washed to reduce nutrient enrichment, the process can provide the foundation for restoration of vegetation (and the species reliant on that vegetation).

3.114 However, in many instances this is not the case and continued intervention and management of beach material to increase crest height and 'improve' the sea defence capability prevents such colonisation, confirming that it therefore represents ongoing negative impacts on many designated sites and their species.

3.115 Doody and Randall (2003) also note that the most damaging activity affecting coastal vegetated shingle is the removal of gravel from the beach itself. This action destroys the vegetation and associated fauna which, due to the complex structure in which these communities develop, is impossible to recreate.

3.116 Therefore, Doody and Randall 2003 question the appropriateness of coastal defence structures and beach reprofiling/nourishment within important nature conservation sites. Sites with a dynamic balance between stability and instability allow for a variety of communities to develop, including those associated with both ephemeral and more stable structures.

3.117 The designated Minsmere to Walberswick SAC, Ramsar and SSSI sites have fixed boundaries, with lines on maps used to define the protected areas. This can impose a rigidity on restoration activities, which is not commensurate with the inherent dynamism of the systems. This is particularly important where shingle beaches or structures move in response to tidal energy and storms, beyond the boundary of the designated site. Hence the importance of considering these as functionality linked to the designated site areas and ensuring adequate consideration is made of them when assessing potential impacts.

3.118 Vegetated shingle is listed as a priority habitat under the UK Biodiversity Action Plan (JNCC 1994)[73]. The Vegetated Shingle Habitat Action Plan recognises two principle issues (2.1 and 2.2 below) relating to sea defence and the sustainability of shingle habitats:

> *"2.1 Sediment supply. The health and ongoing development of a shingle feature depend on a continuing supply of shingle. This may occur sporadically as a response to storm events rather than continuously. It is frequently lacking owing to interruption of coastal processes by coast defence structures or by artificial redistribution of material within the site (e.g. Dungeness). Attempts have been made to rectify the situation by mechanical reprofiling, which is likely to fail in the long run because it does not address the lack of new material, or by beach recharge."*

3.119 Studies[74] tend to confirm the view that in many instances engineering solutions to shingle erosion are unsustainable in the medium to long term, leaving the consideration of approaches which 'work with nature' and accept the 'naturally' dynamic state of shingle beaches.

> *"2.2 Natural mobility. Shingle features are rarely stable in the long term. Many structures exhibit continuous longshore drift and ridges lying parallel to the shoreline tend to be rolled*

---

[72] Doody, Dr P. & Randall, Dr R. (2003) *A Guide to the Management and Restoration of Coastal Vegetated Shingle.* English Nature report

[73] JNCC (1994) Biodiversity. The UK Action Plan. HMSO. London

[74] Specifically Doody and Randall (2003)

over towards the land by wave action in storm events. This movement has a knock-on effect on low-lying habitats behind the shingle. Movement is likely to be accelerated by climate change resulting in sea level rise and increased storminess."

3.120 The reliance on a 'static' approach to conservation, which is so often associated with the identification of boundaries of sites on maps, may be counter-productive for a habitat existing in such a dynamic environment and the importance of functionally linked areas as mentioned above. Removing static artificial features such as groynes and breakwaters and/or ceasing beach nourishment could help bring about major restoration of shingle beaches.

3.121 The UK Biodiversity Action Plan's Vegetated Shingle Habitat Action Plan Target 1 is –

> "Prevent further net loss of existing vegetated shingle structures totalling about 5800 ha. (However local gains and losses due to storm events occur sporadically and should be accepted provided that the national and regional resources are maintained overall.)

3.122 Doody and Randall 2003[75] define a primary concern must be the conservation of the remaining areas of relatively intact and undisturbed areas of vegetated shingle in the UK. All damaging activities must be prohibited on all sites where important areas of this extremely rare habitat exist. The UK has a particularly important role to play here by virtue of the extent of the shingle (gravel) banks that occurs and their world significance.

3.123 Any acceleration of erosion that could lead to a breach in the shingle and dune barrier bank, allowing saline inundation of the low-lying marshes inland would significantly affect the freshwater interest features within RSPB Minsmere. This would extend to SPA designated wetland breeding birds and SSSI bird, flora and invertebrate communities.

Summary of concerns relating to the assessment of coastal processes

3.124 Use of the Rochdale envelope approach has been deployed by the Applicant and said to explain why detailed designs on the coastal defences were not available when the Application was submitted. In the absence of these designs we have been unable to be confident that the approaches to the coastal defences and the interaction with the neighbouring SAC habitat is robust and would conclude that the precautionary principle needs to be followed. This is further emphasised by the inherent uncertainty when predicting likely coastal geomorphological outcomes in this dynamic environment.

3.125 In addition, the RSPB does not agree that the assessments are sufficiently robust. The Applicant have agreed to undertake 'additional bespoke modelling' (see *Written summaries of SZC Co.'s oral submissions at Preliminary Meeting Part 1*[76]) but it is our view that this should not be determined to be 'additional' or 'bespoke' as we believe that the work is necessary to provide a satisfactory environmental assessment given the risk of potential impacts to the Minsmere – Walberswick designated sites.

3.126 It is our view that the potential impacts arising from the Application, should be considered in combination with natural variation. We believe this is the appropriate precautionary approach and should be adopted.

3.127 We recognise that the Applicant is preparing updated models in respect of the revisions to the HCDF, SCDF and BLFs, and in the absence of these we do not believe there has been adequate

---

[75] Doody, Dr P. & Randall, Dr R. (2003) *A Guide to the Management and Restoration of Coastal Vegetated Shingle.* English Nature report

[76] *Written summaries of SZC Co.'s oral submissions at Preliminary Meeting Part 1 (PDB-012)*

assessment on the potential impacts on the Minsmere – Walberswick designated sites through both the ES and HRA processes, as a consequence of potential impacts being screened out. We believe that the current lack of confidence in the modelling and assessment should require a precautionary approach so that the true worst-case scenario is considered for the designated sites and appropriate mitigation measures considered.

3.128 *BEEMS Technical Report TR403 and the Volume 2, Chapter 20 of the ES [APP-311]* identified that, if no further intervention was undertaken, shoreline recession was likely to erode the soft coastal defence feature (SCDF) and expose the hard coastal defence feature (HCDF) within the timeframe of 2053 – 2087 (i.e., within the Sizewell C Project's operational phase). An exposed HCDF, dividing the otherwise continuous shingle beach in two, would partially or fully block the longshore shingle transport corridor. If persistent, shingle starvation and erosion either side of the exposed HCDF would be expected.

3.129 Experience along the Suffolk Coast demonstrates that 'hard' features on the coast influence the shoreline to the north and south. With the HCDF anticipated to become a marine feature at some point in the operational life of SZC it is very likely to affect the coastal geomorphology of the Minsmere frontage. Therefore, we cannot agree with the Applicant's conclusion that no possible impacts are predicted.

3.130 We understand that the purpose of soft coastal defence feature (SCDF) seaward of the HCDF is to mitigate any impacts on sediment transport or coastal processes by maintaining a continued source of accretion during major storm events and that no coastal geomorphological impacts are predicted along the Minsmere frontage with this mitigation in place.This is confirmed in the Applicant's submission (e.g. Volume 3 Chapter 2 Environmental Statement Addendum Coastal Geomorphology and Hydrodynamics Appendix 2.15.A section 6.1)

3.131 The lack of sufficient detail currently on the management of the SCDF provides us with limited confidence in the conclusion that the HCDF will remain a terrestrial feature for much of the operational life of SZC and that the potential impacts can be satisfactorily mitigated.

3.132 We await details of the revised modelling to determine whether the aspects such as the potential value of southeast waves in aiding accretion to the Minsmere shoreline have been considered.

3.133 The suggestion that the southern Minsmere frontage no longer supports the designated Annual vegetation of drift lines and Perennial vegetation of stony banks due to the loss of SSSI Site Unit 113[77] (which has been destroyed through coastal erosion) is incorrect. The implication that Natural England have concluded that any designated vegetation features have been lost from this stretch of the coast is misleading. Natural England's site unit assessment for Unit 113[78], provides a more accurate description of the situation, concluding that the unit has been destroyed through natural processes[79]. It suggests that Unit 113 may have rolled back into Unit 112[80] (which is what you would expect to have happened). It describes Unit 112 as:

> *'Annual shingle vegetation was evidence but appeared to be a single species of Atriplex (Atriplex prostrata). The target should be reconsidered as other shingle sites have shown a*

---

77 *Volume 2 Main Development Site Chapter 20 Coastal Geomorphology and Hydrodynamics Appendix 20A Coastal Geomorphology and Hydrodynamics: Synthesis for Environmental Impact Assessment* (APP-312) *Section 1.1 p15*

78 Natural England's site unit assessment for Unit 113

79 "This unit has been lost through coastal erosion…site visit confirmed that all the unit had gone or if deposition had started to occur again no shingle habitat was present…It may be that Unit 113 has rolled back into Unit 112. A sea wall divides Minsmere Scrapes (Unit 48) from the beach (Unit 112) and supports dune communities. It is likely that if the shingle is trying to rollback back this is inhibitated by the seawall and therefore coastal squeeze could be an issue for unit 112."

80 Natural England's site unit assessment for Unit 112

low diversity of species (notably Orfordness, in discussions with Sue Rees). Perennial shingle vegetation was present including Rumex crispus, Crambe maritime (sic) and Glaucium flavum, all abundant or frequent. Bitter stonecrop and sea sandwort present.'

3.134 Emma Hay, the Natural England officer, who conducted the site assessment has confirmed (*pers comms*) that the 'loss' of Unit 113 should be interpreted as a geographical loss of this unit and it should not be considered that the SAC vegetation interest feature has been lost from this frontage[81].

3.135 This is further confirmed by Cadbury (199682, 200483 & 201584), alongside the NE site assessments which confirm that the southern Minsmere frontage between the sluice and the red line development boundary support the two important vegetated shingle communities: summer annuals (*Atriplex* spp.) reflective of a beach stable over the growing season only and short-lived perennials reflecting a beach stable for 3+ years. Doody and Randall (2003)[85] confirm that vegetation is primarily controlled by the proportion and size of the fine fraction material of the matrix under 2mm diameter, which is critical for vegetation germination and seedling stages. The species characteristic of the Minsmere frontage are those associated with no matrix (e.g. *Atriplex glabriuscula, Crambe maritima, Lathyrus japonicus*) or a sand influence (e.g. *Honckenya peploides*).

3.136 We note that the likelihood of the development accelerating a breach in the barrier bank is considered to be unlikely. However, although this eventuality has low likelihood, it would be a significant risk to the freshwater habitats were it to occur.

Comments on implications of the changes to the application on coastal processes

3.137 The fact that the design parameters have changed significantly between the original Application and the Change Application does cause us concern about the robustness of the assessments including ensuring that the worst-case scenario has been considered. Whilst we appreciate that Addendums for both the ES and HRAs have been provided (and we appreciate the Applicant's signposting document[86] to help navigate between the many volumes and appendices) there do still appear to be some gaps. For example, the movement of the toe of the HCDF 10m seaward of the Application's design at the abutment to the enhanced permanent BLF[87], along with the introduction of a permanent BLF and changes to the temporary BLF require a modelling and further assessment. We do not agree that the application of expert judgements, as proposed in the Environmental Statement Addendum [88] are sufficient.

---

81 Unit 112 "Minsmere Haven South is a shingle beach backed by sand dune vegetation, comprising some mobile dune community of marram grass and fixed dune grassland behind. Shingle vegetation is sparse within the unit due to coastal process/erosion of the beach with annual species limited to occasional spear-leaved orache and some sea sandwort, plus occasional perennial vegetation species - sea kale, sea poppy, sea holly and sea pea….. The Unit was found to be in favourable condition and passed on all its targets for Mobile & Embryonic Dune Feature & Fixed Dune Grassland features…"

86 The Applicant's helpful Navigation Document - REP1-002

87 Environmental Statement Addendum Volume 1: Environmental Statement Addendum Chapters, Chapter 2 Main Development Site 2.15.18 p240 PINS ref AS-181

88 2.15.9 page 237 and 2.15.15 page 238

3.138 We are aware that the Applicant is in the process of some additional modelling of the potential impacts of the proposed changed structures and operation. The changes in the coastal and nearshore marine environment provide no improvement to the potential threats identified above and in our view, increase the potential risk of impacts. This is a consequence of:

- Confirmed designs for the HCDF and SCDF still awaited
- Seaward movement of the proposed toe of the HCDF
- Earlier intervention required to manage the SCDF[89]
- Increased length of the permanent BLF and design changes to enable operation
- Introduction of an additional temporary BLF
- Increase in vessel deliveries and therefore potential impact of vessels on coastal processes

3.139 The change document has relocated the HCDF seaward of the Application site, which has increased these concerns as it would be assumed that the HCDF will become exposed ahead of the timeframe quoted in the Application.

Conclusions regarding impacts on coastal processes on protected sites and species

3.140 In conclusion, based on the above concerns and the evidence provided at this stage, we do not agree that *adverse effect on integrity* can be ruled out for the following sites and features for impacts from the project alone:

- Annual vegetation of drift lines (Minsmere to Walberswick Heaths & Marshes SAC);
- Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC);
- Little Tern (Minsmere-Walberswick SPA);
- Breeding waterbirds (Shoveler, Gadwall, Teal, Bittern, Marsh Harrier, Avocet, Bearded Tit) (Minsmere-Walberswick SPA)

Mitigation and monitoring

Lack of detailed design

3.141 In the absence of a confirmed design approach and full assessment of all *likely significant effects*, it is difficult to evaluate whether the Coastal Processes Monitoring and Mitigation Plan (CPMMP - *Volume 3 Chapter 2 Environmental Statement Addendum Coastal Geomorphology and Hydrodynamics Appendix 2.15.A*) will be appropriate in scope.

3.142 We have immediate concerns regarding the approach to embedded mitigation using the SCDF through the CPMMP. We consider that the design detail of the SCDF needs to be confirmed before the end of the Examination.

Mitigation activity in response to triggers

3.143 In addition, due to the dynamic coastal environment, the CPMMP must be developed in a manner that allows impacts due to the Application to be appropriately addressed. As mentioned above we do not agree, with the assessment of minor or insignificant impacts and therefore have additional concerns as to how trigger points for intervention may be defined and considered within the CPMMP.

---

[89] Earlier intervention to maintain the SCDF has been proposed as a consequence of the seaward movement of the HCDF and therefore the anticipated earlier erosion of the soft coastal defence

3.144 We welcome the commitment[90] that the nearshore bars will be monitored to assess any impacts of the FRR and CDO beyond the predictions in the models, but note that the CPMMP does not appear to identify any mitigation strategy for these nearshore bars, should impacts be identified. Due to the potential to increase the vulnerability of the shoreline if unexpected changes to the nearshore bars occur, it is vital that measures are proposed now.

3.145 In addition, we think it is necessary to consider some form of adaptive mitigation for example the replenishment of the nearshore bars (and therefore maintain protection to the shoreline) should the monitoring reveal predicted impacts.

Mitigation activity and designated sites

3.146 In the CPMMP, section 6.2 Beach management framework, the monitoring framework in Table 1 indicates that monitoring will take place north up to the Minsmere outfall. We welcome the commitment to monitoring the southern RSPB Minsmere frontage, but note that no attempt has been made to understand how mitigation would be implemented if this monitoring established an unexpected adverse impact on the Minsmere frontage. We note also that the CPMMP commits to providing final proposals for monitoring the annual vegetation of drift lines but are unaware of any further details being presented.

3.147 Section 6.5.4 (page 36) of the CPMMP states that

> *no sediment would not be extracted from statutory designated sites (in the cases of bypassing or beach recycling) unless accumulating sediments were a direct effect of the Sizewell C Project (mitigation or presence of the HCDF) and approval was given following demonstration that designated features would not be affected*.

3.148 Sediment accumulation as a direct effect of Sizewell C would represent an *adverse effect* and we are yet to understand how this could be addressed without impacting on designated features as described above.

3.149 Section 6.5.4 also states

> *sediment would not be deposited on the supra-tidal beach within statutory designated sites unless approval was given following demonstration that designated features would not be affected*.

3.150 Again, if this requirement proved necessary, due to effects from the Application exceeding the model predictions or via a need to maintain the SCDF, we do not understand how it could be implemented without affecting the designated features and so do not believe we have enough evidence to support this approach.

3.151 In addition, the approach described in the CPMMP recognises there is the potential for impacts on the RSPB Minsmere frontage north of the red line boundary. Should the CPMMP identify the need for interventions in this area, the Applicant currently (as far as we are aware) has no powers to implement such required measures. As well as our ecological concerns as a neighbouring landowner (as discussed below) we are keen to know now whether land owned by the RSPB could be required.

---

[90] Section 4 p 22-23 CPMMP AS-237 6.14 ES Addendum Volume 3: Addendum Appendices Chapter 2 Main Development Site Appendix 2.15.A Coastal Geomorphology and Hydrodynamics

3.152 We also welcome the commitment to monitor the annual vegetation of drift lines habitat recognising their dependence on coastal geomorphology (i.e., supra-tidal shingle)[91]. However, we are concerned that this dependence has not been captured in the HRA and therefore again concerned about how any trigger points for intervention will be determined.

3.153 In addition, it is important to know now how any evidence of impacts identified by the monitoring would be mitigated. We are not familiar with successful mitigation techniques being implemented in coastal shingle habitats to enhance the annual vegetation of drift lines, where changes in coastal geomorphology are creating adverse effects and therefore have concerns about what might be viable and effective mitigation.

3.154 The statement in section 6.1.1.2 of the CPMMP that the *activities/pressures associated with the use of the SCDF include heavy plant on the beach* also requires greater clarification. At present the red line boundary for the Application abuts the southern boundary of the Minsmere-Walberswick SPA, SAC, Ramsar and SSSI. Without more detailed information regarding the activity of this heavy plant in this sensitive location immediately adjacent to the designated sites we cannot be confident in the conclusion that this activity does not have the potential to impact the designated features.

3.155 What mitigation is proposed[92] appears to be solely focussed on the maintenance of the shingle transport corridor, with the main aim of providing protection for the HCDF. It is unclear how this proposed mitigation for sea defence purposes will be aligned to avoiding *adverse effects* on the designated flora or the integrity of the neighbouring frontage to the north, especially as impacts on the frontage could have significant effects on the integrity of the Minsmere – Walberswick designated sites.

3.156 As mentioned above, it appears that because ES Volume 2, Chapter 20 of the ES [APP-311] showed no significant effects on coastal geomorphology receptors from the SCDF, the potential for effects of this activity on the designated sites' features, such as annual vegetation of drift lines, may not have been adequately taken into consideration. This is of increased concern given the acknowledged value of the existing frontage in front of the proposed SZC site as set out in section 7 of the CPMMP.

Overall approach to Monitoring and Mitigation

3.157 The final paragraph in section 6.1.1. of the CPMMP states:

> *In prolonging the period before any mitigation is needed, a longer evidence base on aspects such as storm erosion and recovery under rising sea levels will be developed, which in turn will lead to more effective mitigation decisions. During this period there may also be advances in our understanding of mixed sandgravel beaches like Sizewell, and in the models used to predict how they respond in the short and long term, which could be used where appropriate to make further refinements to the final monitoring plan.*

3.158 Whilst these aspirations are laudable, we believe this level of uncertainty is unsatisfactory and does not provide confidence in the process. The Applicant and their predecessors have been monitoring shoreline evolution and processes on the Sizewell frontage for more than two decades through the auspices of the Sizewell Shoreline Management Planning Group. Given that after two decades of study this appears not to have provided a sufficient evidence base for making

---

[91] Section 7 page 38 CPMMP - AS-237 6.14 ES Addendum Volume 3: Environmental Statement Addendum Appendices Chapter 2 Main Development Site Appendix 2.15.A Coastal Geomorphology and Hydrodynamics

[92] Section 6.5 p 33-36 CPMMP AS-237 6.14 ES Addendum Volume 3: ES Addendum Appendices Chapter 2 Main Development Site Appendix 2.15.A Coastal Geomorphology and Hydrodynamics

confident predictions regarding potential impacts and appropriate mitigation, we remain concerned that this aspiration is achievable.

3.159 The statement in section 6.1.1.2 of the CPMMP:

> *During construction of Sizewell C, the sedimentary material presently in this location* (the SCDF) *will be impacted as required for landscaping, building the SCDF and some aspects of the HCDF or BLF (e.g., the installation of the BLF decking at c. 5.2 m ODN across the 5 m bund and/or SCDF which has the same elevation).*

3.160 We request more detail on this statement. In combination with the statement in section 6.1.1.1

> *Coffer dams may be required to place the initial toe of the HCDF, but they would be set further back and are unlikely to be exposed to the sea while the HCDF is built, so long as the present beach width and elevation are maintained*

we are not reassured that there is an explicit requirement to retain the shingle feature at this location during construction. Given that the shingle/beach feature in this area has the potential to support annual vegetation of drift lines (as highlighted in section 7 of the CPMMP) and is also integral to the access and amenity planning/recreational displacement in terms of public access during the construction period, we seek a stronger commitment that the feature will be maintained. As noted above, Doody & Randall (2003)[93] highlight the removal of gravel from the beach itself as the most damaging activity affecting coastal vegetated shingle.

3.161 In addition, the CPMMP does not appear to have been revised to address issues arising from the revised approach to coastal defences and infrastructure arising from the Change Application.

Hydrology (surface water impacts)

Introduction

Minsmere RSPB Reserve

3.162 The hydrological management of Minsmere RSPB Reserve is ultimately reliant on the Minsmere Sluice, located at the seaward end of the Minsmere New Cut. The Minsmere Sluice drains the catchment of the Sizewell Marshes SSSI and the Minsmere Level.

3.163 The importance and features of the Sizewell SSSI are described at above but it is worth noting here the importance of water levels for this SSSI and its features (as discussed further below). For example Natural England's list of *operations likely to damage* relevant for this SSSI[94] include:

> 13b: Modification of the structure of watercourses (e.g. ditches, dykes, drains), including their banks and beds, by re-alignment, re-grading and dredging.
>
> 14: The changing of water levels and tables and water utilisation including irrigation, storage and abstraction from existing water bodies and through boreholes.
>
> 15: Infilling of ditches, dykes, drains or marshes.

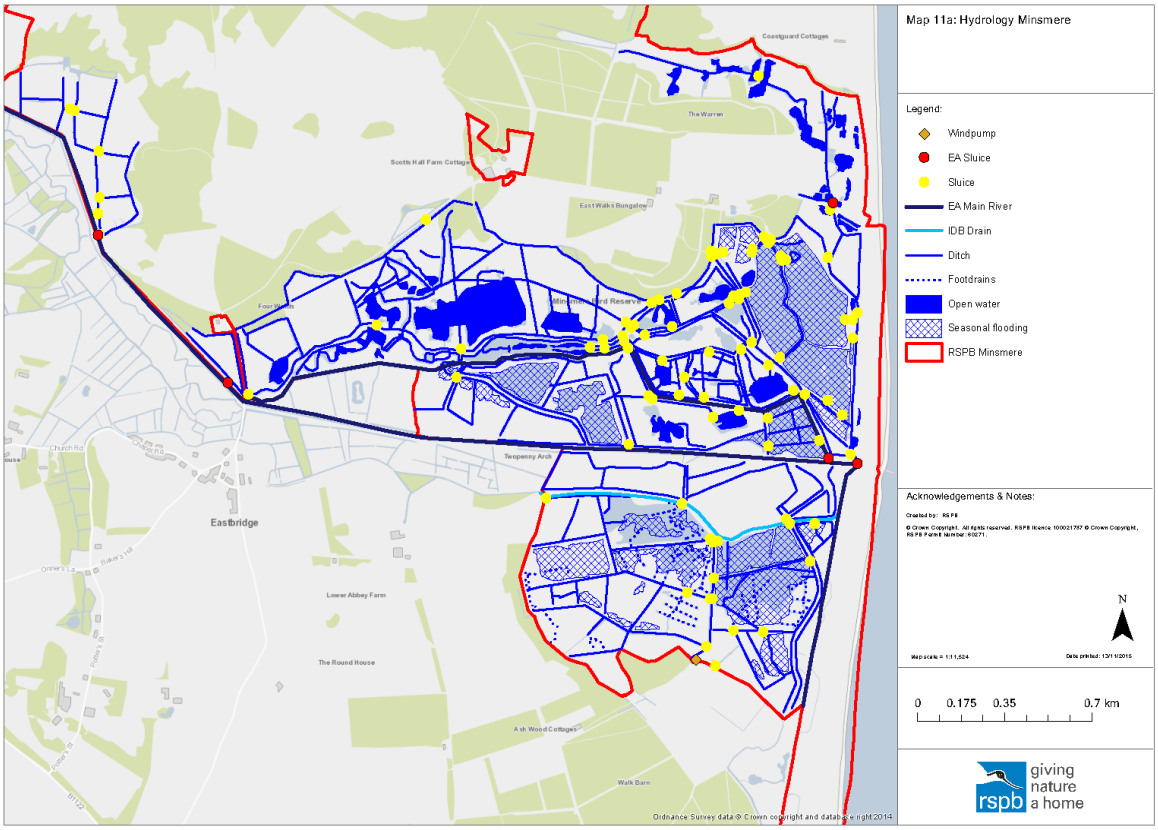
94 Sizewell Marshes OLD - https://designatedsites.naturalengland.org.uk/PDFsForWeb/Consent/1003416.pdf

3.164 The surface water on the marshes south of the New Cut (South Levels) are controlled via the Internal Drainage Board's (IDB)[95] Drain No 7 which is connected to the Leiston Main Drain which discharges into the southern chamber of the Minsmere Sluice.

3.165 The surface water on the land north of the New Cut (North Levels) drains into the Old Minsmere River which drains into the New Cut.



3.166 The water levels in the main reedbed, Scrape and north marsh drain into the Scott's Hall Drain which is discharged via a syphon into the southern chamber of the Minsmere Sluice. The New Cut is discharged via the northern chamber of the Minsmere Sluice. The New Cut can also be discharged via the southern chamber of the sluice during periods of high flow.

Map 1: Locations of key drains and water level monitoring gauge boards (from Main Development Site Flood Risk Assessment Appendices 1- 7 Part 1[96])

[95] Ultimately the IDB is are responsible for the maintenance of the main channel that drains water from the South Levels, but please note that the RSPB have control to manage water levels on the South Levels 'upstream' of this drainage ditch

[96] From p212 of Main Development Site Flood Risk Assessment Appendices 1-7 Part 1 (APP-094)

Map 2: Locations of water control structures

3.167 Any increase in water flows or volume in the Leiston Main Drain has the ability to affect the management of water levels on the RSPB Minsmere South Levels by impeding the rate of discharge from IDB Drain No 7, potentially causing surface water to 'back up' on the South Levels marshes. An increase in flows or volume in the Leiston Main Drain could also reduce the rate of discharge in the Scott's Hall Drain, thus holding surface water levels higher in the main reedbed, Scrape and north marsh on RSPB Minsmere.

The relevance of water levels for the Ecology of RSPB Minsmere[97]

3.168 The primary inputs for the Minsmere Levels are from a predominantly arable catchment, with some heath and mixed woodland. Direct run-off from adjacent arable land is mostly intercepted and diverted by the western boundary ditch that forms the western and southern boundary to the South Levels. Rainfall also provides a significant input and, in extreme events, floodwater from the New Cut and Old Minsmere River (EA Main Rivers) also provide surface water. There is a saline influence to the east. This may be from groundwater beneath the dunes, occasional leaks through the Minsmere Sluice and possibly sea spray.

3.169 The main input to the **reedbeds** are via groundwater springs and rainfall. Water levels within the reedbed are maintained at an optimal depth of 20-30 cm depth throughout the late winter and early spring. Levels drain down as a consequence of evapo-transpiration during most summers. Levels are lowered between September and December when reed-cutting management is taking place. The reedbed water level management is principally to benefit key breeding bird species such as bittern.

97 The areas, features in bold are included in the maps above

3.170 The main inputs to the **coastal lagoons** are from rainfall, freshwater from North Marsh and the eastern reedbed and brackish water from the sea via the Minsmere Sluice (an EA structure). The coastal lagoons are allowed to draw down slowly over late spring and summer, to provide suitable conditions for breeding avocet. They are lowered in late summer to allow management of vegetation on islands, and are maintained at varying depths in autumn and winter to provide a range of feeding and loafing conditions for waders and wildfowl.

3.171 The main inputs to the **South Levels** are from rainfall and groundwater springs. The grazing marsh areas are flooded for winter wildfowl. Other areas remain damp and, if possible, unflooded. Water levels are drawn down through the spring and summer for breeding waders and lowered to allow grazing and mechanical operations as the summer progresses.

3.172 The **wetlands north of the New Cut** drain east and south. The **North Levels** drain into the Minsmere Old River (an EA Main River) and then into the New Cut via an EA sluice. **The Scrape**, **North Marsh and the eastern reedbed** areas drain through the Minsmere Sluice via a chamber separate to the New Cut. Either route can drain the **western reedbed areas**. During periods of heavy rainfall, an EA penstock is operated to give priority to draining the New Cut and this can prevent drainage from the Scrape, North Marsh and eastern reedbed. Heavy rainfall can also cause the New Cut to overtop its banks, displacing water into the western end of the reedbed and Old Minsmere River.

3.173 The **wetlands south of the New Cut** drain east and north. They drain into IDB Drain No. 7 and the Leiston Drain (an EA Main Drain), then through the Minsmere Sluice via the same chamber as the Scrape. **Eastbridge Meadow and Meadow Marsh** drain directly into the New Cut via EA sluices. During periods of heavy rainfall, the New Cut banks near the sluices as well can be over-topped, with water flowing into Eastbridge Meadow and Meadow Marsh.

3.174 Water levels are controlled by structures at the locations shown in Map 2 (above). Most of these are piped sluices in earth banks.

3.175 Levels are monitored at gauge boards shown on Map 1 (above). Salinities are monitored at seven locations in the reedbed, and each of the three main coastal lagoons

3.176 Since 2008, following episodes of heavy rain, the Minsmere Sluice, which is tidally operated, has proved unable to evacuate the consequent run-off quickly enough to prevent detrimental flooding of the reserve's wetland habitats and some visitor trails, as happened in May/June 2012 and in several recent winter periods. The Environment Agency have undertaken improvement works to the main sluice during 2012 – 2014, but these will not always prevent these periodic flooding occurrences. Given this known risk, it is imperative that additional increases in flow are not introduced into the system that may further compromise the ability to manage target water levels following extreme events.

3.177 The risks of increased water levels on the designated bird species of the Minsmere to Walberswick SPA includes reduced breeding success, particularly if there are prolonged periods of raised water levels in April - June. Species particularly prone to nest loss through flooding events are bittern, avocet, common, Sandwich and little terns. Spring flooding has caused nesting failure in several springs in the early 2000s and it is imperative that additional factors that could increase the risk of this situation are not introduced by the Application. Nest failure is caused when the eggs are submerged by flood water for a protracted period. Whilst eggs may tolerate short periods of inundation (such as being flooded by a high tide event) they are not able to survive being flooded for a period of many hours. Equally the inability of the adults to incubate the eggs when they are submerged and of course the very serious issue of nests and eggs being washed away by flood

water. An increase in nest failure events can obviously have a detrimental impact on the species population.

3.178 Foraging opportunities for some Minsmere to Walberswick SPA and Ramsar site designated bird species can also be compromised by changes in water level. Bearded tit (Ramsar feature) population survival has been demonstrated to be adversely affected by raised water levels in the non-breeding season preventing access to food (Wilson & Peach 2006)[98].

3.179 Loss of nest sites for example for avocet and terns who nest on bare substrates exposed by receding water levels, which are at threat of being submerged beneath raised water levels. Also raised water levels can lead to the delaying of breeding attempts. Again, this can result in reduced breeding productivity if the birds only have a shorter breeding season in which to attempt breeding, which, if repeated, could have an effect on local populations over time.

Concerns regarding potential impacts on water levels of the Minsmere to Walberswick designated sites

3.180 The potential for the Application to alter the surface water flow regime and lead to impacts on the Sizewell Marshes SSSI and Minsmere to Walberswick Heaths and Marshes SSSI, SAC, SPA and Ramsar site is acknowledged in table 19.9 on p52 of ES *Vol. 2 Ch. 19 Groundwater and Surface Water*[99].

3.181 Table 5.2 item 3b (p79) of *Shadow HRA Vol. 1: Screening and Appropriate Assessment Part 1*[100] provides a justification for the decision that likely significant effects cannot be excluded, confirming that changes to direct hydrological connections, water levels and water quality/chemistry could be involved for example

> '*A number of factors mean that the potential for measurable hydrological impact as a result of construction (or decommissioning) activities on either side of the sluice is minimal but any increase in water levels at the Minsmere Sluice could potentially affect surface water levels to the north. As such, discharges into watercourses within the development area, or changes in water levels, flow, ditch alignment or sedimentation rates within the watercourses, could have a direct effect on water quality in the Minsmere South or Minsmere North Levels.*

and

> *interrupt*[ions] *or* alter[ations to] *the baseline groundwater regime…could potentially change the hydrological or hydrogeological properties of the site and adjacent land and, in turn, the conditions that support wetland habitat….The potential for direct effects on water quality…. means that likely significant effects cannot be excluded for those qualifying features dependent on wetland habitats.'*

3.182 The operation of the Minsmere Sluice means that the potential impact to the north of the New Cut would be greater than just affecting the Minsmere North Levels. This is because any impediment on the drainage of the Scott's Hall Drain at the Sluice could impact on water levels in the main reedbed, Scrape and north marsh.

3.183 Minsmere Sluice allows some entry of seawater into Minsmere to help maintain the Ramsar designated brackish transition habitats in the ditches and appropriate salinities on the scrape. This means that these habitats are vulnerable to any contaminants entering by this route. The

---

99 ES Volume 2 Main Development Site Chapter 19 Groundwater and Surface Water (APP-297)

100 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 (APP-145)

Application would discharge hydrazine, which is used as an anti-foulant in the cooling water system, during the later stages of construction and throughout its operation. Paragraph 21.6.72 of ES Ch. 21 Marine Water Quality and Sediments (AS-034) explains that at certain states of the tide it is possible that low levels of hydrazine would enter Minsmere via the Sluice. Given the toxic properties of hydrazine, we consider that this requires further consideration through the HRA. This issue is discussed in more detail in our comments on marine ecology below.

3.184 We are grateful to the Applicant for the detailed and technical discussions concerning our hydrological concerns and believe it will be submitting further information in due course. For now therefore we have set out our concerns but will of course review any new information or material and provide further comments.

3.185 All these potential effects could impact the breeding attempts of species such as avocet and bittern (SPA, Ramsar and SSSI species) by flooding nests or affecting feeding sites.

Proposed Primary Mitigation to manage potential impacts

3.186 Section 7.8.15 – 19 (pp294-295) *Shadow HRA Vol. 1: Screening and Appropriate Assessment Part 1*[101] states that due to the potential risk of greater volumes needing to be discharged down Leiston Drain to maintain water levels within the Sizewell Marshes SSSI potential inundation of habitats within the Ramsar site could occur and prevent the control of water levels. Adding that:

> *If the increased discharge flows are sufficient to reduce available capacity in the southern chamber of the Minsmere Sluice, this could cause back flooding within the Scott's Hall Drain, potentially affecting the Minsmere to Walberswick Heaths and Marshes SSSI, part of which is included within the Ramsar site.*

3.187 Therefore the Applicant has included mitigation measures within the surface water management design (during the construction period), arguing that these along with the proposed Sizewell Drain realignment isolate the proposed development from the surrounding areas (Section 7.8.15 – 19 (pp294-295) adding:

> *The mitigation measures also ensure that any flows discharged to an existing surface water receptor would have passed through water quality treatment measures and would be discharged at greenfield rates.*[102]

3.188 Within the same section (Section 7.8.15 – 19 (pp294-295) the Applicant states:

> *The proposed water management structures would also allow for easy manipulation of the water levels and flows and thus levels/flows within the Leiston Drain could be reduced as and when required to allow for the Scott's Hall Drain to discharge efficiently when required. This coupled with the fact that the relatively small contribution from Leiston Drain to the overall flow at Minsmere Sluice, limited effects on the flow regime of the southern chamber of the Minsmere Sluice are anticipated and thus no significant effect is predicted for the Scott's Hall Drain and associated drainage network. It is, therefore, anticipated that the proposed development should create no significant effect on the flow regime or water quality of the existing surface water receptors and, therefore, no effect on the habitats within the Ramsar site.*

3.189 Repeatedly concluding in section 8 (e.g. page 393, section 8.8.4) that with mitigation in place to manage surface water discharges, as described in section 7.8.b (*sic*) of this report above, there

---

101 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 (APP-145)

102 i.e. the flow rates of water discharging from the construction surface will be managed to not exceed the rate that would occur in natural circumstances

would be *no adverse effects on the integrity* on any of the Ramsar qualifying habitats within the Minsmere-Walberswick SPA.

3.190 And since these habitats also support the SPA qualifying bird species, it is concluded that there would not be an *adverse effect on the integrity* of any of the SPA qualifying feature either, including the breeding avocet, during the construction or decommissioning phases.

3.191 We cannot see how a situation of raised water levels throughout the area, particularly in extreme events, can be managed by the proposed mitigation to avoid impacts successfully. In such events, it is inevitable that the mitigation structure controlling the levels in Sizewell Marshes SSSI will need to be adjusted to allow increased discharge. In such circumstances we question how the Applicant proposes to reduce levels/flows in the Leiston Drain as described above to avoid increasing flows into the Minsmere Sluice and affecting water level control at RSPB Minsmere. In extreme events this scenario increases the risk of flooding the nests or reducing feeding opportunities for SPA, Ramsar and SSSI species such as avocet and bittern.

3.192 *Vol. 2 Main Development Site Ch. 14 Terrestrial Ecology and Ornithology*[103] repeats on page 23 that the realignment of the Sizewell Drain and associated water control features would allow for control of the Sizewell Marshes SSSI water levels[104]. Adding that

> *Control structures would include passage for eels and other fish (see Eels Regulations Compliance Assessment, 2019).'*

and on page 24

> '*Construction infrastructure would be in place to ensure all surface runoff and foul water is captured and treated and does not enter adjacent designated sites. Ditches, bunds and swales would be constructed to prevent untreated surface water run-off from leaving the site. Oil/petrol interceptors would be incorporated into the drainage design. Where complete infiltration to ground is not feasible, Water Management Zones (WMZs) have been embedded into the design. These systems would be designed to discharge treated water to the surface water drainage network at greenfield run-off rates. Foul water would be pumped to a central treatment plant, prior to discharge to sea. Run-off would be managed as part of the Construction Drainage Strategy, which would include mitigation measures to manage surface water discharges*[105]

3.193 We understand that further information is to be provided to the Examination and will comment further on this once we have had time to review.

3.194 Section 19.5.1 (page 41) of *ES Vol. 2 Ch. 19 Groundwater and Surface Water* [106] does state

> '*primary mitigation measures have been identified through the iterative EIA process and have been incorporated into the design and construction planning of the proposed development. Tertiary mitigation measures are legal requirements or are standard practices that would be implemented as part of the proposed development.*'

3.195 However we question this assertion since *detailed* mitigation measures to manage surface water flows have yet to be progressed in detail and therefore based on the information currently before

---

[103] Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology (AS-033)

[104] As set out in more detail in *Chapter 19 Ground and Surface Water of the ES (Doc Ref. Book 6)*

[105] With *Chapter 19: Groundwater and Surface Water* and *Chapter 22 Marine Ecology and Fisheries* setting out the full details.

[106] ES Volume 2 Main Development Site Chapter 19 Groundwater and Surface Water (APP-297)

the Examination could not be described as *incorporated in the design…. of the proposed development*. We have detailed these concerns further in section 4.3.4 below.

3.196 There are some further details for example in Section 7.4 (pages 50-51) of ES *Vol. 2 Ch. 19 Appendix 19B*[107]we find the following:

> '*Where it is anticipated that groundwater levels would rise to an unacceptable degree as a result of the development…engineered mitigation features, such as passive drain systems, and/or ditch maintenance will be considered to control groundwater levels.*

3.197 But as far as we are aware there is currently no firm commitment to these measures but for this reference in the Environmental Statement.

3.198 There is confirmation that monitoring of surface water and groundwater and the efficacy of the mitigation measures as well and further assessment will be carried out for example to determine the extent of the predicted change and to allow further mitigation *to be designed where necessary*.

3.199 Adding that

> *The monitoring network will provide the capability for early identification of potentially unacceptable changes in flows and levels allowing control measures to be implemented.'*

3.200 However, to be able to rely on such commitments and the effectiveness of any additional/secondary mitigation proposed – full details must be provided now and included within DCO conditions.

3.201 Similarly, section 19C.4 *Water level control structures* (pages 4-5) of *Volume 2 Main Development Site Chapter 19 Appendices 19F* [108] describes the need for water control structures and suggests tilting weir[109] or piped structure[110] for the realigned Sizewell Drain. We welcome recognition that there is a need for water level control structures to manage the Sizewell Marshes SSSI.

3.202 However, the described approach is limited to the raising or lowering of water levels to manage potential adverse effects within the Sizewell Marshes SSSI. This will have the consequence of potentially reducing or increasing flows to the Leiston Main Drain and therefore potentially interfering with water level control on Minsmere South Levels and potentially at the Minsmere Sluice. This does not appear to have been addressed and we can see no mitigation that achieves this function. In the absence of any further mitigation measures lower in the catchment, we cannot see how potential changes to water levels in the Minsmere to Walberswick SPA, Ramsar and SSSI site could be managed.

3.203 Section 1.3.19 (page 7) of the *Vol. 3: ES Addendum Appendices Ch. 2 Main Development Site Appendix 2.14.*[111] states:

---

[107] ES Volume 2 Main Development Site Chapter 19 Groundwater and Surface Water Appendix 19B: Sizewell C Conceptual Site Model of the Hydrogeological Regime Part 1 (APP-304)

[108] ES Volume 2 Main Development Site Chapter 19 Groundwater and Surface Water Appendix 19F Sizewell Drain diversion outline design information (APP-309)

[109] A tilting weir is **a moveable weir used for raising and lowering a head of water by controlling the flow to a lower catchment area**. Typically, the plate or paddle of the tilting weir moves up and down in a narrow duct by titling, pivoting or rotating on its bottom horizontal axis - which opens or closes the tilting weir thus controlling the flow of water.

[110] A piped structure to control water levels consists of a tubular pipe with a 90 degree up-stand or non-return flap that allows water to be held back or discharged dependent upon how the pipe is operated

[111] Volume 3 Chapter 2 Environmental Statement Addendum Groundwater and Surface Water Appendices 2.14.A (AS-236)

'*It is envisaged that the principal mitigation options would relate to the new control structure to be installed at the northern end of the realigned Sizewell drain and operational practice within the Sizewell Marshes SSSI. Consequently, this approach is consistent with the existing operational management regime within the system.'*

3.204 Our concerns regarding the Leiston Main Drain above remain unanswered and the absence of any form of mitigation for effects transferred downstream also remains.

3.205 As mentioned above we have been unable to locate suitably detailed mitigation plans or a suitably robust approach to monitoring. We have covered this in further detail below. We do not concur that an approach '*allowing control measures to be implemented*' in response to '*unacceptable changes in flows and levels*' is sufficient to conclude that there will be no adverse effect on the interest features of the Minsmere to Walberswick SPA, Ramsar and SSSI site, especially nesting avocet and bittern.

Approach to Monitoring and Mitigation

3.206 Item MDS-GSW16 (page 26) in the *Mitigation Route Map Addendum* [112] identifies the

'repurposing the infiltration basin in WMZ5 to have a dual purpose of infiltration basin and water resources storage area enables the use of the previously identified water resources storage area for flood mitigation and wet woodland habitat creation. The change in use of the area from a water resources storage area to flood mitigation represents a change in a primary mitigation for the project'.

3.207 Whilst we welcome the provision of additional mitigation, we are not clear how the purpose of this additional storage at this location is intended to provide flood mitigation and what the intended benefit will be. We request more information to understand what elements of potential impact this mitigation is intended to address and how it will function to achieve this.

3.208 Section 1.1.2 (page 1) of *Vol. 3: Ch. 2 ES Addendum Appendix 2.14.A* [113] confirms

'This strategy [the Water Level Monitoring and Mitigation Plan] *sets out the principles of the monitoring, and the mitigation approach should monitoring identify that construction works within the main development site are leading to materially worse environmental effects on groundwater levels or quality at the site or surrounding area.'*

3.209 We welcome this intention.

3.210 Section 1.3.1 (page 3) of *Vol. 3: Ch. 2 ES Addendum Appendix 2.14.A* also states

'The assessment of potential changes to the water environment shows that the predicted changes are limited in extent, magnitude and duration such that no significant environmental impacts should occur. However, it is recognised that reassurance monitoring is required to demonstrate that the predicted change is realised, and not exceeded, as the project progresses.'

3.211 Again, we welcome this intention. However, given that we are not reassured that the primary mitigation measures are sufficiently progressed to satisfactorily support the predicted changes we regard it as essential to ensure that monitoring of the predicted changes and a further

[112] Mitigation Route Map (Consolidated) (REP1-006)
[113] Volume 3 Chapter 2 Environmental Statement Addendum Groundwater and Surface Water Appendices 2.14.A (AS-236)

adaptive mitigation strategy are required to ensure adequate protection of the Sizewell Marshes SSSI and Minsmere to Walberswick SPA, Ramsar and SSSI.

3.212 Section 1.2.5 (page 2) of *Vol. 3: Ch. 2 ES Addendum Appendix 2.14.A* describes the velocity and stage monitoring at the Applicant's monitoring location G8 – installed approximately 500m south of Minsmere Sluice in 2015 in order to monitor changes in flow and level in the Leiston drain downstream of the Applicant's monitoring location G1. This appears to be the only surface water monitoring point in or relevant to the Minsmere to Walberswick SPA, Ramsar and SSSI. Whilst we recognise that this is a key location to monitor any potential changes arising from the proposed development and their potential effects on the Leiston Main Drain, should it identify any changes then it will not be possible to assess any further potential impacts in other areas of RSPB Minsmere which could be affected by changes in the Leiston Main Drain, as described above.

3.213 We welcome the intention expressed in sections 1.3.2, 1.3.6 and 1.3.11 (pages 2 – 6) of *Vol. 3: Ch. 2 ES Addendum Appendix 2.14.A* to include sentinel boreholes to identify any potential changes that may extend to the Minsmere Walberswick Heaths and Marshes SSSI, committing to the monitoring focussing on the impact of the proposed development on the Sizewell Marshes SSSI and Minsmere Walberswick Heaths and Marshes SSSI. However, we would welcome the opportunity to understand the locations of these boreholes to ensure that these risks can be adequately monitored.

3.214 Section 19.5.8 (page 44) ES *Vol. 2 Ch. 19 Groundwater and Surface Water*[114] confirms some of the details discussed above including

- 'Sizewell Drain would be diverted
- At its northern extent, it would discharge to the Leiston Drain upstream of the SSSI crossing.
- revised water level management may be required for the drainage units and watercourses adjacent to the construction site, including water level control structures along the realigned Sizewell Drain and the revised operation of other existing structures.

3.215 To allow for *fine tuning of the management regime over time.* And to *prevent any detrimental impacts on groundwater from the Sizewell Drain.*

3.216 This paragraph also confirms that

> *The specific position, nature and operational parameters of the control structures will be determined in conjunction with stakeholders. This information could form part of an update to the Water Level Management Plan for the Sizewell Marshes SSSI*

3.217 With Section 19.5.12 (page 47) stating

> *'The permanent realignment of the Sizewell Drain could lead to a change in groundwater flow patterns, that could have an associated effect on the groundwater dependent ecological receptors (e.g. the Sizewell Marshes SSSI). To mitigate this, the realignment has been engineered to maintain a surface water level that will prevent alteration of the groundwater flow regime. Control structures would be installed along the realigned Sizewell Drain to manage water flow and prevent changes to groundwater. The specific position, nature and operational parameters of the control structures will be determined in conjunction with stakeholders.*

[114] ES Volume 2 Main Development Site Chapter 19 Groundwater and Surface Water (APP-297)

3.218 And will also form part of *an update to the Water Level Management Plan for the Sizewell Marshes SSSI,* confirming that the detail of the primary mitigation measures is yet to be determined and does not make it clear that this will be in place in time for the conclusion of the Examination.

3.219 We note in section 13.10 (page 5) of *Vol. 3: Ch. 2 ES Addendum Appendix 2.14.A* that

> *'the monitoring plan will be kept as a live document and revised regularly to ensure it remains fit for purpose for the activities being undertaken at the site. The monitoring plan, including any revisions, would be developed following consultation with East Suffolk Council, Suffolk County Council, the Environment Agency, Natural England and Suffolk Wildlife Trust, as appropriate.'*

3.220 We welcome the commitment to maintain a live document but question why the RSPB, as the main landowner in the adjacent sections of the Minsmere to Walberswick Heaths and Marshes SSSI and holding significant experience and expertise is not identified as a consultee. We also note the proposed role of the East Suffolk IDB in the document but note that they are not identified as a consultee for the monitoring plan.

3.221 Overall Vol. 3: Ch. 2 ES Addendum Appendix 2.14.A has no recognition that a mitigation plan is in place should the predicted change be exceeded in any circumstance beyond changes to water levels in the Sizewell Marshes SSSI.

3.222 No mitigation strategy is proposed to address changes to water levels in the Minsmere – Walberswick SPA, Ramsar and SSSI designated site and wider monitoring in this catchment beyond G8 and the sentient boreholes (at unspecified locations) is not presented. There is a lack of clear framework throughout the document. It proposes the monitoring plan will inform a Water Level Management Plan prepared and owned by the IDB (1.3.2, p3), but then describes a monitoring strategy in section 1.3.6 (p5) where a framework of 'trigger' and 'action' levels may be captured in an updated Water Level Management Plan. Section 1.3.14 and 1.3.15 (p6) proposes an adaptive trigger level approach to mitigation which would be implemented as a standalone control measure but could be used by the IDB to inform any update to the Water Level Management Plan for Sizewell Marshes SSSI not allowing for a clear understanding of the intended approach.

Potential impacts of water levels on the Minsmere to Walberswich SPA, Ramsar site and SSSI

3.223 Table 5.1 (page 18) of ES*Vol. 2 Ch. 19 Appendix 19B: Sizewell C Conceptual Site Model of the Hydrogeological Regime*[115] assess the ecological receptors and their hydrological sensitivity for the adjacent SPA using wetland habitats located within South Minsmere Levels (south of the new cut) and Sizewell Marshes. It proposes a medium hydrological sensitivity for breeding waders (but depends on how important groundwater is in the maintenance of damp ditch edges during the breeding season i.e. April to June) and a low sensitivity for breeding and wintering wildfowl and foraging marsh harrier and bittern.

3.224 Whilst we agree with the Applicant's approach for the sensitivities to species (and the species' sensitivities) using the South Levels, the assessment does not take into account the hydrological sensitivity of the SPA species utilising habitats north of the New Cut which could be affected by increased flows to the Minsmere Sluice.

---

[115] ES Volume 2 Main Development Site Chapter 19 Groundwater and Surface Water Appendix 19B: Sizewell C Conceptual Site Model of the Hydrogeological Regime Part 1 (APP-304)

3.225 We therefore believe the assessment of impacts on SPA bird species in hydrological models has not taken account of all potential impacts.

Summary of Hydrological Concerns affecting Minsmere

Surface Water Levels conclusions

3.226 The assessment of no likely significant effect relies on a series of proposed primary mitigation features which have yet to be defined in sufficient detail as to confirm that they will be effective. Without this assurance of effective embedded mitigation we cannot support the assessment conclusion. A monitoring strategy to assess whether predicted changes are exceeded is proposed. However, we do not believe the proposed monitoring is sufficient and the mitigation strategy to address any change to predicted levels is lacking. In addition, the geographical scope of the monitoring and mitigation strategy does not adequately address the risks to designated interest features in the Minsmere to Walberswick SPA.

3.227 We note that our concerns are reflected by the Secretary of State's 2019 Scoping Opinion on the project. Scoping opinion[116] paragraph 4.11.8 states *Paragraph 6.12.28 of the Scoping Report states that "a control structure" is proposed in the realigned Sizewell Drain. No further information regarding the "control structure" is included in this chapter or in the project description in the Scoping Report. The ES should describe the control structure in the project description including where it will be located, how it will operate, and include environmental assessments where relevant within the technical assessments.* The Applicant has responded[117] *The assessment of the likely effects associated with the realignment of drains, including the incorporation of a new control structure, is addressed in the relevant ES chapter (Volume 2, Chapter 19).* However, as we have highlighted, the Applicant has yet to describe where the control structure will be located and how it will operate and without the details requested, we cannot ascertain its likely effectiveness.

3.228 We are disappointed to have reached this stage of the Application process with so much required information still missing.

Hydrological Impacts and Risks to Sizewell Marshes SSSI.

Sizewell Marshes

3.229 As set out in more detail above Sizewell Marshes SSSI is situated to the west of Sizewell nuclear power station and is a complex of marshes with a unique mix of geology and hydrology that has created nationally significant botanical and invertebrate diversity. The value of the SSSI is enhanced by its close proximity and connectivity to RSPB Minsmere. The site has three main habitats;

- species rich grazing marsh - floristically, the grazing marshes and its network of dykes is one of the best examples of this habitat remaining in East Anglia. The dominant vegetation group is M22 fen meadow, with intermediate areas between this dominated by MG10 rush pasture. The M22 communities are very species rich and contain a wide range of plants of conservation interest. The dyke system supports a wealth of plant species including nationally scarce species
- tall herb fen; and

---

[116] From page 56 of the Scoping Opinion for Proposed Sizewell C Nuclear Development. The Planning Inspectorate, July 2019

[117] From page 35 of ES Volume 1 Introduction to the Environmental Statement Chapter 6 EIA Methodology Appendix 6C - Responses to EIA Scoping Opinion Comments

- wet alder carr woodland - also supporting a very high invertebrate diversity.

3.230 In addition

- 18 species of dragonfly have been recorded including rarities such as Norfolk hawker (*Aeshna isosceles*), hairy dragonfly (*Brachytron pratense*) and lesser red eyed damselfly (*Erythromma viridulum*).
- 236 moth species have been recorded since 1996 including nationally rare species.
- 12 species of grasshopper and cricket; a good range of spiders, including the nationally rare *Leiobunum rotundum*; and three nationally rare species of fly
- 148 bird species have been recorded with a total of 80 breeding species including little egret, gadwall, kingfisher, barn owl & water rail and Cetti's warbler and wintering birds include bittern, bearded tit and snipe.
- Mammals include otters, water voles, water shrews and harvest mouse as well as red deer.
- Bats - the SSSI is thought to hold an excellent bat community including barbastelle, Natterer's, all three pipistrelle species, brown long eared, noctule, serotine, and Daubenton's recorded annually. It is likely that nationally rare barbastelle and regionally scarce Natterer's bat breed on site.

3.231 We are grateful to Friends of the Earth and their Experts (Dr Rob Low, Dr David Mould and Jon Graham) for considering these issues in detail in their written representations: "A critical review of Sizewell C Co's site characterisation, impact assessment, and proposals for impact mitigation, in relation to risks posed to the ecohydrological integrity of Sizewell Marshes SSSI."

3.232 We refer the Examining Authority to those representations for full consideration of the issues summarised below.

Data Adequacy

3.233 The omission of a comprehensive surface water and shallow groundwater monitoring programme has prevented the development of a satisfactory conceptual understanding of the fine-scale ecohydrological dynamics of the system. Such an understanding is critical for an effective assessment of risk;

3.234 The hydro(geo)logical functioning of the shallow zone within Sizewell Marshes SSSI, which controls the variables which define the hydrological supporting conditions for the M22 fen-meadow, should have been monitored, analysed and characterised in much more detail, using a contemporary ecohydrological approach;

3.235 For example, fully-screened shallow (c. 1 m deep) dipwells should have been installed in the Peat at the most notable stands of M22 (e.g., FM2 and FM3c, see Section 4.3), in order to allow assessment of the relative contribution of groundwater discharge as a water source at these points;

3.236 The water table elevation in the Peat is never plotted in relation to the ground surface. This variable is very widely recognised as the most important in relation to defining hydrological supporting conditions for M22;

3.237 The absence of rainfall data, which obviously represents a primary control on surface water and groundwater behaviour, will have compromised the analysis of all other hydrological responses at a fundamental level;

3.238 By adopting a more comprehensive approach, it may have been possible to identify the actual, rather than the 'likely' mechanisms which explain the expression of M22, and therefore to develop a more detailed and certain ecohydrological conceptual model;

3.239 Where the qualitative assessment concluded that a potential impact was not significant, further detailed analyses were not undertaken. This is a process failure, not following the precautionary principle, to account for potential errors in the qualitative assessment.

Interpretation of the data and the numerical model

3.240 The ecohydrological analysis and conceptual model presented by EDF has failed to identify the controlling variables and mechanisms which directly control the variables defining the hydrological supporting conditions for the M22 community within Sizewell Marshes SSSI;

3.241 Paragraph 19.4.26 in APP-297 states that '*Groundwater levels within the Peat Deposits were noted to be highly responsive to temporary pumping during maintenance works at the Minsmere Sluice from October 2013 to February 2014 suggesting a high degree of connectivity between the surface water network and the Peat groundwater system*'. This high degree of connectivity fundamentally undermines the qualitative assessment, as it shows that changes to water levels in one part of the site will induce a change in other parts. As demonstrated below, the impacts of these changes are significant;

3.242 Projected drawdown could easily take the water table elevation outside of the optimal range for the summer water table, and therefore shows that the M22 community and key aquatic plants within the associated ditch system are significantly vulnerable to the projected drawdowns. This is not considered as anything more than a 'not significant' risk to the designated site, which is a major failing of the risk assessment process;

3.243 Consideration of only a doubling in hydraulic conductivity is unrealistically optimistic, and that the possibility that the overall hydraulic conductivity would be three- to five-times higher than designed should be assessed. If the directly proportional relationship between hydraulic conductivity of the cut-off wall and water table drawdown is assumed, this would give predicted drawdowns of the summer water table in the region of 30-50 cm. M22 is clearly extremely sensitive to this magnitude of drawdown.

Ecological relevance of Groundwater to M22 Fen Habitat

3.244 Upward groundwater flow and discharge, in response to the hydraulic gradient from the Crag to the Peat, is almost certainly a critical source of water to some of the stands of M22;

3.245 Most stands of M22 are associated with permanent or intermittent seepages or where the water table is shallowly subsurface all year, sometimes peripheral to permanent seepages. This indicates a strong preference for soligenous wetness, where wet conditions are maintained by continuous incoming flow, rather than downstream (usually topographic) impoundment;

3.246 M22 is typically found is base-rich conditions over a wide range, but usually with a moderate level of fertility. Some of the least fertile sites were the most species-rich.

Impact Pathways on the M22 Fen Habitat

3.247 As a consequence of the critical role of groundwater, there are three major developments that have the potential to have a major impact on the sensitive ecohydrological functioning of the wetland system. These are:

1. The new cut-off wall adjacent to the platform base for the new site, and related internal lowering of groundwater levels (dewatering) during the construction phase;

2. The re-routing of the Sizewell Drain; and

3. The new crossing at the drainage outlet for the Sizewell Drain and the Leiston Drain.

3.248 Changes to the wetland system will have unknown impacts given the lack of understanding of how the system is operating at the fine scale, as noted in the section above. This is compounded by a lack of detail on the design of the three main critical developments;

3.249 Sizewell Marshes SSSI nitrate thresholds are close to UKTAG (2014) levels for M22 fen. Irrigation of the M22 fen-meadow vegetation with surface water i.e. the proposed mitigation, is therefore likely to cause further damage;

3.250 Paragraph 1.3.33 (Appendix 19E, APP-309) notes that '*the consented discharge from Leiston STW contains higher levels of nutrients (including phosphates) than the rest of the drainage system*', and that '*in order to reduce the ingress of nutrients into the wider drainage network, SWT (Suffolk Wildlife Trust) have attempted to reduce connectivity between Leiston Drain and the drainage network on either side (Sizewell Belts and Sizewell Marshes) via the use of flow regulating structures'*. It is of significant concern to note that the proposed mitigation strategy appears to reverse this established protective practice;

3.251 M22 is strongly associated with soligenous conditions (see Section 4.2), and therefore fostering of more topogenous conditions is completely inappropriate;

3.252 A wider span bridge design would be far less impacting, as it would leave a significantly wider corridor unchanged, to facilitate original hydraulic control and subsurface drainage of the SSSI site.

Monitoring and mitigation plan

3.253 It is important to note that a monitoring plan does not yet exist. The description of the proposed monitoring plan within the strategy document is insufficiently detailed;

3.254 The proposed in-field monitoring programme across the Sizewell Belts appears to have been poorly designed and not able to facilitate an appropriately detailed understanding of the hydrological dynamics of the wetland system.

3.255 The implied assumption that the development of a hydro(geo)logical 'monitor and mitigate' plan with stakeholders will be relatively straightforward and to schedule is completely unrealistic. Development and agreement of the monitoring and mitigation plan, since it forms a part of the ecohydrological viability of the proposed development, should therefore be addressed at the earliest stage in the planning process.

Summary and conclusions regarding Sizewell Marshes

3.256 From the available evidence, Friends of the Earth's Experts have concluded that direct, upward groundwater flow and discharge, in response to the hydraulic gradient from the Crag to the Peat, is almost certainly a critical source of water to some of the stands of M22. This is critical because it allows favourable hydrological supporting conditions to be maintained, in terms of water table elevation regime and water quality, to enable the favourable condition of the SSSI to be maintained.

3.257 Our view is that EDF's conceptual model is significantly flawed and therefore that the prediction of impacts (including the design and use of the numerical model) has not been informed to the best possible degree.

3.258 Development and agreement of a detailed monitoring and mitigation plan, since it forms a part of the ecohydrological viability of the proposed development, should be addressed at the earliest stage in the planning process. The required contents of the plan, such as the scope of monitoring, data quality-checking procedures and reporting, detailed actions and timescales in relation to the loss of a monitoring point, periodic reporting requirements, and the requirements of the stakeholders which review the reports, all have long-term cost and logistical implications for the developer and should be agreed before determination.

3.259 The primary measure for mitigation of ecohydrological impacts from the development appears to be that, if drawdown of the water table in the Peat within Sizewell Marshes is larger than predicted, water levels in the SSSI drainage ditch network will be raised, such that water migrates from the ditches into the Peat layers to maintain in-field water table elevations. This measure is fundamentally inappropriate and would actually cause further damage to the M22 within the SSSI. This is because the historical recorded nutrient concentrations within the ditch network indicate that the threshold value for potential damage of mesotrophic and fen-meadow fens would frequently be exceeded. This is unsurprising as a significant percentage of incoming flow comes from the Leiston STW.

Final summary regarding Sizewell Marshes

3.260 The Applicant's understanding of the environmental processes which support the nationally important M22 fen community and associated communities within Sizewell Marshes SSSI is flawed, because up-to-date ecohydrological knowledge and techniques have not been applied. This has led to ill-informed impact prediction, which has resulted in the likelihood, magnitude and significance of potential impacts being significantly underestimated. These problems have been compounded by the Applicant's proposal of a mitigation technique which would actually cause further damage to the SSSI, rather than mitigating any unexpectedly large impacts.

Noise and visual disturbance (birds)

Background

3.261 Our main concerns in relation to noise and visual disturbance relate to the construction phase of the development and in particular to the main development site and impacts on bird features of the Minsmere-Walberswick SPA and Ramsar site (designated sites) and the Sizewell Marshes SSSI[118]. Construction activity may result in disturbance and/or displacement of birds, through responses to visual or acoustic stimuli, and the level and type of sensitivity varies by bird species and by season. In brief, disturbance as a result of construction activity may affect birds by causing:

- reduced food intake rates
- increased energy expenditure
- decreased breeding productivity
- physiological changes
- habitat loss due to displacement

3.262 Please note that birds generally use the most suitable habitats available to them at any point in time, therefore displaced birds are likely to be pushed into less suitable habitats, meaning

[118] See ES Vol. 2, Ch. 14 Terrestrial Ecology, App 14A2 - Designated Sites Annex 14A2.1: Figures 14A2.1 - 14A2.3 (APP 228)

displacement itself may also lead to other impacts listed above, with effects on reproductive success potentially leading to a population decrease (Alves *et al*., 2014[119]).

3.263 The evidence base for the Applicant's assessment of noise impacts is set out in section 8.8 b) iv. of the Shadow HRA Report Vol. 1 Part 1[120] while ES Vol. 2 Ch. 11 Noise and Vibration[121] section 11.3 d) describes the scenarios assessed as part of the noise modelling. It explains the types of activities planned to take place over the five construction phases during both the daytime and night-time construction shifts. It is stated that construction Phase 1 (site establishment and preparation for earthworks) and Phase 5 (removal of temporary facilities/restoration of the land) will result in the highest noise levels, although it is also noted that the construction phases will overlap. The outputs of the noise modelling relevant to important ecological receptors are presented as noise contour maps and are found in the Shadow HRA Report Vol. 1 Part 3[122] with updates in the Shadow HRA Report Addendum Appendices 1A-10A Part 5[123].

3.264 The evidence base for the Applicant's assessment of visual disturbance impacts is also set out in section 8.8 b) iv. of the Shadow HRA Report Vol. 1 Part 1. Again, concerns primarily relate to the construction period and in particular to lighting of the construction site, however, the presence of human activity and large or moving machinery/infrastructure on the skyline may also have an effect. In general, the predicted impacts of visual disturbance are encompassed within the areas predicted to be affected by noise disturbance, although a few exceptions are noted and discussed further below.

Sites and bird species of concern

3.265 Our concerns primarily relate to potential impacts on breeding marsh harrier and breeding and non-breeding waterbirds of the Minsmere-Walberswick SPA and Ramsar site and on two sites functionally linked to the SPA: Minsmere South Levels (part of Minsmere-Walberswick Heaths and Marshes SSSI) and Sizewell Marshes SSSI.

3.266 The Minsmere-Walberswick SPA[124] was classified in 1991 and contains extensive areas of freshwater and coastal grazing marsh, coastal reedbeds, saltmarsh, lowland heathland, woodland, intertidal mud and mixed sediment. It supports the following qualifying features:

- Avocet (*Recurvirostra avosetta*), Breeding
- Bittern (*Botaurus stellaris*), Breeding
- Gadwall (*Mareca strepera*), Breeding
- Gadwall (*Mareca strepera*), Non-breeding
- Greater white-fronted goose (*Anser albifrons albifrons*), Non-breeding
- Hen harrier (*Circus cyaneus*), Non-breeding
- Little tern (*Sternula albifrons*), Breeding
- Marsh harrier (*Circus aeruginosus*), Breeding
- Nightjar (*Caprimulgus europaeus*), Breeding
- Shoveler (*Spatula clypeata*), Breeding
- Shoveler (*Spatula clypeata*), Non-breeding
- Teal (*Anas crecca*), Breeding

---

122 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 3 (APP-147)

123 Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)

124 The SPA designation - http://publications.naturalengland.org.uk/file/5944954236960768

3.267 Natural England has set site conservation objectives for the Minsmere-Walberswick SPA[125] as follows:

> "*The objectives are to ensure that, subject to natural change, the integrity of the site is maintained or restored as appropriate, and that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring:*
>
> - *the extent and distribution of the habitats of the qualifying features*
> - *the structure and function of the habitats of the qualifying features*
> - *the supporting processes on which the habitats of the qualifying features rely*
> - *the populations of each of the qualifying features*
> - *the distribution of qualifying features within the site*"

3.268 The Minsmere-Walberswick Ramsar site[126] was designated in 1976 under:

- Ramsar criterion 1 for containing a mosaic of marine, freshwater and marshland with a rare transition in grazing marsh ditch plants from brackish to fresh water and;
- under criterion 2 for supporting nationally scarce plants, British Red Data Book invertebrates and nationally important numbers of breeding and wintering birds (bittern, gadwall, shoveler, teal, marsh harrier, avocet and bearded tit).

3.269 The Minsmere South Levels form part of the Minsmere-Walberswick Heaths and Marshes SSSI[127] which comprises a suite of habitats including mudflats, shingle beach, reedbeds, heathland and grazing marsh. It is designated for its breeding and wintering birds, scarce plants and important invertebrate populations.

3.270 Sizewell Marshes SSSI128 contains lowland, unimproved wet meadows which support outstanding assemblages of invertebrates and breeding birds along with ditch systems, reedbeds and fens. Several nationally scarce plants are also present.

Comments on the baseline data

Breeding bird survey methodology

3.271 Paragraph 3.2.8 of the Breeding Bird & Waterfowl Survey Report 2020[129] explains that breeding waders and waterfowl were surveyed on the Minsmere South Levels in 2020 from vantage points. This is a departure from standard methodologies which require a walked transect route, such as those carried out by the RSPB. Vantage point surveys are likely to underestimate breeding activity for waders and wildfowl, particularly given the viewing distances involved. Whilst there were understandable constraints on surveying in 2020 due to covid restrictions, this potential for underestimation (and potential lack of comparability between surveys in different years) should be acknowledged and taken into account. We note that distributional data for breeding birds were not collected by the Applicant prior to 2020, and whilst figures for breeding birds have been obtained from the RSPB, the lack of longer-term distributional data (following a standard repeated visit methodology and usually for a minimum of two years) represents a significant limitation to the Applicant's impact assessment.

129 Breeding Bird & Waterfowl Survey Report 2020 in the Additional Ecology Baseline Survey Reports November 2020 (AS-021)

Comments on the assessment methods for potential noise and visual effects on birds during construction

Comparison of predicted noise levels with those recorded at Minsmere

3.272 Shadow HRA Report Vol. 1 Part 1[130] paragraphs 8.8.185-186 refers to a survey of noise levels at RSPB Minsmere conducted near South Hide which is used to assess noise levels experienced by breeding birds. The noise effects described include anthropogenic sources including motor vehicles and visitors, resulting in maximum sound levels of over 70dB.

3.273 We note the acknowledgement that the acoustic data collected at Minsmere were from an area close to visitor routes and may not be representative of the wider area. South Hide is on a visitor route between the main scrape and the eastern end of the reedbed and is therefore not appropriate for assessing the noise levels likely to be experienced by most breeding birds – it would not be expected that visitors and motor vehicles would result in the noise levels quoted 'at the bird' given the distance of the birds from these sources. It should also be clarified as to whether any atypical management work was being carried out at that location during the survey period.

3.274 With regard sound levels attributed to insect noise and birdsong, it is important to draw a distinction between anthropogenic noise which is likely to cause alarm to birds and noise sources that are natural (e.g. birdsong, the sea) and hence much less likely to cause disturbance.

Definitions of daytime and night-time

3.275 Paragraph 1.2.2.2 of ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment[131] explains that assessment scenarios have been defined separately for daytime (07:00–23:00hrs) and night-time (23:00–07:00hrs) construction. However, this means that "daytime" will include a significant proportion of dark hours particularly in winter. With full construction activities ongoing until 11pm, we are concerned regarding the potential for ecological impacts of noisy activities during dark hours – e.g. potential displacement of birds arriving to roost. Impacts under the daytime scenario could therefore be greater than predicted.

3.276 For ecological receptors 'day' is dawn to dusk and 'night' is dusk to dawn. Assessing impacts during those time periods would therefore be more relevant.

Overlapping construction phases

3.277 Plate 3.1 in ES Vol. 2 Ch. 3 Description of Construction[132] indicates that that the main construction phases are expected to overlap. The outputs of the noise modelling are presented for each construction phase and it is not always clear whether these overlaps have been accounted for. Combined worst case scenario (WCS) maps where construction phases are expected to overlap and impacts would be worse than each construction phase treated alone should be provided where necessary to avoid under-estimation of potential impacts.

Assumptions regarding construction timelines

3.278 Paragraphs 8.8.190 – 202 of the Shadow HRA Vol. 1 Part 1[133] provide a more detailed breakdown of noise effects by construction phase, and assert that, as most noisy activities will not occur at same time, noise impacts are overestimated in peak noise levels and duration. Construction

130 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
131 ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204)
132 ES Vol. 2 Main Development Site Ch. 3 Description of Construction (APP-184)
133 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

timelines at weekly/monthly scales are highly likely to be subject to change, and as acknowledged in paragraph 1.3.1.3 of ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment[134], the final construction timelines will only be confirmed once contractors have been appointed meaning that some changes would be expected.

3.279 We therefore do not agree that sufficient reliance can be placed on these breakdowns to assume the results are over-precautionary. The WCS is the only safe scenario for assessment.

Assumption that acoustic fence will be in place during Phase 1 of the construction period

3.280 Paragraph 8.8.67 of the Shadow HRA Report Vol. 1 Part 1[135] explains that the impact assessment for the Phase 1 construction period is based on the assumption that a 5m high fence (or equivalent mitigation) will be in place to reduce potential noise impacts. It is crucial that the 5m acoustic fence is constructed at the beginning of the Phase 1 construction period, especially as Phase 1 of the construction period is one of the phases with the highest noise impacts on sensitive areas[136]. If there is a period where construction is taking place without mitigation in place, the assessment of Phase 1 impacts could be under-precautionary.

Noise modelling limitations

3.281 Section 1.3.3 of ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment[137] explains the assumptions and limitations behind the noise modelling. There are several activities where sufficient details are not currently available to properly model resultant noise. These include early morning unloading of HGVs, night-time dewatering activities and marine unloading. It is noted that these issues will require additional modelling once further details are known and therefore, we consider that it is possible that some impacts may have been underestimated at this stage.

Uncertainty regarding noise impacts during construction Phase 5

3.282 Section 1.3.3 of ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment[138] explains that limited details were available regarding the removal of temporary facilities and land restoration during construction Phase 5 and therefore that indicative average noise levels are presented for this Phase. Paragraph 1.3.4.3 explains that short term noise levels during Phase 5 are likely to be similar to those of Phase 1 but that:

> *"it is not currently possible to define the duration or activities during this period (or associated noise predictions) based on the limited assumptions presented for Phase 5".*

3.283 Also, paragraph 1.3.4.4 acknowledges that:

> *"short periods of higher sound levels can be expected when restoration works (which may include breaking up of hardstanding areas) are taking place at the edges of the site nearest receptors".*

3.284 The potential for high noise levels during this Phase needs to be recognised throughout the assessments as in many instances Phase 1 is referred to as the worst case for ecological impacts of noise. Given that Phase 5 spans the final two to five years of construction (noting inconsistency regarding phase length between documents) this would significantly increase the duration of

---

134 ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204)
135 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
136 See page 17, Figure 8A.8 in Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)
137 ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204)
138 ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204)

major noise impacts. Also, the uncertainty in these predictions should be clarified and any resulting differences in how the figures presenting the noise contours for each Phase should be interpreted should be explained.

3.285 In addition, the figure for Phase 5 (Figure 8.6 in Shadow HRA Report Vol. 1 Part 3[139]) appears to be missing the noise contour representing 64-70dB, making it impossible to identify the area subject to potential impacts in this Phase (no figure for Phase 5 is presented in the updated noise modelling in Shadow HRA Report Addendum Appendices 1A-10A Part 5[140]).

Chronic noise modelled for Construction Phases 3 and 4 only

3.286 Paragraph 1.2.9 of the Shadow HRA Report Addendum[141] explains that additional modelling of chronic noise levels is presented for Phases 3 and 4 of the construction period. Whilst we welcome the provision of this information, based on the original modelling of impulsive noise levels, it appears that Phases 3 and 4 are overall the least noisy construction phases. Although the Shadow HRA Report Addendum states that these phases were chosen as they are the longest construction phases and hence would represent the longest period of impact, we query why Phases 1, 2 and 5 are not included as noise levels might be expected to be higher during these phases.

Noise and visual disturbance evidence base

Impulsive noise disturbance threshold

3.287 We have in previous consultations noted that we have some reservations around the use of a 70dB L_{Amax} threshold for impulsive noise impacts on marsh harrier (please see below regarding specific impacts on marsh harriers), although we also acknowledged that there was limited evidence on which to challenge this. These reservations also apply to waterbirds. We acknowledge that a lower threshold of 65dB L_{Amax} has been applied for this assessment of impacts on breeding waterbirds, while the 70dB L_{Amax} threshold is used for wintering waterbirds.

3.288 We also acknowledge the discussion of the evidence for noise impacts on waterbirds in the Shadow HRA Report although we note that much of this evidence relates to impacts on estuarine birds in winter and that limited evidence exists regarding impacts from construction noise specifically. We therefore reiterate the importance of robust and demonstrably successful mitigation for any impacts.

Temporary effects of noise disturbance

3.289 Paragraph 8.8.33 of the Shadow HRA Report Vol. 1 Part 1[142] states that:

> *"Evidence from studies into this type of noise pollution [infrequent intense noise] indicates that generally birds, if undertaking a flight response, will return to the affected area once the noise has dissipated."*

3.290 One of the references provided for this statement applies to a study of wintering waterbirds on a field near the Humber Estuary (Wright *et al*., 2010)[143] and the other refers to a study of the

---

139 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 3 (APP-147)
140 Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)
141 Shadow HRA Report Addendum (AS-173)
142 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
143 Wright, M.D., Goodman P. & Cameron. T.C. (2010) Exploring behavioural responses of shorebirds to impulsive noise. Wildfowl 60: 150-167

Mexican spotted owl (Delaney *et al.*, 1999)[144]. The statement is part of the noise disturbance evidence base for breeding and non-breeding bird species. We consider that this statement is too general to be of use in an assessment such as this as there are a wide variety of responses exhibited by birds of different species, in different habitats and with varying life histories and at different seasonal stages; any such generalisations should where possible be taken from species with characteristics in common with the species of concern here. If such evidence is not available, the limitations of any conclusions drawn should be acknowledged. We also consider that where possible, evidence around disturbance and displacement effects should arise from similar causes, although we acknowledge that evidence relating to construction specifically is limited.

3.291 It should also be noted that the statement does not indicate how long it may take for birds to return following the removal of the source of disturbance, or whether desertion may eventually occur if infrequent intense noise occurs over a long period.

Generalisations regarding impacts of noise

3.292 As discussed above, the noise disturbance evidence base relates to a range of different species with different life histories and sensitivities. It is presented in the Shadow HRA Report section for breeding avocet, but then referred to in assessments for other species. We acknowledge the limited research evidence available for the individual species covered by the Shadow HRA Report but we recommend that where evidence is available for the species in question or a closely related species, that this is discussed in the individual species accounts rather than applying the generic evidence base to all species.

Lack of sensitivity threshold for chronic noise

3.293 Paragraphs 8.8.42-50 of the Shadow HRA Report Vol. 1 Part 1[145] discusses a selection of studies that have shown that chronic noise disturbance has the potential to affect densities of breeding birds. Effects can include:

- the masking of acoustic communication,
- effects on detection of predators
- the ability to hunt

3.294 Such impacts can result in changes to bird abundances and distributions and effects on adult and nestling fitness.

3.295 The Shadow HRA Report goes on to suggest sensitivity thresholds for impacts on both breeding and wintering birds, however thresholds are only suggested in relation to impulsive noise (as it is stated in paragraph 8.8.51) which is considered more likely to result in a behavioural response. Based on the evidence around breeding birds, we disagree with this statement and note that as chronic noise has been shown to affect densities and distribution of breeding birds, impacts of chronic noise could have a direct effect on the conservation objectives of designated sites.

3.296 We also note that impacts of chronic noise on birds have been shown even at low levels, although we acknowledge the limited number of studies available which include figures for chronic noise levels and the lack of evidence regarding the particular species of interest here. Senzaki *et al.* (2016)[146] studied the effects of traffic noise on foraging short-eared owls *Asio flammeus* and long-eared owls *Asio otus*. They reported that "Owls' ability to detect prey was affected even at the

---

144 Delaney, D.K., Grubb, T., Beier, P., Pater, L. & Hildegard Reiser, M. (1999) Effects of helicopter noise on Mexican spotted owls. Journal of Wildlife Management, 63(1): 60-76.

145 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

146 Senzaki, M., Yamaura, Y., Francis, C.D. & Nakamura, F. (2016) Traffic noise reduces foraging efficiency in wild owls. Scientific Reports 6: 30602.

lowest level of [traffic noise] (40 dB[A]) and was approximately 17% lower than that of ambient conditions". McClure *et al.* (2013)[147] used speakers to create a 'phantom road' to experimentally test the effects of road traffic noise on bird distributions. They found over a one-quarter decline in bird abundance along the 'phantom road' and almost complete avoidance by some species, compared to control conditions. They also found negative relationships between bird abundance and average noise levels (which ranged from approximately 37 to 57 dB(A)) for over half the species studied. Therefore, based on the limited evidence available, we consider that some level of impact may be likely above noise levels of around 45dB L_{Aeq}.

Visual disturbance

3.297 As discussed for noise disturbance, much of the research evidence presented in the visual disturbance evidence base in the Shadow HRA Report relates to impacts on intertidal estuarine habitats, which may not be directly comparable to the species and habitats under consideration here. It is also notable that evidence relating to disturbance specifically from construction is also limited, as acknowledged in the evidence base.

3.298 Therefore, much of the evidence relating to non-lighting impacts is around recreational activities on estuaries. Given the lack of evidence around the specific impacts under consideration here, we are concerned that in many areas the proposed visual disturbance buffer of 300m has been further reduced to 150m due to the presence of natural screening. We are concerned that, due to the height of some of the infrastructure, cranes etc involved and the lighting of the site, the screening will not reduce all potential visual impacts.

Summary of extent of noise and visual disturbance impacts on birds during construction

Daytime impulsive noise

3.299 This discussion of daytime (07:00 – 23:00) impulsive noise levels is based on the modelling outputs presented in Figures 8.2 – 8.6 in the Shadow HRA Vol. 1 Part 3[148] and the updated modelling presented in Figures 8A.1 – 8A.3 and 8A.8 – 8A.9 of the Shadow HRA Addendum Appendices 1A-10A Part 5[149]. Paragraph 8.8.76 of the Shadow HRA Vol. 1 Part 1[150] explains that:

> "*Encroachment of the 64dB L_{Amax} footprint onto both areas [South Levels and Sizewell Marshes] is substantive during Phases 1 and 2… A large part of the Sizewell Marshes continues to be encompassed by the 65dB$_{LAmax}$ contour during Phases 3 and 4, but by Phase 5 there is little encroachment…*"

3.300 The encroachment of the 65dB L_{Amax} contour shown in the updated modelling outputs for Phase 2 (Fig. 8A.9) is greater still, noting that the update for Phase 1 only applies to the winter period (see Shadow HRA Report Addendum Appendices 1A-10A Part 5, and our concerns noted above should this scenario extend into the breeding season).

3.301 With regard to the stated encroachment for Phase 5, this is not clear from the original figure referred to as a contour is missing from the map (see comments above) and no updated modelling is provided for Phase 5 – we therefore request that evidence is presented to support this statement as based on the map, it appears that impacts could be significant.

---

147 McClure, C.J.W., Ware, H.E., Carlisle, J., Kaltenecker, G., & Barber, J.R. (2013) An experimental investigation into the effects of traffic noise on distributions of birds: avoiding the phantom road. Proceedings of the Royal Society B 280: 20132290.

148 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 3 (APP-147)

149 Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)

150 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

3.302 Based on the noise impacts of Phases 1 to 4 only (given the uncertainty regarding Phase 5), this equates to potentially significant noise impacts on breeding birds of the Minsmere South Levels for the first 4-5 years of construction and to those of Sizewell Marshes for first 10-11 years. Should impacts during construction Phase 5 also be significant then breeding birds on Sizewell Marshes would be affected throughout the entire construction period of 12 years and on the Minsmere South Levels for up to 9 ½ years (see 'Background' section above for potential effects of disturbance and displacement on birds).

3.303 As noted above, updated modelling has been provided for the first winter of Phase 1 to incorporate the construction of the flood compensation and wetland area in the northern part of the construction area and the construction of the second Beach Landing Facility (BLF). This has the effect of extending the area of the Minsmere South Levels affected by the 70dB L_{Amax} noise contour (in relation to wintering bird species), to include parts of the southern and western areas of the Levels and a small area of the Minsmere reedbeds. Parts of the eastern block of Sizewell Marshes and the western tip are also within the 70dB L_{Amax} contour during this period, extending potential impacts to birds species into those additional areas.

3.304 The areas affected by the 70dB L_{Amax} contour during Phase 2 are smaller than those in Phase 1 but with significant parts of the eastern area of Sizewell Marshes still affected. During Phases 3 and 4 the encroachment reduces further still.

3.305 As discussed above, no updated modelling is provided for Phase 5 and the original outputs are missing a key contour, hence impacts during this phase are unclear but appear to be significant.

Daytime chronic noise

3.306 This discussion of daytime chronic noise levels is based on the updated modelling presented in Figures 8A.4 of the Shadow HRA Report Addendum Appendices 1A-10A Part 5[151]. Paragraph 8.3.14 of the Shadow HRA Report Addendum[152] explains that:

> *"In terms of chronic noise during the daytime period, predicted levels are lower than for impulsive noise during the same construction phase, as would be expected... For Phases 3 and 4, predicted noise levels are relatively low (at 40 - 50dB L_{Aeq}) across much of the Minsmere South Levels but higher across the Sizewell Marshes (where much of the eastern parts are encompassed by values above 55 dB L_{Aeq})."*

3.307 We are concerned that during Phases 3 and 4 much of Sizewell Marshes and Minsmere South Levels will experience chronic noise levels of above 40-45dB L_{Aeq} and could therefore experience impacts on breeding birds. As discussed above, we are also concerned that chronic noise levels for Phases 1, 2 and 5 are not included as noise levels might be expected to be higher during these phases.

Night-time chronic and impulsive noise

3.308 This discussion of night-time (23:00 – 07:00) chronic and impulsive noise levels is based on the updated modelling presented in Figures 8A.5 and 8A.6 of the Shadow HRA Report Addendum Appendices 1A-10A Part 5[153]. Paragraph 8.3.15 of the Shadow HRA Report Addendum[154] explains that:

---

151 Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)
152 Shadow HRA Report Addendum (AS-173)
153 Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)
154 Shadow HRA Report Addendum (AS-173)

"Night-time construction noise would occur at low levels across the Sizewell Marshes and, particularly, Minsmere South Levels, as indicated by the predicted LA_{max} [impulsive noise] and LA_{eq} [chronic noise] values… Thus, noise levels would be below 55dB L_{Amax} and 45 L_{Aeq} across almost all of the Minsmere South Levels, and much of the Sizewell Marshes".

3.309 This means that some ecologically important areas will experience noise levels above these thresholds. We acknowledge that ES Vol. 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment[155] indicates that night-time noise could be most significant during Phases 3 and 4 due to the operation of the rail route and potentially night-time tunnelling activities. However, it is explained that freight unloading during Phase 2 may also produce significant night-time noise and we therefore query why the night-time noise modelling presented only covers these two phases and not Phases 1, 2 and 5.

3.310 We also query the scope of the updates to the noise modelling following the Changes to the Application and whether for example the modelling of night-time noise incorporates the additional freight trains proposed as part of the Change Application.

3.311 We also note our disagreement with the assertion in Table 2.34 of the Vol. 1 ES Addendum Ch. 2 Main Development Site[156] that the increased numbers of night time movements of freight trains will not affect birds to a different level to that originally assessed. The increased numbers of trains have the potential to increase chronic noise disturbance and/or lead to repeated disturbance (repeated instances of peak noise levels) and could therefore affect birds on the Minsmere South Levels and Sizewell Marshes.

Visual impacts

3.312 This discussion of visual disturbance is based on the maps presented in Figure 8.7 in the Shadow HRA Report Vol. 1 Part 3[157] and the updated map in Figure 8A.7 of the Shadow HRA Report Addendum Appendices 1A-10A Part 5[158] (although note that the extent of the visual buffer has not changed despite the Changes to the Application). From these it can be seen that for the majority of areas the visual buffer falls within areas also affected by noise disturbance, however, there are notable exceptions where the visual buffer indicates additional impacts, including the southern part of Minsmere South Levels, the central part of the eastern section of Sizewell Marshes and part of the western section of Sizewell Marshes.

3.313 It should also be noted that these maps only allow the comparison of noise and visual impacts for Phase 1 of construction when noise impacts are greatest. During phases with lower noise impacts larger areas of both Minsmere South Levels and Sizewell Marshes will be affected by visual disturbance alone. This has the effect of increasing the duration of significant impacts throughout the construction period when noise and visual disturbance are considered together.

Impacts on breeding birds of the Minsmere-Walberswick SPA

Impacts on breeding gadwall

3.314 Gadwall breeding on the Minsmere South Levels and Sizewell Marshes are acknowledged to be functionally linked to the Minsmere-Walberswick SPA population, which we welcome and

[155] ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204)
[156] Vol. 1 ES Addendum Ch. 2 Main Development Site (AS-181)
[157] Shadow HRA Report Vol. 1 Part 3 (APP-147)
[158] Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)

consider to align with the NE Guidance (and previous decisions) regarding functionally linked populations (Chapman and Tyldesley, 2016[159]).

3.315 Paragraph 8.8.360 of the Shadow HRA Report Vol. 1 Part 1[160] explains that, based on a wider SPA population of 106 pairs (including birds breeding on land within the SPA and on the Minsmere South Levels and Sizewell Marshes) these two areas hold 16% and 5% of the wider SPA population respectively.

3.316 The Shadow HRA Report goes on to assess the extent of encroachment of the 65dB L_{Amax} contour onto the Minsmere South Levels and Sizewell Marshes during Phase 1 of the construction period. This assessment is summarised and updated in sections 8.3 b) and f) of the Shadow HRA Report Addendum[161]. It is noted that distributional data for gadwall were only collected in 2020 and therefore the assessment of numbers of gadwall affected is based on an assumed even distribution across the South Levels and Sizewell Marshes. Given the encroachment of the 65dB L_{Amax} contour onto around 40% of the Minsmere South Levels and the majority of Sizewell Marshes during Phase 1 of construction is the Applicant has calculated that 11% of the wider SPA breeding gadwall population will be displaced due to impacts on the South Levels and Sizewell Marshes.

3.317 Paragraph 8.8.362 of the Shadow HRA Report goes on to state that this level of displacement would not apply to the whole construction period as the encroachment of the 65 dB L_{Amax} contour is lower in the subsequent construction phases and because the modelling for each phase is based on the worst case scenario within that phase and is not likely to occur for the full duration. However, we note our concerns above regarding overlapping construction phases, the lack of certainty regarding construction timelines and concerns that the impacts of construction Phase 5 have not been fully considered.

3.318 Paragraph 8.3.30 of the Shadow HRA Report Addendum also states that impacts are likely to be overestimated based on the distribution data obtained from the 2020 surveys. These indicated that the majority of breeding gadwall on the South Levels in that year were confined to pools in the north eastern corner of the levels which are not likely to be affected by significant noise levels or visual impacts. However, such generalisations should be treated with caution as the data are based on one year of surveys only, and as noted in the Shadow HRA Report, suitable habitat is found across the South Levels. Patterns of waterbird usage of the South Levels may vary year on year depending on water levels.

3.319 The Shadow HRA Report Addendum discusses the additional modelling of night-time noise and chronic noise. Whilst we have some concerns about the scope of these assessments, as noted above, the additional information is welcomed. With regard to chronic noise, paragraph 8.3.14 notes that the areas expected to be affected are those acknowledged to be affected by impulsive noise hence the conclusions of those original assessments are not changed. However, we note that chronic noise impacts on Minsmere South Levels and Sizewell Marshes do appear significant during Phases 3 and 4 of the construction period (and we assume in other phases) and therefore have the potential to exacerbate impacts on breeding birds in particular, as discussed above.

3.320 Paragraph 8.3.15 discusses the outputs of the night-time noise modelling and explains that "noise levels would be below 55dB L_{Amax} and 45 L_{Aeq} across almost all of the Minsmere South Levels, and much of the Sizewell Marshes." Based on Figure 8A.5 in the Shadow HRA Report Addendum

---

159 Chapman, C. & Tyldesley, D. (2016) Functional linkage: How areas that are functionally linked to European sites have been considered when they may be affected by plans and projects - a review of authoritative decisions. Natural England Commissioned Reports, Number 207, see in particular pages 10-14

160 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

161 Shadow HRA Report Addendum (AS-173)

Appendices 1A-10A Part 5[162] significant parts of the eastern block of Sizewell Marshes would be affected by peak noise levels of above 55dB L_{Amax} overnight during Phases 3 and 4 along with the southern extremities of the Minsmere South Levels. Again, this lends weight to the need to consider the potential for significant effects throughout the construction period rather than just in Phase 1.

3.321 The construction of the flood compensation area and wetland habitat is stated not to affect breeding gadwall as this will occur in the first winter of Phase 1 of the construction period. As discussed above, we are concerned that should timelines slip and this construction extend into the following breeding season, impacts on breeding birds, including breeding gadwall, could be more significant than predicted.

3.322 The Shadow HRA Report and the Shadow HRA Report Addendum conclude that *adverse effect on* integrity arising from noise and visual impacts on breeding gadwall of the Minsmere-Walberswick SPA can be ruled out. In justifying this conclusion, paragraph 8.8.363 of the Shadow HRA Report states that the affected birds are part of the functionally linked population rather than the designated population and hence their displacement would not act to reduce the designated SPA population. We do not agree that any distinction can be drawn between designated and functionally linked populations for the purposes of HRA, since as agreed by the Applicant, these *linked* areas are equally important to these species. This statement appears to be inconsistent with the approach taken for marsh harrier within this Application and with the guidance regarding functionally linked populations produced by Natural England (Chapman and Tyldesley, 2016[163]), which states that:

> *"If effects on functionally linked land or sea are likely to have a significant effect on the population of species for which a European site was designated or classified, those effects must be considered fully in a Habitats Regulations Assessment."*

3.323 It is also noted that the current population is around three times higher than the population at the time of designation and again this is used to conclude that the impacts will not be significant, with paragraph 8.8.363 stating that:

> "*This* [displacement]… *would not prevent achievement of the supplementary advice on the generic conservation objectives to maintain the SPA population size of this qualifying feature at above 24 breeding pairs, whilst avoiding deterioration from its current level"*

3.324 The Supplementary Advice on Conservation Objectives[164] for breeding gadwall at this SPA sets a target to:

> *"Maintain the size of the breeding population at a level which is above 24 pairs, whilst avoiding deterioration from its current level as indicated by the latest mean peak count or equivalent."*

3.325 The Supplementary Advice on Conservation Objectives also note that the population has increased, with a five year peak mean count for the SPA of 84 breeding pairs between 2011/12 and 2015/16. We consider that displacement of 11% of the SPA population would constitute a significant deterioration from the current population level and would therefore compromise the

[163] Chapman, C. & Tyldesley, D. (2016) Functional linkage: How areas that are functionally linked to European sites have been considered when they may be affected by plans and projects - a review of authoritative decisions. Natural England Commissioned Reports, Number 207

[164] Natural England Supplementary Advice on Conservation Objectives (SACOs) - Minsmere-Walberswick SPA, please note once webpage opened you have to tick which species and then ask it to show *attributes and targets for selected features*. It does not appear to be possible download the entirety of the Supplementary Advice to provide page numbers

ability of the site to meet its conservation objectives. The level of displacement predicted, and our concerns outlined above mean we do not agree that *adverse effect on integrity* can be ruled out based on noise and visual impacts on breeding gadwall of the Minsmere-Walberswick SPA.

Impacts on breeding shoveler

3.326 Shoveler breeding on the Minsmere South Levels and Sizewell Marshes are acknowledged to be functionally linked to the Minsmere-Walberswick SPA population. Paragraph 8.8.384 of the Shadow HRA Report Vol. 1 Part 1[165] explains that, based on a wider SPA population of 77 pairs (including birds breeding on land within the SPA and on the Minsmere South Levels and Sizewell Marshes) these two areas hold 16% and 0.5% of the wider SPA population respectively. The Shadow HRA Report goes on to assess the extent of encroachment of the 65dB L_{Amax} contour onto the Minsmere South Levels and Sizewell Marshes during Phase 1 of the construction period. This assessment is summarised and updated in sections 8.3 b) and g) of the Shadow HRA Report Addendum[166]. It is noted that distributional data for shoveler were only collected in 2020 and therefore the assessment of numbers of shoveler affected is based on an assumed even distribution across the South Levels and Sizewell Marshes. Therefore given the encroachment of the 65dB L_{Amax} contour onto around 40% of the Minsmere South Levels and the majority of Sizewell Marshes during Phase 1 of construction it is calculated that 7% of the wider SPA breeding shoveler population will be displaced due to impacts on the South Levels and Sizewell Marshes.

3.327 The discussion of potential impacts on breeding shoveler in the Shadow HRA Report and Shadow HRA Report Addendum covers the same points as those covered for breeding gadwall above hence, we will not repeat our concerns in full, but our key points can be summarised as follows:

- Concerns regarding overlapping construction phases, the lack of certainty regarding construction timelines and that the impacts of construction Phase 5 have not been fully considered
- Conclusions regarding shoveler distribution should be treated with caution as the data are based on one year of surveys only and suitable habitat is found across the South Levels
- The assessments of night-time noise and chronic daytime noise during Phases 3 and 4 of construction indicate that significant effects are likely throughout the construction period rather than just in Phase 1.
- Should timelines for the construction of the flood compensation area and wetland in the first winter of Phase 1 of construction slip and this construction extend into the following breeding season, impacts on breeding shoveler could be more significant than predicted
- The significance of impacts should not be disregarded or downgraded because they affect a functionally linked population
- Whilst the current population level may be above that at the time of designation, any deterioration from current population levels would compromise the site's ability to meet the requirement to "avoid deterioration from its current level" set in the Supplementary Advice on Conservation Objectives[167].

3.328 Therefore, we do not agree that *adverse effect on integrity* on the breeding shoveler population of the Minsmere-Walberswick SPA can be ruled out.

---

167 Natural England Supplementary Advice on Conservation Objectives (SACOs) - Minsmere-Walberswick SPA, please note once webpage opened you have to tick which species and then ask it to show *attributes and targets for selected features.*

Impacts on breeding teal

3.329 Impacts on breeding teal are ruled out on the basis of sporadic recent breeding on the Minsmere South Levels and Sizewell Marshes and because noise impacts are not expected on the main areas of habitat suitable for breeding teal. In our view, this is not accurate as much of the South Levels are likely to provide suitable habitat.

3.330 It is notable that evidence of potential breeding (1 pair) was recorded during the 2020 surveys on the South Levels, although breeding is difficult to ascertain unless young are seen. Natural England's Supplementary Advice on the Conservation Objectives[168] for the site note that the population of breeding teal at the time of the SPA's designation was 73 pairs, but since that point the population has declined dramatically to a five year mean peak count (2011/12 - 2015/16) of one pair. The conservation objectives for the site therefore require the feature to be restored, although it is noted that the reasons for the decline are not understood.

3.331 Therefore, the potential for the proposed development to affect the ability of conservation measures to restore this feature (if causes are understood and suitable solutions can be proposed) should be considered.

Impacts on breeding bittern

3.332 Construction of the flood compensation area and wetland is planned for the first winter of construction Phase 1. We are concerned that, if this work were to stretch into the breeding period, the 65dB$_{LAmax}$ contour stretches into the Minsmere North Levels reedbeds (part of the SPA) and has potential for impacts on breeding bittern.

3.333 It should be noted that bitterns typically start booming[169] in February and that noise disturbance could have the potential to interfere with this. We therefore recommend that the commitment to carry out this work in the winter period (October – February inclusive) must be secured through a condition to ensure that this mitigation can be relied on and to justify conclusions.

Impacts on breeding marsh harrier

3.334 Noise and visual impacts on breeding marsh harrier of the Minsmere-Walberswick SPA are acknowledged to result in *adverse effect on integrity* and are discussed in detail below.

Impacts on non-breeding birds of the Minsmere-Walberswick SPA

Impacts on non-breeding gadwall

3.335 Paragraphs 8.8.469 – 492 of the Shadow HRA Report Vol. 1 Part 1[170] discuss impacts on non-breeding gadwall of the Minsmere-Walberswick SPA. It is acknowledged that the Minsmere South Levels hold an average of 53% of the SPA population (range 5-70%) and Sizewell Marshes hold 4-18% and that these populations are functionally linked to the SPA. It is noted that a high proportion of the gadwall which use Sizewell Marshes may be affected by construction-related disturbance although impacts on the South Levels are considered unlikely as the areas used by gadwall are outside the noise and visual disturbance zones, with the main area used by wintering gadwall on the South Levels likely to experience peak noise levels of approximately 64dB L_{Amax} during Phase 1 of construction and of between 54 and 64dB L_{Amax} during Phases 2 to 5. No

---

168 Natural England Supplementary Advice on Conservation Objectives (SACOs) - Minsmere-Walberswick SPA, please note once webpage opened you have to tick which species and then ask it to show *attributes and targets for selected features*.

169 The breeding call of male bitterns

170 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

estimates of the numbers of birds or proportion of the SPA population likely to be displaced are presented. This omission makes it difficult to assess the likely significance of the impacts.

3.336 The Shadow HRA Report makes reference to a small number of studies that indicate gadwall are likely to make regular movements between sites during winter. These are used to conclude that impact on Sizewell Marshes (and therefore on the SPA population) are overestimated. As this discussion refers to non-breeding birds, we consider that any such movements are a part of the natural function of the SPA population and that the key point should be whether the SPA (and functionally linked areas) are able to continue to support current numbers of birds. If noise and/or visual disturbance mean that part of the supporting habitat is unable to provide that function and that the numbers of birds the SPA is capable of supporting reduces as a result, we consider this an indication of impact.

3.337 It is stated in paragraph 8.8.490 of the Shadow HRA Report that impacts on the ability to achieve the site's conservation objectives are unlikely given that the population is currently at more than three times the level at the time of designation. The Supplementary Advice on Conservation Objectives[171] for non-breeding gadwall at this SPA sets a target to:

> *"Maintain the size of the non-breeding population at a level which is above 90 individuals, whilst avoiding deterioration from its current level as indicated by the latest mean peak count or equivalent."*

3.338 The Supplementary Advice on Conservation Objectives also note that the population has increased, with a five year peak mean count for the SPA of 440 individuals between 2012/13 and 2016/17. We consider that displacement of a likely minimum of 4% of the SPA population (based on the lowest estimates above of the total population of Sizewell Marshes and noting that a displacement figure is not presented) would constitute a significant deterioration from the current population level and would therefore compromise the ability of the site to meet its objectives. The level of displacement predicted, and our concerns outlined above mean we do not agree that *adverse effect on integrity* can be ruled out based on noise and visual impacts on non-breeding gadwall of the Minsmere-Walberswick SPA.

Impacts on non-breeding shoveler

3.339 Paragraphs 8.8.510 – 527 of the Shadow HRA Report Vol. 1 Part 1[172] discuss impacts on non-breeding shoveler of the Minsmere-Walberswick SPA. It is acknowledged that the Minsmere South Levels hold an average of 49% of the SPA population (range 16-66%) and Sizewell Marshes hold 4-10% and that these populations are functionally linked to the SPA. It is noted that any shoveler which use Sizewell Marshes may be affected by construction-related disturbance although impacts on the South Levels are considered unlikely as the main areas used by shoveler are outside the noise and visual disturbance zones, with the main area used by wintering shoveler on the South Levels likely to experience peak noise levels of approximately 64dB L_{Amax} during Phase 1 of construction and of between 54 and 64dB L_{Amax} during Phases 2 to 5. As for gadwall above, no estimates of the numbers of birds or proportion of the SPA population likely to be displaced are presented. This omission makes it difficult to assess the likely significance of the impacts.

3.340 The discussion of potential impacts on non-breeding shoveler in the Shadow HRA Report and Shadow HRA Report Addendum covers the same points as those covered for non-breeding

---

171 Natural England Supplementary Advice on Conservation Objectives (SACOs) - Minsmere-Walberswick SPA, please note once webpage opened you have to tick which species and then ask it to show *attributes and targets for selected features*.

172 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

gadwall above hence, we will not repeat our concerns in full, but our key points can be summarised as follows:

- Movements of birds within and between sites are a part of the natural function of the SPA population and that the key point should be that if noise and/or visual disturbance mean that the ability of part of the SPA or functionally linked areas to continue to support current numbers of birds is reduced, this is an indication of impact.
- Whilst the current population level may be above that at the time of designation, any deterioration from current population levels would compromise the site's ability to meet the requirement to "avoid deterioration from its current level" set in the Supplementary Advice on Conservation Objectives[173].

3.341 The level of displacement predicted, and our concerns outlined above mean we do not agree that *adverse effect on integrity* can be ruled out based on noise and visual impacts on non-breeding shoveler of the Minsmere-Walberswick SPA.

Impacts on non-breeding white-fronted goose

3.342 Paragraphs 8.8.541 - 542 of the Shadow HRA Vol. 1 Part 1[174] discusses potential noise impacts on non-breeding white-fronted geese which roost on the Minsmere South Levels. It is stated that the closest areas of open water which are likely to be used as roosts occur beyond the 64dB L_{Amax} contour for daytime noise levels during all construction phases, so that disturbance from noise impacts to the roosting birds is unlikely and that as roosting birds will only be present at night, noise levels will be "considerably lower". However, given that daytime, for the purposes of noise modelling, is defined as 7:00 AM to 11:00 PM and that these roosts are present in winter, roosting white fronted geese are likely to be exposed to daytime noise levels during the hours of darkness. We also note that, to date, surveys of nocturnal white-fronted goose usage of the South Levels have not been presented so it is not possible to attach any confidence to conclusions regarding the likely noise levels experienced by roosting geese.

3.343 However, we note that the Shadow HRA Report Addendum[175] states that these surveys have been carried out over winter 2020-2021 and we look forward to seeing the outputs of these surveys.

3.344 White-fronted geese commute from their main feeding areas at North Warren and the roosting sites at Minsmere around 2-3 hours after sunset and, as acknowledged in paragraph 8.8.541 of the Shadow HRA Report, a direct flight would take birds over the main development site. The Shadow HRA Report Addendum in paragraph 8.3.55 concludes that the resulting disturbance to commuting birds is:

> *"likely to result in small deviations to the flight routes only, and are considered highly unlikely to prevent birds from using the roosting areas".*

3.345 Given that early sunsets in winter mean that these flights are likely to be exposed to daytime construction noise levels, we consider that impacts could be more significant than assessed.

Impacts on birds of the Minsmere-Walberswick Ramsar site

3.346 Section 8.9 of the Shadow HRA Report Vol. 1 Part 1[176] covers impacts on the Minsmere-Walberswick Ramsar site and states that as the breeding assemblage species designated under

---

[173] Natural England Supplementary Advice on Conservation Objectives (SACOs) - Minsmere-Walberswick SPA, please note once webpage opened you have to tick which species and then ask it to show *attributes and targets for selected features*.

[174] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

[175] Shadow HRA Report Addendum (AS-173)

[176] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

Ramsar criterion 2 are also SPA features (with the exception of bearded tit, which is briefly discussed in paragraph 8.9.6), the assessment of impacts is covered by the SPA section. Therefore, our comments above under the Minsmere-Walberswick SPA section for breeding bittern, gadwall, teal and shoveler also apply to the Minsmere-Walberswick Ramsar site.

Impacts on breeding birds of the Sandlings SPA

Woodlark and nightjar

3.347 Paragraph 14.12.106 of ES Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[177] explains that:

> *"The north-west extremity of a relatively small, discrete, block of the [Sandlings] SPA approaches to within 0.7 km to the south of the main development site, with this discrete block likely to support approximately 3% of the SPA breeding nightjar population and approximately 9% of the SPA breeding woodlark population."*

3.348 It is stated that this area is within the zone of visual impacts although outside the area of predicted significant noise impacts. The Shadow HRA Report concludes that no *adverse effect on integrity* will arise as a result, but no justification is given for this conclusion. Given the significant percentage of the SPA population affected for both these species, we consider that potential impacts warrant further assessment.

3.349 Paragraphs 3.7.6-7 of the Shadow HRA Report Addendum Appendix 1A Further Analysis of Inter-Pathway Effects[178] also consider that the proportion of the SPA populations affected are small and there is no potential for inter pathway effects to occur when combined with other impacts from the Sizewell C proposals. This assessment therefore fails to consider the potential for combined effects of recreational pressure and visual disturbance during construction on this part of the Sandlings SPA and we therefore consider the assessment requires updating.

Impacts on the Minsmere-Walberswick Heaths and Marshes SSSI and Sizewell Marshes SSSI

3.350 Paragraph 14.12.117 of ES Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[179] discusses the potential impacts of noise and visual disturbance on the Minsmere-Walberswick Heaths and Marshes SSSI and explains that during Phase 1 of construction the encroachment of the 70dB L_{Amax} contour covers:

> *"…approximately 16.4ha (0.7% of the total 2,325.89ha) of the Minsmere to Walberswick Heaths and Marshes SSSI. During Phase 2, this reduces to 13.4ha (0.53%) with virtually no encroachment of the 70dB L_{Amax} contour during Phases 3, 4 and 5…"*

3.351 No assessment is made of feature species[180] found in the area most affected or their sensitivity to impacts. Also, no discussion of the encroachment of the 65dB L_{Amax} contour relevant to breeding birds is provided. We also note that as the SSSI underpins the Minsmere-Walberswick SPA our conclusions relating to the SPA are also relevant here.

3.352 With regard to the Sizewell Marshes SSSI, paragraph 14.12.121 of the same document states that:

---

177 ES Vol 2 Chapter 14 Terrestrial Ecology and Ornithology (AS-033)
178 Shadow HRA Report Addendum Appendix 1A Further Analysis of Inter-Pathway Effects (AS-174)
179 ES Vol 2 Chapter 14 Terrestrial Ecology and Ornithology (AS-033)
180 Species relevant to this assessment could include (but not necessarily be limited to) bittern, marsh harrier, snipe, lapwing, gadwall, shoveler and teal.

"…the noise contour modelling figures show that during Phases 1 and 2 of the construction the 70 dB L_{Amax} contour would encroach across approximately 57ha of Sizewell Marshes SSSI (55% of Sizewell Marshes SSSI total of 194.33ha). During Phases 3 and 4 this would reduce to approximately 14ha (13% of Sizewell Marshes SSSI). The 65dB L_{Amax} contour would encroach further in both cases"

3.353 This indicates that impacts of noise on Sizewell Marshes SSSI are likely to be significant. Paragraph 14.12.125 goes on to state that:

"Sizewell Marshes SSSI supports a diverse bird assemblage but populations are relatively small … Potential disturbance impacts are considered to be a short-term but of large magnitude. For any given species the impacts on a relatively small number of individuals associated with the SSSI would not result in a significant effect on any of the overall populations for any species."

3.354 Again, no assessment has been made of the feature species likely to be affected or their sensitivity to impacts and the conclusion around overall bird populations does not give adequate recognition to the importance or integrity of the SSSI itself. We therefore cannot agree with the conclusions of the assessment as provided.

Monitoring

3.355 Given the potential impacts of noise and visual disturbance on both the Minsmere South Levels and Sizewell Marshes, we consider that a robust programme of monitoring should be proposed for the construction period. A monitoring programme should include both monitoring of noise levels for the purpose of verification of noise modelling predictions and monitoring of the distribution of key bird species to detect impacts and this programme should be secured through a requirement in the DCO with the need for additional mitigation to be considered should noise levels and/or potential impacts be higher than predicted.

In-combination impacts

Offshore windfarm cable routes

3.356 Vol. 3 Ch. 10 Inter-relationships, Project-wide, Cumulative and Transboundary Effects Appendix C[181], provides an assessment of cumulative terrestrial ecology and ornithology effects with the onshore cable route construction of the Scottish Power Renewables (SPR) offshore wind schemes. This notes the potential for in-combination effects of direct land take and disturbance from the SPR projects along with recreational pressure and noise and visual disturbance from Sizewell C construction.

3.357 It concludes that since the main part of the SPA to be directly affected, the 0.7km SPA block "only" supports approximately 3% of the SPA breeding nightjar population and approximately 9% of the SPA breeding woodlark population that, with the mitigation proposed by both developers, effects would not be significant. This assessment does not consider the potential for displacement due to the construction of this Application to increase/change the predicted impacts of the SPR projects and we therefore consider that this assessment requires updating.

[181] Vol. 3 Ch. 10 Inter-relationships, Project-wide, Cumulative and Transboundary Effects Appendix C (AS-201)

Sizewell B relocated facilities works

3.358 We note that paragraph 1.1.4 of ES Vol. 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment[182] explains that:

> *"the noise impact assessment for the relocation of Sizewell B facilities was undertaken as a separate exercise, and noise sources and activities associated with relocated facilities were therefore not included in the prediction models".*

3.359 Given that the relocated facilities work is expected to take place over a period of 4.5 years and overlap with Sizewell C construction Phase 1 and part of Phase 2, the impacts of both works must be considered together and combined noise modelling outputs should be presented.

Conclusions regarding noise and visual impacts on birds

3.360 In conclusion, based on the above concerns and the information available at present, we do not agree that *adverse effect on integrity* can be ruled out for the following sites and species for impacts from the project alone:

- Breeding gadwall and shoveler and non-breeding gadwall, shoveler and white-fronted goose of the Minsmere-Walberswick SPA and Ramsar site

3.361 We consider that the Applicant must consider how the mitigation hierarchy could be applied to avoid, reduce, mitigate or, where appropriate, compensate this impact.

3.362 We also consider that further information is required to support the conclusions for breeding bittern and teal of this site.

3.363 We agree with the conclusion that *adverse effect on integrity* cannot be ruled out for breeding marsh harrier of the Minsmere-Walberswick SPA and Ramsar site and this is discussed further below.

3.364 We also consider that significant impacts from the Application's alone are likely on the following sites:

- Minsmere-Walberswick Heaths and Marshes SSSI
- Sizewell Marshes SSSI

3.365 In relation to this project in combination with other projects, we do not agree that *adverse effect on integrity* can be ruled out for the following site and species:

- Breeding woodlark and nightjar of the Sandlings SPA

Noise and visual disturbance to marsh harriers of the Minsmere-Walberswick SPA and Ramsar site

Background

3.366 The following sections discuss the assessment of noise and visual disturbance effects on marsh harrier at RSPB Minsmere (part of the Minsmere-Walberswick SPA and Ramsar site). Our comments relate primarily to the assessment of impacts and conclusions regarding AEOI in the

[182] ES Vol 2 Ch. 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204)

Shadow HRA Report Vol. 1 Part 1[183] and the proposals for compensatory habitat set out in the Shadow HRA Report Vol. 4: Compensatory Measures[184].

3.367 In brief, it has been concluded that noise and visual disturbance is likely to result in significant displacement of breeding marsh harrier from their functionally linked foraging areas on the Minsmere South Levels and Sizewell Marshes. This loss of foraging habitat is proposed to be compensated through the provision of habitats managed to provide an uplift in marsh harrier prey abundance and availability. However, we have significant concerns regarding the sufficiency of the compensation proposed. Note that marsh harriers are features of both the SPA and Ramsar site and therefore although in our comments below we refer to the SPA, these comments also apply to the Ramsar site.

The Minsmere-Walberswick SPA and Ramsar site marsh harrier population

Population at designation

3.368 At the time of SPA designation in 1991, the Minsmere-Walberswick SPA[185] supported 15 breeding females which represented 20% of the British population.

Site Conservation Objectives and Supplementary Advice

3.369 The SPA site conservation objectives[186] relevant to the breeding marsh harrier population are to:

> *"Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;*
>
> - *The extent and distribution of the habitats of the qualifying features*
> - *The structure and function of the habitats of the qualifying features*
> - *The supporting processes on which the habitats of the qualifying features rely*
> - *The population of each of the qualifying features, and,*
> - *The distribution of the qualifying features within the site."*

3.370 Natural England's Supplementary Advice on Conservation Objectives[187] specific to the marsh harrier feature sets a target to:

> *"Maintain the size of the breeding population at a level which is above 15 breeding females, whilst avoiding deterioration from its current level as indicated by the latest mean peak count or equivalent."*

3.371 It is noted that the marsh harrier population is dynamic and that this target represents a minimum value for conservation measures to achieve. Importantly, it is also stated that:

> *"Given the likely fluctuations in numbers over time, any impact assessments should focus on the current size of the site's population, as derived from the latest known or estimated level established using the best available data. This advice accords with the obligation to avoid deterioration of the site or significant disturbance of the species for which the site is classified,*

---

and seeks to avoid plans or projects that may affect the site giving rise to the risk of deterioration."

3.372 A number of targets are also set relating to supporting habitats which are relevant to the issues raised by this Application. These include the following targets:

- Restrict the frequency, duration and / or intensity of disturbance affecting roosting, foraging, feeding, moulting and/or loafing birds so that they are not significantly disturbed – it is noted that such effects may operate within or outside the site boundary and include changes to feeding behaviour.
- Maintain the extent, distribution and availability of suitable habitat (either within or outside the site boundary) which supports the feature for all necessary stages of its breeding cycle (courtship, nesting, feeding) – it is noted that the target applies year-round, but that quantified figures for extent are not available.
- Maintain the distribution, abundance and availability of key food and prey items (e.g. mammals, birds) at preferred sizes (e.g. voles, mice, rabbit; birds of pipit to duck size) – it is noted that direct or indirect impacts which may affect the distribution, abundance and availability of prey may adversely affect the population and alter the distribution of birds.
- Maintain safe passage of birds moving between nesting and feeding areas – this is noted as critical to their breeding success and to the adult fitness and survival and the target applies within the site boundary and where birds regularly move to and from off-site habitat.

3.373 Note that these targets are set in relation to the SPA but would of course equally benefit the Ramsar site.

Current SPA and Ramsar site population and trends

3.374 The SPA population remains slightly above the Supplementary Advice on Conservation Objectives[188] target of a minimum of 15 pairs, but has experienced a decline since the early 2000s, as can be seen in Table 1 below. The causes of this are not currently clear, and the Site Improvement Plan notes a need for further research in this area.

[188] Natural England Supplementary Advice on Conservation Objectives (SACOs) - Minsmere-Walberswick SPA, please note once webpage opened you have to tick which species and then ask it to show *attributes and targets for selected features*.

Table 1 Marsh harrier nests within the Minsmere-Walberswick SPA and Ramsar site 2004-2020 (updated from Table 6.6 in the Shadow HRA Report Vol. 1 Part 1[189])

Year	Minsmere	Hen Reedbed	Walberswick NNR	Total
2004	10	2	9	21
2005	12	4	8	24

[189] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

Marsh harrier sensitivity to noise and visual disturbance

3.376 Our comments below relate to the evidence base for the assessment of the sensitivity of marsh harriers to noise and visual disturbance impacts.

Threshold for noise disturbance

3.377 We note the statement in paragraph 8.8.192 of the Shadow HRA Report Vol. 1 Part 1[190] that a 70dB L_{Amax} threshold has been proposed to represent the level at which a potentially adverse behavioural response could occur.

3.378 We are concerned about specific effects of noise on foraging marsh harriers. It is unclear how increased noise levels will affect the behavioural response of foraging birds, as the effect most likely to be in question is avoidance of the area rather than flushing. As avoidance may be less energetically costly than flushing (and foraging birds are less constrained to a particular location than when at the nest), it may be that birds will display avoidance at lower noise levels than those which would flush birds already present in an area.

3.379 As discussed in paragraph 8.8.175, it is also known that harriers in general make significant use of their hearing when foraging, to enable them to detect prey, particularly within taller vegetation. Marsh harriers (as in other harrier species) have large ear openings relative to their size, and a facial disc similar in structure to those of owl species. Rice (1982) (cited in Clarke, 1995[191]) found that the directional hearing of northern harriers is similar to that of owl species.

3.380 Whilst marsh harriers may employ hearing to a slightly lesser degree than other harriers when hunting (due to differences in foraging flight height), it is thought that hearing may be as important as sight for foraging marsh harriers (Clarke, 1995). It is therefore likely that foraging harriers may be less efficient if construction noise levels mask the auditory cues which are important for prey detection, and that this may result in avoidance of affected areas and/or reduced efficiency of prey capture.

3.381 Despite the concerns above, we acknowledge that there is a very limited evidence base with which to generate a species-specific noise disturbance threshold for marsh harrier. Therefore, we have concluded that, based on currently available information, there is insufficient *alternative* evidence to challenge the 70dB L_{Amax} threshold set by the Applicant. However, concerns remain, and it is therefore important that the proposed compensation is adequate in terms of area, location, and the success of measures proposed to increase prey availability.

Marsh harrier sensitivity to visual disturbance from human activity

3.382 Paragraphs 8.8.207 – 8.8.208 of the Shadow HRA Report Vol. 1 Part 1[192] quotes Madders and Whitfield (2006)[193] regarding the sensitivity of marsh harrier to windfarms. This study reports that the sensitivity of marsh harriers to displacement by operational windfarms is "Low?". The question mark indicates that not enough studies were available to draw a definite conclusion for the species, indeed, in the case of marsh harrier, the conclusion is based on two pers. comm. references rather than published studies.

3.383 It should also be queried as to how relevant the effects of an operational windfarm are compared to a large-scale construction project. Madders and Whitfield (2006) makes no further reference

192 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
193 Madders, M. & Whitfield, D.P (2006) Upland raptors and the assessment of wind farm impacts. Ibis 148: 43-56

to marsh harriers, perhaps as this paper focuses on upland areas. For comparison, Clarke (1995)[194] reports studies showing that marsh harriers avoid nesting, or even flying, near areas used by people and Alves *et al.* (2014)[195] studying habitat preferences found that marsh harriers using arable areas showed clear disturbance and avoidance when farmers and machines were present. They noted that:

> *"Due to high human pressure, individuals may be forced to seek less favourable locations, which may ultimately have a negative impact in reproductive success and thus lead to a population decrease."* (Alves *et al.* 2014)

3.384 It is therefore unclear why, when the paragraphs 8.8.213 – 215 of the Shadow HRA Report Vol. 1 Part 1 quotes Ruddock and Whitfield (2007)[196] who recommend that a 300-500m buffer be applied for visual disturbance to marsh harrier at their breeding locations, a buffer of only 150m for visual disturbance has been applied by the Applicant[197]. Whilst we acknowledge that the buffer for this development applies to foraging birds rather than birds at the nest, no evidence is presented to support the conclusion.

Assessment of baseline conditions – current noise levels and habitat usage by marsh harriers

3.385 The points below relate to the discussion within the Applicant's assessments of baseline conditions with regard existing noise levels and habitat use relevant to marsh harriers at Minsmere.

Comparison of predicted noise levels with those recorded at Minsmere

3.386 As discussed above regarding noise impacts on breeding birds in general, the Shadow HRA Report Vol. 1 Part 1[198] paragraphs 8.8.185-186 refers to a survey of noise levels at RSPB Minsmere conducted near South Hide which is used to assess noise levels experienced by breeding marsh harriers. The noise effects described include anthropogenic sources including motor vehicles and visitors, resulting in maximum sound levels of over 70dB. We note the acknowledgement that the acoustic data collected at Minsmere were from an area close to visitor routes and may not be representative of the wider area. South Hide is on a visitor route between the main scrape and the eastern end of the reedbed. Marsh harriers do not nest in close proximity to this route. This survey location is therefore not appropriate for assessing the noise levels likely to be experienced by breeding marsh harriers – it would not be expected that visitors and motor vehicles would result in the noise levels quoted 'at the bird' given the distance of the birds from these sources. Decay rates[199] would indicate that noise levels of 70-80dB at South Hide would have reduced significantly at the distances that nests are likely to be from these sources.

3.387 The location of the South Hide survey is also not within a primary foraging area for marsh harriers. The reduced foraging activity in this area could be influenced by a number of factors. These include the presence of the visitor trail and the close proximity to the main coastal lagoons (the

195 Alves, M., Ferreira, J., Torres, I., Fonseca, C. & Matos, M. (2014) Habitat Use and Selection of the Marsh Harrier *Circus aeruginosus* in an Agricultural-Wetland Mosaic. Ardeola. 61(2): 351-366

196 Ruddock, M. & Whitfield, D. P. (2007) A review of disturbance distances in selected bird species, Natural Research (Projects) for SNH

197 Use of the word "buffer" is perhaps misleading since it is used to describe the area in which impacts are assumed to occur so Ruddock and Whitfield (2007) are actually saying that *impacts would occur* within 300- 500 metres whereas the Applicant is saying impacts would only extend to 150 metres. At 150 metres this means that the area assumed to be affected by visual disturbance is within the area also assumed to be affected by noise disturbance.

198 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

199 The manner by which sound decreases with distance from the source

Scrape) where a high density of colonial nesting avocets, gulls and terns will attack marsh harriers and drive them away. Therefore, the impacts of noise alone are difficult to interpret at this location. It should also be clarified as to whether any atypical, noise producing, management work was being carried out at that location during the survey period.

3.388 With regard sound levels attributed to insect noise and birdsong, it is important to draw a distinction between anthropogenic noise which is likely to cause alarm to birds and noise sources that are natural (e.g. birdsong, the sea) and hence much less likely to cause disturbance.

Accuracy of flight location records and use of flight length vs flight number metrics

3.389 Paragraphs 6.6.76 – 6.3.84 of the Shadow HRA Report Vol. 1 Part 1[200] describe the flight path length and flight path number metrics used to analyse intensity of use of Minsmere South Levels and Sizewell Marshes by foraging marsh harriers. In general, we agree that the metric based on flight length is the more useful measure of marsh harrier activity. However, we note that that there may have been differences in recorded locations of flights depending on the position of the surveyor. While both the flight length and flight number metrics could be affected by any such bias, the flight length metric does assume a greater level of accuracy in recording and hence is potentially vulnerable to error.

Marsh harrier usage of Minsmere South Levels

3.390 We note the conclusion in paragraph 6.3.92 of the Shadow HRA Report Vol. 1 Part 1[201] that most flight activity is concentrated over the north western part of the South Levels. We agree that this is likely to be due to proximity to nesting areas, however, we also note that the majority of the South Levels are well used (R. Harvey[202], pers. comm.), and that use may vary depending on season and amount of surface water. For example, when the eastern parts of the Levels are flooded, they are likely to be productive for marsh harriers hunting waterfowl (A. Rowlands[203] pers. comm.).

Conclusions regarding noise and visual impacts on marsh harriers of the Minsmere-Walberswick SPA and Ramsar site

3.391 Our general comments on sources of noise and visual impacts during the construction period and the adequacy of the modelling of noise levels during the different phases of construction can be above in our overarching comments on noise and visual disturbance. The comments below are points which relate specifically to potential impacts on marsh harrier.

Noise disturbance of marsh harriers foraging over the Minsmere South Levels and Sizewell Marshes

3.392 Paragraphs 8.8.190 – 8.8.202 of the Shadow HRA Report Vol. 1 Part 1[204] discuss the extent of noise and visual disturbance predicted to affect the Minsmere South Levels and Sizewell Marshes during the construction phase, based on the outputs of the noise modelling shown in Figures 8.2 to 8.7 in Shadow HRA Report Vol. 1 Part 3[205]. It should be noted that both these areas are acknowledged to provide functionally linked foraging habitat for the SPA marsh harrier population.

203 RSPB Suffolk Area Manager
204 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
205 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 3 (APP-147)

3.393 Paragraphs 8.8.194 and 8.8.196 acknowledge that the 70dB L_{Amax} displacement threshold will be exceeded over the southernmost part of Minsmere South Levels and the eastern side and southern end of Sizewell Marshes during Phase 1 and Phase 2 of the construction period (see also Figures 8.3 and 8.4 of Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 3), with the extent predicted to be smaller in Phases 3 and 4 and greater again in Phase 5 (although slightly smaller than in Phases 1 and 2, and please note our concerns raised above regarding the mapped outputs for this stage). Paragraph 8.8.195 explains that these predictions are based on the WCS noise levels for each phase and that modelling across narrower time periods shows that these maximum levels will not occur throughout each phase. Paragraph 8.8.201 indicates that this assessment based on WCS noise levels is therefore highly precautionary, however, we note that it is standard practice to base such assessments on the WCS, that the modelling based on narrower time periods relies on the construction timetable proceeding exactly according to plan without delays or changes, which is unlikely to be the case, and that there are several sources of uncertainty in the assessment requiring a high level of precaution to be used, such as the uncertainty about the application of the 70dB L_{Amax} threshold to marsh harrier.

Acoustic fence

3.394 Paragraph 8.8.67 of the Shadow HRA Report Vol. 1 Part 1[206] explains that the impact assessment for the Phase 1 construction period is based on the assumption that a 5m high acoustic fence (or equivalent mitigation) will be in place. It is crucial that the 5m acoustic fence is constructed at the beginning of the Phase 1 construction period, especially as marsh harrier compensation is not likely to be fully functional at this point (we discuss this further below) and Phase 1 of the construction period is one of the phases with the highest noise impacts on this area.

Barrier effects on Sizewell Marshes

3.395 The baseline surveys of marsh harrier flight activity demonstrated that marsh harriers nesting at RSPB Minsmere not only forage over the wetland habitats of the Minsmere South Levels and Sizewell Marshes (as mentioned above), but also nearby arable habitats. Given the location of the main construction area in an arc between the nesting sites at RSPB Minsmere and the foraging areas at Sizewell Marshes and the significant human activity that will take place within this area (to which marsh harriers are known to be sensitive, as discussed above), we consider it unlikely that marsh harriers will continue to over-fly this area during the construction phase in order to access foraging habitats at Sizewell Marshes[207]. We therefore support the conclusion in paragraph 8.8.200 of the Shadow HRA Report Vol. 1 Part 1[208] that noise levels over the main development site (as well as visual disturbance) should be considered to lead to a "barrier effect" on foraging marsh harriers, meaning their complete displacement should be assumed from the entirety of Sizewell Marshes.

3.396 With regard to the discussion of marsh harrier use of Trimley Marshes (next to the Port of Felixstowe) in paragraphs 8.8.180-103 of the Shadow HRA Report Vol. 1 Part 1, it should be noted that conclusions about barrier effects cannot be drawn from this site. At Trimley, there is no suitable marsh harrier habitat in any location which would require harriers to fly over the Port in order to access it from their breeding sites, therefore this site provides no evidence from which inferences can be made about whether marsh harriers from Minsmere will continue to use Sizewell Marshes during the construction period.

208 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

Visual disturbance of marsh harriers foraging over the Minsmere South Levels and Sizewell Marshes

3.397 As discussed in the section on marsh harrier sensitivity to visual disturbance from human activity above, we have concerns about the Applicant's use of a 150m buffer[209] to represent the area around the main development site subject to visual disturbance displacement. Paragraphs 8.8.204 – 8.8.210 of the Shadow HRA Report Vol. 1 Part 1[210] discuss the application of this buffer, which is illustrated in Figure 8.10 in the Shadow HRA Report Vol. 1 Part 4[211]. Based on this buffer, visual displacement will affect the southern extremities of the Minsmere South Levels along with parts of the periphery of Sizewell Marshes, however, the visual buffer is generally encompassed within the area affected by the 70dB L_{Amax} noise displacement threshold. As discussed above, we consider that insufficient evidence has been presented to support deviation from the recommended 300-500m buffer (based on Ruddock and Whitfield, 2007)[212] and hence argue that this assessment risks underestimating impacts.

Conclusion that adverse effects on integrity on the Minsmere-Walberswick SPA and Ramsar site cannot be excluded

3.398 Due to the predicted extent of disturbance displacement affecting the Minsmere South Levels (based on the application of the 70dB L_{Amax} threshold and the visual buffer) and the predicted barrier effect resulting in complete displacement of foraging harriers from Sizewell Marshes SSSI during the construction period, we agree with the conclusion in paragraph 8.8.243 of the Shadow HRA Report Vol. 1 Part 1[213] that *adverse effect on integrity* on the Minsmere-Walberswick SPA (and Ramsar site) cannot be excluded. We therefore agree that, subject to consideration of *alternative solutions* and *imperative reasons of overriding public interest*, suitable compensation measures must be proposed.

Calculation of the compensatory requirement

Compensatory requirement based on area of habitats "lost"

3.399 As stated above, we agree with the Applicant's conclusion that the likelihood of barrier effects from the construction area will lead to complete displacement of marsh harrier from suitable foraging habitats within Sizewell Marshes. Paragraph 8.8.232 of the Shadow HRA Report Vol. 1 Part 1[214] explains that this loss of 78ha of wetland foraging from Sizewell Marshes, when combined with the predicted displacement from parts of Minsmere South Levels leads to a total loss of around 100ha of wetland foraging habitats (grazing marsh and reedbed), based on the WCS (although note our concerns around the visual disturbance buffer applied – see below).

3.400 Table 8.12 of the Shadow HRA Report Vol. 1 Part 1 estimates the percentage of foraging resource lost within various distance bands from the nest site at Minsmere. This concludes that around 20% of the total wetland habitats available within 4km of the nest site will be lost due to

---

209 Use of the word "buffer" is perhaps misleading since it is used to describe the area in which impacts are assumed to occur so Ruddock and Whitfield (2007) are actually saying that *impacts would occur* within 300- 500 metres whereas the Applicant is saying impacts would only extend to 150 metres. At 150 metres this means that the area assumed to be affected by visual disturbance is within the area also assumed to be affected by noise disturbance.

214 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

displacement during the construction phase, or 23% of total foraging resource available if also considering loss of agricultural habitats.

Lack of compensation for loss of arable habitats

3.401 Arable habitats near nest sites can be very important for foraging marsh harriers, especially male birds. This is illustrated by paragraph 6.3.94 and Table 8.12 in the Shadow HRA Report Vol. 1 Part 1[215] which discuss marsh harrier flight activity intensity. It is notable that some of the agricultural areas have levels of flight activity that are comparable to parts of the wetland habitat at Sizewell Marshes. Table 8.12 shows that 24% of the arable foraging area within 4km of the nesting area will be 'lost' to harriers during construction, yet the calculation of the foraging area required to mitigate lost foraging areas only considers wetland habitats. While we recognise that wetland habitats may represent optimal foraging areas and are more limited in availability, the loss of arable foraging is likely to be important to this population due to the level of use of these areas shown by the Applicant's surveys and based on the literature discussed in the section above. We therefore disagree with the statement in the Shadow HRA Report Volume 4: Compensatory Measures[216] paragraph 1.3.6 that arable habitats provide low quality foraging and its loss is unlikely to be limiting in this area.

3.402 We welcome the update to the marsh harrier baseline surveys carried out in 2020 and outlined in paragraphs 6.3.31 – 6.3.33 of the Shadow HRA Report Addendum[217], noting there are some slight changes to a few viewpoint locations. We note that the outputs of these surveys are presented using the flight intensity metric (m/hr/ha) and that paragraph 6.3.54 states again that the flight intensity over agricultural land is lower than that over Sizewell Marshes and the South Levels. However, it can be seen that when areas not used at all (possibly relating to crop type) are excluded, levels at other viewpoints are similar to South Levels and Marshes. This lends further support to our concern about the lack of consideration of arable habitats in the compensation provision.

3.403 We are therefore concerned with the statement in paragraph 8.8.259 of the Shadow HRA Report (and echoed in paragraph 3.4.13 of the Shadow HRA Report Vol. 4: Compensatory Measures), which states that "foraging birds would be able to counteract the potential 'loss' of the foraging resource on arable habitats… via behavioural mechanisms, such as modifying foraging ranges to exploit alternative areas of arable habitat … or by increasing foraging effort." We do not agree that marsh harriers will simply be able to increase foraging effort to counter the loss of arable habitats. This would involve an energetic and time cost which could result in reduced prey delivery rates and potentially affect the species' productivity.

3.404 We therefore disagree with the approach of excluding the loss of foraging resource from all agricultural habitats from the calculation of the compensation requirement.

Visual disturbance

3.405 As discussed above, we are concerned that the Applicant's use of a 150m buffer in the assessment of displacement arising from visual disturbance risks under-estimating impacts. Paragraph 8.8.206 of the Shadow HRA Report Vol. 1 Part 1[218] identifies 300 – 500m as an adequate buffer from human disturbance for nest sites and paragraphs 8.8.204 – 8.8.205 also discuss studies identifying an adverse impact on habitat use by marsh harriers from human disturbance. We

[215] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
[216] Shadow HRA Report Volume 4: Compensatory Measures (APP-152)
[217] Shadow HRA Report Addendum (AS-173)
[218] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

therefore consider that this potential underestimation of impacts may mean that the compensatory habitat requirement is also underestimated.

Compensatory requirement based on levels of flight activity

3.406 Table 8.14 in the Shadow HRA Report Vol. 1 Part 1[219] shows the results of an analysis of the foraging habitat resource lost to displacement based on estimated flight activity within the affected areas. This applies data from the baseline surveys of flight activity to all similar habitats within the same distance band from the nest site at Minsmere to estimate the percentage reduction in flight activity of foraging marsh harrier arising from displacement. It is estimated that 15% of the flight activity over wetland habitats within 4km of the nest site would be lost and that this would rise to 19-20% of total flight activity when considering both wetland and agricultural habitats.

3.407 We note our concern that compensatory habitat requirements should not be calculated solely on the basis of the flight activity. Whilst the level of flight activity may give some indication of the importance of an area for foraging, it does not distinguish between commuting and foraging flights and does not give an indication of the hunting success rate or level of biomass provided to foraging harriers. We therefore consider that greater weight should be given to habitat extent and quality in assessing the compensatory requirements.

Residual loss of foraging resource

3.408 Table 8.15 in the Shadow HRA Report Vol. 1 Part 1[220] indicates the different levels of wetland resource lost given different levels of increased marsh harrier activity over the compensation area and varying levels of displacement/barrier effect. We are concerned about the accompanying statement (paragraph 8.8.254) that "small" residual losses of total wetland foraging resource of less than 5% would be unlikely to have a population level impact, given the total wetland resource supports 50% of the SPA population. Given the difficulty likely to be encountered in assessing performance of the compensation area (as replacement of nutritional provision may not directly equate to flight activity), the precautionary principle must be applied.

3.409 We therefore do not agree with the statement in paragraph 3.4.10 of the Shadow HRA Report Vol. 4: Compensatory Measures[221]) that:

> *"If displacement and (particularly) barrier effects operate at less than 100% then the overall functional replacement (and therefore compensation) requirement would also be reduced."*

3.410 It would not be appropriate to take active steps to reduce the extent of the compensation area in this instance due to our concerns that the compensation area is not adequate in terms of extent or likely prey provisioning and the possibility that marsh harrier behavioural response may change again in future due to changing construction activities. In addition, again in line with the precautionary principle, should there be any doubt as to the effectiveness of the compensation area, more rather than less compensation should be provided. The EC guidance on "Managing Natura 2000 sites" (EC, 2018)[222] explains that the extent of compensation required is directly related to:

- the quantitative and qualitative aspects inherent to the elements of integrity likely to be impaired

---

219 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
220 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
221 Shadow HRA Report Volume 4: Compensatory Measures (APP-152)
222 European Commission (2018) Managing Natura 2000 sites. The provisions of Article 6 of the 'Habitats' Directive 92/43/EEC

- the estimated effectiveness of the measure(s)

3.411 EC (2018) also states that ratios are best set on a case-by case basis, but should generally be well above 1:1. Ratios of 1:1 or below should only be considered when it can be shown that measures will be fully effective in reinstating structure and functionality in a short period of time.

Ecological considerations for design of the compensatory marsh harrier foraging habitat

3.412 The Applicant has proposed the management of an area of 48.7ha of former arable land close to the Minsmere South Levels for foraging marsh harrier, with the aim of providing compensation for loss of foraging resource through a significant uplift in prey abundance and availability at this site. The following sections discuss the design of the proposed compensatory habitats and assess the adequacy of the compensation in comparison to the predicted impacts.

Habitat preferences of foraging marsh harriers

3.413 Much of the literature regarding marsh harrier foraging habitat preference recognises that whilst wet habitats are preferred by marsh harriers for nesting and are heavily used for foraging (particularly by females), arable farmland is also regularly used by foraging (and in some areas, nesting) harriers. The level of use of arable habitats appears to depend partly on its proximity to the nest site, with areas within 3km of the nest being most heavily used, and partly on the availability and accessibility of prey (Cardador and Mañosa, 2011[223]).

3.414 Prey accessibility is an important consideration in arable habitats (Schlaich *et al.*, 2015)[224], with some crops holding relatively good prey populations but having a level of vegetation cover during the breeding season which precludes hunting by marsh harriers (although these habitats may be suitable for foraging when the crop is at different vegetative stages at other times of year). For example, several studies report that maize fields are avoided by foraging harriers during the breeding season probably because the vegetation is too high and the cover too dense for harriers to hunt successfully, although they may be used outside the breeding season (Alves *et al.* 2014[225], Cardador and Mañosa 2011, Cardador *et al.* 2011[226]). Cardador *et al.* (2011) and Cardador and Mañosa (2011) note that a similar pattern of use was found for wheat and barley fields in their studies of the Ebro Delta in Spain, with use of these fields largely in the winter and spring before dense cover develops.

3.415 A number of studies report that alfalfa (lucerne) fields provide high quality foraging habitat for marsh harriers (and other birds of prey) throughout the breeding season (e.g. Cardador and Mañosa 2011, Cardador *et al.* 2011, Schlaich *et al.* 2015). This is thought to be partly due to prey abundance as alfalfa supports good numbers of small mammals and attracts insects which in turn attract small birds, and partly due to prey accessibility; alfalfa requires regular mowing which means that the crop does not get too tall and dense. Similarly, Clarke (1995)[227] reports an example from Norfolk of marsh harriers foraging over pea fields, hunting starlings attracted by the large number of insects present.

227 Clarke, R. (1995) The Marsh Harrier. Hamlyn Species Guides. London

3.416 Schlaich *et al.* (2015) report on agri-environment scheme options aimed at Montagu's harrier (but also used by marsh harrier) in the Netherlands, which comprise strips of alfalfa interspersed with strips of set-aside (cereals, grasses and herbs).

3.417 The success of these areas was thought to be due to the high numbers of small mammals supported by the set-aside, which were made accessible to harriers following the cutting of the alfalfa. This corresponds with studies of small mammal diversity in different arable habitats by Aschwanden *et al.* 2007[228] and Scott *et al.* 2008[229], from which it can generally be stated that small mammals are most abundant in tall (unmown) grass and mosaic habitats. Clarke (1995) also notes the benefits of linear features such as ditches and edges between taller and shorter vegetation as these aid the element of "surprise" used by marsh harriers in hunting.

3.418 Male and female marsh harriers show different foraging habitat preferences. Males typically take smaller prey than females and forage more widely (Clarke, 1995 and Witkowski, 1989[230]). They also make more use of arable areas than females, with females being more likely to forage on wetland (Clarke, 1995, and Witkowski, 1989), including reedbeds. Females are also less agile than males so prefer the taller vegetation of wetlands where they can use the element of surprise in their hunting (Clarke, 1995). This may mean males are more likely to use the dry habitats within the proposed compensation area than females. Therefore, later in the breeding season when females start to forage, these birds could be more affected by the reduction in wetland foraging habitat available as they may be less willing to use grassland foraging areas.

3.419 We query therefore whether there could there be a resulting reduction in food supply for older (unfledged) chicks. This issue is acknowledged in Paragraph 6.3.88 of the Shadow HRA Report Vol. 1 Part 1[231], which briefly discusses the potential for male and female marsh harriers to exploit prey resources differently during the breeding season and the need to consider this in the provision of foraging habitat compensation.

Habitat components of the proposed compensation area

3.420 Sections 2. 1 And 2.2 and Table 1.1: Habitat components of the preferred compensation option(s) of the Shadow HRA Report Vol. 4: Compensatory Measures[232] summarise the principles of design and habitat components of the proposed marsh harrier compensation area. We agree with the principles set out in 2.1.2 and our comments on the various habitat components proposed are provided below.

Short grassland

3.421 Whilst we acknowledge that short grassland can be productive in terms of numbers of rabbits, we are concerned that marsh harriers may not make significant use of such areas. At Minsmere it is notable that marsh harriers rarely forage over the acid grassland, despite these areas holding the highest densities of rabbits, perhaps due to the difficulty of 'surprising' prey in these areas where the sward height is maintained below 10cm to provide suitable habitat for stone-curlew and woodlark. Areas of short grassland should be limited in extent, and the expansion of rabbits

232 Shadow HRA Report Volume 4: Compensatory Measures (APP-152)

monitored (and if necessary, managed) to ensure that areas intended to support taller vegetation are not overgrazed.

3.422 It is also worth noting that rabbit numbers have crashed in many parts of the country, probably as a result of disease (in particular, a new strain of viral haemorrhagic disease) and so are not necessarily a reliable food source. This does not appear to have happened in the Minsmere area so far but could do, and in this case, it would be unlikely that habitat improvements could result in a significant uplift to population numbers.

Tussocky grassland

3.423 We agree that, with regard to dry habitats, tussocky grassland is a useful element to include due to the relatively large numbers of small mammals it is likely to support. A review of small mammal populations in the UK by Mathews *et al.* (2018)[233] found that unimproved grassland (here equivalent to rough or tussocky grassland) supported high densities of rabbits and field voles in particular. Studies by Aschwanden *et al.* 2007 and Scott *et al.* 2008[234] also found that, in farmland areas, small mammals are most abundant in tall (unmown) grass and mosaic habitats.

Scrub foci

3.424 We acknowledge the potential benefits of scrub foci to aid establishment of rabbits in short grassland and support its provision in small patches, as recommended in the report. We would not support the inclusion of larger patches of scrub/woodland as prey species using them may not be available to harriers.

Hedges and banks

3.425 We agree that providing some 'edge habitats' between vegetation of different heights in the form of hedges and earth banks could be useful as these may aid the element of "surprise" used by marsh harriers in hunting (Clarke, 1995)[235]. Edges between mown and unmown strips of grassland could also be beneficial.

Wild bird seed and nectar mixes

3.426 As discussed above, Schlaich *et al.* (2015)[236] found that strips of set-aside (cereals, grasses and herbs) provided good numbers of small mammals which were made accessible to harriers following the mowing of adjacent strips. We therefore support the inclusion of these habitats, although request further detail as to how these would be managed to maximise prey availability.

Wet woodland and reedbed

3.427 Paragraph 2.2.1-3 of the Shadow HRA Report Vol. 4: Compensatory Measures[237] explains that approximately 0.7ha of wet woodland and 1.2ha of reedbed habitat will be included within the marsh harrier compensation area. Whilst we welcome in principle the inclusion of reedbed habitat in the proposals for habitat compensation, we are concerned that this area is not due to be constructed until the first winter of the construction period. This means it is unlikely to be

237 Shadow HRA Report Volume 4: Compensatory Measures (APP-152)

functional during the early phases of construction during which noise levels are highest and therefore its construction at this stage could effectively result in a loss to the compensatory habitat provided. This component therefore should be constructed prior to the main construction period commencing or be removed from the calculation of the area of compensatory habitats for marsh harrier.

3.428 The Marsh Harrier Mitigation Area Feasibility Report (Wood, 2018) (ES Vol 2 Ch. 14 Appendix 14C5[238]) acknowledges that trees and woodland should be avoided as prey they may provide would not be accessible to harriers. We therefore do not agree that the 0.7ha of wet woodland proposed can be counted towards marsh harrier compensation.

Open water (water resource storage area)

3.429 Paragraph 2.1.5 of the Shadow HRA Report Vol. 4: Compensatory Measures[239] explains the "inclusion of a water resource storage area in the north-eastern area of the 48.7ha [compensation] site". Based on the description in paragraphs 3.4.133-138 of ES Vol. 2 Ch. 3 Description of Construction[240], this will comprise a reservoir with raised embankments of up to 3m and surrounded by tree/hedge planting. This type of structure is not likely to provide suitable foraging habitat for marsh harriers unless significant amounts of emergent vegetation develops attracting wildfowl use. This is considered unlikely to occur unless relatively large areas of shallow sloping edge are provided and will not establish immediately even if the design is suitable. We therefore do not agree that this area can be included in the area proposed as compensation for marsh harrier foraging.

Conclusions regarding habitat components of the compensation area

3.430 In general, we agree with the dry habitat components proposed, although we still have concerns around the overall loss of valuable wetland foraging habitats for marsh harrier. The wetland habitats additionally proposed at present are unlikely to address this, either because the habitat types are of limited usefulness to foraging harriers (e.g. wet woodland) or are unlikely to be established before construction starts (e.g. reedbed), however, the inclusion of ditches would be likely to be beneficial.

3.431 Based on the information discussed above, in order to maximise abundance and accessibility of small mammals and birds in the dry habitats as prey for marsh harriers, strips of taller vegetation providing optimal habitat for small mammals along with strips of mown/shorter vegetation allowing access to foraging harriers should be considered, along with flowering crops which may attract small birds foraging for insects. These habitats should form a mosaic to produce "edges" between taller and shorter vegetation and should include other linear features, such as hedges and ditches. Consideration must be given to the management of the area to maintain a balance between the needs of rabbits and other small mammals and birds e.g. to avoid detrimental effects of overgrazing by rabbits during the establishment of seed mixes. Careful consideration must also be given to other potential conflicts e.g. effects of any mowing/cutting on ground nesting birds. The use of insecticides in the compensation area should be avoided.

3.432 Further details must be provided in a comprehensive management plan for the compensation site including details of how management will be carried out and performance monitored.

Marsh harrier prey species

3.433 Paragraphs 3.4.1 to 3.4.4 of the Shadow HRA Report Vol. 4: Compensatory Measures[241] discuss the main components of marsh harrier diet. Table 3 below summarises a number of studies of marsh harrier diet in the breeding season. This supports the conclusions in the report that marsh harriers are able to take a range of prey species as opportunity allows.

3.434 While we therefore agree that the prey items likely to be provided by the compensatory habitats would be suitable for marsh harriers, we reiterate our concern that the overall loss of wetland foraging habitat could negatively affect prey provisioning later in the breeding season when females also bring prey to the chicks. As discussed in section above and noted in several of the studies summarised in table 3, females typically take larger prey than males and forage proportionately more in wetland habitats than males. Therefore, the loss of wetland habitat could increase intra-specific competition and reduce the biomass provided by females or increase female energetic costs in order to provide similar levels of biomass.

Predictions of prey abundance

Rabbits

3.435 Section 3.2 of the Shadow HRA Report Vol. 4: Compensatory Measures[247] discusses predictions of the prey abundance which could be provided by the compensatory habitats and draws on the information provided in Appendices B of ES Vol. 2 Ch. 14 Appendix 14C5 Marsh Harrier Mitigation Area Feasibility Report[248] ("Appendix B"). Appendix B concludes that the compensation area is likely to have supported rabbits at a density of 0.5-1 per hectare during agricultural use. This is based on average figures of 2.5 per hectare for arable areas from Harris (1995)[249] and the statement that "Arcadis however has reported virtually never seeing a rabbit within the proposed mitigation area during site visits".

3.436 Given that rabbits are primarily active at night (we assume Arcadis' visits were carried out during the day) and that surveys specifically looking for rabbits at night may only detect around 60% of the rabbit population (Matthews *et al.*, 2018), this is not sufficient justification to reduce the estimated density of rabbits from the recognised UK sources of such information (Harris, 1995, also cited in the review by Matthews *et al.*, 2018). Whilst it is acknowledged that limited evidence is available for rabbit densities in the UK and that densities are known to be highly variable, it should also be considered that the area is on sandy soils which are known to support rabbit densities at the higher end of such estimates (Cowan, 1991, cited in Harris, 1995).

3.437 Appendix B goes on to discuss the densities of rabbits that may be possible on the compensation area once the new habitats are established. Based on statements that Harris (1995) reports a range of rabbit abundances and that there are currently high (but unquantified) densities of rabbits in neighbouring areas, it is assumed that winter densities of 15-20 rabbits per hectare would be achievable (higher in the breeding season) on the short grassland and 2.5-5 per hectare on the tussocky grassland.

3.438 This does not accord with the estimated densities of 2.5 per hectare on lowland grassland used by the Harris (1995) review or the Statutory Nature Conservation Bodies' more recent review (Matthews *et al.*, 2018) which quote densities of between around 0.5 and 6 per hectare for improved grassland and 5 per hectare for unimproved grassland. It is stated that the abundance of rabbits will increase by 15-40 times in the short grassland compared to baseline and by 2.5-10 times on the tussocky grassland.

3.439 Therefore, the Applicant's estimates appear extremely optimistic when compared to the figures in the two reviews cited and we do not agree that any confidence can be attached to these figures. Whilst we acknowledge the limitations of the evidence available from the literature, we do not

249 Harris, S., Morris, P., Wray, S. & Yalden, D. (1995) A review of British mammals: population estimates and conservation status of British mammals other than cetaceans. JNCC, Peterborough

agree that any site-specific evidence has been presented which would justify such a significant departure from the literature. We therefore consider that the figures in Matthews *et al.* (2018) which are based on Harris (1995) and others should be used and would indicate that the original arable is likely to have supported around 2.5. rabbits per hectare and that the upper range figure of 6 per hectare for improved grassland could be achieved, equating to an increase of 2.4 times the original density.

Total small mammal numbers

3.440 Appendix B also calculates the numbers of small mammals provided by the baseline habitats and the various habitat options for the compensation area. It provides summaries of a number of studies relating to small mammal numbers in various habitats, but most provide information regarding the relative importance of habitats for small mammals, with only one summary including figures for mammal densities which could be used in the metric to calculate densities for the compensation area.

3.441 The key review of small mammal population in the UK by Mathews *et al.* (2018)[250] for the Statutory Nature Conservation Bodies has not been included, and as the most up to date and authoritative recent review relevant to the UK we query why this is the case. Mathews *et al.* (2018) provides density estimates for various habitats for the key small mammal species – this is discussed further below. A brief summary of a study of small mammals in the compensation area is also provided. Whilst this provides useful information (e.g. regarding the species present) and some estimates of density, it is noted that the data are limited. No information is provided regarding these data limitations which would allow the robustness of the data to be assessed and we recommend that a report of this study is provided.

3.442 The report then goes on to suggest mammal densities for habitats within the compensation area for use in calculating a metric to compare the numbers of small mammals likely to be found in the compensatory habitats to those in the baseline habitats. Very little justification is provided for the figures used.

3.443 We have compared these figures with the density figures provided in the UK review by Mathews *et al.* (2018) in Table 4 below based on all the small mammal species expected to be present in the area for which data are available. We would also expect that weasel, brown rat and harvest mouse could also be present, however, Mathews *et al.* (2018) conclude that there is too little evidence available to support density figures for these species and habitats.

[250] Mathews, F., Kubasiewicz, L.M., Gurnell, J., Harrower, C.A., McDonald, R.A. & Shore, R.F. (2018) A Review of the Population and Conservation Status of British Mammals. Figures from Marsh Harrier Mitigation Area Feasibility Report Appendix B					
All small mammals (including rabbits)	0 - 21	10 – 35	102.5 - 305	500 – 1000 ha^{-1}	50 - 101

[+]No direct figures for this habitat are available from Mathews *et al.* (2018), but as habitat structure is key and this is most similar to longer (Mathews *et al.*'s unimproved) grassland, these figures are tentatively applied

* Figures are for hedgerows in agri-environment schemes

3.444 From the table, it can be seen that the numbers used in Appendix B for some habitats, particularly tussocky grassland and hedgerows, appear high in comparison to Mathews *et al.* (2018), particularly as the assessments go on to use the highest figures from the ranges presented (e.g. 300 per hectare for tussocky grassland).

3.445 It should be noted that Mathews *et al.* (2018) explain that in many instances the data regarding density are limited and hence their estimates for different species and habitats may vary in their reliability. Also, the lack of data for some species, particularly brown rat, will mean that the total figures above are underestimates, but it appears unlikely that this would account for the significant discrepancy with the figures used in Appendix B.

3.446 Table 5 below compares the habitat areas for the compensation area under baseline conditions and the preferred compensation option 2b (note scrub foci are excluded as the areas are so small). These are then used with the density figures from Table 4 above to calculate a comparison

(in Table 6) of small mammal numbers within the compensation area using the figures in Appendices B (noting that outputs are presented in Appendix C) and those of Mathews *et al.* (2018).

Table 5 Comparison of habitat areas under baseline conditions and for compensation option 2b

	Baseline (ha)	**Compensation option 2b (ha)**
Arable	39.4	0
Short grassland	1	8
Tussocky grassland	0.71	24
Hedgerow	0.5 (1650m)	6.95 (6320m)
Wildbird seed and nectar mix	5.35	8

Table 6 Comparison of projected small mammal numbers (including rabbits) based on Appendices B and C of the Marsh Harrier Mitigation Area Feasibility Report and Mathews *et al.* (2018) for baseline and compensation option 2b habitats

	Baseline – using Appendix B max density figures	**Baseline – based on Mathews *et al.* (2018)**	**Compensation option 2b – using Appendix B max figures**	**Compensation option 2b – based on Mathews *et al.* (2018)**
Arable	827	156.8	0	0
Short grassland	35 (App C: 40)*	3.48	280 (App B: 320)*	27.8
Tussocky grassland	217	53.3	7320	1801.4
Hedgerows	500 (App C: 495)	61.5	6952	156.3
Wildbird seed and nectar mixes	540	401.6	808	600.5
TOTAL small mammals	2119	676.7	15360 (App B: 15400)	2586
Uplift compared to baseline using same source of density figures			x7.25	x3.82

*Note there are some discrepancies in the density figures used for rabbits in Appendix B – although the density stated for short grassland is 10-15 per hectare, the calculations use 15-20 per hectare

3.447 From the above it can be seen that the high small mammal densities applied have the effect of significantly overestimating small mammal abundance for the compensatory habitats and exaggerating the uplift from baseline conditions.

3.448 We therefore disagree with the statements in Section 3.2 of the Shadow HRA Report Vol. 4: Compensatory Measures[251] regarding the level of uplift in small mammal abundance that can be expected from the habitat compensation area. Paragraph 3.2.3 states that this is expected to be between 6.6 and 10.7 relative to baseline conditions, but whilst noting there are limitations to

[251] Shadow HRA Report Volume 4: Compensatory Measures (APP-152)

the figures discussed above, we consider that the uplift in abundance is likely to be around half of this level.

3.449 We also note that whilst many of the potential prey species are primarily herbivorous, not all of them are, and their food supply also needs to be considered. Given the arable history of this land and likely associated chemical use, we can expect invertebrate populations to be significantly depressed and unlikely to support an immediate uplift in insectivorous species. The wider context of the ongoing decline in bio-abundance across all taxonomic groups across the UK described in the most recent State of Nature Report (Hayhow *et al.*, 2019[252]), may also make this unrealistic.

Effect of water resource storage area and wetland habitats

3.450 Paragraph 3.2.2 of the Shadow HRA Report Vol. 4: Compensatory Measures[253] states that the additional benefits of the water storage area and wetland habitats have not been considered and that these are expected to enhance they prey resource. As discussed above, this would rely on these habitats being functional by the beginning of the construction period, otherwise they represent a loss from the compensatory habitat.

Predictions of uplift in flight activity

3.451 At present, 48.7ha of habitat is proposed to replace a potential loss of around 100ha of foraging habitat, on the assumptions that it is closer to the nesting area than Sizewell Marshes, and that it is possible to increase resource provision sufficiently to attract greater levels of activity. Paragraph 8.8.249 of the Shadow HRA Report Vol. 1 Part 1[254] explains that when taking into account loss of wetland habitat only, the level of flight activity required at the compensation site will be 18-19 m/ha/hr which is greater than average levels on Sizewell Marshes and parts of Minsmere South Levels.

3.452 We are also concerned that loss of arable foraging habitat has not been included in the calculation of the compensation requirements. Paragraph 8.8.257 explains that if loss of arable foraging were to be considered alongside loss of wetland, the resulting level of flight activity required at the compensation site to account for this would be 34-35 m/ha/hr. It is acknowledged that this would be close to or above the highest level of activity on the baseline surveys and was observed over a small area of the Minsmere South Levels only.

3.453 We therefore do not agree that the level of uplift in flight activity likely to be achievable will be comparable with that required based on this calculation (although note our concerns with reliance on this metric, discussed above).

Additional constraints on the functionality of the compensatory habitats

Additional visual disturbance constraints

3.454 We note that the footpath running from Eastbridge to Minsmere Sluice passes through the northern extremity of the proposed marsh harrier compensation area and therefore that visual disturbance from human activity along this route could compromise the function of the parts of the compensation area.

---

252 Hayhow, D.B., Eaton, M.A., Stanbury, A.J., Burns, F., Kirby, W.B., Bailey, N., Beckmann, B., Bedford, J., Boersch-Supan, P.H., Coomber, F., Dennis, E.B., Dolman, S.J., Dunn, E., Hall, J., Harrower, C., Hatfield, J.H., Hawley, J., Haysom, K., Hughes, J., Johns, D.G., Mathews, F., McQuatters-Gollop, A., Noble, D.G., Outhwaite, C.L., Pearce-Higgins, J.W., Pescott, O.L., Powney, G.D. & Symes, N. (2019) The State of Nature 2019. The State of Nature partnership

253 Shadow HRA Report Volume 4: Compensatory Measures (APP-152)

254 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

Noise levels in compensation area

3.455 As acknowledged in paragraphs 8.8.188 and 8.8.195-8.8.197 of the Shadow HRA Report Vol. 1 Part 1[255], noise levels in parts of the marsh harrier compensation area itself will also exceed the 70dB L_{Amax} threshold for all construction phases, except Phases 3 and 4, and we are therefore concerned that this could limit the functionality of the compensation area through avoidance by marsh harrier and/or avian prey species.

3.456 It is also not clear how the overlap of construction phases in some years will affect this assessment. It is explained that higher levels of noise within the compensation area (over 70dB L_{Amax}) are likely to occur for limited time periods and over limited spatial extents, however, this does represent a further reduction in the functionality of the area, which even at its full extent, is significantly smaller than the area subject to displacement and barrier effects.

Additional stockpile

3.457 We note that paragraph 2.2.108 of Vol. 1 Environmental Statement Addendum Ch. 2 Main Development Site[256] refers to an additional stockpile up to 15m above ground level next to the proposed marsh harrier compensation area and query whether the potential for additional noise impacts on the compensation area has been considered.

Water resource storage area and flood mitigation measures

3.458 Paragraph 8.3.22 of the Shadow HRA Report Addendum[257] states that

> *"The differences in the Phase 1 modelling associated with this area are not relevant to breeding marsh harrier because the construction of the water storage area would occur during the first winter of the construction period. As such, the noise disturbance from these works would not coincide with the seasonal period relevant to the SPA breeding marsh harrier population."*

3.459 Based also on Figure 8A.1 of the Shadow HRA Report Addendum Appendices 1A to 10A Part 5[258], construction of the water storage area in the first winter of construction phase 1 would cause the 70dB L_{Amax} contour to affect the southern part of the North Levels (part of the core part of RSPB Minsmere) – this is a significant northward extension of this contour as a result of the proposed change. If this work were to stretch into the breeding period, the 65dB L_{Amax} contour stretches even more significantly into the North Levels reedbeds and has potential for significant impacts on breeding marsh harrier and breeding bittern.

3.460 It should be noted that Clarke (1995)[259] states that marsh harriers take up their breeding territories in March and that courtship commences immediately while bitterns typically start booming in February and noise disturbance could have the potential to interfere with this.

3.461 In addition, the vast majority of the marsh harrier compensation area is also within the 70dB L_{Amax} contour meaning that should such impacts extend into the breeding season, the compensation would not function. Given the timing of these works is therefore crucial to the conclusion of no additional impact, we query how will these timing restrictions be confirmed and secured.

258 Shadow HRA Report Addendum Appendices 1A-10A Part 5 (AS-178)
259 Clarke, R. (1995) The Marsh Harrier. Hamlyn Species Guides. London

3.462 We also query the expected noise contours during the breeding season in Phase 1 using the updated modelling. The updated figures include the first winter of Phase 1 and separate figures for Phase 2 – they do not account for the breeding season in Phase 1 or the fact that the construction phases are expected to overlap (see Plate 3.1 in ES Vol. 2 Ch. 3 Description of Construction[260]). Combined WCS maps where construction phases are expected to overlap and impacts would be worse than each construction phase treated alone should be provided to avoid under-estimation of impacts.

3.463 Paragraphs 2.2.121 and 2.9.53 of Vol. 1 Environmental Statement Addendum Ch. 2 Main Development Site[261] explain that the water storage area's original proposed location will now be used to create open water and wet reedbeds which will provide foraging habitat for marsh harriers. But, in addition to the concerns above regarding any slippage in the timing of the excavation works (noting this is proposed for the early stages of construction Phase 1), we also note that these habitats may take some time to establish and hence may not be functional (in terms of prey provision for marsh harriers) during key phases of construction.

3.464 This area could therefore be viewed as a loss to the area of compensation provide until these habitats become functional, therefore we recommend that any wetland habitat is created in advance of the main construction period.

Timing of functionality

3.465 With regard to the marsh harrier compensation site, paragraph 2.4.1 of the Shadow HRA Report Vol. 4: Compensatory Measures[262] states that:

> *"The proposed habitat enhancement land was taken out of agricultural production approximately 4 years ago and some habitat management – for the purposes of offsetting the effects of the Sizewell C Project – has been implemented in the intervening period and is ongoing. Further habitat enhancement, including scrub and hedgerow planting was undertaken in early 2020."*

3.466 No further details of the works already carried out are provided and it is not clarified as to whether the works carried out so far are in line with the management recommendations in ES Vol. 2 Ch. 14 Appendix 14C5 Marsh Harrier Mitigation Area Feasibility Report[263].

3.467 Paragraph 2.4.4 states that the habitats will be functional by the time construction commences due to being out of agricultural production for 7 years, however, it will be necessary to demonstrate that the habitat measures in place will be aligned with the agreed and finalised compensation plan and sufficiently established to provide the required levels of prey provisioning when construction commences. Further details of the habitat management carried out to date and any subsequent uplift in marsh harrier activity should therefore be provided.

3.468 We also query the construction timeline in Plate 2.1 of the Shadow HRA Report Vol. 1 Part 1[264], which shows that the marsh harrier habitats will be established during construction Phases 1 to 3. This appears to contradict the statements discussed above, but if Plate 2.1 is correct, this would be of significant concern as we understand that the early phases of construction will generate some of the highest noise levels and would therefore lead to unacceptable residual impacts. This

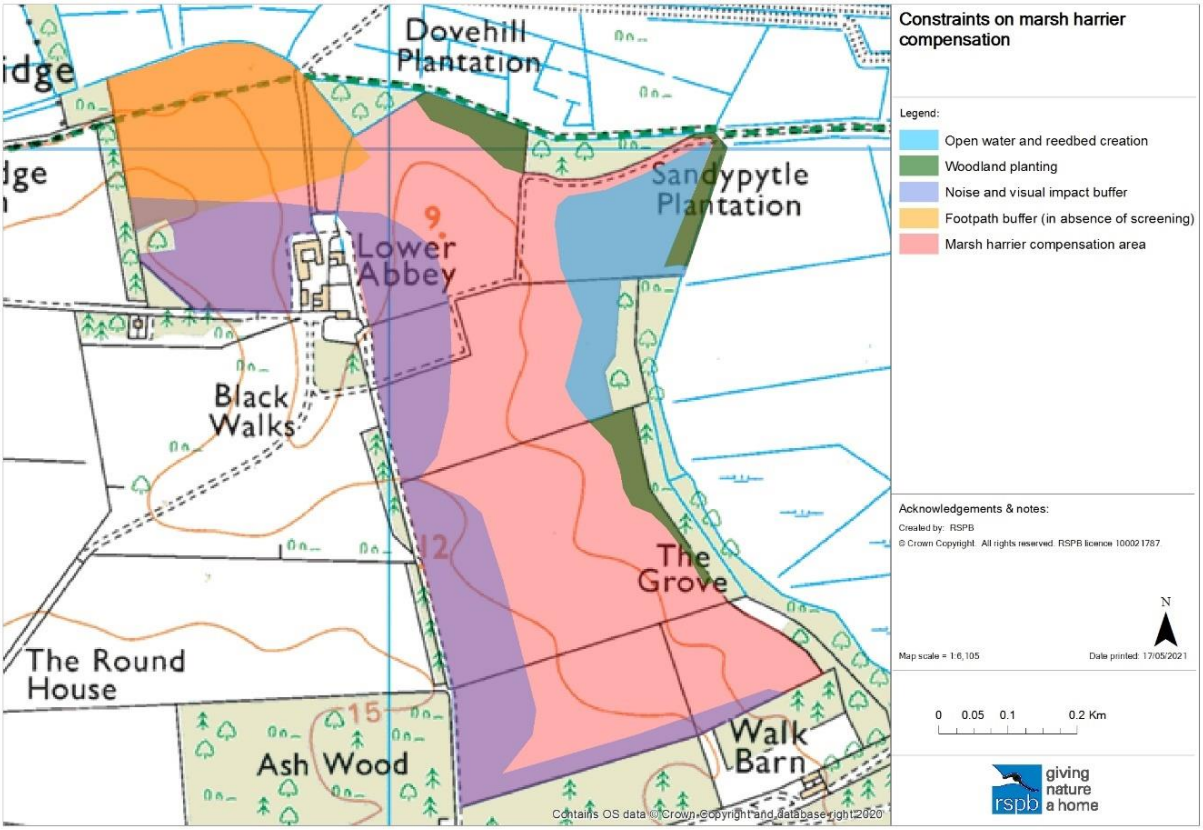
263 ES Vol. 2 Main Development Site Ch. 14 Terrestrial Ecology and Ornithology Appendix 14C5 Marsh Harrier Mitigation Area Feasibility Report (APP-259)
264 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

approach would also be contrary to the criteria for compensatory habitats set out in Section A.7 of Annex A of NPS EN-6 (Nuclear Power)[265], that they must be:

> *"capable of ensuring that the Natura 2000 site is not irreversibly affected by the project before the compensation is in place".*

3.469 Paragraph 8.8.244 of the Shadow HRA Report Vol. 1 Part 1 implies that the marsh harrier compensatory habitats will still be available for use by harriers during the decommissioning process. Whilst we would welcome this, we request that further detail is provided to clarify the intended approach and how the area will be managed during the construction period.



Summary of constraints on the functionality of the marsh harrier compensation area

3.470 As discussed above, there could be a number of constraints affecting the functionality of the marsh harrier compensation area, particularly during the first few years of construction. The map (Figure 1) shows the approximate area of the marsh harrier compensation area affected by the following:

- The maximum extent of the 70dB L_{Amax} noise contour and 150m visual disturbance buffer during the breeding seasons in the Phase 1 and 2 construction periods – based on Figure 8.10 of the Shadow HRA Report Vol. 1 Part 4[266]. Note that as discussed above, the maps based on the revised modelling in the Change Application are not clear for the first breeding season, or for the overlap between construction phases 1 and 2.
- The woodland planting illustrated in Figure 2.2.14 of Vol. 2 ES Addendum Ch. 2 Main Development Site Figures Part 1[267]
- The reedbed and open water creation also shown in Figure 2.2.14 as above. We would not expect this to be functional in terms of prey provision for marsh harrier during this period.
- A 150m buffer (based on the Applicant's chosen visual buffer, although note that this lacks precaution) around the footpath on the northern edge of the site, where this does not appear to be screened by woodland.

[265] National Policy Statement for Nuclear Power Generation (EN-6) Volume II Annex A
[266] Shadow HRA Report Vol. 1 Part 4 (APP-148)
[267] Vol. 2 ES Addendum Ch. 2 Main Development Site Figures Part 1 of 4 (AS-190)

Figure 1 Constraints on the functionality of the marsh harrier compensation area during the breeding seasons in construction phases 1 and 2.

3.471 It should be noted that this assumes that the planned winter construction of the wet habitats does not over-run into the following breeding season. If this were to occur, very little of the compensation area would remain outside the 70dB L_{Amax} noise contour.

3.472 Also we note that the planned woodland planting does have the effect of reducing the areas which would otherwise be affected by disturbance from the footpath on the northern edge of the site, however, as woodland is unsuitable for foraging marsh harriers, we still consider it should not be included in the calculations of compensatory habitat provision.

3.473 As a result of these constraints, we estimate that only around half of the marsh harrier compensation area will be functional during the early stages of construction. Given that we do not agree that the full area is adequate to fully compensate for the foraging resource lost, this significantly increases our concerns about unacceptable residual impacts based on the current proposals.

Conclusions regarding compensatory habitats proposed for loss of marsh harrier foraging resource

3.474 The points below relate to Table 1.3 of the of the Shadow HRA Report Volume 4: Compensatory Measures[268]) which compares the compensation measures proposed to the requirements of EN-6[269]. We address each of these requirements in turn.

[268] Shadow HRA Report Volume 4: Compensatory Measures (APP-152)

[269] National Policy Statement for Nuclear Power Generation (EN-6) Volume II Annex A

Be appropriate for the area and the loss caused by the Sizewell C Project

3.475 We do not at present have confidence that the compensation area can sustain the necessary level of prey provision or harrier activity to fully address the loss of foraging resource caused by noise-induced displacement/barrier effects.

3.476 This is due to our concerns about noise levels in the current compensation area, its limited extent compared to the area to be lost (especially when also considering arable habitats) and doubts about the ability to achieve the level of uplift in prey provision and flight activity predicted.

3.477 We also disagree that the assessment of noise impacts involves a "high degree of precaution" as we note there are several areas of uncertainty (for example, the robustness of the 70dB L_{Amax} impact threshold) due to which it is appropriate that the assessment is precautionary.

Be capable of protecting the overall coherence of the Natura 2000 network

3.478 Based on the above, we do not agree at this stage that the compensation measures are sufficient to protect the overall coherence of the National Sites Network (formerly known as the Natura 2000 Network of European sites within the UK) for breeding marsh harriers.

Be capable of implementation

3.479 Whilst we agree it is likely that the dry habitats could be implemented, a detailed habitat management plan and a robust monitoring will be required in order to assess whether the habitats will be fully established and functional (in terms of prey provisioning) before construction starts and whether the proposed habitat management of the compensation area will maintain it in suitable condition for the required period.

Be capable of ensuring that the Natura 2000 site is not irreversibly affected by the Sizewell C Project before the compensation is in place

3.480 As above, it must be demonstrated that the habitats provided meet the specification set out in a detailed habitat management plan.

3.481 As discussed above we also have concerns about the likelihood of being able to establish the wet habitats before construction starts.

3.482 We also recommend that prey population levels are monitored to determine whether the habitats are performing as required in terms of prey availability and abundance (as discussed further below).

Be directed in measurable proportions to the habitats and species negatively affected

3.483 Whilst we agree that the proximity of the compensation area to Minsmere is beneficial, we do not agree that 48.7ha of dry habitats are adequate to compensate for the foraging provided by 100ha of wet habitats due to the differences in habitat extent and type and the likely effects on prey provisioning levels. We also are concerned that loss of access to arable habitats is not compensated.

Be related to the same biogeographical region (within the UK)

3.484 We agree and note the benefits of the proximity of the compensation site to the habitats effectively lost.

Serve functions that are comparable to those that motivated the original area's submission for designation

3.485 We agree that the compensatory habitats will provide a similar supporting function to the SPA to those habitats effectively lost through providing foraging opportunities for marsh harriers, however, we consider that this supporting function will be reduced compared to that provided by the area lost.

Be clearly defined, with implementation goals and managed so that the compensatory measures can achieve the goal of maintaining or improving the overall coherence of the National Sites Network (formerly known as the Natura 2000 network)

3.486 A detailed habitat management plan is required, which should include appropriate and meaningful objectives and targets to ensure the appropriate compensatory habitats are provided and ensure the effectiveness of compensation measures can be appropriately monitored and remedial measures taken if needed. This should include targets in relation to prey populations and marsh harrier activity as targets purely in relation to vegetation type will not demonstrate functionality.

3.487 We also recommend that a monitoring programme is developed to ensure that the compensation area functions as required to avoid effects on the marsh harrier population. Alongside monitoring of the usage of the area by marsh harriers, we also consider that monitoring of prey populations (small mammal and bird populations) is needed, as the functionality of this area depends on its ability to provide replacement foraging rather than purely on the type of vegetation present. This is particularly important given the adequacy of this provision depends on the area being able to support levels of prey in excess of those found in the areas of wetland habitat from which birds will be displaced. Prey monitoring would therefore enable the identification of any need for further habitat creation.

Overall conclusion in relation to requirements of EN-6

3.488 Paragraph 3.5.2 of the Shadow HRA Report Vol. 4: Compensatory Measures[270]states that:

> *"In summary, the analysis presented in Table 1.3 demonstrates that the proposed compensatory measures would meet the requirements of EN-6."*

3.489 Based on our assessment against the requirements of EN-6 and set out in Table 1.3 (as well as the additional criteria contained in the EC's 2018 Managing Natura 2000 guidance[271]), we do not agree that the compensation package is acceptable and meets these requirements.

Impacts of Increased Recreational Pressure on Protected Sites and Species

Background

3.490 Our main concerns in relation to increased recreational pressure on protected sites and species concern both the construction and operation phases of the development and the potential impacts on the Minsmere-Walberswick SPA, SAC and Ramsar site (designated sites) and Sandlings SPA in particular. During the construction phase of the development it is expected that recreational users who may previously have used the Sizewell area and its surroundings may be

[270] Shadow HRA Report Volume 4: Compensatory Measures (APP-152)

[271] European Commission (2018) Managing Natura 2000 sites. The provisions of Article 6 of the 'Habitats' Directive 92/43/EEC

displaced directly by construction activity and associated footpath closures and diversions[272] or indirectly by the perception of loss of tranquillity.

3.491 In addition, the new accommodation campus for workers during the construction phase brings around 2,400 new residents close to the Minsmere-Walberswick designated sites and the Sandlings SPA, part of a total of 7,900 new residents in the wider area during the construction phase. While the effects of the accommodation campus are expected only to last during the construction phase, it is worth remembering the length of that construction period and the effects of recreational displacement of existing users could extend into the operational phase as a result of the formation of new habits and preferences[273].

3.492 Recreational activity may result in disturbance and/or displacement of birds, with the level and type of sensitivity varying by bird species and by season. Ground nesting birds on heaths and beaches are particularly vulnerable to disturbance by people and dogs through potential to cause damage through trampling or predation of nests. Sensitive habitats, such as heathland and vegetated shingle, are also vulnerable to impacts including trampling, nutrient enrichment by dog faeces and fire.

3.493 The Applicant's assessment of recreational changes is set out in ES Vol. 2 Ch. 15 Amenity and Recreation[274] while the ecological implications of increased recreational pressure are assessed in ES Vol. 2 Ch. 14 Terrestrial Ecology and Ornithology[275] and associated appendices and the Shadow HRA Report Vol. 1, Part 1[276] and Part 4 Appendix 5.10E Recreational Disturbance Assessment[277]. In addition, the Shadow HRA Report Addendum[278] and Vol. 1 ES Addendum Ch. 2 Main Development Site[279] discuss the implications of the Changes to the Application on recreational pressure.

3.494 The National Trust and the RSPB have commissioned Footprint Ecology to review the evidence submitted as part of the Application on recreation issues. Footprint Ecology have therefore provided a report on the sensitivity of designated sites and their features to recreation impacts and the potential for suitable mitigation and a review of the specific ecological reports included in the Application with the aim of checking the robustness of the Applicant's conclusions. These documents form the basis of our representations at this stage and are submitted in full as Annexes to these Written Representations (See Appendix 2 (which contains both reports) Impacts of recreation related to Sizewell C and implications for European sites (Liley & Saunders, 2020a) and Review of Sizewell C application documents and evidence in relation to recreation impacts (Liley & Saunders, 2020b)). We respectfully request that the Examining Authority review these reports in full as the text above and below are only summaries of the points covered within those Reports.

[279] Vol. 1 ES Addendum Ch. 2 Main Development Site (AS-181)

Sites and species of concern

3.495 The Minsmere-Walberswick SPA[280] was classified in 1991 and contains extensive areas of freshwater and coastal grazing marsh, coastal reedbeds, saltmarsh, lowland heathland, woodland, intertidal mud and mixed sediment. It supports the following qualifying features:

- Avocet (*Recurvirostra avosetta*), Breeding
- Bittern (*Botaurus stellaris*), Breeding
- Gadwall (*Mareca strepera*), Breeding
- Gadwall (*Mareca strepera*), Non-breeding
- Greater white-fronted goose (*Anser albifrons albifrons*), Non-breeding
- Hen harrier (*Circus cyaneus*), Non-breeding
- Little tern (*Sternula albifrons*), Breeding
- Marsh harrier (*Circus aeruginosus*), Breeding
- Nightjar (*Caprimulgus europaeus*), Breeding
- Shoveler (*Spatula clypeata*), Breeding
- Shoveler (*Spatula clypeata*), Non-breeding
- Teal (*Anas crecca*), Breeding

3.496 The Sandlings SPA[281] was classified in 2001. It comprises acid grassland and heather heathland on sandy soils and supports the following qualifying features:

- European nightjar (*Caprimulgus europaeus*), Breeding
- Woodlark (*Lullula arborea*), Breeding

3.497 Natural England has set site conservation objectives for the SPAs[282] as follows:

> *"The objectives are to ensure that, subject to natural change, the integrity of the site is maintained or restored as appropriate, and that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring:*
>
> - *the extent and distribution of the habitats of the qualifying features*
> - *the structure and function of the habitats of the qualifying features*
> - *the supporting processes on which the habitats of the qualifying features rely*
> - *the populations of each of the qualifying features*
> - *the distribution of qualifying features within the site"*

3.498 In addition, the Sandlings SPA and Minsmere-Walberswick SPA and surrounding suitable habitats support important populations of breeding stone curlew and breeding Dartford warbler. Both of these species are particularly vulnerable to recreational pressure, with stone curlew known to be very sensitive to human disturbance. The population of stone curlew on the Suffolk coast is around 16 pairs based on the five year mean from 2016 to 2020 while that of Dartford warbler is around 130 pairs for the same period (Mel Kemp[283], pers. comm.).

3.499 The Minsmere-Walberswick Ramsar site[284] was designated in 1976 under

- Ramsar criterion 1 for containing a mosaic of marine, freshwater and marshland with a rare transition in grazing marsh ditch plants from brackish to fresh water and

283 RSPB Minsmere Warden

284 Minsmere-Walberswick Ramsar: http://jncc.gov.uk/jncc-assets/RIS/UK11044.pdf

- Ramsar criterion 2 for supporting nationally scarce plants, British Red Data Book invertebrates and nationally important numbers of breeding and wintering birds (bittern, gadwall, shoveler, teal, marsh harrier, avocet and bearded tit).

3.500 As the breeding assemblage species designated under Ramsar criterion 2 are also SPA features (with the exception of bearded tit, which as a reedbed species is unlikely to be significantly affected by changing recreational use), our comments regarding breeding marsh harrier, bittern, gadwall, teal and shoveler of the Minsmere-Walberswick SPA also apply to the Minsmere-Walberswick Ramsar site.

3.501 The Minsmere to Walberswick Heaths and Marshes SAC[285] was designated in 2005 for its annual vegetation of drift lines, perennial vegetation of stony banks and European dry heaths. Natural England has set site conservation objectives[286] for the SAC as follows:

"Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the Favourable Conservation Status of its Qualifying Features, by maintaining or restoring;

- *the extent and distribution of qualifying natural habitats and habitats*
- *the structure and function (including typical species) of qualifying natural habitats, and*
- *the supporting processes on which qualifying natural habitats rely"*

Summary of concerns relating to increased recreational pressure

3.502 The following is taken from the Summary section of the Footprint Ecology report found in Appendix 2, Impacts of recreation related to Sizewell C and implications for European sites (Liley & Saunders, 2020a). This report sets out Footprint Ecology's evidence review of the impacts of increased recreational pressure and explains our concerns regarding the likely impacts on designated sites arising from the Sizewell C proposals. Please see Appendix 2 for detailed comments.

"The area around Sizewell is of outstanding importance for nature conservation and contains a mix of habitats and species that are unique in the UK. The area is also popular for recreation, which includes tourists, day visitors, and local residents. There is a difficult balancing act to ensure access and conservation do not conflict in a relatively small area.

The Sizewell C proposal would result in changes in recreation use as it would involve a large construction workforce that would be living and working in the area. In addition, construction work would displace existing recreation use (for example through footpath diversions, noise, traffic, etc). We review the impacts of recreation on the nature conservation interest of relevant sites, focussing on the European sites (i.e. those that are subject to particularly strict protection) and their qualifying features.

We highlight a wide range of vulnerable features and risks to their conservation interest resulting from recreation use. Likely significant effects are clear for a range of sites and interest features and, in particular, we highlight:

- *Annual vegetation of drift lines (Minsmere to Walberswick Heaths & Marshes SAC), risks from damage and contamination;*
- *Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC), risks from damage and contamination;*

---

285 Minsmere to Walberswick Heaths and Marshes SAC

286 Minsmere to Walberswick Heaths and Marshes SAC Site Conservation Objectives

- *European dry heaths (Minsmere to Walberswick Heaths & Marshes SAC), risks from fire and contamination;*
- *Wintering waterbirds, including White-fronted Goose (Minsmere to Walberswick SPA), risks from disturbance;*
- *Breeding birds, including Nightjar, Avocet, and Little Tern (Minsmere to Walberswick SPA), risks from disturbance;*
- *Breeding Nightjar (Minsmere to Walberswick SPA), risks from fire, and;*
- *Breeding Woodlark and Nightjar (Sandlings SPA), risks from disturbance and fire.*

People coming to the area to live and work in the vicinity will seek nearby greenspace for recreational use that is not necessarily related or connected to the area's conservation interest, and such use will include exercise and dog walking. It may extend to sea angling, barbeques, swimming, and beach recreation. Such use is likely to be away from areas perceived as 'nature reserves' (i.e. where there are hides, wardens, and a fee to enter) and instead focus their use at more peripheral locations. These are often still part of the European site and do not have necessary infrastructure to manage access. We would expect construction workers based in the area to utilise more informal parking and locations where they can easily access beaches, quiet areas of heath, etc. Use by construction workers is also likely to take place in the early mornings, evenings, and around shift work and therefore not necessarily fit with peak visitor use and the current visitor profile.

We provide an overview of the mitigation that is likely to be necessary, highlighting that a package of measures will be required, and this will need to include monitoring to help pick up emerging issues."

Summary of concerns relating to the assessment of recreational pressure

3.503 The following is taken from the Summary section of the Footprint Ecology report found in Appendix 2, Review of Sizewell C application documents and evidence in relation to recreation impacts (Liley & Saunders, 2020b). This report sets out Footprint Ecology's review of the Applicant's assessment of increased recreational pressure arising from the Sizewell C proposals and explains our concerns regarding the adequacy of the assessment and the mitigation and monitoring proposed thus far. Please see Appendix 2 for detailed comments.

"Footprint Ecology have been commissioned by the National Trust and RSPB to provide a review of evidence (submitted as part of the Sizewell C application) on recreation issues. The construction of the power station will require a peak workforce of 7,900 construction workers, leading to a marked increase in the number of residents in the area. In addition, construction will result in the closure of access routes and the displacement of visitors due to path closures, noise, additional traffic, etc. Marked changes in local access are therefore likely. The Sizewell C site is directly adjacent to multiple European sites where there are existing rights of access and numerous species and habitats vulnerable to recreation impacts.

Recreation impacts include disturbance, trampling, increased fire risk, and contamination (e.g. spread of invasive species, dog fouling, etc). Some of the key sensitive areas are already carefully managed, with resources in place to both manage access and allow visitors to experience the area while minimising harm. Areas such as the main car park at Minsmere draw visitors from across the country and are well-known visitor destinations, drawing visitors for the wildlife spectacle and nature interest. Here there are well marked paths, hides, screens, wardens and careful management to allow wildlife to flourish and people to be able to experience it.

Concern with respect to the Sizewell C proposals and recreation impacts therefore relates to vulnerable features within the more peripheral areas of the European sites, where public footpaths, informal parking, and open access provide opportunities for recreational use, and where any issues arising from access are much harder to manage. Access to these locations is more likely to be for dog walking, jogging, picnics, barbeques, fishing, etc. (rather than to see wildlife).

Our review highlights that:

The baseline for current visitor use is inadequate. Count data (visitor numbers) are only provided for a small number of locations (surveyed in 2014) and just for August and November. Many of the smaller, more vulnerable, locations (from an ecological perspective) have not been surveyed.

Predictions of increased use are confusingly presented, with different estimates given in different reports alongside some clear errors. Estimates appear very low compared to national data and are much lower than we would expect, based on our experience of visitor surveys and recreational use of the countryside.

Impacts are poorly assessed, and the consideration of impacts for the following are particularly poor and inadequate:

- *Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC);*
- *European Dry Heaths (Minsmere to Walberswick Heaths & Marshes SAC);*
- *Little Tern (Minsmere-Walberswick SPA);*
- *Nightjar (Minsmere-Walberswick SPA);*
- *Hen Harrier (Minsmere-Walberswick SPA);*
- *Wintering waterbirds (Shoveler, Gadwall, White-fronted Goose) (Minsmere-Walberswick SPA);*
- *Breeding waterbirds (Shoveler, Gadwall, Teal) (Minsmere-Walberswick SPA), and;*
- *Woodlark (Sandlings SPA).*

Mitigation measures are scant and fail to address the nature conservation issues that are likely to arise.

Ultimately the Suffolk Coast is of unique importance for nature conservation and supports a diversity of habitats and species that is unparalleled in the UK, particularly in the area between Slaughden and Southwold. The area also draws high numbers of visitors, resulting in a difficult balancing act to manage both access and nature conservation; it is a crowded area.

Sizewell C would disrupt the balance and the application documents do not provide the robust assessment and mitigation package that we expected. The assessment of impacts is inadequate, and predictions of changes in visitor use are full of inaccuracies, confusing, and poorly put together. Necessary mitigation, targeted to the vulnerable locations, is virtually non-existent. Ultimately, the information as presented in the Shadow HRA does not allow a conclusion of no adverse effect on integrity, from recreation impacts, to be drawn for a range of different species and habitats across multiple European sites."

3.504 This document also sets out suggested points that should be clarified by the Applicant. These can be found in section 5 of the report and are listed below:

"1. There are errors in the calculations of visitor estimates and discrepancies between the different reports. These need to be explained and clear analysis of the recreation impact issues

and necessary mitigation presented. Without this information it is not possible to rule out adverse effects on integrity.

2. There is a lack of detail on assessment of ecological impacts. For example Little Tern, Hen Harrier, and trampling of shingle seem to be poorly addressed. For some of the coastal features there is little indication of how mobile species of dynamic habitats can be protected from disturbance. We would have expected to see much more detailed mapping of visitor flows and numbers (both current and predicted), providing heat maps of footfall. These maps would then be overlaid with ecological data and checked with site managers/local organisations287.

3. Further information is required concerning the coast path diversion. How often will the diversion of visitors to Eastbridge be in place? How will parking issues be addressed in Eastbridge and how will the diverted path cope with increased use, given that it is prone to waterlogging in the winter?

4. There is a lack of mitigation to resolve recreation impacts at the following locations[288]:

- *Eastbridge area (including path to coast);*
- *Periphery of Minsmere Reserve, particularly between Eastbridge and Westleton;*
- *Dunwich Heath;*
- *Beach at Dunwich, including vegetated shingle below the cliffs and marshes to north;*
- *Dunwich Forest;*
- *Walberswick Marshes;*
- *Beach area at Minsmere and south towards Sizewell;*
- *Beach area between Thorpeness and Aldeburgh (vegetated shingle);*
- *North Warren, and;*
- *Aldringham Walks.*

5. As part of a robust mitigation package we would expect to see provision for an increased wardening presence, public education and awareness raising (including a focus on dog fouling and dogs running off-lead), protocols to resolve fire risks, etc. These seem to be alluded to in the Planning Statement but nowhere else.

6. There is no comprehensive monitoring programme to address visitor numbers and use. This needs to be drawn up and integrated into mitigation delivery."

3.505 We request that the Applicant submits further information to the Examination to address these points.

Comments on implications of the Changes to the Application on recreational pressure

3.506 The two reports referenced above were commissioned before the proposals for Changes to the Application were made. The below comments therefore explain how the changes to the proposals affect our concerns around recreational pressure.

---

287 We understand some checks were made early on in the assessment with relevant organisations, but the expertise of site managers in checking model predictions and pin-pointing where there are concerns with recreation impacts and how they should be addressed has been missed entirely.

288 See Figures 001 and 002 of Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 4 Appendix 5.10E Recreational Disturbance Assessment (APP-148)

Estimated additional visits to Minsmere and Dunwich Heath

3.507 Paragraphs 8.3.5–10 of the Shadow HRA Report Addendum[289] discusses the uplift in visitor numbers at key locations obtained when those participants in the visitor surveys who stated they would be displaced but not where they would be displaced to are attributed to the main preferred alternative sites. A significant uplift in visits to Eastbridge (from an increase of 20.1% to 31.8%) and Minsmere Outer (from an increase of 50.3% to 79.3%) is described, however, despite reference to Dunwich Heath no figures are provided for this site. It is stated that the two sites of relevance to the HRA are Eastbridge and Minsmere Outer but given that Dunwich Heath forms part of the Minsmere-Walberswick SPA those figures should also be provided here. We have also not been able to find these figures elsewhere in the updated documents. Also, despite the assertions that mitigation for breeding heathland birds has already been proposed, at this stage details of the mitigation and monitoring (of the effectiveness of that mitigation and to check potential effects are as predicted) plan are not available, hence we cannot agree with the conclusions that no impacts are likely. The significance of the uplift at the sites quoted (and assumed at Dunwich Heath in the absence of figures) increases our concern and increases the need for robust mitigation, including additional wardening.

Changes affecting beach users

3.508 The Changes to the Application include moving the marine tunnelling works outside the cut-off wall and the added construction of the new temporary BLF[290]. Vol. 1 ES Addendum Ch. 2 Main Development Site[291] section 2.10 acknowledges additional adverse effects on noise and views experienced by beach users as a result of these changes but argues that they are of limited significance as impacts are already *major adverse*. However, we are concerned that the potential for additional displacement particularly affecting the beach frontage of the Minsmere-Walberswick designated sites is not assessed.

3.509 Paragraph 2.2.67 of Vol. 1 ES Addendum Ch. 2 Main Development Site also explains that the Suffolk Coast Path would be redirected up and down the shoreline as necessary to facilitate construction of the enhanced permanent BLF. We consider that the potential for increased impacts on vegetated shingle of the Minsmere-Walberswick SAC should therefore also be assessed.

In-combination assessment

3.510 Vol. 3 Ch. 10 Inter-relationships, Project-wide, Cumulative and Transboundary Effects Appendix C (AS-201)[292], provides an assessment of cumulative terrestrial ecology and ornithology effects with the onshore cable route construction of the Scottish Power Renewables (SPR) offshore wind projects. This notes the potential for in-combination effects of direct land take and disturbance from the SPR projects along with recreational pressure and noise and visual disturbance from Sizewell C construction. It concludes (regarding the area of direct effect) that as the 0.7km SPA block "only" supports approximately 3% of the SPA breeding nightjar population and approximately 9% of the SPA breeding woodlark population that, with the mitigation proposed by both developers, effects would not be significant. This assessment does not consider the potential for displacement due to the construction of Sizewell C to increase/change the predicted impacts of the SPR projects and we therefore consider that this assessment requires updating.

292 Vol. 3 Ch. 10 Inter-relationships, Project-wide, Cumulative and Transboundary Effects Appendix C (AS-201)

Conclusions regarding impacts of recreational pressure on protected sites and species

3.511 In conclusion, based on the above concerns and the evidence provided at this stage, we do not agree that adverse *effects on integrity* can be ruled out for the following sites and features for impacts from the project alone:

- Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC);
- European Dry Heaths (Minsmere to Walberswick Heaths & Marshes SAC);
- Little Tern (Minsmere-Walberswick SPA);
- Nightjar (Minsmere-Walberswick SPA);
- Hen Harrier (Minsmere-Walberswick SPA);
- Wintering waterbirds (Shoveler, Gadwall, White-fronted Goose) (Minsmere-Walberswick SPA);
- Breeding waterbirds (Shoveler, Gadwall, Teal) (Minsmere-Walberswick SPA);
- Woodlark (Sandlings SPA), and;
- Nightjar (Sandlings SPA).

3.512 In relation to this Application in combination with other projects, we do not agree that *adverse effects on integrity* can be ruled out for the following sites and features:

- Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC);
- European Dry Heaths (Minsmere to Walberswick Heaths & Marshes SAC);
- Little Tern (Minsmere-Walberswick SPA);
- Nightjar (Minsmere-Walberswick SPA);
- Hen Harrier (Minsmere-Walberswick SPA);
- Wintering waterbirds (Shoveler, Gadwall, White-fronted Goose) (Minsmere-Walberswick SPA);
- Breeding waterbirds (Shoveler, Gadwall, Teal) (Minsmere-Walberswick SPA);
- Woodlark (Sandlings SPA), and;
- Nightjar (Sandlings SPA).

Mitigation and monitoring

3.513 One of our key concerns described above and in the detailed reports by Footprint Ecology is the lack of detail around the proposals for mitigation and monitoring of impacts. The Application documents variously refer to monitoring and mitigation of recreational pressure on designated sites through the Rights of Way and Access Strategy[293] and through a monitoring and mitigation plan. However, no detailed monitoring or mitigation proposals have been presented for the Minsmere-Walberswick designated sites or the Sandlings SPA and therefore, as discussed above, we cannot agree that this is a sufficient basis on which to rule out *adverse effects on integrity*.

3.514 We note that there has been some progress with mitigation for the effects of the worker campus with a proposed contribution to the Suffolk Councils' Recreation Avoidance and Mitigation Strategy contained within Schedule 11 of the most recent iteration of the Draft Section 106 Agreement[294]. As discussed further in Appendix 2, we consider that a robust and detailed plan for monitoring and mitigation of recreational impacts on designated sites from recreational displacement must also be developed along with provision of suitable alternative natural green

[293] Volume 2 Main Development Site Chapter 15 Amenity and Recreation Appendices Appendix 15I Rights of Way and Access Strategy (APP-270)

[294] Draft s106 Agreement (REP1-007)

space for additional residents during the construction period. We consider that such provisions should be secured through requirements in the DCO**.**

3.515 We welcome the continued engagement of the Applicant with us and others in discussions on this topic. We understand that the Applicant intends to submit mitigation and monitoring plans for the relevant protected sites at a forthcoming deadline. We look forward to the opportunity to update our position on the impacts of recreational pressure on protected sites and species following submission and review of these plans.

Marine ecology - sites and species of concern

3.516 Our concerns primarily relate to potential impacts on

- **non-breeding red-throated diver, foraging common and little terns (during the breeding season) of the Outer Thames Estuary SPA,**
- **breeding little terns of the Minsmere-Walberswick SPA and**
- **breeding Sandwich terns of the Alde-Ore Estuary SPA[295].**

3.517 Natural England has set site conservation objectives[296] for all three of the SPAs as follows:

> *"Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;*
>
> - *The extent and distribution of the habitats of the qualifying features,*
> - *The structure and function of the habitats of the qualifying features,*
> - *The supporting processes on which the habitats of the qualifying features rely,*
> - *The population of each of the qualifying features, and,*
> - *The distribution of the qualifying features within the site."*

3.518 The population of little terns at **the Minsmere-Walberswick SPA[297]** at the time of designation in 1991 was 32 breeding pairs. Since then Natural England's **Supplementary Advice on Conservation Objectives[298]** for the SPA notes that there has been a significant decline with a five year mean peak count of 1.6 breeding pairs from 2014 to 2018. It is notable that the little tern population of the SPA varies significantly year on year with 10 pairs noted at RSPB Minsmere in 2019 but no breeding at RPSB Minsmere prior to that since 2009 (R. Harvey[299], pers. comm.). The Supplementary Advice on Conservation Objectives note that this may be because the little tern population of Norfolk and Suffolk behave as a metapopulation with birds moving between sites year on year. However, given the general decline in numbers at the Minsmere-Walberswick SPA, a restoration target has been set for this species to over 32 breeding pairs.

3.519 The little tern population of the Minsmere-Walberswick SPA also form part of the designated population of the **Outer Thames Estuary SPA[300]**. This SPA was reclassified in 2017 following changes to the designated site boundary and to add breeding common and little terns to its qualifying features, as this marine SPA provides foraging habitat for these species. The population

299 RSPB Minsmere Site Manager

300 Outer Thames Estuary SPA

of little terns at the time the SPA was reclassified in 2017 was 746 breeding individuals which are derived from colonies at Great Yarmouth North Denes, Minsmere-Walberswick, Benacre to Easton Bavents, Alde-Ore Estuary, Foulness and Thanet Coast and Sandwich Bay SPAs. The common tern population of the SPA at the time of reclassification was 532 breeding individuals made up of birds from around the south-east of England. The target for both of these species at this SPA has been set as "maintain" the population as insufficient time has elapsed since reclassification to establish trends, however it should be noted that the targets include a need to avoid deterioration from current levels.

3.520 The Outer Thames Estuary SPA is also designated for its non-breeding red-throated diver population. The SPA was originally classified in 2010 on the basis that it supported an internationally important population of 6,466 individual wintering red-throated divers. Subsequent aerial surveys of the site have revealed that it currently supports significantly higher numbers of red-throated divers - the current SPA population is estimated at 18,079 overwintering individuals (peak mean 2012/3 – 2017/18) (Irwin *et al.*, 2019)[301]. Importantly, the Supplementary Advice on Conservation Objectives[302] for this feature set a target to:

> *"Reduce the frequency, duration and / or intensity of disturbance affecting roosting, foraging, feeding, moulting and/or loafing birds so that they are not significantly disturbed"*

3.521 The Supplementary Advice on Conservation Objectives note the vulnerability of red-throated diver to disturbance by boats and the strong stress response exhibited by birds in response to such disturbance from marine activity and construction. The population target for this feature is to maintain the population at over 18,079 individuals, again noting the need to avoid deterioration from current levels.

3.522 The Sandwich tern population of **the Alde-Ore Estuary SPA[303]** appears to have undergone significant decline since the site's designation. The Supplementary Advice on Conservation Objectives[304] for this site note that nesting has been sporadic with a maximum of 15 pairs recorded in 2003. Although a numeric population target has not been set for this species, the target is to restore the population. We acknowledge that the lack of recent breeding data for Sandwich terns at the Alde-Ore Estuary SPA makes it difficult to assess potential impacts of the Application on this species, however, as above with the little tern population, there is a need to ensure that the development does not compromise the ability to restore this population.

3.523 We are also concerned that impacts on the Minsmere-Walberswick Ramsar site[305] require further investigation. The Minsmere-Walberswick Ramsar site was designated in 1976 under Ramsar criterion 1 for containing a mosaic of marine, freshwater and marshland with a rare transition in grazing marsh ditch plants from brackish to fresh water and under criterion 2 for supporting nationally scarce plants, British Red Data Book invertebrates and nationally important numbers of breeding and wintering birds (bittern, gadwall, shoveler, teal, marsh harrier, avocet and bearded tit).

305 Minsmere-Walberswick Ramsar, Minsmere-Walberswick Ramsar Information Sheet

Indirect impacts on birds from fish mortality arising from the cooling water system

Introduction

3.524 Our concerns around the intake of marine organisms via the cooling water system and the subsequent discharge of dead and moribund biota (fish and other organisms) via the Fish Recovery and Return (**FRR**) system relate to the potential effects on bird predator species arising from reduced prey availability and the effects of changes to water quality as a result of the discharged material.

3.525 We understand that water will be abstracted during the operational phase via two cooling water intakes situated around 3km offshore. The cooling water intakes are proposed to be fitted with Low Velocity Side Entry (**LVSE**) heads with the aim of reducing the abstraction of marine organisms, however, some marine organisms will be impinged on the drum screens protecting the intake heads, while other smaller organisms will be entrained into the power station cooling water system. Larger organisms impinged on the drum screens would be removed and discharged via the FRR system, and while some organisms may survive, others would suffer high mortality rates due to pressure or mechanical stress. Those organisms entrained into the cooling water system would be exposed to thermal uplift, increased pressure, hydrazine and chlorination and are likely to experience high levels of mortality.

Impingement and entrainment

3.526 We are concerned about the potential impacts of impingement and entrainment on important prey species for birds from the SPA populations. Ecologically important species present in the Greater Sizewell Bay include sprat, herring, anchovy, whiting, seabass, Dover sole, gobies and dab. Paragraph 8.10.63 of the Shadow HRA Report[306] also notes that the diet of non-breeding red-throated diver in the North Sea includes clupeids (herring and sprat), gadoids (including whiting and cod), gobies, sandeels and smelt.

Thresholds for assessing the effects of impingement and entrainment

3.527 Paragraphs 8.3.78 – 8.3.86 of the Shadow HRA Report[307] explain the approach to the assessment of significance of the effects of impingement and entrainment on bird prey populations. This is based on the use of a percentage of the Spawning Stock Biomass (**SSB**) of each fish species as an indicative threshold for significance, with 1% of the SSB used for commercially exploited stocks and conservation species (including stocks that are currently unexploited) and 10% of the SSB used for other unexploited stocks. The scale of the SSB for most species will be large – paragraph 8.3.84 quotes the examples of cod, whiting, herring and sprat, which are all based on the North Sea or a still larger area. It is acknowledged that local effects on fish populations may occur, for example entrainment and impingement would be likely to affect prey populations within the Greater Sizewell Bay[308], and that these could have significant impacts on the SPA birds, particularly during the breeding season when birds are central place foragers tied to foraging within a certain radius of their nest site. Such local impacts however, may not be detected through the use of thresholds based on the SSB and we therefore do not agree that these are suitable for use in the HRA to assess the significance of changes to prey availability for birds from SPA populations.

306 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

307 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

308 See Figure 1 on p16 of ES Vol. 2 Ch. 20 Coastal Geomorphology and Hydrodynamics Appendix 20A Coastal Geomorphology and Hydrodynamics: Synthesis for Environmental Impact Assessment (APP-312)

3.528 We therefore welcome the updated assessment provided in section 8 of Report TR406[309] which includes consideration of fish depletion at the scale of Greater Sizewell Bay. This explains that:

> *"Local scale depletion due to Sizewell C and Sizewell B acting in-combination is predicted to be less than 2.5% for demersal species[310], 1.5% for pelagic species[311] and less than 1% of epibenthic species[312] during periods of seasonal presence… assuming 10% daily replenishment of fish from the wider area… Even at exchange rates as low as 5% per day local depletion of pelagic species is expected to be in the order of 3% with the abundance of epibenthic species reduce by less than 2% and demersal species by less than 5% with both stations operating."*

3.529 It is then stated that, as these levels are smaller than the interannual variability in the populations of these species, the effects will be insignificant. We disagree with this statement as low levels of fish availability (even within the bounds of natural variability) are known to affect the breeding success of tern populations. We also request that an assessment is provided of how the predicted local scale depletions are likely to affect fish populations in Greater Sizewell Bay over the time scale of the operation of the power plant, as the current assessment does not appear to consider the year on year (cumulative) nature of such impacts. This constant removal of fish year every year could lead to increasing failures of e.g. tern breeding colonies and compromise the ability to meet SPA conservation objectives to restore or maintain such populations.

Use of Equivalent Adult Values (EAVs)

3.530 The projected losses from entrainment for the Application are set out in Tables 22.105 (unadjusted for survival and Equivalent Adult Values – EAV) and 22.106 (adjusted for equivalent spawning females or EAVs) of ES Ch. 22 Marine Ecology and Fisheries[313]. The unadjusted values for Sizewell B are also presented in Table 22.104 and from this it can be seen that the Application is predicted to entrain roughly 2½ times as many individuals of each species as Sizewell B. Although we understand that entrained fish are usually at the egg, larvae and juvenile stage and that many of these would not survive to adulthood even if they were not entrained, we do have some concerns around the use of EAVs in the assessment of impacts on predatory birds.

3.531 Paragraph 22.8.503 explains the approach of calculating EAVs for eggs, larvae and juvenile fish entrained, based on the likely proportion surviving to adulthood, for the purposes of assessing commercial impact. However, it is likely that juveniles of some species are taken by predatory birds, particularly as e.g. little terns are known to feed smaller prey to young chicks (Bogliani *et al.*, 1994[314], Paiva *et al.*, 2006[315]) and hence EAVs could underestimate ecological impacts. We therefore recommend that the unadjusted values for juvenile fish are considered within the assessment of indirect impacts on birds. We also support the Environment Agency's concerns[316] that EAVs do not account for the spawning potential of fish and hence under-estimate mortality, and therefore support the need for consideration of Spawner Production Foregone (**SPF**) figures in this assessment.

316 p15 of the Environment Agency's Relevant Representation (RR-0373)

Impingement and fish nursery grounds

3.532 Tables 22.111 and 22.112 of ES Ch. 22 Marine Ecology and Fisheries[317] show the predictions of impingement mortality for Sizewell C without mitigation and with mitigation (**LVSE and FRR**) respectively. These show that the species with the highest predicted levels of impingement are those that are known to be ecologically important, including sprat, herring, whiting, seabass, sand goby, sole, dab and anchovy[318]. These species are important prey species for SPA bird populations, with sprat, herring and whiting in particular noted in the diet of red-throated diver. Paragraph 22.4.60 also notes that of these, sprat, herring, whiting and seabass have nursery grounds within the Greater Sizewell Bay and that Dover sole has both spawning and nursery grounds in this area.

3.533 Section 8 of Report TR406[319] (p101) also acknowledges the potential for localised effects if fish depletion affects nursery grounds, although it is concluded that nursery grounds for the species found in Greater Sizewell Bay are widely distributed and hence of low importance. We are however concerned that impingement affecting these nursery grounds could affect local prey availability for predatory birds, particularly those with restricted foraging ranges, such as little tern.

Impingement of eels

3.534 We note that Tables 22.111 and 22.112 of ES Ch. 22 Marine Ecology and Fisheries[320] also indicate that eels are likely to be impinged by the Application. This assessment is expanded in the updated information in section 6.6.2 of Report TR406[321] and impacts on the European eel stock are concluded to be negligible. However, we note that in the absence of mitigation (or if mitigation proved ineffective), combined impingement and entrainment mortality exceeds 1% SSB[322] for European eel. Therefore, given that eels form an important food source for bittern of the Minsmere-Walberswick SPA, impacts on local stocks should be assessed in the Shadow HRA.

Assessment of entrainment of sand gobies323

3.535 Paragraph 22.8.516 of ES Ch. 22 Marine Ecology and Fisheries[324] states that:

> *"the estimated number of sand gobies that would be entrained by Sizewell C represents approximately 1.4% of the abundance".*

3.536 As sand gobies are not a commercially exploited species, a threshold of 10% of the SSB is applied to indicate significant effects and it is therefore concluded that this level of effect will not be significant. However, using the criteria for recommended thresholds set out in paragraph 8.3.78 of the Shadow HRA Report[325], a threshold of 1% should be applied where a species is of ecological importance (defined within ES Ch. 22 Marine Ecology and Fisheries as being common and/or abundant enough to play a key trophic role within the ecosystem[326]). We argue that as sand goby are an ecologically important species (as they are prey species to red-throated diver, little tern and common tern of the Outer Thames Estuary SPA, little tern of the Minsmere-Walberswick SPA

326 Or a key role in the food chain

and Sandwich terns of the Alde-Ore Estuary SPA), the 1% threshold should be applied and this impact considered potentially significant.

Entrainment and climate change

3.537 Paragraphs 22.6.242 – 22.6.247 explain that mortality due to temperature shock for the egg and larval life stages of many fish species increases rapidly once maximum temperatures exceed 30°C. Climate change will result in an increasing number of days per year where entrainment temperatures (ambient +11.6°C) exceed 30°C; 57 days per year by 2030 and 100 days per year by 2055. It is acknowledged that this would lead to higher entrainment mortality rates and we are concerned that this could affect species of ecological importance and potentially combine with other climate pressures to negatively affect SPA seabirds (which has not been considered).

Total mortality from impingement and entrainment

3.538 Sprat and herring are ecologically important species likely to be present in the diet of red-throated diver, little tern and common tern of the Outer Thames Estuary SPA, little tern of the Minsmere-Walberswick SPA and Sandwich terns of the Alde-Ore Estuary SPA and are the species predicted to be most affected by impingement and entrainment from the Application. Paragraph 8.3.97 of the Shadow HRA Report[327] states that:

> *"for sprat the combined estimated annual mortality for entrainment and impingement at Sizewell C (with the low velocity side entry and FRR[328] in place) was 2,249,905 equivalent adult values"*
>
> while:
>
> *"for herring the estimated combined annual mortality was 724,095 equivalent adult values".*

3.539 The paragraph goes on to conclude that each of these impacts are lower than the 1% threshold of the relevant SSBs. This appears to be a significant level of fish mortality and again we raise our concerns that assessing this at the level of SSBs may miss local impacts on Greater Sizewell Bay which will be more relevant to the assessments of impacts on bird predators required for the purposes of HRA. We also note our concerns with the use of EAVs[329] which may lead to underestimation of ecological effects, as discussed above.

3.540 Based on section 6.7 of Report TR406[330] we note that in the absence of mitigation (or if mitigation proved ineffective), combined impingement and entrainment mortality exceeds 1% SSB for sea bass, European eel, thin-lipped grey mullet and sand goby. As discussed below, we are concerned that the mitigation proposed does not accord with industry best practice (Turnpenny *et al.* 2010)[331] and therefore are concerned that impacts on these species could be significant (also noting our concerns about the use of 1% SSB as a threshold for significance).

3.541 The Shadow HRA goes on to report conclusions for the indirect impacts of impingement and entrainment on predator species including red-throated diver (8.10.63-65), little tern (8.10.9) and common tern (8.10.44-45) of the Outer Thames Estuary SPA, little tern of the Minsmere-Walberswick SPA (8.8.348-350) and Sandwich terns of the Alde-Ore Estuary SPA (8.3.99-100). Conclusions that the mortality of each fish species equates to less than 1% of the SSB (or less than

10% for sand goby – see our comments above) are used to justify a conclusion of no *adverse effects on the integrity* of those SPAs from this impact. We are concerned that these discussions do not consider total prey availability losses or local effects within Greater Sizewell Bay, especially when considered together and the potential cumulative effects of losses year on year.

3.542 Section 8 of Report TR406 updates this assessment through consideration of the effects of local scale depletions in fish populations and the effects on foraging birds of the Minsmere-Walberswick, Outer Thames Estuary and Alde-Ore Estuary SPAs. This acknowledges that the restricted foraging range of little terns makes them particularly vulnerable to the effects of prey depletion. However, we note that we consider this concern relevant to all the SPA tern populations. It explains that little tern numbers at the Minsmere-Walberswick SPA have declined since designation but should recognise the requirement to avoid impacts that could compromise the restoration of this population. The assessment compares the level of local prey depletion with the biomass required to sustain the designated population of little terns. This assessment is inadequate as it does not recognise the impacts of prey depletion on foraging efficiency and success rates. We are concerned that such impacts could reduce their breeding success/productivity as was seen when the construction of Scroby Sands offshore wind farm reduced prey availability for a colony of little terns, as reported in Perrow *et al.* (2011)[332].

Discharge of dead and moribund biota

3.543 Paragraphs 7.4.25- 44 of the Shadow HRA Report[333] explain that the discharge of dead and moribund biota from the FRR system during operation will contribute to biochemical oxygen demand (BOD) and increase nutrient inputs and levels of un-ionised ammonia in the water column. Whilst these impacts would be expected to be fairly local to the outfalls within the Greater Sizewell Bay we are concerned that changes to water quality could combine with other operational impacts on Greater Sizewell Bay, such as the thermal and chemical plumes, to affect prey distribution for SPA bird populations. In paragraph 22.10.29 of ES Ch. 22 Marine Ecology and Fisheries[334], the Applicant states that the discharged material may attract scavenging seabirds in a similar manner to fisheries discards and hence may have beneficial effects on bird populations. It should be noted that red-throated diver (Outer Thames Estuary SPA) and little tern (Outer Thames Estuary SPA and Minsmere-Walberswick SPA) do not forage on discards and hence will not benefit in this way.

3.544 We also note that likely levels of contaminants from the cooling water system in dead and moribund fish are not discussed and the potential for any impacts on gull species which may take dead fish should be considered.

Mitigation

3.545 We are concerned that the design of the cooling water system does not include an Acoustic Fish Deterrent (AFD) or other repulsive technology and therefore that the overall design does not comply with best practice (Turnpenny *et al.* 2010)[335]. Inclusion of an AFD would reduce the potential impacts on fish populations in Greater Sizewell Bay, including species for which nursery or spawning grounds are present and species that are important prey resources for bird features of all the SPAs. Use of an AFD would also have beneficial effects on water quality through reducing the amount of dead and moribund biota discharged to Greater Sizewell Bay. We note that section

2.3 of Report TR406[336] states that AFD are too complex to install and maintain in an offshore environment and may not have sufficient longevity. Whilst we defer to the expertise of others (particularly the Environment Agency) regarding this, we request that evidence and case studies around the use of AFDs are presented in order to consider this more fully. We also recommend that figures comparing levels of predicted impingement and entrainment with and without AFD are provided in order to assess its potential efficacy and inform the consideration of their inclusion within the mitigation proposals.

Direct and indirect impacts on birds from the thermal plume

Introduction

3.546 Our concerns around the thermal plume (the warm water discharged from the cooling water system to the sea) during the operational period relate to the potential for indirect impacts on prey species important to bird populations of the Outer Thames Estuary SPA, Minsmere-Walberswick SPA and the Alde-Ore Estuary SPA and the potential for direct effects through displacement of birds loafing or foraging on the water surface. The effects of the thermal plume are assessed on the basis of the uplift in temperature compared to the baseline and the absolute sea surface temperature, with further investigation recommended if uplift exceeds +2°C over the baseline or for absolute temperatures the 98th percentile[337] of less than or equal to 28°C (paragraph 7.4.12 of the Shadow HRA Report[338]).

Increase in absolute sea temperature

3.547 Paragraph 22.6.301 of ES Ch. 22 Marine Ecology and Fisheries[339] explains that:

> *"During the operation of both stations, absolute temperatures of 23°C increase from 89.6ha at the surface… to a worst case of 506.2ha at the surface and 264.4ha at the seabed in 2055."*

3.548 Whilst it goes on to note that if Sizewell B is decommissioned as expected that this extent will reduce significantly after 2055, the increase up to this point is significant and could be of ecological concern. Paragraph 22.8.660 explains that where the thermal plume results in absolute temperatures of less than 27 °C, there are no clear deleterious impacts on species, but in the longer term, that changes in species composition may occur.

3.549 We query whether any such long-term community changes could have effects on predators, e.g. terns foraging in coastal waters in the breeding season. Table 22.123 also indicates the preferred temperatures and upper lethal temperatures for various cold-water fish species, several of which are of importance as prey for SPA bird species. This indicates that temperatures of over 23°C will exceed the preferred temperature for adults of key species such as herring, smelt, dab, whiting and cod and may even exceed the lethal temperature for some species. This could have the effect of displacing these species from the areas affected by the thermal plumes, and the potential effects on prey availability and distribution could result in the short term, in unsuccessful breeding/poor productivity, and in the longer term, displacement of SPA bird species.

337 Meaning that, based on a frequency distribution of temperature observations, 98% of observations are less than or equal to 28°C

338 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

339 ES Vol. 2 Main Development Site Ch. 22 Marine Ecology and Fisheries (AS-035)

Uplift in sea temperature compared to baseline

3.550 Paragraph 8.8.287 of the Shadow HRA Report[340] states that:

> *"Based on the 98th percentile, the 2°C and 3°C thermal plumes for the combined effects of Sizewell B and Sizewell C encompass 61.5% and 41.3% of the foraging range of the Minsmere colony, respectively (Plate 8.12). This compares with overlaps of 48.9% (for the 2°C uplift) and 34.0% (for the 3°C uplift) for the existing thermal plumes that result from Sizewell B. For the Dingle colony foraging range, the equivalent percentage overlaps are 31.9% and 3.3% for the 2°C and 3°C uplifts, respectively, for the combined effects of Sizewell B and Sizewell C, and 11.7% and 0.1% for the 2°C and 3°C uplifts, respectively, for the existing thermal plumes resulting from Sizewell B."*

3.551 This indicates a significant overlap between the foraging area of little terns from the Minsmere-Walberswick SPA (and foraging within the Outer Thames Estuary SPA) and both the +2°C and +3°C thermal plumes and that the extent of the plume increases significantly compared to the baseline with Sizewell B only in operation. It is later stated that little terns currently forage within the Sizewell B +2°C thermal plume, but we note that it is not known whether they will continue to forage in the area encompassed by the +3°C plume. Paragraphs 8.8.292 and 8.10.4 conclude that no *adverse effects on the integrity* of the little terns of the Minsmere-Walberswick SPA or the Outer Thames Estuary SPA exists on the basis that +2°C is an overly precautionary threshold and that the overlap of their foraging range with the +3°C plume is relatively small. On this basis and because common terns from Minsmere and Orfordness only make up a small part of the Outer Thames Estuary SPA population of this species, a conclusion of no *adverse effects on the integrity* is also reached for the common tern feature of the Outer Thames Estuary SPA.

3.552 Regarding red-throated divers of the Outer Thames Estuary SPA, paragraph 8.3.15 states that the overlap of the maximum extent of the predicted 2°C thermal plume at the sea surface for Sizewell C encompasses 4.3% of the area of the Outer Thames Estuary SPA. It is also stated that this part of the SPA holds a relatively small proportion of the red-throated diver population and hence impacts would not be as significant as indicated.

3.553 However, we disagree with this assertion on the basis of the Red-throated Diver Reports for 2012-2013 and 2013-2014 in the Annexes to ES Ch. 14 Appendix 14A7 Part 2[341] indicate the importance of the Greater Sizewell Bay for red-throated diver, with the peak number of red-throated divers recorded across the whole survey area (approximately 2km offshore from Dunwich to Orfordness) during the winter of 2012/13 equating to 19% of the SPA population. These surveys are likely to have underestimated abundance as they were carried out from vantage points (discussed further below) but give an indication of the importance of the area. Mason (Ed.) (2015)[342] also states that red-throated diver densities off the coast of Suffolk are significantly higher north of Orfordness than south of this point. Given that red-throated divers both loaf and forage from the sea surface (rather than diving direct from the air), we are concerned that the thermal plume could result in direct displacement effects on this species in this part of the Outer Thames Estuary SPA (designated for this species originally) and consider that further assessment of the potential for these effects should be provided.

3.554 We also consider that the potential for impacts of the thermal plume to combine with other operational impacts on Greater Sizewell Bay, such as the chemical plumes and other changes to

water quality (the cumulative effects), to cause displacement of SPA bird species as a result of direct effects or through effects on prey distribution have not been fully considered.

Direct and indirect impacts on birds from the chemical plumes

Introduction

3.555 The cooling water system will be dosed with chlorine during operation to prevent biofouling and hence maintain the safe operation of the power station. Chlorination is applied seasonally when water temperatures exceed 10°C and occasionally when needed outside this period. As noted by paragraph 22.3.94 of ES Ch. 22 Marine Ecology and Fisheries[343], due to climate change, the period when chlorination is required is expected to lengthen as water temperatures increase (from 219 days per annum in 2030 to 244 days per annum in 2085). This cooling water will be discharged via the cooling water outfall and will contain measurable Total Residual Oxidants (**TRO**) and bromoform (a chlorination by-product) when dosing has been applied.

3.556 Hydrazine will also be added to the cooling water during commissioning (during construction) and on a daily basis (although not continuously) during operation to prevent corrosion. We are concerned that the chemical plumes resulting from the discharge of TROs, bromoform and hydrazine have the potential to affect prey species of birds from the Minsmere-Walberswick, Outer Thames Estuary and Alde-Ore Estuary SPAs and may also have direct displacement or toxic effects on birds.

Effects of the TRO and bromoform plumes on birds and their prey

3.557 Paragraph 22.6.310 of ES Ch. 22 Marine Ecology and Fisheries[344] explains that the Sizewell C TRO plume concentration is expected to exceed the Environmental Quality Standard (EQS) of 10µg/l as a 95th percentile over a sea surface area of 338ha and a seabed area of 2.1ha. For bromoform, the Predicted No-Effect Concentration[345] (**PNEC**) of 5µg/l is exceeded by the Application plume over an area of 52ha at the surface and 0.67ha at the seabed. Both plumes are aligned along the shore and tidally transported north and south of the outfalls. They are distinct from the Sizewell B plumes, which are closer to shore due to the location of the outfalls.

3.558 Our concerns largely relate to potential impacts on fish as prey for bird species of the Outer Thames Estuary, Minsmere-Walberswick and Alde-Ore Estuary SPAs and the potential for fish to be locally displaced from areas affected by the plumes through avoidance behaviour. This potential is acknowledged for both TROs and bromoform in paragraphs 22.8.759 and 22.8.783 respectively of ES Ch. 22 Marine Ecology and Fisheries, although the Shadow HRA Report concludes that impacts of changed prey distribution are not significant due to the limited overlap of the plumes with foraging areas of red-throated diver and common tern of the Outer Thames Estuary SPA and Sandwich terns of the Alde-Ore Estuary SPA and no overlap with foraging areas of little tern of the Outer Thames Estuary and Minsmere-Walberswick SPAs. Whilst we accept that such effects are likely to be localised, we are concerned that effects of these plumes could work in-combination with other potential impacts on prey distribution, for example, from the thermal plume.

3.559 We query the potential for the TRO and bromoform plumes to have direct toxic effects on birds, particularly species such as red-throated diver which loaf and forage from the sea surface and note that no evidence has been provided regarding this. Whilst we understand that chlorination

[343] ES Vol. 2 Main Development Site Ch. 22 Marine Ecology and Fisheries (AS-035)

[344] ES Vol. 2 Main Development Site Ch. 22 Marine Ecology and Fisheries (AS-035)

[345] The PNEC can be defined as the concentration of a chemical which marks the limit at which below no adverse effects of exposure in an ecosystem are measured and can be calculated for acute (short term) or chronic (long term) exposure

will be applied seasonally and that red-throated diver are a non-breeding feature of the Outer Thames Estuary SPA, given the number of days per annum that chlorination is likely to required, some overlap would be expected (with red-throated diver typically being present in the area from October to April, although occasionally are seen in other months). Given that potential impact pathways exist, this impact should be considered within the HRA.

3.560 We also query the potential for these plumes to elicit avoidance behaviour from birds and whether the fact that the plumes from Sizewell C will be further offshore than those of Sizewell B could mean that red-throated divers are more likely to be affected adding to our view that this should be considered within the HRA.

Effects of the hydrazine plume on birds and their prey

3.561 Hydrazine will be discharged via the Construction Drainage Outfall (**CDO**) during the commissioning phase of construction as part of cold flush testing. This phase is likely to last several years and will result in a hydrazine plume with a mean sea surface area exceeding the chronic Predicted No-Effect Concentration PNEC of 30.5ha. The Shadow HRA Report[346] acknowledges that this has the potential to affect prey availability for SPA qualifying features (paragraph 8.8.279) and concludes that the peak instantaneous plume overlaps with 3.7% of the foraging range of little terns from the Minsmere-Walberswick SPA. No *adverse effects on integrity* is concluded on the basis of the small overlap and the short duration of the plume at 0.5 – 4.5 hours. For common tern of the Outer Thames Estuary SPA an overlap of 0.1% of the foraging range with the peak instantaneous plume above the acute PNEC is noted and again no *adverse effects on integrity* is concluded. A similar conclusion is reached for red-throated diver of the Outer Thames Estuary SPA, noting the small proportion of the SPA likely to be affected.

3.562 As the discharge of hydrazine during the commissioning phase of construction will be via the CDO, the hydrazine plume will form relatively close to the shoreline. Paragraph 22.8.367 acknowledges the potential for this plume to act as a barrier to migrating eels entering the Minsmere-Walberswick SPA via the Minsmere Sluice[347]. As eels form an important part of the diet of bittern (an SPA qualifying feature) this is of concern. Whilst we acknowledge that concentrations at the Sluice are expected to be well below levels at which toxic effects are expected, it is not clear whether the likelihood of impacts has been assessed under all potential tidal/weather scenarios.

3.563 We also note that paragraph 21.6.72 of ES Ch. 21 Marine Water Quality and Sediments[348] indicates that there is the potential for hydrazine to enter the Minsmere-Walberswick designated sites via Minsmere Sluice on ebb tides. It is explained that this potential is expected to be very low and that concentrations would be orders of magnitude below the PNEC.

3.564 However, given the sensitivity and high conservation value of areas that could be affected, further consideration should be given to possible scenarios under which even low levels of hydrazine could enter the system and any potential ecological effects. The Sluice contains a tide flap to the Leiston Main Drain which has a delay mechanism to allow tidal water to enter the Minsmere South Levels and maintain a brackish element to keep the Ramsar designated transition from brackish to freshwater within the ditches. The RSPB also open the Sluice to allow water northwards from the sea to maintain the brackish elements of the Minsmere Scrape. If hydrazine were to enter via the Sluice, the areas affected would therefore be Leiston Main Drain, the eastern section of Minsmere South Levels (including the brackish pool in the north east section regularly used by waterfowl, including gadwall and shoveler of the Minsmere-Walberswick SPA) and Minsmere Scrape, which is used by a variety of breeding, passage and wintering wildfowl,

---

346 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

347 See Fig. 21.3 of ES Volume 2 Main Development Site Chapter 21 Marine Water Quality and Sediments Figures (APP-316)

348 ES Vol. 2 Main Development Site Ch. 21 Marine Water Quality and Sediments (AS-034)

waders, terns and gulls, again including birds of the Minsmere-Walberswick SPA, such as breeding avocet and little tern.

3.565 It appears that hydrazine is more persistent in soft, neutral/acidic water and it is our understanding that the spring water uprisings on the South Levels are soft and acidic meaning that the longevity of any toxic effects should be considered. We therefore consider that further detail of the potential effects of low-level hydrazine exposure to the relevant designated SPA and Ramsar features is required.

3.566 We note that paragraph 7.7.61 of the Shadow HRA Report[349] explains that hydrazine will be treated before release during the commissioning phase but that the treatment option had not at this stage been finalised. We request that this information is provided so that predictions regarding impacts can be confirmed.

3.567 During operation, the cooling system will be dosed with hydrazine on a daily basis for the lifetime of the development and a plume will form from the discharge point at the cooling water outfall. Two dosing strategies are considered, both of which result in the same annual load - 69ng/l for 2.32h a day and 34.5ng/l for 4.63h a day. The area of sea surface that exceeds the chronic PNEC is 158ha for the 69ng/l release and 157ha for the 34ng/l release, while sea surface exceedance for the acute PNEC is 17.4ha and 13.8ha for the 34.5ng/l and 69ng/l strategies respectively. For common tern of the Outer Thames Estuary SPA, the chronic PNEC overlaps with 3.2% of the mean foraging range of the birds nesting at Minsmere and the acute PNEC overlaps with 0.4% of this colony's mean foraging range. As this colony only forms part of the SPA population, no *adverse effects on integrity* is concluded.

3.568 For Sandwich terns of the Alde-Ore Estuary SPA, the chronic PNEC overlaps with 0.08% of the mean foraging range and the acute PNEC overlaps with less than 0.01% of the mean foraging range. For red-throated diver of the Outer Thames Estuary SPA 0.04% of the SPA is affected by the chronic PNEC concentrations and less than 0.01% for the acute PNEC values and no *adverse effects on integrity* is concluded.

3.569 Again, our concerns primarily relate to the combination of pressures on these species during the operational phase, including any potential impacts of hydrazine on prey within these species' foraging areas. However, we also query the potential for the hydrazine plume to have direct toxic effects on birds (during both commissioning and operation) and note that no evidence has been provided regarding this. Given that potential impact pathways exist, this impact should be considered within the assessment.

Direct and indirect impacts on birds from the sediment plumes

Introduction

3.570 Dredging will be required primarily during the construction phase for the construction of marine infrastructure (the Beach landing Facility (**BLF**), Construction Drainage Outfall (**CDO**), Fish Recovery and Return (**FRR**) and cooling water intakes and outfalls) and the maintenance of access to the BLF, but BLF maintenance dredges will also be required during operation. This will lead to increases in suspended sediment concentration (**SSC**) and in some cases the formation of a sediment plume. Our concerns relate to the potential for increased turbidity due to increased SSC to lead to avoidance behaviour by fish, particularly the prey species of SPA bird features and to lead to direct impacts on birds through avoidance behaviour by them or reduced hunting success (due to potential effects of increased turbidity on the ability of birds to forage successfully).

[349] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

Sources of increased SSC during construction and operation

3.571 Paragraph 22.6.66 of ES Ch. 22 Marine Ecology and Fisheries[350] explains the purpose, frequency and effects of capital and maintenance dredging required for the BLF:

> *"Navigational dredging for the BLF would include an initial capital dredge followed by maintenance dredging to maintain the navigable channel... Following the capital dredge, a plume with an instantaneous suspended sediment concentration (SSC) of >100mg/l above daily maximum background levels is expected to form inshore over an area of up to 108ha at the sea surface and 83ha as a depth averaged plume. A small area of up to 7ha would experience an instantaneous SSC plume of >1,000 mg/l above background levels…*
>
> *Assessments assume maintenance dredging of approximately 10% of the initial capital volume to occur at approximately monthly intervals during the campaign period when the BLF is in most frequent use... Maintenance dredging is predicted to result in up to 28ha of sea surface expected to experience >100mg/l, and 1ha expected to experience >1,000 mg/l above background SSC on each occasion…"*

3.572 Paragraph 7.3.10 of the Shadow HRA Report[351] explains that the plume resulting from the capital dredge is expected to form near to the shore and extend in a north-south direction and that it would be expected to disperse within four days. A relatively large area would be affected, as described above, although the plume is of short duration. Paragraph 7.7.56 of the Shadow HRA explains that:

> *"The average mean suspended particulate matter value at Sizewell from April to August is 31 mg/l (an average monthly maximum 80 mg/l) and during September to March is 73 mg/l (an average monthly maximum 180 mg/l)."*

3.573 The modelling of the impacts of dredging described above therefore indicates that significant uplifts from baseline SSC levels are expected, and whilst impacts from each individual dredge may be of short duration, the regularity of maintenance dredging during the construction (and operation) period and the additional dredging for construction of other marine infrastructure means that the potential for impacts on prey availability and accessibility for bird features of the Outer Thames Estuary and Minsmere-Walberswick SPAs must be considered.

3.574 Vol. 1 ES Addendum Ch. 2 Main Development Site[352] explains the proposals in the Change Application to enhance the permanent BLF and add a temporary BLF during the construction phase. Table 2.48 summarises the changes to dredging for the construction of the enhanced permanent BLF. This explains that the initial capital dredge volume and area are within the envelope of the original Application and therefore as no changes were required despite the permanent BLF being enhanced there was no further assessment needed. However, maintenance dredging is anticipated to increase in frequency but dredge volumes and thus suspended sediment concentrations would reduce. We query the level of increase in frequency and any potential for this to impact breeding birds in particular.

3.575 Table 2.52 explains that during operation:

> *"The advancement of the [enhanced permanent] BLF by 16m in comparison to the ES means more of the longshore bar will need to be removed. This is not necessary during the construction phase due to the installation of the grillage. The dredge volume estimate would*

---

350 ES Vol. 2 Main Development Site Ch. 22 Marine Ecology and Fisheries (AS-035)
351 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
352 Vol. 1 ES Addendum Chapter 2 Main Development Site (AS-181)

be double the volume assessed in the Application…, therefore additional assessments are required."

3.576 Paragraph 2.17.105 goes on to explain that:

"A near doubling in dredge volume is anticipated based on the current bathymetry. This would result in instantaneous SSC plumes of 100mg/l above background over an area of several hundred hectares (compared to 83ha in the Application). In close proximity to the dredge area, SSC may exceed 1,000mg/l above ambient during dredging activities over tens of hectares (compared to 6ha in the Application)."

3.577 We note that paragraph 2.17.15 of Vol. 1 ES Addendum Ch. 2 Main Development Site explains that:

"the temporary BLF would cross the outer longshore sand bar. As such, there are no requirements for dredging and vessels could berth alongside with sufficient under keel clearance."

3.578 Dredging will also be required for the installation of the intakes and outfalls for the cooling water system. Paragraph 22.6.149 of ES Ch. 22 Marine Ecology and Fisheries states that for cooling water system dredging and dredge disposal:

"Plumes with instantaneous SSC of >100mg/l above background levels are expected to form over an area of up to 373ha (depth averaged, and 291ha at the sea surface). A smaller area of up to 14ha is expected to experience a depth averaged instantaneous SSC of >1,000mg/l above background levels (34ha at the sea surface)…"

3.579 The plume is expected to form parallel to the coast but not directly adjacent to it. Dredging for the installation of the cooling water infrastructure would be required six times and would not overlap (but could be consecutive), but SSC levels are expected to recover to background levels within two days each time.

3.580 Paragraph 22.6.163 of ES Ch. 22 Marine Ecology and Fisheries describes the dredging required for the FRR headworks and states that:

"Plumes with instantaneous SSC of >100mg/l above daily maximum background levels are expected to form over instantaneous areas of up to 89ha at the surface. A small area of 1ha is expected to experience an instantaneous SSC of >1,000mg/l above background at the sea surface".

3.581 A similar plume is expected to form during dredging for construction of the CDO. Again, the plumes would be expected to form parallel to the coast but would be closer to shore than those expected to arise from dredging for the cooling water system. Although impacts from dredging of the FRR headworks and CDO are of short duration (several days) and would only occur twice separated by around a year, as with the other dredges discussed, it will be necessary to consider whether these works could overlap with other marine impacts affecting prey species and therefore foraging birds.

3.582 Paragraph 22.6.176 of ES Ch. 22 Marine Ecology and Fisheries explains that the dredges required for BLF maintenance, installation of cooling water infrastructure and installation of the southern FRR headworks during the construction phase are likely to coincide. The plumes for the BLF maintenance dredge and the cooling water infrastructure are expected to remain as separate plumes, therefore affecting a greater area of the Greater Sizewell Bay at any one time. However, the plumes for BLF maintenance and the FRR dredge interact and increase the maximum

instantaneous area of sea surface exceeding 100mg/l to 111ha, although the duration of the plumes is reduced due to the temporal overlap. We also query whether there is any potential for further overlaps in dredging activities should construction timelines change due to poor weather or other delays. Impacts of any such scenarios should also be considered.

Impacts of increased SSC on birds

3.583 The potential impacts of the construction phase dredges on birds in terms of potential displacement of fish prey and the effects of increased turbidity on the ability of birds to forage successfully are not discussed in any detail. The Shadow HRA Report does discuss the overlap of the various dredge plumes with the foraging ranges of SPA species but should also consider the ecological consequences of this.

3.584 For breeding little tern of the Minsmere-Walberswick SPA, the extent of overlap of the foraging ranges of the Minsmere and Dingle little tern colonies is compared with the instantaneous SSC plume of over 100mg/l. Table 8.16 in the Shadow HRA Report[353] indicates that for the Minsmere little tern colony, the largest overlaps are 6% from dredging of the BLF navigational channel at spring tide, 3% for BLF dredging at neap tide, 2% for dredging for FRR1 at neap tide and 1% for dredging for FRR1 on a spring tide.

3.585 For the Dingle little tern colony, the largest overlaps are 4% for dredging for FRR1 on a spring tide, 2% for FRR1 on neap tides, 3% for dredging the BLF navigational channel on spring tides, 1% for BLF dredging on neap tides. The foraging range referred to in this table should be clarified – it is not stated whether this uses the mean or mean-maximum foraging range, and this would affect the areas quoted.

3.586 The potential for plumes to combine is also not illustrated in this table and, based on the points above, we would expect the total overlap for the combination of e.g. FRR and BLF dredging to be higher than indicated here.

3.587 The Shadow HRA Report concludes that no adverse effects on integrity on the Minsmere-Walberswick SPA will arise during construction on the basis that there is a relatively small overlap of the plumes and the little tern foraging range and the temporary/short term nature of the plumes and a similar conclusion is drawn for little tern of the Outer Thames Estuary SPA. However, we consider that the effects of combined and repeated SSC plumes have not been fully considered cumulatively or the potential ecological impacts on birds adequately explored.

3.588 For red-throated diver of the Outer Thames Estuary SPA, the Shadow HRA Report provides a limited assessment of potential impacts. Paragraphs 8.10.47-48 simply state that as the entirety of the SPA is available to foraging birds and the SSC plumes are relatively small and short-lived, no adverse effects on the SPA non-breeding red-throated diver population are predicted. Despite SSC plumes occurring within the SPA itself, no assessment has been undertaken of the potential effects on red-throated diver including birds being displaced and the ecological consequence of such displacement. Whilst we acknowledge that any displacement may be to elsewhere in the SPA, this still represents a loss in availability of part of the protected site.

3.589 In addition, even though each individual SCC plume may be relatively small and short lived, the effects of combined and repeated SSC plumes on red-throated divers have also not been fully considered nor any potential effects cumulatively with other potential effects such as loss of prey, thermal and chemical plumes (as discussed above).

---

[353] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

3.590 As discussed above within the UK SPAs and SACs have tightly drawn boundaries, with no buffer zones and with everything included within that boundary being justified *ecologically*. Therefore, the potential for loss of availability of part of a protected site within the season for which it is designated, must be considered taking account of the protected sites' conservation objectives (as listed above) particularly

- The extent and distribution of the habitats of the qualifying features,…and,
- The distribution of the qualifying features within the site."

3.591 The potential impacts on birds arising from dredging for the enhanced permanent BLF during operation are given limited consideration in paragraph 2.17.131 of Vol. 1 ES Addendum Ch. 2 Main Development Site[354]:

> *"Fish may exhibit limited movements away from the areas of highest SSC, remaining in proximity to the plume and utilising the area once the plume dissipates. Localised and temporary displacement of sensitive taxa may occur. No significant changes in the availability of fish as prey items for designated features and as fisheries resources are predicted."*

3.592 While we acknowledge the sporadic nature of this impact, given the potential for this activity to coincide with key periods of the breeding bird season, we do not consider that it is possible to rule out all potential effects on the basis of the information presented. Exact figures for the area of the plumes are not presented and we request that these are provided and compared to the foraging ranges of SPA species to give an indication of potential impact.

Indirect impacts on birds from disturbance of prey species by underwater noise and vibration

Introduction

3.593 Paragraphs 8.8.311-312 of the Shadow HRA Report[355] explains that fish have varying levels of vulnerability to the effects of underwater noise and vibration, with potential effects including direct mortality, recoverable injury, Temporary Threshold Shifts (TTS) (temporary hearing impairment) or behavioural responses. Fish whose swim bladder is involved in their hearing are considered most vulnerable to negative effects of underwater noise and these include some of the main prey species for SPA bird species.

3.594 Underwater noise and vibration could therefore lead to reduced prey availability for birds if disturbance is significant enough to lead to mortality or displacement of their fish prey. Sources of noise and vibration include impact piling during the construction of the BLFs, dredging and drilling for construction of cooling water intakes and outfalls.

Impacts of noise disturbance on fish prey of little terns

3.595 A significant area of the foraging range of little terns from the Minsmere-Walberswick and Outer Thames Estuary SPAs (Minsmere colony) is expected to coincide with the area over which a fish 'behavioural response' (including displacement) is predicted. Table 8.17 in the Shadow HRA Report[356] shows that the overlaps are up to 46.5% of the colony's foraging range for the worst-case hammer energy scenario for piling of the BLF, with 29.1% of the range affected by the likely hammer energy scenario.

355 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
356 Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)

3.596 Dredging for BLF construction would affect 37.1% of the colony foraging range and if this coincides with dredging for the south cooling water intake this would affect 43.3% of their range. However, the Shadow HRA Addendum[357] describes the changes to predicted impacts as a result of construction of the enhanced permanent and temporary BLFs. Although the total number of piles has increased dramatically (from 12 to 148), this document makes a commitment to the avoidance of piling (and other BLF construction) activity during the bird breeding season, May to August. This would resolve concerns about noise disturbance from piling affecting foraging terns from the Minsmere-Walberswick and Outer Thames Estuary SPAs but requires all relevant details to be secured by way of a condition to ensure that this mitigation can be relied on and to justify conclusions.

Impacts of noise disturbance on fish prey of red-throated divers

3.597 Given that the Applicant has committed to avoid piling activity associated with construction of the BLFs during the bird breeding season, impacts on red-throated diver of the Outer Thames Estuary SPA during the non-breeding season must be considered. The Shadow HRA Report Addendum[358] states in paragraph 8.8.26 that:

> *"…Taking a worst-case in terms of underwater noise effects (i.e. as represented by the installation of the mooring dolphins and based on sprat, as a hearing specialist), the range of behavioural effect for the enhanced BLF (with mitigation) is predicted to cover an area of 1,206ha, representing 0.31% of the total SPA area. For the temporary BLF, the area is predicted to be 1,769ha, representing 0.45% of the total SPA area"*

3.598 It is concluded that no *adverse effects on integrity* will arise from indirect effects on the prey of red-throated diver due to the relatively short duration of the works, and because the area affected is limited to the north-west corner of the SPA where the Applicant asserts that diver concentrations are lower than the southern part of the SPA. As discussed above, we disagree with the assertion that this part of the SPA is of lower importance and we also note that the construction is expected to take place over two winters. We therefore consider that potential effects of displacement should be taken into account particularly when combined with other impacts on this species, for example, direct disturbance from vessel traffic.

Other potential noise/vibration effects on fish

3.599 We note that paragraph 2.7.2 of the Shadow HRA Report[359] indicates that tunnels would be created to around 3km offshore as part of the cooling water infrastructure. This tunnelling would take place around 30m below the seabed. Given the duration of the works (24 hour working for 15 months) we query whether any noise or vibration effects would be apparent within the water column which could affect fish distribution as this does not appear to be assessed within the Shadow HRA.

Direct disturbance of birds arising from vessel movements and other marine activity

Introduction

3.600 The revised proposals include the construction of permanent and temporary BLFs (described in 2b) ii) of Vol. 1 ES Addendum Ch. 2 Main Development Site[360]) to enable the delivery of Abnormal Indivisible Loads (AILs) and bulk aggregates during the construction period, with the permanent

[357] Shadow HRA Addendum (AS-173)
[358] Shadow HRA Addendum (AS-173)
[359] Shadow HRA Report Volume 1: Screening and Appropriate Assessment Part 1 of 5 (APP-145)
[360] Vol. 1 ES Addendum Chapter 2 Main Development Site (AS-181)

BLF also in occasional use during the operational period. In brief summary, we understand that the permanent BLF would be around 100m long, would operate in daylight only and be capable of receiving up to 100 beach landings per annual campaign (approximately 1 April to 31 October), which equates to 12-13 per month. Deliveries to the permanent BLF will be accompanied by two barges. The temporary BLF would be operational during the construction period only and located to the south of the permanent BLF and would be around 505m long, will operate both day and night and would be capable of receiving up to 400 deliveries per campaign, equating to 44 per month, or up to 600 per annum as this facility could additionally operate in the winter months. No additional vessels are required for deliveries to the temporary BLF.

3.601 Given the number of vessel movements expected, primarily during the construction period, our main concerns relate to direct disturbance of non-breeding red-throated divers. In addition, due to the presence of the two BLFs, and the length of the temporary BLF in particular, we are concerned about the potential for direct disturbance of these species from noise, lighting and visual disturbance from both the BLFs.

Potential disturbance impacts on non-breeding red-throated divers

3.602 As noted above, the proposals now include the potential to use the temporary BLF outside the campaign period of April to October (inclusive). This means that vessel disturbance may affect non-breeding red-throated divers of the Outer Thames Estuary SPA, likely to be present in Greater Sizewell Bay from around September to April. As discussed above, around 200 deliveries (400 movements) would be expected in each winter period (November to March inclusive), which gives an average of 2.7 movements per day.

Night-time vessel movements

3.603 The temporary BLF has the capacity to operate during the night as well as the day. Night-time use will require lighting of the temporary BLF and conveyor and we assume that this would be difficult to screen. This along with the noise associated with the operation of the enhanced BLF should be considered for potential impacts on loafing/roosting red-throated diver. Observations of red-throated diver from Thorpeness (Thurlow, 2009)[361] indicate that this species can have large roost movements in the early morning and suggest that the birds move from roosting to feeding areas in relation to tide. These indicate a need to understand the diurnal movements of red-throated diver given the need to assess impacts at night as well as daytime. Likewise, the indication that vessel movements will be influenced by tides and weather introduces a need to understand the impacts of tide and weather on the red-throated diver population to be able to adequately assess impacts.

Vessel movement corridor

3.604 Paragraph 8.8.16 of the Shadow HRA Addendum explains the assumptions made about vessels travelling through the SPA during the construction period. For the purposes of the assessment it has been assumed that vessels will originate from the Inner Thames meaning that they will pass through around 92km of the Outer Thames Estuary SPA to reach the BLFs at Sizewell. The vessel corridor will be approximately between two nautical miles and six nautical miles offshore, with the majority of vessels travelling through the SPA from the south and with those docking at the temporary BLF making their final approach from the north of Sizewell Bank.

3.605 Paragraphs 8.8.13-20 of the Shadow HRA Addendum go on to summarise the potential effects of the increase in vessel traffic associated with both BLFs. This assessment calculates the hours of vessel activity per km^2 of the SPA per month and concludes that the BLFs will only add 0.1 hours

[361] Thurlow, D. (2009) Wintering Red-throated Divers, Thorpeness, Suffolk 2000/01 – 2008/09. Suffolk Birds 2008.

of activity per km^2 per month. This appears to be averaged across the whole SPA area, while the figures quoted in paragraph 8.8.18 for comparison with existing levels of activity relate to specific vessel corridors, hence this assessment by comparison underestimates the impacts. It would be more helpful to calculate this uplift for the transit corridor within the SPA – at 92km long and 4km wide this would experience an uplift of nearly 1 hour per km^2 per month. This enables a more robust comparison with the statements about levels of movements in other specific corridors/areas within the SPA. Existing levels of use are stated to be between 1.5 and 10 hours per km^2 per month, with the busiest areas being within shipping lanes and around windfarms. The addition of a further 1 hour per km^2 per month would therefore represent an increase of 10% even in the busiest areas and an increase of 67% for the quieter areas. We therefore consider that the additional vessel activity due to the construction of Sizewell C is likely to significantly increase disturbance within the Outer Thames Estuary SPA.

3.606 We also note that we would expect to see greater certainty around the details of the proposals at this stage and request that more detail is provided regarding the vessel route. We would expect that such a route would attempt to minimise impacts on the SPA through use of existing shipping channels were possible, the grouping of vessel movements and route choice to minimise the time vessels spend in the SPA. These details should be provided in a vessel management plan.

Sensitivity of red-throated divers to vessel movements

3.607 In assessing the impacts of the additional activity described above the Shadow HRA Addendum states that any disturbance is likely to be short lived and temporary with birds likely to return after the vessel has passed. We disagree with those assumptions as red-throated divers are known to be particularly sensitive to disturbance, including that from vessel movements. Mendel *et al.* (2019)[362] assessed the effects of offshore windfarms and shipping on the distribution and density of diver species (predominantly red-throated diver) in the German North Sea. They found significant reductions in abundance of divers around windfarms and around shipping areas and noted that one in three divers are likely to leave an area as a ship approaches, resulting in a significant reduction in diver densities within 5km of vessel activity. It is also notable that no habituation to the presence of windfarms was observed after 3 years. Schwemmer *et al.* (2011)[363] also reported high avoidance of shipping lanes by red-throated divers, noting that habituation to vessel disturbance is unlikely to occur and categorised the flush distance of red-throated divers in response to vessels as "very high". Irwin *et al.* (2019)[364] also noted strong avoidance of shipping lanes by red-throated diver in their aerial surveys of the Outer Thames Estuary SPA.

Further assessment needed

3.608 Paragraph 8.8.20 of the Shadow HRA Addendum suggests that the increase in vessel traffic arising from the enhanced permanent BLF and the addition of the temporary BLF will not give rise to *adverse effect on integrity* of the Outer Thames Estuary SPA. Little evidence is presented to justify this conclusion. We consider that assessment of the effects of displacement arising from vessel movements on red-throated divers from the Outer Thames SPA should be carried out following the standard methodologies used for offshore windfarm and cable route assessments and more

---

362 Mendel, B., Schwemmer, P., Peschko, V., Müller, S., Schwemmer, H., Mercker, M. & Garthe, S. (2019) Operational offshore wind farms and associated ship traffic cause profound changes in distribution patterns of Loons (Gavia spp.), Journal of Environmental Management. 231: 429-438.

363 Schwemmer, P., Mendel, B., Sonntag, N., Dierschke, V., & Garthe, S. (2011) Effects of ship traffic on seabirds in offshore waters: implications for marine conservation and spatial planning. Ecological Applications 21:1851–1860.

364 Irwin, C., Scott, M., S., Humphries, G. & Webb, A. (2019) HiDef report to Natural England - Digital video aerial surveys of red-throated diver in the Outer Thames Estuary Special Protection Area 2018. Natural England Commissioned Reports, Number 260.

detailed consideration of potential mortality (through increased mortality elsewhere in the SPA) is needed. We suggest the following approach to the assessment:

1. Application of 5km buffer around the BLFs and vessel routes (based on recent evidence, including Mendel *et al.*, 2019).

2. Assessment of scale of possible displacement. Present a matrix showing a range of displacement percentages (0% to 100%) and resulting percent mortality (0% to 100%), then review relevant offshore wind farm cases (e.g. Kentish Flats – Percival 2010[365], and Horns Rev – Petersen *et al.*, 2006[366], London Array – APEM, 2021[367]) to indicate what might be the most realistic percentage displacement. The mortality consequences are unknown and so it will be necessary to consider the full range of possibilities. Having determined the sensitivity of divers to different levels of displacement and additional mortality, the next step will be to determine the need for population modelling.

3. Potential implications for the Outer Thames Estuary SPA population may require population modelling using a density independent model[368]. There is no evidence for density dependence operating on wintering red-throated divers and no suitable measures of density dependence are available to apply, so the outcome of an assessment using a density dependent model could be meaningless. Therefore, a density independent approach is arguably more appropriate, and would be precautionary.

3.609 Points 2 and 3 relate to mortality impacts arising through displacement. However, the maintenance of diver abundance is not the sole Conservation Objective of concern for this species within the Outer Thames Estuary SPA with regard to the HRA. The Conservation Objectives to maintain diver distribution and to maintain the extent of supporting habitat are also likely to be compromised as divers will redistribute within, and outside, the SPA due to the disturbance from shipping. This redistribution compromises the ability of the supporting habitat within the SPA to continue to support the same numbers and distribution of birds as before (Natural England, 2020[369]). As such, these should also be included in the consideration of whether *adverse effects on integrity* can be ruled out.

Population data for assessment

3.610 With respect to the local population numbers of red-throated divers, as these birds move around based on food supply, during some periods in some years a substantial number of divers may be present in the area and potentially displaced. We therefore advise that a reasonable worst-case scenario should be based on such local maxima. However, it should be noted that the data

368 Density dependence refers to processes which act on a population as it grows to regulate its growth rate. Density dependence may include factors such as competition between individual birds for resources and disease which become more prevalent with a larger population. However, whilst density dependence is known in many bird populations, species and site-specific evidence about the strength of such factors is often lacking, meaning that for the purposes of population modelling the most precautionary approach is usually to use a density independent model (unless evidence about the type and strength of density dependent factors acting on a particular population is available).

369 Natural England (2020) Appendix A12 to the Natural England's Deadline 4 Submission NE advice on Red-Throated Divers in the Outer Thames Estuary Special Protected Area related to Deadline 3 submissions for East Anglia ONE North Offshore Windfarm.

provided in Annexes to ES Ch. 14 Appendix 14A7 Part 2[370] are based on vantage point surveys based along the coastline.

3.611 We do not consider that vantage point surveys alone provide a robust methodology as data are required up to 3km (preferably 4km) to seaward of the shipping channel. Viewpoints on a low coast are very unlikely to reliably accomplish this and may be less likely to record birds on the water than those in flight. A correction factor will also be required to account for the number of birds likely to have been diving at any time. Therefore, while the survey data do indicate the importance of Greater Sizewell Bay for red-throated divers, the resulting population figures may be underestimates.

3.612 These surveys also only cover the Greater Sizewell Bay area whereas the whole vessel route through the SPA requires consideration. Aerial surveys in 2013 have shown red-throated diver densities in the SPA have increased and indicate that previous surveys may have underestimated numbers (Irwin *et al.,* 2019[371]). The species is known to be sensitive to flushing by boats (Schwemmer *et al.*, 2011[372], Jarrett *et al.*, 2018[373]) and recent surveys have been conducted using aircraft, originally with observers on board to count birds in strip or line transects and most recently recording high resolution digital imagery using either still photography or video footage. We recommend that these data should be used to inform the assessment of the relative usage of this area by divers and the propensity for this species to be disturbed by boats needs to be taken into account in the impact assessment.

Conclusion

3.613 In conclusion, we disagree with the approach to the assessment of impacts of vessel movements on red-throated divers of the Outer Thames Estuary SPA and the assumptions made about responses of divers to disturbance. We recommend that additional assessment of displacement effects is carried out. We consider that vessel disturbance impacts from Sizewell C could compromise the SPA objective to maintain the distribution of the qualifying features within the site and therefore do not support the conclusion of no *adverse effects on integrity* in the Shadow HRA Addendum.

Combined marine impacts

3.614 We are concerned that the combined effects of disturbance resulting from dredging, piling and vessel movements, the various discharges (including those of thermal discharges, bromoform, hydrazine and organic matter (dead fish and other organisms)) and increased suspended sediment concentrations and the resulting total displacement of marine birds (particularly red-throated diver of the Outer Thames Estuary SPA) have not been fully considered. We acknowledge that these issues are covered in the Shadow HRA Report Addendum Appendix 1A[374] but we consider that this does not advance understanding much beyond the assessment of the individual impacts. For example, for combined marine impacts on red-throated diver, little and

374 Shadow HRA Report Addendum Appendix 1A Further Analysis of Inter-Pathway Effects (AS-174)

common terns of the Outer Thames Estuary SPA during construction and operation, paragraph 3.6.6 of the Shadow HRA Addendum Appendix 1A states that:

> *"… marine water quality effects during construction and decommissioning and disturbance effects on species populations during operation are essentially inconsequential. Therefore, inter-pathway effects could only occur via the pathways for the marine water quality effects and interaction with project infrastructure during the operational phase. These pathways both have the potential to affect the foraging conditions and / or food availability for the qualifying features of the Outer Thames SPA. However, the effects from both pathways on each of the qualifying features are predicted to be small and consequently no adverse effect on site integrity is predicted when the respective effects are considered together."*

3.615 As we consider that the individual effects have been underestimated, particularly of disturbance by vessel traffic and impacts on prey species, we do not agree with this conclusion. No discussion of the potential for interactions is provided, for example through consideration of effect timelines and seasonality and no discussion of the consequences for fitness and survival of these populations is included. Similar conclusions are reached for common and little terns of the Minsmere-Walberswick SPA.

3.616 Known synergistic issues have also not been covered in sufficient detail. Paragraph 22.6.391 of ES Ch. 22 Marine Ecology and Fisheries[375] acknowledges that toxicity of chlorinated discharges to many marine organisms increases with temperature, meaning the potential exists for synergistic effects of the thermo-chemical plumes on fish. This increase in toxicity with temperature also applies to the hydrazine discharge. It is concluded that whilst toxicity may be enhanced, this would only affect small areas and would be insignificant in the context of natural variability. The effects are not expected to extend beyond the existing TRO EQS contour (as the largest of the chemical plumes likely to have synergistic effects with thermal uplift), although as this covers 338ha as a 95th percentile, the area affected could be relatively large. Potential ecological effects (e.g. on birds as predators) are not explained.

Monitoring

3.617 Given the potential for impacts on bird distributions arising from the combination of marine impacts, monitoring of these populations during the construction period will be required. At present, we note that no such monitoring is proposed and that monitoring of direct impacts (e.g. of discharges on water quality, of impingement and entrainment numbers) is covered through a number of separate routes. We are therefore concerned that at present, there is no mechanism to detect ecological impacts of the combined marine activities and discharges, particularly on bird features of the Minsmere-Walberswick and Outer Thames Estuary SPAs. We recommend that an appropriate monitoring package is developed to verify impact predictions and identify the potential need for mitigation.

Marine impacts in-combination with other projects

3.618 Potential exists for in-combination effects on red-throated divers of the Outer Thames Estuary SPA from the Sizewell C project and several offshore windfarms, particularly during the construction phase. For example, the cable routes for the East Anglia One North and East Anglia Two projects pass through the Outer Thames Estuary SPA, vessels associated with the projects will transit through the SPA and part of the 4km buffer (for assumed bird displacement impacts) for East Anglia One North is also within the SPA. Given that the construction of Sizewell C could coincide with construction and operation of these projects and others, in-combination

[375] ES Vol. 2 Main Development Site Ch. 22 Marine Ecology and Fisheries (AS-035)

disturbance and displacement of marine birds is likely. Table 8.30 in the Shadow HRA Report[376] concludes that no AEOI of the Outer Thames Estuary SPA will arise as impacts of these two windfarms are each predicted to be small and vessels will stay within existing shipping routes. However, we again consider there is a need to look at sum total of disturbance impacts affecting this SPA in the style of an offshore windfarm assessment of displacement. This would consider disturbance displacement from Sizewell C and all relevant windfarms together rather than the approach taken by this assessment, which only considers Sizewell C plus each windfarm individually and will significantly underestimate in-combination impacts.

3.619 We also note that the assessment of SzC in-combination with other projects in Section 4.15 Marine Ecology and Water Quality of ES Vol. 10 Ch. 4 Assessment of Cumulative Effects with Other Plans, Projects and Programmes[377] does not consider impacts on marine birds. This is a key omission, particularly with regard to in-combination impacts of vessel traffic on red-throated divers.

Conclusions regarding marine impacts

3.620 In conclusion, based on the above concerns, we do not agree that AEOI can be ruled out for the following sites and species for impacts from the project alone:

- Breeding little terns of the Minsmere-Walberswick SPA
- Non-breeding red-throated divers of the Outer Thames Estuary SPA
- Breeding Sandwich terns of the Alde-Ore Estuary SPA

3.621 In relation to this project in combination with other projects, we do not agree that AEOI can be ruled out for the following site and species:

- Non-breeding red-throated divers of the Outer Thames Estuary SPA

Bats

Introduction

3.622 Our response focusses on two bat species, primarily barbastelle and secondarily, Natterer's bat. Barbastelle are found only in southern England and Wales. Very few breeding sites are known (Sizewell estate being one) and the species is protected in the UK under the Wildlife and Countryside Act, 1981. It is also a Priority Species under the UK Post-2010 Biodiversity Framework. Within the European Union, it is a Protected Species under Annex IV of the European Habitats Directive. Internationally the rarity of barbastelle is recognised, being listed as Near Threatened on the global IUCN Red List of Threatened Species. Natterer's bats are protected in the UK under the Wildlife and Countryside Act, 1981. The species is widespread, but scarce in the UK.

3.623 Following Wray *et al* (2010)[378], the Sizewell barbastelle population on the Sizewell estate is recognised as being of national importance and the population of Natterer's bat, as of county importance.

3.624 Much of the content of this response draws on the findings and conclusions of two reports by BSG consultants, commissioned by East Suffolk Council and Suffolk Wildlife Trust. These reports have already been submitted into the examination as part of the Local Impact Report: Joint Local

Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092]. The majority of the concerns raised below are directly related to findings and concerns within these reports. Where we have made additional points of concern, we have clearly indicated this.

Summary of Concerns

3.625 The following section is a summary of our main concerns over potential impacts on bats, the full details of which can be found in the main bat section following the summary.

Hinkley C

3.626 There is repeat reference of Hinkley C as an analogous example. The footprint of Hinkley C is dominated by an intensively managed mixed farmed landscape, likely supporting low levels of bat activity, whereas the Sizewell estate includes a wetland SSSI, mixed woodland and a wider woodland/wetland complex in close proximity to RSPB Minsmere, supporting a nationally important population of barbastelle and Natterer's population of county importance. Therefore, Hinkley C does not have a comparable bat population from which to base conclusions on potential impacts or effectiveness of mitigation;

3.627 There is very little evidence of roosting within the footprint at Hinkley and therefore it would be expected to have far lower levels of activity due to the poor quality foraging habitats;

3.628 The combination of survey and monitoring at Hinkley is only robust enough to say there continued to be some use of a retained feature across the construction site (a green lane) by barbastelle during construction. The key factors such as number of bats, timing and frequency of movement and the nature of this use (such as foraging and commuting) are not commented on.

Data Adequacy and Analysis

3.629 The removal of static recorders from the footprint of the development site means there is a loss of baseline data that makes true impact impossible to determine;

3.630 There is a distinct lack of bat data within the area of Sizewell Marshes SSSI that will be lost to the development;

3.631 There is a lack of data from Goose Hill. This has led to a general risk that the importance of Goose Hill has been significantly underestimated in terms of roost provision as well as usage by pregnant females and juvenile barbastelle;

3.632 There is a lack of quantitative data, such as thermal imaging in the dataset, making it impossible to determine actual numbers. This in turns affects the quality of the data analysis. For example, it will be a lot more difficult to monitor actual changes in use that could be linked to population effects;

3.633 There is limited temporal coverage across the dataset, especially during June for the 2020 dataset. Only half of the detector locations (28) were subject to sampling. This is the month in which barbastelle activity on the EDF Estate has been highest and is clearly key in the context of the locally-breeding population;

3.634 There is not enough emphasis on rarer species within the analysis of the data. The use of a percentage metric means common species mask the actual (rather than relative) importance of a specific location for rare species;

3.635 The way in which the data have been analysed is leading towards a generic monitoring protocol that is unlikely to pick up population changes in rarer species such as barbastelle;

3.636 There are no conclusions as to what the predicted residual effects may be for barbastelle. Having concluded significant impact on barbastelle due to habitat fragmentation, there appears to be no attempt to explain what that will actually mean to the population or, how conclusions can be tested through an appropriately detailed monitoring protocol;

3.637 There can be no confidence that the habitat creation will effectively compensate habitat loss (supporting the conclusion in the ES of a minor adverse (not significant), as the data are not used to underpin a detailed evaluation of this;

3.638 Overall, the generic approach i.e. to look at the community broadly as opposed to the key species is of considerable concern. The likely consequence of this is that there is limited understanding of how Natterer's bat and barbastelle populations will respond to the construction. Any age / sex or life-stage related effects are likely to be missed.

Noise

3.639 There are very little data on the impacts of noise on bats and therefore a more precautionary in the approach to assessment should have been adopted;

3.640 Acceptable levels of noise in relation to features (such as roosts and commuting routes), have not been defined. It is unclear why the developer needs to wait to do this and what is practical and achievable;

3.641 There is no confidence that where noise exceeds thresholds (if there were any), that impacts on bats can be effectively mitigated as there are no clearly defined mitigation measures are in place;

3.642 The likely effectiveness of key mitigation approaches such as the hording or bunding at Ash Wood remains unclear and the practicalities of how monitoring will establish its effectiveness are not explored;

3.643 The threshold for licencing is not identified and no indication of how it might be derived is provided;

3.644 There is no practical framework from which an Ecological clerk of Works (ECoW) team can derive a working system that will identify exceedances and allow the implementation of controls;

3.645 In addition to concerns identified in the consultant's report we consider:

- Clarification is required to determine that noise is being properly assessed, with a focus on frequency that is ecologically relevant to bats, rather than the use of human noise modelling;

- There appear to be discrepancies between ES chapter AS-033 and the updated bat impact assessment AS-208 despite both referring to noise modelling data and results presented in the Bat Mitigation Strategy (APP-252 and APP-253). It is unclear which is correct and hence it is impossible to determine noise impacts in some key areas;

- Concerns over spatial coverage of monitoring with limited coverage in many key areas including, but not restricted to; Ash Wood, the southern end of Bridleway 19, Fiscal Policy, along Kenton Hills and areas bordering the SSSI;

Lighting

3.646 Overall, it is difficult to take an independent view on the approach to and conclusions of the assessment based on the limited information provided. The combination of the acknowledged lack of certainty in the assessment and the indication that it may not be practically possible to implement further mitigation adaptively then leads to the conclusion that ultimately effects of lighting on bats will be a secondary concern during construction;

3.647 We therefore consider the assessment should be more precautionary;

3.648 There is a failure to define acceptable thresholds of light at key features;

3.649 There is a lack of clarity over lighting of the Sizewell Marshes and light spill from the bridge to cross the SSSI;

3.650 The use of the phrase 'reasonably practicable' with regard to lighting. This and other statements suggest that health and safety will determine lighting levels during construction, and implementing adaptive mitigation for impacts on bats may be impossible in practice;

3.651 In reference to the above point, there is no indication of a practical framework from which an ECoW team can derive a working system that will identify exceedances and allow the implementation of controls.

3.652 In addition to concerns identified in the consultant's report we consider:

- The rationale for choosing the locations for modelling light levels are unclear. There are concerns over the spatial coverage of light level in the baseline survey especially around Ash Wood, at Upper Abbey Farm, Fiscal Policy, along Bridleway 19 especially the southern end near the plaza and security areas, alongside Kenton Hills especially opposite green rail offload area and areas bordering the SSSI;

Evaluation of the value of Goose Hill

3.653 We are concerned over the conclusion that there is 'minimal roosting resource for bats' within Goose Hill when the data show the total loss of 111 trees of moderate and high roost potential. We believe this conclusion may have led to a significant underestimation of the effect the loss of Goose Hill will have, especially on barbastelle. Climbed assessment is required to confirm the overall roost potential;

3.654 The foraging and commuting value of Goose Hill has not been properly mitigated.

3.655 The importance of Goose Hill for breeding females and juvenile barbastelle has not been recognised and the effect displacement will have on their foraging, given their ability to fly longer distances~~,~~ is reduced. This is the sort of issue that will drive potential changes in populations / their potential relocation.

Mitigation

3.656 We are concerned that the development has reached an advanced stage in the planning application process, with almost 15 years of data to draw on, but there are no detailed mitigation proposals or a structured monitoring plan in place. It is difficult for stakeholders to be asked to comment on these very detailed assessments without the details of the mitigation that allow the conclusions in the ES to be reached;

3.657 There is a need to overlay both noise and light contours over the mitigation areas and core bat areas that apparently are un-impacted (Ash Wood, Bridleway 19, Fiscal Policy, Kenton Hills, the SSSI triangle, the SSSI west of platform, the proposed 'dark' corridors, areas around the Lower Abbey Farm bat house and around Upper Abbey Farm);

3.658 Impacts from task specific lighting are uncertain due to statements such as, 'if safe to do so' and 'where reasonably practicable'. More certainty is required and if this cannot be given, then the proposal has to assume impacts based on the precautionary principle and hence a need for mitigation;

3.659 Concerns over limited amount of buffering of light spill in key roosting and foraging areas;

3.660 Uncertainty and lack of detail with regard the type of lighting that will be used and how this will inform mitigation;

3.661 There appears to be a limited number of bat boxes. Given the low level of effort put into searching for roosts, especially within the SSSI, it seems highly likely that the number of bat boxes needed to sustain barbastelle, has been significantly underestimated. Additionally, given the most important bat roost found on the entire estate is a dead conifer, some thought should be given to veteranisation of a variety of trees species in suitable locations.

3.662 There appears to be no commitment to monitor 'dark' corridors or the SSSI culvert during the development to determine use and hence effectiveness of the mitigation proposed.

3.663 A monitoring protocol needs to consider the ecology of the key bat populations and how they behave at different ages and stages in the breeding cycle. It needs to consider what are the actual impacts on barbastelle and Natterer's bat and how they reflect those predicted in the ES.

3.664 In addition to concerns identified in the consultant's report we consider:

- We have concerns over the functionality of the new bat house at Lower Abbey Farm as a result of it being cut off from commuting routes due to light and noise;

In-combination (Synergistic) Effects

3.665 Little has been done to understand the combined impacts of light, noise and fragmentation together;

- There is an underestimation of the importance of the landscape affected by the footprint of the Sizewell Link Road but additionally how this area may increase in importance during the development as bats are displaced from the main development site. The assessment states very low levels of use of hedgerows along the road route by barbastelle. This is not the case if the data set is reviewed in the context of the data set for the main development site. Some of the highest rates of encounter of barbastelle from static detectors have been noted along the potential route.

Data Adequacy

Spatial Coverage

3.666 There is concern about the removal of many of the static bat monitoring points during the 2020 data collection and especially MS10, MS8, MS11, MS16 and MS32. The statements explain the reasons for removal are because the sites are, *'lost under construction footprint therefore this is not an appropriate location to assess against future construction impacts'* (static monitoring report, Table 4, AS-037). These monitoring sites include the hedge line north from Kenton Hills,

the junction of Stonewall Belt and Hilltop Covert and the eastern edge of Goose Hill close to the SSSI. All of these locations appear to be areas of high barbastelle use in the past, so it would be expected these areas need to be included to determine a pre-construction baseline. Consequently, the conclusion for removal of these sites is difficult to explain or justify if the aim is to understand impacts of the development on bats. It is noteworthy that previous surveys from 2013 and 2014 (static monitoring report, Table 1, AS-037) have all recorded commuting or foraging bats at these locations and hence further data would have helped establish a robust baseline from which to determine overall use of the estate around and within the development. Without these data it will be difficult to determine how overall bat use has changed once construction starts.

3.667 The 2020 Backtracking Report (AS-037) section 2.3.6 states, *'Tree roost potential assessments were conducted on trees likely to be impacted by the works to inform the potential for impacts upon bat roosting within trees'.* However, the baseline dataset does not include any bat monitoring within the SSSI 'triangle' itself i.e. the area of the SSSI that will be lost under the SSSI crossing. Consequently, this statement is factually incorrect. This omission is likely to be significant especially in light of the comment in 2.3.7, *'Barbastelle commuting has been noted with individuals commuting north to south (in the direction of Sizewell Marshes SSSI)'.* This creates significant uncertainty that the dataset is a true reflection of the baseline in terms of commuting and foraging, risking inadequate mitigation measures related to noise and lighting spillage into the SSSI. Furthermore, given the significant tree cover in this area, it is possible there will be multiple loss of roosts that are not recorded and therefore not mitigated.

3.668 There is very limited monitoring to the west of the platform within the SSSI and to date, there appears to be no roost assessments in this area. MS29, the one monitoring station within the locality appears to be very important for rare bats and so the paucity of data from this area of SSSI, which will be lost under the footprint of the development, is a significant omission.

3.669 The 2020 data (AS-037) show clearly that barbastelle use Goose Hill and Fiscal Policy but there are no data or analysis that help with frequency of use to determine numbers, or direction of flights. Overall, there is very limited monitoring within Goose Hill and this appears to be a significant omission, given the evidence that is available, which suggests the area may be very important for barbastelle (please see the Section 1.7 for further detail).

3.670 Plot 4 in the static monitoring report (AS-037), which shows the location of the static monitoring sites, only has 25 of the 29 locations marked. A notable omission is MS06 at NE corner of Ash Wood. This location had a barbastelle maternity colony from previous work and so is an important site to have omitted.

3.671 There are no static detectors located in open ground which appears to be an omission given barbastelle are well known for commuting over open ground. This may result in an underestimation of the overall importance of the development site for barbastelle.

Temporal Coverage

3.672 Temporally there is a substantial recent data gap for barbastelle. The 2020 static survey data covered three months but with limited data from June (Table 5, AS-037), despite Table 2 (AS-037) clearly showing in previous years static monitoring work that the average barbastelle activity was the highest in this month. In the report it is stated that static detectors could not be deployed before 18 June but there is no explanation of why or any acknowledgement that this gap will invariably create more uncertainty in conclusions.

3.673 Back tracking surveys at one survey per month (Table 4, AS-037) in densely wooded habitat which is inherently difficult to survey, seems relatively low effort especially during the maternity period. Again, this will create further uncertainty in any conclusions.

3.674 The temporal coverage does not comply with good practice guidelines for survey effort (Collins, 2016)[379]. Table 8.3 recommends static detector surveys between April/May and September/October. Section 8.4.7 recommends back tracking surveys should be continued until roosts are located unless alternative methods are considered more appropriate.

Data Collection Methodology

3.675 Overall, there is a lack of complementary observational data, such as from thermal imaging cameras which would help to quantify bat use in any given area. Currently the nature of the data means there is no way of telling the numbers of different individual bats of a specific species using an area. In static surveys there are no links between the number of bat calls and actual bat numbers. For example, a high number of calls could be from a single bat, conversely a low number of calls could be from a number of bats moving through an area. Despite the limitation in the data, there is very little recognition of this fact. Overall, this calls into question the use of the data and how useful it will be to inform a baseline for a future monitoring protocol.

3.676 The Environmental Statement notes that too few individual Natterer's bats were radio tracked to enable home ranges to be identified. This is a notable omission but despite this, little attempt has been made to draw conclusions from the available evidence of radio tracked data or comment on differences between age classes.

Data Analysis

3.677 Throughout the assessment there is not enough detailed analysis on the rarer species. Data analysis has focussed on cumulative population as opposed to single species activity. The design of the static work means that it will only be possible to determine overall volume of use with little idea on actual numbers of bats to enable year-on-year comparisons. This limitation in the dataset is further weakened by the fact that the nationally important population of barbastelle and county level important population of Natterer's bat are reflected as a percentage of the bat population as a whole. This is a common error in the treatment of ecological data. The use of a percentage as a metric risks rare species being masked by more common bats. For example, where the locations of soprano pipistrelle are under 90%, this is used to say where the species rich sites are. However, this might merely be a reflection of the fact that soprano pipistrelle don't like that particular location; calls from rare species in total could still be lower. Conversely a really species rich site could have many soprano pipistrelle, rendering rare bats low as an overall percentage of the population, despite having high numbers and being more important for barbastelle and Natterer's bat. The use of percentage as a metric only weakens what is already a poor quality dataset. The lack of quantitative data means the failure to capture static detector data at 14 locations in June appears all the more significant.

3.678 In conclusion, a survey protocol designed to provide a high resolution baseline has not been achieved because: a) the specification of the data are not of high enough resolution to allow a reliable identification of changes of behaviour that could lead to a determination of population level effect; b) There has been inadequate consideration of the nationally important barbastelle population and county level important Natterer's bat population; c) too much weight and consideration has been given to more common species.

---

[379] Collins, J. (ed.) (2016) Bat Surveys for Professional Ecologists: Good Practice Guidelines (3rd edn). The Bat Conservation Trust, London.

3.679 The overall result of this is a lack of barbastelle monitoring and focus with incoherent conclusions in terms of the importance of the Sizewell estate to this species.

Future Monitoring

3.680 Overall, no conclusion is drawn on what the predicted significant residual effect of habitat fragmentation on barbastelle will mean for the population. Understanding how the population is likely to respond is key to understanding the likely outcome for the species and hence in formulating a monitoring strategy. Given the fact that no conclusions have been drawn on what the predicted significant residual effects might be is of significant concern, compounded by the fact that no monitoring strategy has been provided.

3.681 Overall, the monitoring detail is limited[380] and if the development is consented based on the current information, then there will be a great deal of pressure from construction timelines to come up with a monitoring protocol. In our view, there needs to be a condition in place on the development that a detailed Bat Monitoring Strategy is produced prior to any construction taking place, with clear objectives, as a headline of maintaining a breeding population of barbastelle. This should include protocols for monitoring, method statements, identification of triggers for light and noise impacts (for further mitigation) and evidence based examples of possible future mitigation and must be secured through the DCO. Funding for possible future mitigation must be secured through the DCO.

3.682 Future bat monitoring at Sizewell should focus on understanding the drivers for development-related population change in key species (barbastelle and Natterer's bat) and should be of high enough resolution to achieve this. It is concerning that current bat monitoring locations do not include roosting barbastelle and Natterer's bat at Goose Hill, Ash Wood or Fiscal Policy. In our view further survey work needs to be done in these areas in addition to furthering baseline work within the SSSI (see below).

3.683 Despite predicted residual significant impact on barbastelle as a result of fragmentation, there is no explicit commitment to monitor the SSSI crossing for usage, the effectiveness of the retained dark corridors along the Upper Abbey Farm bridleway or the central corridor running north from Kenton Hills. Furthermore, there is no commitment to monitor the usage of the newly formed habitat of arable reversion once construction is complete, which, it is assumed, will be used by bats for forage.

3.684 If the nature, scale and duration of a development are such that noise could cause disturbance to important bat populations, then unweighted, high-frequency noise measurements of existing ambient levels based on frequencies audible to bats (~8 kHz upwards) should be collected (Reason and Bentley, 2020)[381] at these locations. This should continue during construction to monitor the bats' response to noise.

3.685 As outlined above, it is concerning that the static survey work of 2020 was not complemented by other survey work to give an indication of bat numbers. Therefore, it is unclear how monitoring can be designed to detect changes in bat commuting and foraging resulting from the development and hence is likely to be unable to detect population level effects. Comparing generic activity levels is less relevant especially as much of the work has focussed on commoner species.

---

[380] Terrestrial Ecology Monitoring and Mitigation Plan (REP1-016)

[381] Reason, P., & Bentley, C. (June 2020) Noise Impacts on Bats – A Sound Assessment? Chartered Institute of Ecology and Environmental Management In Practice 108: 15-18

3.686 Volume 2 Main Development Site Chapter 11 Noise and Vibration (Doc Ref 6.3) 11.1.1 [App-202]) states routine monitoring will be carried out during construction in accordance with the Code of Construction Practice (CoCP) AS-273. The CoCP outlines noise monitoring for human receptors, not for bats and therefore it appears that noise monitoring will not be at ecologically relevant frequencies (8kHz and above), or at heights used for foraging. Hence we have significant concerns over adequacy of monitoring and mitigation. The noise levels in key areas of the site for bats must be monitored at 8kHz and at 10m above ground level throughout the construction phase. This is discussed in more detail in following sections.

Noise

Use of Human Noise Modelling

3.687 The following section (1.4.1) is in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092].

3.688 Bats are most responsive to frequencies above 8 kHz which is towards the end of human hearing and therefore standard human noise assessments are not appropriate for the assessment of bat impacts (8.2.33 in 6.14 vol3 Chap2 ES Addendum Terrestrial Ecology & Ornithology Appendices 2.9A-2.9D (AS-208)). Barbastelle use passive listening and calls for hunting (rather than echolocation) and could be adversely affected by 8-20 kHz noise. It is therefore difficult to justify the use of human focussed modelling which is at a lower frequency (below 8 kHz) for the bat impact assessment (AS-033 14.13.105). Not only that, the human-focussed modelling uses average noise levels for the noise impact assessment which may not reflect true levels of impact compared to maximum noise levels (Volume 2 Main Development Site Chapter 11 Noise and Vibration Appendix 11B Construction Noise Assessment, App-204).

3.689 This approach has been used to assess impacts on Bridleway 19 and Stonewell Belt foraging and commuting areas. The noise modelling conducted, as outlined in this ES (Doc Ref. Book 6) (Vol 2, Chapter 11) APP-204 concludes that noise levels are unlikely to be significant at these locations (AS-033, Table 14.44). Unfortunately, this conclusion reflects the major limitations of the study in that it utilises noise estimates based on what humans can hear, using an average rather than maximums and hence may have little relevance in terms of impacts on bats.

3.690 Whilst it is recognised that the updated bat impact assessment (AS-208) has removed the reference to human noise modelling, it still draws the same conclusion of no impact from noise as the ES chapter AS-033. The modelling data from Volume 2 Main Development Site Chapter 11 Noise and Vibration APP-202 is the average noise levels for the two locations (Roundhouse for Upper Abbey bridleway and Ash Wood Cottage for Stonewell Belt) using modelling with a 5 metre acoustic screen. It is these data that concludes a non-significant impact. Critically, the noise and vibration chapter predicts night-time maximum noise levels at the Roundhouse could be as high as 67dB LAmax when the green rail route materials unloading and stockpiling is underway. In our view, this represents a potential significant adverse impact (References Chapter 11 Noise and Vibration Appendix 11B Construction Noise Assessment (APP-204) paragraph 2.5.5 and 2.21.5 and APP-202 paragraph 11.6.47 and 11.6.49) that appears to have not been fully recognised.

3.691 The limitations of the conclusions above are further compounded by the fact that the human-focussed modelling used noise levels at only 1.5m above the ground. This has only very limited application to a high-flying bat species such as barbastelle, which commonly roosts and forages between 10-20m above the ground.

3.692 Vibration from piling has been dismissed as an impact for bat roosts as no known roosts have been found close to the western platform or the SSSI crossing (8.2.3, updated bat impact assessment (AS-208)). We question how these conclusions can be reached definitively, given there has been no roost monitoring in the SSSI triangle and areas bordering where the piling will go.

Foraging

3.693 The updated bat impact assessment (AS-208) states, 'studies which have measured effects of noise >65dB have found that bats typically avoid habitats exposed to this level of noise' and 'noise levels exceeding 65dB have a negative impact on a broad spectrum of bat species' (8.2.51). The report then goes on to say (8.2.52) 'The evidence outlined above suggests that bats are able to quickly adapt when exposed to a range of 'high level' noise'. However, there is no evidence to support this conclusion in light on the evidence presented.

3.694 The ES chapter (Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology - Revision 2.0 [AS-033]) Table 14.43 and paragraph 14.13.100 show eight barbastelle foraging and commuting areas have the potential to experience noise levels above 65dB (at 8kHz and 10 metres height).

3.695 Specifically, along Kenton Hills, given the structure of the dense conifer plantation (in contrast to more naturalised deciduous wood) barbastelle will not forage as much in the actual woodland itself. They are more likely to forage along the edge of the wood, to the north, which is closer to the noise source and hence may be impacted by noise in this area. Consequently, any displacement forcing barbastelle to forage within the conifer plantation, is likely to result in sub-optimal feeding and potentially loss of condition for individuals. There appears to be no consideration of this.

3.696 The following section (from this point until the end of 1.4.2) is in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092].

3.697 There is also very little in the way of determination of noise impacts from the Green Rail depot along the edge of Kenton Hills. This is especially important given the recent proposed increases in night rail movements. It is likely that unloading of loads will create a significant noise source. If this is done at night, there is a risk to foraging bats along the fringes of the wood and bund. However, if unloading occurs during the day, there appears to be no assessment on the impacts on the barbastelle roosts close by.

3.698 Other areas of significant noise include the SSSI crossing, around the whole of Ash Wood and along Bridleway 19. Table 8.22 (updated bat impact assessment (AS-208)), for example, clearly shows Bridleway 19, which is proposed as a quiet/dark corridor for bats, to be over 65 dB at 22kHz, levels of which are very likely to disturb foraging. It is unclear how it is envisaged barbastelle will adapt and connectivity will be maintained in this instance.

3.699 The ES chapter AS-033 Table 14.43 says Goose Hill's eastern boundary is used as a commuting and foraging area, which will be subject to high frequency noise above 65dB. However, the updated bat impact assessment AS-208 Table 8.22 says noise levels will be below 65dB despite both referring to noise modelling data and results presented the Bat Mitigation Strategy (APP-252 and APP-253). It is unclear which is correct and hence it is impossible to determine noise impacts in this area.

Roosting

3.700 A threshold of 60 dB at 8kHz has been set for disturbance at roosts (APP-253 14.13.82). The noise assessment indicates (APP-253 14.13.96-97) there will be noise >65dB at 9 barbastelle roosts and multiple potential tree roosts during Phases 1 and 2 of construction. This equates to four active bat seasons (i.e. four potential generations), which is easily long enough for significant deleterious impacts on populations. Whilst it appears likely that most barbastelle roosts identified by radio-tracking are unaffected there is no information to say how many and therefore it appears hard to justify that adverse effect is not significant. Given there are significant levels of noise >65 dB and the threshold for disturbance at roosts is 60 dB, it is likely that many more potential roosts are affected.

3.701 Barbastelle move roosts regularly and this appears to be given for the reason there will be no significant impact. However, for a robust approach and conclusion, a noise impact on total roost resource should be assessed to determine overall impact but this does not appear to have been done.

3.702 From the evidence presented roosts R1, R2, R11, R150 within Kenton Hills will all be over the level of significant impact, as well as the five Ash Wood roosts. Given this, the conclusion that no noise license is required even though modelling clearly shows there will be impacts on roosts appears difficult to sustain (AS-208 8.3.64).

Location of Noise modelling

3.703 The following section (1.4.4) is in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021. [REP1-092].

3.704 Bats, especially barbastelle, roost and forage at up to 20m above ground. However, the noise modelling for bats was located at a maximum of 10m above ground level (APP-253 14.13.93). Furthermore, the noise modelling for human receptors which was used to determine impact, was at 1.5m (and 4.5m) above ground level. This further adds to the uncertainty of the conclusions: not only the use of inappropriate human noise modelling in the assessment but also the location of the noise modelling itself is not appropriate to determine impacts on barbastelle.

Timing of Noise Modelling

3.705 Clarification is required over hours of night-time noise modelling and assessment. Paragraph 1.2.2.2 of ES Vol 2 Chapter 11 Noise and Vibration and Appendix 11B Construction Noise Assessment (APP-204) explains that assessment scenarios have been defined separately for daytime (07:00–23:00hrs) and night-time (23:00–07:00hrs) construction. This means that "night-time" does not include all the dark hours throughout all of the active bat season. With full construction activities ongoing until 11pm, we are concerned regarding the potential for impacts of noisy activities during dark hours. Bats are active from around dusk to dawn which varies throughout the year and consequently modelling noise and assessing impacts from dusk to dawn may be more relevant. We would like clarification that all hours of bat activity are being assessed in a similar way.

3.706 It is uncertain from the data presented whether the noise modelling and assessment accounts for phase 5 of the construction and for significant overlap between construction phases. ES Vol. 2 Main Development Site Chapter 11 Noise and Vibration (APP-202) section 11.3 d) describes the scenarios assessed as part of the noise modelling and explains the types of activities planned to take place over the five construction phases during both the daytime and night-time construction

shifts. It is stated that construction Phase 1 (site establishment and preparation for earthworks) and Phase 5 (removal of temporary facilities/restoration of the land) will result in the highest noise levels, although it is also noted that the construction phases will overlap. It is therefore important that Phase 5 impacts are fully considered as are the times when the phases overlap.

Lighting

3.707 The following sections (1.5.1-1.5.4) are in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092].

Limited Spatial Coverage of Light Monitoring

3.708 Information provided on the lighting (Volume 2 Main Development Site Chapter 2 Description of Permanent Development Appendix 2B Lighting Management Plan APP-182 1.3.21) only uses three examples and does not include key areas used for roosting, foraging and commuting bats, especially for barbastelle. Key areas omitted include Ash Wood, areas around Upper Abbey Farm, southern end of Bridleway 19, Leiston Old Abbey, Fiscal Policy, much of Kenton Hills or the SSSI. Additionally, the examples that are used, are in areas of the development that will be inherently darker and hence not a true reflection of potential impact.

Bridleway 19

3.709 Bridleway 19, which is retained as a dark corridor, is most heavily used by commuting barbastelle towards the southern end, close to Fiscal Policy and Kenton Hills. This is also the area where there is most risk of impact by light and so it seems incongruous that the light monitoring and modelling is at the northern end of the bridleway, where there will be less light spill and evidence of lower use by barbastelle. Therefore, it is questionable if the light modelling in this area is of the accuracy needed to determine impact. Area 1 is located along the northern section of Bridleway 19, which will be some distance from the brightly lit access routes further to the south, areas which are also indicated from the bat survey data, to be more important for bats. In Area 1 where the modelling was undertaken, the accommodation light spill will be much lower than the access routes. Table 1.13 of APP-182 shows areas of very high lighting towards the lower end of Bridleway 19; Checkpoints (150 min lux), Gatehouse (200 min lux), Service areas (100 min lux) and Inspection areas (50 min lux) but there is no detail where these are located exactly in relation to the 'dark corridor' of Bridleway 19. Importantly, the light modelling does not appear to capture these. We would expect obvious light level contours showing them clearly, but this does not appear to be the case.

3.710 The actual light modelling along Bridleway 19 has focussed on calculation 2 (8.2.100 of AS-208 and APP-182 1.3.24), but this is at ground level. There was only one test carried out above ground level. Therefore, not only was the location of the tests in a suboptimal location, the testing was largely at ground level that has less ecological relevance to barbastelle that typically commute and forage at heights greater than 10 metres.

3.711 There are no details in terms of the width of each of the four severances along Bridleway 19. This is a significant omission given the bridleway is being championed as a dark corridor despite being severed by 2 haul roads, the main access road and a railway line.

Kenton Hills

3.712 Area 2 is along the northern part of Kenton Hills, however, it will be well away from the green railway drop down area and hence will also be subject to significantly lower levels of light spill. In

Table 1.8 of APP-182, in our view the most ecologically relevant calculations for the north side of Kenton Hills are calculations 6, 7 and 8 and these have a maximum lux of 42.7, 23.3 and 13.5. These are levels that without mitigation may have significant impacts on bats but there appears to be no consideration of these findings. Section 8.2.109 of AS-208 suggests calculation 5 is the most important for bats at Kenton Hills but the location of this monitoring is at ground level and appears to be behind the earth bund. Consequently, this site will have little relevance on commuting and foraging bats between 10-20 metres, such as barbastelle, as the light will not be buffered by the bund at this height.

Ash Wood

3.713 Section 8.2.97 (plate 8.61) of AS-208 indicates that Ash Wood has not been modelled for lighting impacts at all. Given Ash Wood is one of the most important areas of the estate for barbastelle and the fact that development activity will occur on three of the four sides of the wood, this appears to be a significant omission. For example, the contractor compound is directly to the south of Ash Wood, likely with a high level of light and disturbance noise, plus close proximity of the haulage road. None of the modelling appears to reflect this (AS-208).

SSSI

3.714 The lighting assessment for the SSSI is all at ground level (8.2.115 of AS-208) and hence only has limited relevance in determining possible impacts on barbastelle foraging and commuting, or on roosts in the area. This coupled with the fact there has been no monitoring for bats in the SSSI, or even search for bat roosts, means there is no way to determine impacts.

3.715 Despite this, the Lighting Table 1.9 of APP-182 still shows there will be modelled light spill onto the SSSI of up to 18.4 lux, but there is no explanation as to the possible impact this will have on bats within the SSSI. If the modelling was done at a more ecologically relevant height for barbastelle, the light levels may indicate significant impact on this species. Unfortunately, given there has been no data collection for barbastelle within the SSSI, either for roosts or commuting and forage, we would be unable to determine what the impact would be, even if we had these data.

Mitigation

Uncertainty of Effectiveness due to Task Specific Lighting

3.716 It remains unclear how, in practical terms, unacceptable levels of light (and noise) will be defined and mitigated during construction. There appear to be potential conflicts between health and safety and further controls being implemented. We have major concerns over the lack of detail on task-specific lighting during construction and how this will be mitigated i.e. controlled, practically speaking on-the-ground on a day-to-day basis and at present there is nothing presented that could be easily adapted to provide the basis for a Working Method Statement for an Ecological Clerk of Works.

3.717 There is considerable uncertainty over how effective the mitigation proposed will be in practice. In section 8.2.89 of AS-208, the lighting mitigation states that if a dark corridor is dissected by a road there would be a gap in the lighting of 30 metres but only ‘if safe to do so’. There is no information which areas are ‘safe’ to include and which are not. Section 1.3.17 of APP-182 states, ‘where foraging routes and flight paths interconnect over the temporary construction area, where reasonably practicable these connecting areas shall be left dark’. It is left unclear as to what ‘reasonably practicable’ means in reality. As a result, it is impossible to determine the actual level of impact and hence how effective the dark corridors will actually be.

3.718 In section 1.4.16 of APP-182, it states that Sizewell Marshes SSSI should be kept as dark as 'reasonably possible' but as with elsewhere in the report, there is no way of knowing what this actually means. More information is needed to determine impact on the SSSI not only bordering the culvert but also on the western edge of the SSSI, bordering the main platform.

3.719 There is very little work and consideration over the type of lighting. It is not just the level of Lux that is important, but whether it is blue-white or yellow-white light. Differences between tone of light can have a considerable difference in levels of disturbance. Volume 2 Appendix 2B Lighting Management Plan for Construction and Operational Sites (APP-182) Section 1.2.59 proposes that the use of UV lighting, which the scientific literature suggests has a bigger impact on bats, will kept to a minimum 'where practicable'. However, there is no supporting evidence that shows there has been any analysis of what the impacts would be where this is not be practicable and hence the reader is unable to determine impact.

3.720 Section 1.2.69 of APP-182 illustrates the use of LED could increase white source light and white source light may increase impacts on bats, but there is no detail on how LED lighting will be kept to a minimum in areas of high bat activity, or how this lighting will be changed to less impactful lighting. Section 1.4.18 does mention that the use of lights with no UV, warm colour and tuneable LED will be used, 'where reasonably practicable'. Again, there is no way for the reader to determine what this actually means and hence determine final impact.

3.721 The borrow pit and stockpiles will have occasional task specific lighting (Table 1.6 of APP-182) but there are no details for how long, how bright and what type of lighting they will be and so there is no way to judge impact. Task specific lighting 'may be switched off when required' but there is no commitment or detail when or how this will happen in practice.

3.722 In essence, the lighting strategy needs to define exactly what is meant by '*where reasonably practical*' in all circumstances in which this, or similar, terms are used. Without this clarification, it is impossible to determine impact. There is also a need to be clear how, operationally, this will be done. This is especially important around controlling task-specific lighting, close to key features such as Ash Wood.

3.723 The strategy then needs to inform an operational lighting plans for construction that needs to include a clear and realistic worst-case scenario that can be compared to the planned mitigation. The lighting plans should follow best practice guidance for bats.

Limited Buffering of key Areas

3.724 Paragraph 1.3.19 of APP-182 also states that if lighting runs parallel to commuting routes and flightpaths (such as along the dark corridor of Bridleway 19 and around Ash Wood), then the buffer will only be 10m. Figure 2B.1 puts much of Ash Wood surrounded by Zone B (as is much of the SSSI). Bridleway 19 is crossed in 3 places by Zone B, areas which appear to include Gatehouses and Checkpoints and therefore subject to significant lighting. In areas of high intensity lighting, which appear to be very close to Bridleway 19, it is very unlikely a buffer of 10 metres will be enough to prevent significant fragmentation of what is supposed to be a dark corridor. A buffer of only 10 metres around Ash Wood may also result in significant impacts on roosting and emergence.

3.725 Pill Box field still appears in plans with an apparent footpath directly across the SSSI. What are the impacts from lighting on the SSSI (in addition to the direct land take from the SSSI)? No details are given.

3.726 Across the site, it would be helpful if there were figures showing the retained dark corridors with light modelling overlaid (from more areas and at heights that are ecologically relevant to barbastelle) pre and post mitigation. This would also help to understand light spill into the SSSI.

In Combination and Synergistic Impacts

3.727 Table 10.1 within the 6.14 vol3 Chap2 ES Addendum Terrestrial Ecology & Ornithology Appendices 2.9A-2.9D (AS-208), assesses in-combination effects for light and noise but there appears to be no in-combination assessment for light, noise and physical fragmentation (e.g. felling of Goose Hill woodland) all together. This appears to be a significant omission given the conclusion that there is likely to be a significant impact on a nationally important population of barbastelle bats and a county important Natterer's population, as a result of habitat fragmentation as an effect, when considered in isolation. However, in addition to this, there is considerable uncertainty relating to the impact from light and noise which may increase the residual impact already noted, due to synergistic effects.

3.728 Furthermore, there has been no attempt to understand the interrelationship between noise and light, especially the likely direct correlation between task specific intensive lighting and subsequent noise. The only reference to this is 8.2.125 in AS-208, 'when increased levels of task-specific lighting do correlate with higher noise levels, these events are likely to be short in duration relative to the construction period'. Given the length of the construction period is likely to be well over a decade, this is likely to be correct, but this still means the impact could span several years and across multiple breeding seasons.

Goose Hill

Barbastelle roosts within Goose Hill

3.729 The evidence presented suggests that Goose Hill may contain barbastelle roosts that have not yet been located, that will be lost due to felling. There were notable levels of barbastelle activity from 23-24th June 2020 between Hilltop Covert and Goose Hill. Based on these data, the back tracking report concludes the most likely barbastelle roost locations are in Kenton Hills or to the north, at Minsmere, with no justification as to how these conclusions were reached. However, data illustrated in Plot 4 (page 40) from the static survey (AS-037) suggests no early emergence of barbastelle from detectors around Kenton Hills but a number of early emergence records from a detector (MS20) on the southern edge of Goose Hill. These early emergence records strongly indicate roost sites either within Goose Hill or at least very close to the edge. No attempt has been made to investigate these findings further in the 2020 static or back-tracking surveys. Therefore, there remains considerable uncertainty over the conclusion that all the barbastelle roosts are within Kenton Hills and none within Goose Hill.

3.730 Section 5.3.7 of APP-253 says that Goose Hill has 'minimal roosting resource for bats', although it is hard to sustain that position given there are 7 trees with High and 104 with Moderate roost potential, all of which will be felled. Furthermore and perhaps most importantly, Figure 2.9B.1 of the updated bat impact assessment (AS-208) shows a barbastelle roost in Hilltop Covert, which is part of the western block of Goose Hill. It is unclear if this will be lost.

Importance of Goose Hill for Commuting and Foraging

3.731 There is a confirmed loss of barbastelle commuting and foraging habitat through Goose Hill including activity at MS11, identified in section 5.3.16 (6.14 AS-208 Vol. 3 Ch. 2 ES Addendum Terrestrial Ecology & Ornithology Appendices 2.9A-2.9D). This suggests consistent barbastelle activity within the development footprint, especially around and within Goose Hill. Section 5.3.20 of AS-208 also observed that some of the most important areas for bats included the northern

edge of Goose Hill woodland bordering the SSSI crossing and the southern edge of Goose Hill adjacent to the SSSI 'triangle'. Further, in section 5.3.27 there is an acknowledgement that Goose Hill is the only confirmed barbastelle commuting route on the estate, which will be lost. Within the Backtracking Report (AS-037), Table 5 notes there were notable levels of barbastelle foraging at TM464 645502. This is within Goose Hill and again suggests the importance of this area which will be directly lost under the development.

3.732 In Section 5.3.28 of the updated bat impact assessment (AS-208), four Natterer's bats were radio tracked and two were found to be using Goose Hill exclusively and a further individual foraging exclusively within Goose Hill and Hilltop Covert. Table 8.24 states that Goose Hill is of particular value to Natterer's bats 'later in the season'. Again, the importance of the total loss of Goose Hill to the development does not appear to have been fully recognised or the impact mitigated.

Importance of Goose Hill for breeding female and juvenile barbastelle

3.733 The Baseline surveys show Goose Hill as important for feeding resource for breeding females and juveniles, with their restricted range and flying ability. Table 8.18 (AS-208) indicates that the 2011 radio tracking work concluded that Goose Hill was a key foraging area for barbastelle on the estate during pre-lactation period and again in 2014, was important for females post breeding. Table 8.20 states that a pre-lactation commuting route from Ash Wood through to Goose Hill has been identified for barbastelle.

3.734 Due to the small hunting ranges of breeding females, Goose Hill is likely to be close to, or even include, a maternity site that will be lost. This has not been fully recognised and there remains a significant risk that there is both a direct loss of a barbastelle maternity colony and subsequent impact from the development on foraging for poor flying pregnant females and juveniles. Due to their limited ranges, it is unclear whether these bats would be able to use the SSSI crossing and hence may face significant impact. Despite this, there has been no work to understand what percentage of home range of females and juveniles will be lost and what this impact would look like. Whilst the SSSI crossing is likely to be used for bats (assuming the lighting plan is adequate) there is still likely to be a significant effect on barbastelle even if they use the culvert, due to an increased distance required to reach foraging areas after Goose Hill has been felled. It is not clear either how this residual effect will be compensated for, or how this effect will specifically impact poor flying juvenile and lactating female barbastelle using Goose Hill previously.

Sizewell Link Road (SLR)

Importance of the SLR to bats

3.735 We are concerned that the importance of the SLR has been underestimated, the bat usage of which is described in the report as 'very low levels'. However, Detector 7 at this location Volume 6 Sizewell Link Road Chapter 7 Terrestrial Ecology and Ornithology Appendix 7A Ecological Baseline and Method Statements (APP-462) Table 1.19) has the second highest encounter rate across the development site, including across the Main Development Site. Further evidence highlighting the importance of the SLR for rare bats is illustrated by the fact that of the 64 static recordings, 50 registered barbastelle. There are no follow up data to determine if this is simply a few bats moving up and down, or a significant directional movement (for example, by using thermal imagery with static recording) but it does suggest that the conclusion of very low levels is incorrect.

3.736 Furthermore, whilst the importance of the SLR is underestimated based on current use, its importance for barbastelle is only likely to increase during the construction if displacement occurs.

SLR Mitigation

3.737 Given the likely importance of the SLR area during the development period, we believe that there needs to be more mitigation provided, especially in relation to the provision of bat boxes suitable for barbastelle. There is also concern over effectiveness of the current mitigation using standard trees; these will need to be set back from the road, in dark areas and will be to be planted at a height that aids commuting.

3.738 Furthermore, it is not clear what work has been done on determining impact resulting from road collisions along the SLR and what the combined effect might be with other stressors such as light and noise.

3.739 The design and location of road crossing points for bats should follow best practice (Berthinussen and Altringham, 2012[382] and 2015[383]). Data from studies on mitigation for bats and roads showed that bats used underpass located on a pre-construction commuting route that allowed bats to pass without changing flight height or direction. Attempts to divert bats from their original commuting routes were unsuccessful.

3.740 Table 1.2 of the bat mitigation strategy (APP-252) notes these requirements relate to the provision of safe crossing points over linear developments (road, rail) and are of less relevance to the provision of a protected corridor through a 'hostile' landscape. We consider these requirements are directly relevant to the SLR.

Mitigation

3.741 The following sections (1.9.1-1.9.3) are in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092].

Central Dark Corridor (CDC)

3.742 The Addendum appendices rightly points out that barbastelle, 'would experience direct habitat loss and fragmentation of commuting routes and be impacted by increased noise and lighting'. (6.1.8, 6.14 vol3 Chap2 ES Addendum Terrestrial Ecology & Ornithology Appendices 2.9A-2.9D AS-208). On this basis, we believe a CDC which is unimpacted by light and noise, is established through the centre of the site. This may offset, to some extent, the loss of Goose Hill.

Use of SSSI crossing as Mitigation

3.743 Whilst the wider culvert over the SSSI is an improvement on the original design, it cannot be said to 'promote connectivity' (AS-208 8.4.35) beyond what is already there, as the baseline is of SSSI quality and likely to be well used by commuting bats anyway. Given no monitoring has been carried out within the SSSI triangle, there is no current baseline from which to judge but despite this, it seems strange that the crossing and loss of SSSI is being proposed as mitigation for bat connectivity.

---

382 Berthinussen, A. & Altringham, J. (2012) Do bat gantries and underpasses help bats cross roads safely? PLoS ONE 7(6): e38775. doi:10.1371/ journal.pone.0038775

383 Berthinussen, A. & Altringham, J. (2015) Development of a cost effective method for monitoring the effectiveness of mitigation for bats crossing linear transport infrastructure. University of Leeds/DEFRA.

Lower Abbey Farm Bat House

3.744 The provision of a new bat house at Lower Abbey Farm is a welcome further improvement to the mitigation package (2.2.112 in 6.14 6. Environmental Statement Volume 1 Addendum Chapter 2 MDS AS-181). However, the relative lack of wider mitigation to ensure the location within the wider development itself will remain attractive to bats, places considerable uncertainty over whether the barn will be used, or its potential maximised. The surrounding area is very likely to be severely impacted by light and noise and so we question the mitigation value of the bat house in its current location unless a more robust plan for lighting and noise mitigation is provided, especially along the southern end of Bridleway 19 where there is likely to be significant light and noise. Furthermore, if the bat house is proposed to mitigate the loss of the barn at Upper Abbey Farm (this is not clear in the documents), it is unlikely to provide suitable mitigation for the multiple species roost within the barn that will be lost at Upper Abbey Farm. To achieve this, a larger and more complex design will be needed to achieve the differences in access, light, temperature and humidity required by multiple species currently found in the existing barn. Finally, it is a missed opportunity not to provide accessible, sensitively designed subterranean spaces below the house that could act as hibernacula. This may be especially important to barbastelle given there is no clarity where the bats go to hibernate at times of very cold weather and hence there is currently considerable doubt as to whether the development will prevent access to historic hibernation sites. The provision of a further hibernation sites at Lower Abbey Farm would help to mitigate this risk.

Light and Noise Mitigation

3.745 There remain a number of areas that have high levels of barbastelle activity that appear to have insufficient mitigation in terms of light and sound. As discussed previously, the lack of monitoring in many of these areas means there is considerable uncertainty of impact. Specifically, mitigation appears likely to be lacking along the Bridleway 19 corridor, Fiscal Policy, along three sides of Ash Wood, Black Walks and the link to Minsmere and around the SSSI crossing and to the west of the main platform.

3.746 Triggers for noise and lighting remain undefined, especially in relation to task-specific lighting. Until there is some indication of how noise and lighting impacts will be practically controlled, it is difficult to determine impact and effectiveness of mitigation.

3.747 The following sections (from here until 1.9.4) are in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092].

3.748 In the bat mitigation strategy, APP-253, Fig 14C1A.5 suggests that the earth bund mitigation to the north of Kenton Hills covers four of the barbastelle roosts within the red line boundary. It is not clear which side of the roosts the bund will be. The figure also shows foraging along the northern edge of Kenton Hills boundary actually within the conifer plantation. However, the foraging is much more likely to be directly under the bund footprint i.e. along the edge of the oak trees, than within the conifer plantation. So, the bund in its current location appears to directly impact on barbastelle roosts by covering the oak trees.

3.749 As a general, but important comment, the proposed mitigation bunding across the site, such as at Kenton Hills and Ash Wood, will not buffer from light and noise impacts due to the fact the barbastelle will be naturally foraging over the top of the bund; the proposed bunds are five metres tall, whilst barbastelle are known to forage and commute in excess of ten metres.

Concern over Assumptions of benefits to bats from other Mitigation Sources

3.750 We are concerned that the provision of Aldhurst Farm, the marsh harrier improvement area and Studio Field Complex (updated bat impact assessment, AS-208 8.5.32) are mentioned in relation to wider mitigation, especially given the clear loss of home ranges for some barbastelle are found to be of medium to high magnitude significance (8.3.29). It is unlikely these areas will provide adequate compensation for this residual impact due to: a) difficulty in accessing these sites due to loss of overall connectivity; b) poor forage habitat of these areas for barbastelle – much of these areas will consist of open, dry grassland with low levels of invertebrate prey and it is noticeable that overall the Environmental Statement is too simplistic as it assumes overall biodiversity gain with changing land use on the estate will benefit bats. This is a significant assumption as large losses of woodland may not be offset by acid grassland creation, which is not prime bat foraging habitat compared to woodland edge; c) the sensitivity of pregnant females and juvenile barbastelle around Goose Hill and Fiscal Policy and their small home ranges, being unable to access these sites due to distance effect; d) lack of evidence as to what the baseline was in these areas – there is no evidence these new areas will provide any better foraging habitat compared to what was already there.

Bat Box Mitigation Strategy

3.751 Much emphasis has been placed on the provision of bat boxes as part of the mitigation and whilst barbastelle will use bat boxes, they are not an effective compensation for the wholesale loss of trees, given barbastelle switch trees on a regular basis. Barbastelle also switch bat boxes regularly and many boxes are required, not just to replace known roosts, as known roosts are likely to be a fraction of the actual roosts lost. For example, 74 medium and high potential tree roosts in Ash Wood are likely to be impacted by noise and light in addition to the 111 medium and high potential roosts in Goose Hill that will be lost entirely. Furthermore, there has been no work done on roost potential within the SSSI triangle or to the west of the platform. Consequently, the current provision of boxes appears to be very low. The Backtracking Report records that 'potential roosts have been noted but not identified for barbastelle in Goose Hill and Broom Covert' (AS-037, 2.3.4). Again, this suggests the box replacement mitigation is not enough to offset the numbers of potential roosts being lost, especially within Goose Hill and other areas such as the SSSI triangle and to the west of the platform and SSSI edge. There is an urgent need to map areas that can take more boxes, or areas which currently have limited opportunities for roosting bats currently, as places for suitable further mitigation. In essence, there needs to be a much greater commitment for box provision over a wider area. We request details of the design of bat boxes installed on the estate and if there is any evidence barbastelle have used them. Greenaway and Hill (2004)[384] note special boxes 'designed to offer narrow gaps with a long access length appear much more attractive to them' (section 3.6).

3.752 It is also worth noting that bat boxes should not be the only approach to roosting provision. For example, it is notable that a single dead Scot's pine on the eastern edge of Kenton Hills is the most important roost found for biggest range of species. It would also make sense to veteranise a number of pine trees in suitable locations (with features added to enhance their desirability), between 20-30, across the estate.

3.753 There should be key foraging areas close to retained and newly provided roosting resource and along bat flightlines. Greenaway (2004) note 'When too many foraging opportunities are lost along a flightline, the bats will cease to use it, even if its connectivity is maintained. Increasing

[384] Greenaway, F. & Hill, D. (2004) Woodland management advice for Bechstein's bat and barbastelle bat. English Nature Research Report No. 658, English Nature, Peterborough

foraging opportunities along the sections of flightline used in early evening lowers the requirement for long distance commuting in poor weather.'

3.754 Greenaway and Hill (2004)[385] note 'abundant productive forage close to the roost' when juvenile bats first start fly is 'key to the success of any bat colony' (section 3.4) and suggest management plans for nursery roosting sites should include areas of five to ten times the area that bats are presently using to ensure a continuing supply of roost sites for barbastelle bat colonies into the future (section 3.5).

Deer Management

3.755 The following sections (1.9.7) is in addition to observations raised in the Joint Local Impact Report - Appendix 2.3 BSG Ecology Review of Bat Impact Assessment October 2020 [REP1-091] and Appendix 2.4 BSG Ecology Review of Bat Impact Assessment: Second Review March 2021 [REP1-092].

3.756 It is apparent that the control of deer has ceased on the estate. Why this is the case is currently unclear, but increased deer numbers over time will increase pressure on the woodland edge as well as the developing scrub/edge habitats in the arable reversion. It is highly likely over time this would further reduce the quality of foraging habitat for bats. A planned and sustained deer control policy would go some way to retain high quality habitat for foraging bats over the longer term.

Lack of Compensation for Residual Impact

3.757 Perhaps most importantly, the updated bat impact assessment (AS-208) notes there remains a residual Moderate Adverse Effect on barbastelle that is Significant even with the new connectivity corridor, wider culvert, bat box provision and bat house. Despite this, there appears to be no attempt to provide any compensation (8.3.47).

Conclusion

3.758 We are concerned that a lack of abundance data, a low coverage of data gathering from across the site and limited data gathered from key times of year, has resulted in a poor-quality baseline, from which to draw robust conclusions. This has been compounded by analysis focussing on the entire bat population rather than a focus on the rarer species found on the estate.

3.759 As a result, the mitigation provided is unlikely to be enough. Where mitigation has been provided, due to a lack of detail regarding specific working practices, there is considerable uncertainty as to whether this will be effective. Due to inherent uncertainty over noise and light impacts on barbastelle, there is a lack of a precautionary approach around key areas of the site.

3.760 Having concluded significant effect on barbastelle bat, there is no attempt to compensate for residual effect.

3.761 There is no structured monitoring plan in place to determine future population trends, from which to respond to potential future impacts.

3.762 If barbastelle continue to roost within the EDF estate, there is likely to be a population level effect as a result of displacement of females from foraging habitats, due to the construction area representing a partial barrier to movement.

Natterjack Toads

Summary

3.763 This natterjack section is informed by the report; Amphibian and Reptile Conservation (2020). Sizewell C Project: comments on natterjack toad mitigation proposals. Report to Suffolk Wildlife Trust. ARC report. ARC, Bournemouth. The report is attached as an appendix. We respectfully request that the Examining Authority review the Report in full as text below is just a summary of the points covered within that Report.

3.764 The main findings of that Report are:

- The framing of impacts as "temporary" when they would in fact last for three natterjack toad generations is a notable misinterpretation of the potential impact on the viability of the population;
- There is insufficient reassurance that habitat creation and management proposals would generate and maintain a resilient population of natterjack toads; and
- The proposals do not adequately take into account the ecology and local conservation status of the population.

Dataset

3.765 The data are generally well presented and largely sufficient for this type of impact assessment with the notable exception of surveys in terrestrial habitat.

3.766 We agree with the conclusions about the status of the natterjack toad population whereby the report adequately summarises the long-term monitoring data and the suggestion of a population size of around 30 adults is reasonable[386]

3.767 However, it would have been appropriate to caveat this with a note about the fact that surveying/monitoring effort has not been consistent and intensive enough for a precise and reliable population estimate. Although we do not think that the use of terrestrial habitat in Retsom's Field and surrounding areas has been well described.

3.768 Additionally, there are concerning comments on the ecology of natterjack that raises the question over the level of expertise the author has with regard natterjack ecology specifically. There is an implication that natterjack toads might be considered poor swimmers which needs further clarification [387] as well as the intention of the comment about natterjack toads not being found during reptile surveys [388] Both require further context to further understand what is meant by these comments and how this has influenced the design of the mitigation.

3.769 We note that there is an error in the section describing the legislation applying to natterjack toads.[389]. The text indicates that that killing, injuring or taking natterjack toads is an offence under the Wildlife and Countryside Act 1981 (as amended), but this is not the case. Most provisions of Section 9 of that Act do not apply to natterjack toads, with the main protection for these species

389 ES V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species.pdf – pdf pg 350, para 1.1.2 (doc pg: ES V2 C14 App 14C7A Natterjack Toad Mitigation Strategy - pg 19) (APP-252)

being within the Conservation of Habitats and Species Regulations 2017 (as amended). Again, this raises the question of the depth of knowledge of the author specific to natterjack toad.

Future Monitoring

3.770 The monitoring proposals are inadequate. It is not explained precisely what would be monitored or the methods, effort, timing, responsibility for delivery, use of monitoring results and sharing of data.

3.771 In a clear example of the current limitation with regard future monitoring, there is mention of monitoring being delivered annually during Water Management Zone (WMZ) operation and biannually over a 6 year period afterwards[390], but in order to obtain a mark recapture estimate we would expect annual monitoring.

3.772 In terms of monitoring objectives, we suggest that the following should be covered:

- Assessing the efficacy of mitigation measures put in place to reduce harm to natterjack toads during WMZ construction and operation;
- Assessing the efficacy of habitat creation and enhancement measures in the short and long term.

3.773 In terms of field survey methods used, we suggest two broad categories are included:

(1) Standard monitoring methods for this species: counts of spawn strings laid, assessment of metamorph production, counts of adults in ponds during the breeding season, assessment of habitat quality;

(2) A finer resolution of population status assessment: an estimate of adult population size through repeat surveys of adults and applying standard mark-recapture statistics, using natural markings to identify individuals (see, e.g. Smith et al 2018[391]; McMurray undated[392]).

3.774 Routine monitoring during the construction phase should be undertaken annually with at least 7 survey visits per year, as recommended for standard natterjack toad monitoring (e.g. see guidance on ARC's website at: https://www.arc-trust.org/targeted-surveys-for-natterjack-toads). During the capture phase, we would expect active capture by searching at night with a powerful torch, rather than a reliance on pitfall traps which appears to be the case with current proposals.

3.775 Monitoring should be undertaken annually for at least 6 years following completion of WMZ operation, in order to detect any residual impacts of the development and to trigger remedial actions. Monitoring should cover all the existing ponds (N1-4) and newly created ponds. There should be a clear statement of investigations and potential remedial actions should monitoring detect problems such as a failed pond liner. These investigations and remedial actions should be costed and secure resourcing plans put in place.

3.776 Assessment of habitat quality should include a note of management operations (e.g. grazing) and natural factors (e.g. rabbit activity, weather) likely to be influencing habitat condition. Monitoring should be carried out by personnel meeting standard criteria (CIEEM, 2013)[393]. Monitoring results

should be shared with those with an interest or involvement in managing the natterjack toad population, and with the national monitoring programme operated by ARC.

Potential Impacts

3.777 There is a high likelihood that rabbit grazing would be reduced or possibly re-distributed by WMZ construction activities arising from noise and lighting. Rabbits play a crucial role locally in the ongoing maintenance of a low sward, important for natterjack and this could be compromised. Displacement of rabbits would also reduce the provision of bare ground and underground voids through rabbit warren excavations, leading to a reduction in refuge availability. It appears this impact has not been recognised in the assessment[394].

3.778 There is the possibility that the WMZ construction and operation would result in significant changes to the hydrology of Retsom's Field and surrounding areas. If the field were to be either inundated, or conversely made significantly drier by the works, this would likely have an adverse effect on the natterjack toad population. We do not agree with the simplistic conclusion[395]

3.779 That hydrology is not an issue simply because the existing breeding pond (N1) is lined and the substrate is sandy. Were the Field to be inundated during the winter, this would have a significant impact on the survival rates of hibernating natterjack. Conversely, if the field were to become significantly drier, this might impact the suitability of the substrate for natterjack toads, which require some water content in the substrate to avoid desiccation when taking refuge. Hydrological changes might also affect prey availability. In addition, there is the possibility that hydrological changes might affect pond N4, which is unlined.

3.780 We believe the impact of the "temporary" loss of terrestrial habitat during WMZ construction and operation has been significantly under-estimated and is not adequately explained[396]. Natterjack toads are highly terrestrial, with most adults spending the majority of time on land and only a small fraction of the year in aquatic habitat; post-metamorphic immature individuals rarely, if ever, enter aquatic habitat. The exclusion of 3.5 ha of good quality terrestrial habitat close to the breeding pond for 3 generations could have a noticeable impact on the population through reduced foraging and refuge opportunities. The small size of the population, and its isolation, may exacerbate any negative effects.

Mitigation

3.781 The mitigation proposals indicate at several points that conventions used in great crested newt mitigation have simply been applied to natterjack toads, despite the fact that there are marked differences in the ecology of the two species. Again, this raises a question over the expertise of the author specific to natterjack toad. The mitigation proposals do not take into account some important ecological characters of natterjack toads, nor have they been sufficiently adjusted to account for this particular population.

3.782 There is a disconnect between the section of the EDF proposals which discusses natterjack toad ecology[397], and the proposals for mitigation and compensation: the former do not appear to have sufficiently informed the latter. For example, it is unlikely that 30 days of capture effort would be

---

394 ES V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species.pdf – pdf pg 341-342, para 1.3.1-1.3.10 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 10-11) (APP-252)

396 ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species.pdf – pdf pg 341, para 1.3.6 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 10) (APP-252)

397 ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species.pdf – pdf pg 353 App 14C.7A.3 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 22) (APP-252)

sufficient to adequately deplete the population in the fenced area, and the apparent reliance on pitfall trapping is insufficient[398].

3.783 There appears to be no mitigation in place to ensure the local rabbit population, who's activity is critical to create the right conditions for natterjack and might be otherwise displaced by the Water Management Zone construction activity, are not displaced by noise and light. More thought needs to be given to encouraging rabbit activity to create burrows and open, bare ground habitat.

3.784 There needs to be a thorough and comprehensive hydrological study on whether the WMZ might impact on the pond, hibernation site and surrounding area to understand if this might affect the natterjack population. If impacts are possible, mitigation needs to be sought to protect the hibernation site and wider foraging areas.

3.785 The mitigation currently fails to consider the potential impact on the 'temporary' loss of terrestrial habitat so close to the breeding pond over the course of three generations. Far more mitigation, specific to the ecological requirements of natterjack, is required to negate the likely impact on the wider terrestrial environment.

3.786 More generally, the particular vulnerabilities of this population, in conservation status terms, are not sufficiently addressed. This population is currently based on a single breeding pond, and if that were compromised the population would perish, resulting in a loss of range of significance at a much wider spatial scale.

Compensation

3.787 The proposed compensation for the loss of terrestrial habitats is inadequate.

3.788 The compensation proposals should be prefaced by a clear ambition. We would like to see a commitment to securing a resilient population in the long term, based on the availability of several breeding ponds set in good quality terrestrial habitat, with a local distribution expansion to the north.

3.789 A cluster of ponds of slightly differing profiles would be more appropriate than a single pond. This would increase the chance that in any one year suitable breeding habitat would be available, buffering against changes in environmental conditions. Habitat creation should involve a network of at least four new ponds, with slightly differing profiles and designed to provide good breeding habitat for natterjack toads. These should be sited in Retsom's Field, around the location currently proposed for N5, providing breeding opportunities between the existing breeding pond and N4.

3.790 Presently the proposal is that a single new pond would be created, and that this would effectively generate new terrestrial habitat. However, the terrestrial habitat in the field where the pond is proposed to the north is currently poor for natterjack toads, largely because the vegetation is rank. There is no meaningful mention of how the new breeding pond and terrestrial habitat would be maintained in suitable condition for natterjack toads after construction. Therefore, there is a lack of confidence that sufficient terrestrial habitat would in fact be created and maintained.

3.791 This is further illustrated by the fact that N3 to the north has not yet been colonised; this is likely because of the small source population, distance to that source but also because of the poor surrounding terrestrial habitat. These issues would not be sufficiently addressed by the EDF proposals for the new pond, N5. However, it is in principle a sensible idea to create a "stepping

[398] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species.pdf – pdf pg 346-347, Table 1.3 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 15-16) (APP-252)

stone" pond between N1 and N4 but more needs to be done to ensure the surrounding habitat is suitable.

3.792 In setting out any plans for new lined ponds, it has not been recognised that they have a finite lifespan, typically 20 years, though this can be much shorter depending on materials and local conditions. Therefore, a programme of pond restoration and creation needs to be in place.

3.793 More detail on the specifics of the management of the surrounding area is required to understand how the landscape surrounding the ponds, from N1 up to N4 will be improved. For example, type and numbers of grazing animals. In addition, the newly created ponds will need to be well designed, with shallow margins, and be maintained so that aquatic vegetation, competitors and predators do not proliferate. In effect, measures have not been suggested as to how there will be continued provision of suitable breeding habitat.

3.794 The proposed linear feature[399] is unlikely to have any effect on connectivity. Natterjack toads are more likely to disperse over flat grassland, were it to be of a suitable sward, than to use a linear mound for dispersal; it is a feature that would be more suitable to other species of amphibians. The feature would, however, create terrestrial refuge opportunities if well constructed but improvements to connectivity would need to supplement this feature.

3.795 Overall, the scale of the proposed compensation habitat is inadequate given the potential impacts. Given the significance of the population, its vulnerability in terms of size and isolation, and the risks posed by the development, it would be appropriate to create a larger extent of quality habitat, with the aim of extending the local distribution of the species and increasing its viability. That could buffer against any residual impacts caused by the construction and operational phase. The natterjack toad is a pioneer species and populations can decline rapidly if habitat (both terrestrial and aquatic) conditions are not adequately maintained. The EDF proposals do not give reassurance that there would be measures in place to ensure a sufficient extent and quality of habitat in the long term.

Landscape strategy

Summary

3.796 We are concerned the Application will have a significant visual impact on visitor experience and the views available at RSPB Minsmere and the landscape strategy lacks measures to minimise and mitigate for this potential impact.

3.797 We are concerned the landscape strategy lacks sufficient details of baseline information, ecological objectives for habitats, species and ecological connectivity, habitat creation and management, robust monitoring and further interventions to be implemented if required and legal means of securing this throughout the lifetime of the development. We consider the Application should be focusing on landscape scale net gains and providing a functional ecological mosaic/ecotone and improving the actual ecological functionality of the surrounding area.

[399] [SZC_Bk6_ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species.pdf – pdf pg 343, para 1.4.8 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 13) (APP-252)]

Introduction

3.798 We have engaged with the Applicant throughout the pre-application and pre-examination period. We reviewed the DCO application and expressed our concerns in our relevant representations [RR-1059 (RSPB)[400] and RR-1180 (SWT)[401] and our Change Application responses].

3.799 We outline our current position below.

Main Development Site

RSPB Minsmere visitor experience

3.800 As noted in our Land Matters section below the Application will have a significant visual impact on visitor experience and the views available at RSPB Minsmere. We do not agree with the Applicant's position that, impacts on the landscape and visual effects are only localised, across the AONB. For example in the Landscape and Visual Impact Assessment[402], the Applicant does recognise this impact but states it would be localised across the AONB and the effects are not significant. In our view the landscape strategy should include measures to minimise and mitigate for potential impacts on RSPB Minsmere.

Landscape strategy

3.801 As we noted in our comments on the biodiversity net gain strategy we consider the Application should be focusing on landscape scale net gains and providing a functional ecological mosaic/ecotone and improving the actual ecological functionality of the surrounding area. We recommend the landscape strategy has a coordinated landscape scale approach linked into the Nature Recovery Network[403] and commitments related to this.

3.802 We recommend bigger, better and connected[404] landscape scale habitat creation to connect and extend habitats to benefit protected species such as

- Acid grassland, bare ground, scrub and ponds for turtle dove
- Acid grassland in closed undisturbed areas with no public access, no lighting, noise or cats for stone curlew
- Mixed species hedgerows for bats, turtle dove, reptiles
- Broadleaved woodland, with good understory and scrub margins for bats, especially barbastelle
- Areas of 'hands off' or low intensity management buffering key habitat types
- Wet woodland for scarce invertebrate assemblages
- Rough grassland for barn owl
- Nesting habitat for little tern and common tern
- Creation of lowland heathland, dry acid grassland and scrub mosaic to link up existing habitats across Priority Landscape to benefit multiple priority species including stone curlew, woodlark, nightjar, natterjack toad and turtle dove
- Creation and maintenance of lowland wet grassland to benefit breeding waders and wintering wildfowl

(2010) Making Space for Nature: a review of England's wildlife sites and ecological network. Report to Defra.

- Creation of reedbed and fen for breeding birds and scarce plant and invertebrate communities
- Adaption of coast to create more resilient, naturally functioning landscapes including inter-tidal mudflats, shingle and sand dunes, saltmarsh and coastal lagoons
- Improvement of wetland areas to provide improvements for wildlife and to provide natural flood management
- Creation of lineal connectivity between Sizewell Marshes SSSI and Minsmere

Habitat enhancement, reinstatement and creation

3.803 We are concerned the framework outlined in the Outline Landscape and Ecology Management Plan (oLEMP)[405] currently lacks sufficient details of baseline information, ecological objectives for habitats, species and ecological connectivity, habitat creation and management, robust monitoring and further interventions to be implemented if required and legal means of securing this throughout the lifetime of the development.

3.804 The oLEMP[406] paragraph 1.1.3 notes the oLEMP provides the framework for the Landscape and Ecological Management Plan which will be secured by requirement

> *The oLEMP provides the framework for the Landscape and Ecological Management Plan (LEMP) which will provide further details of the management measures and implementation of the habitat created, along with ongoing monitoring arrangements. This is secured by a requirement within Schedule 2 of the Draft DCO.*

3.805 Table 7.1 of the oLEMP[407] considers monitoring proposals for target communities before and after habitat enhancement, reinstatement or creation that will be included in the detailed LEMP and notes

> *Before and after enhancement, reinstatement or creation a full botanical species list and quality assessment should be carried out to monitor the success of restoration and as a baseline for monitoring, this should include the presence and abundance of species. The NVC may be an appropriate method for collecting data for monitoring or this may be bespoken to the target communities.*
>
> *…*
>
> *Target communities would be set for each habitat type for years 1, 2, 5 and 10.*

3.806 We consider target communities and monitoring methods should be defined and secured in the DCO.

3.807 Table 7.1 goes onto consider monitoring proposals for each habitat type, and for example for dry Sandlings grassland notes

> *Targets would be set for acid grassland according to the species list gathered before construction and thresholds identified for Section 41/Biodiversity Action Plan quality lowland meadow in the Countryside Stewardship Higher Tier Scheme made specific to the site, as well as the Joint Nature Conservation Committee guidance. Grassland habitat indicators would typically include the presence and abundance of key herb species present. This would weight desirable species against the injurious ones.*

405 8.2 Outline Landscape and Ecology Management Plan (oLEMP) (REP1-010)
406 8.2 Outline Landscape and Ecology Management Plan (oLEMP) (REP1-010)
407 8.2 Outline Landscape and Ecology Management Plan (oLEMP) (REP1-010)

3.808 The monitoring proposals lack detail and we consider detailed targets should be set and secured in the DCO.

3.809 The Applicant proposes creation of dry Sandlings grassland[408] from arable however this land will be under the construction site footprint for 10-12 years. We query how the Applicant envisages 10-12-year construction land use impacts will affect habitat establishment post construction.

3.810 We query the reason for semi-improved grassland[409] and propose scrub would be better if the soil type is not suitable for acid grassland.

Two Village Bypass

3.811 We query whether there may be opportunities for enhancements to provide habitat for protected species of bats and birds. We recommend an innovatively designed green bridge linking Foxburrow Wood County Wildlife Site with the woodland to the west. We also recommend additional tree planting to strengthen wildlife corridors.

Sizewell Link Road

3.812 The Sizewell Link Road remains a concern with regard the impact on barbastelle bats. Additional short lengths of hedgerow and approximately 0.17ha of additional woodland would be permanently lost as a result of the proposed changes[410]. This additional habitat loss further reduces habitat connectivity for bats and birds. We recommend additional hedgerow and tree planting to strengthen wildlife corridors.

Environmental Trust

3.813 Paragraph 1.1.6 of the Consultation Document for the Proposed Changes[411] proposed the establishment of an independent environmental trust to oversee the re-wilding and biodiversity of the Sizewell estate. We would need to understand this proposal in more detail. Plans for governance, implementation and ongoing financing will be required and we note that in order to be of most benefit to Suffolk's wildlife, plans for the estate should be targeted at declining locally-relevant habitats and species and should aim to increase connectivity with the wider landscape. We consider that this may sit better under the Applicant's corporate environmental and community responsibilities and other instruments would be more appropriate to address the impacts of the Sizewell C project. There is a need to ensure that legal requirements regarding protected sites and species are not compromised and that this aspiration is providing benefits over and above statutory requirements. We also request clarification of how this links in with the approach to biodiversity net gain.

Conclusions

3.814 We are concerned the Application will have a significant visual impact on visitor experience and the views available at RSPB Minsmere and the landscape strategy lacks measures to minimise and mitigate for this potential impact. In our view the landscape strategy should include measures to minimise and mitigate for potential impacts on RSPB Minsmere.

3.815 We consider the Application should be focusing on landscape scale net gains and providing a functional ecological mosaic/ecotone and improving the actual ecological functionality of the

surrounding area. We recommend the landscape strategy has a coordinated landscape scale approach linked into the Nature Recovery Network and commitments related to this. We recommend bigger, better and connected landscape scale habitat creation to connect and extend habitats to benefit protected species.

3.816 We are concerned the landscape strategy lacks sufficient details of baseline information, ecological objectives for habitats, species and ecological connectivity, habitat creation and management, robust monitoring and further interventions to be implemented if required and legal means of securing this throughout the lifetime of the development.

4. LEGISLATION AND ASSOCIATED POLICY AND GUIDANCE

4.1 Please note that although the domestic legislation has now amended due to the UK leaving the EU, the caselaw and most of the policy and guidance has not. Therefore many of the quotes (particularly in caselaw) will have *old language*. We have left these as they are but tried to ensure new words, phrases etc are flagged in footnotes to ensure consistency with the legislation.

Outline Initial Submissions

4.2 Please note we have requested a further opportunity to make legal submissions towards the end of the Examination, acknowledging the helpful further discussions and documentation that has been promised by the Applicant and wishing to take account of for example further drafts of the DCO, s.106, plans and schemes as well as further requirements and measures.

4.3 Therefore these are very much our initial legal concerns.

The Ramsar Convention

4.4 Due to the presence of a Ramsar site, it is mentioning the Ramsar Convention on Wetlands of International Importance especially as Waterfowl Habitat 1971[412], which is an intergovernmental treaty that provides the framework for the conservation, protection and wise use of wetlands and their resources. And the longstanding Government policy that Ramsar sites have the same level of protection as SACs and SPAs: see paragraph 118 of the National Planning Policy Framework[413].

The Birds Directive

4.5 Due to the SSSI bird features and the SPA and its designated species, as well as the general duties set out below (including to ensure compliance with the Birds Directive), it is important to briefly consider the Birds Directive.

4.6 The main reasons for the Directive 2009/147/EC on the conservation of wild birds (the Birds Directive[414]) was the perilous state wild bird populations were in when the Directive was first introduced and the great need for the restoration of those populations. This represented a "serious threat to the conservation of the natural environment", with the measures to be taken needing to apply to *"the various factors which may affect the numbers of birds, namely the repercussions of man's activities"*. The conservation of wild bird species was identified as necessary to meeting the Community's objectives regarding the improvement of living conditions and sustainable development, and aimed at the long-term protection and management of natural

412 Ref. 1.4
413 Ref 1.14
414 Ref. 1.5

resources as an "*integral part of the heritage"* of the peoples of Europe and "to prevent commercial interests from exerting a possible harmful pressure on exploitation levels"[415].

4.7 Hence the preambles/recitals to the Birds Directives so clearly including this great concern as well as the Directive's aims and objectives, in particular paragraphs 3 and 8[416].

4.8 Unfortunately we find ourselves in a similar perilous state with species and habitats declines[417].

4.9 Unlike most species' protection, the Birds Directive provides protection for all wild birds (Article 1). By Article 2, Member States *"shall take the requisite measures to maintain the population of the species referred to in Article 1 at a level which corresponds in particular to ecological, scientific and cultural requirements while taking account of economic and recreational requirements, or to adapt the population of these species to that level."*[418] Article 5 requires Member States to take "requisite measures" to establish a general system of protection for all species of birds referred to in Article 1 prohibiting (inter alia) deliberate killing or capture by any method, or deliberate disturbance particularly during the period of breeding and rearing in so far as disturbance would be significant having regard to the objectives of the Directive.

4.10 These, along with the substantive provisions which give effect to those Article 2 obligations – namely Articles 3 and 4 – are the main protection provisions.

4.11 Article 4 includes a specific requirement for Annex I and migratory species, namely the classification of their 'most suitable territories' as SPAs, but the overall requirement for *special conservation measures concerning their* habitat *in order to ensure their survival and reproduction in their area of distribution* should not be forgotten (as discussed further below and its relevance for the consideration of the use of the SPAs and SSSIs by species other than those for which the sites were designated and notified).

4.12 The Joint Nature Conservancy Council's[419] guidance to SPA designations[420] highlighting the requirement to choose the most important sites within the UK confirms this by stating:

> *"As noted in the recitals to the Birds Directive (especially (3), (7) and (8)) and is clear from the structure of the Directive itself the overriding purpose of it was to arrest the decline in bird populations in Europe by imposing generalised population maintenance duties on Member States (Article 2) and to identify and classify the 'most suitable territories' for Annex I and migratory birds, to deliver an ecologically coherent network of SPAs (Article 4(1) and 4(2)) "in order to maximise the contribution of the sites to achieving favourable conservation status at the national, biogeographical or European level": Commission Note on Setting Conservation Objectives for Natura 2000 Sites (23 December 2013). "*

---

415 Recital 6, 5, 7 and 9

416 (8) The preservation, maintenance or restoration of a sufficient diversity and area of habitats is essential to the conservation of all species of birds. Certain species of birds should be the subject of special conservation measures concerning their habitats in order to ensure their survival and reproduction in their area of distribution. Such measures must also take account of migratory species and be coordinated with a view to setting up a coherent whole.

417 Hayhow et al (2019) The State of Nature 2019. The State of Nature partnership. https://nbn.org.uk/wp-content/uploads/2019/09/State-of-Nature-2019-UK-full-report.pdf

418 There has not, as yet, been clear guidance on the interpretation of Article 2 (See, for example, what was said by Carnwath L.J. at §38 of *Sustainable Shetland v Scottish Ministers* [2015] UKSC 4, and at §17 identifying some apparent inconsistencies in CJEU case law. There are no set 'levels' in the UK for the purposes of Article 2

419 JNCC is the public body that advises the UK Government and devolved administrations on UK-wide and international nature conservation, provide evidence, information and advice

420 The UK SPA network: its scope and content, Volume 1: Rationale for the selection of sites – with the start of section 4 setting out the site selection process, section 4.5 (pgs 11- 12)

4.13 Article 4 does not, however, displace the wider, more general obligations, contained in Articles 1-2 and 5-9, but rather makes specific provision for birds within Annex 1 and migratory birds: see §19 of the CJEU's judgment in *R v Secretary of State for the Environment* [1997] Env LR 55.

4.14 Those obligations are generally implemented through the protections contained in the Wildlife and Countryside Act 1981 (as amended), but are also given effect through the obligations on appropriate authorities, nature conservation bodies and, in relation to marine areas, competent authorities in regulations 9 and 10 of the Conservation of Habitats and Species Regulations 2017 (as amended)(as discussed further below).

4.15 Importantly, the preambles/recitals to the Birds Directive and the structure of the Directive itself, highlight its purpose - to arrest the decline in bird populations in Europe by imposing protection requirements generally as well as specifically for Annex I and migratory species including the creation and protection of SPAs. But the requirements of course do not stop there as explained below.

SPA tightly drawn boundaries

4.16 It is important to note that the UK has transposed and implemented Article 4 through the creation of Special Protection Areas (SPAs) **only**, and therefore its approach to SPAs is relevant.

4.17 It is therefore worth noting here that unlike other countries, the UK does not include any buffer zones in and around its SPAs (nor its SACs and Ramsar sites) and therefore everything within those sites is included for ecological reasons. It is also notable that the UK has one of the lowest amounts of area designated as SACs or SPAs compared to other member states[421].

4.18 This means that any loss will directly impact the reasons for which the site was designated which makes it difficult for decision makers to be able to conclude that there will be no *adverse effect* if even a small part of that designated site is to be lost to the development.

The Habitats Directive

4.19 **The Habitats Directive**[422] requires EU Member States to maintain or restore, at favourable conservation status, natural habitats and species of wild fauna and flora of community interest, which are listed under Annex I, II, IV and/or V.

4.20 The Habitats Directive's aim is to promote the maintenance of biodiversity throughout the EU through the restoration and maintenance of natural habitats and of wild fauna and flora (listed in its Annex I and II). The Habitats Directive (and its implementing domestic regulations) must be interpreted and applied by reference to the Precautionary Principle, which reflects the high level of protection pursued by European policy on the environment and in the light of its broad objective –namely a high level of protection of the environment.

4.21 Unlike the Birds Directive the Habitats Directive protects specific habitats and species by way of the creation of protected sites for them (SACs) and further provisions in relation to both European Protected Species (e.g. Natterjack toad and the bat species present and therefore of relevance here) and additional protections for priority species (not of relevance here).

[421] European Environment Agency Website, Natura 2000 barometer https://www.eea.europa.eu/data-andmaps/dashboards/natura-2000-barometer. This is an official EU barometer for SPAs and was last updated in February 2011 – table and then graph on page 2.

[422] Council Directive 92/43/EEC on the conservation of natural habitats and of wild fauna and flora (Habitats Directive) 1992 - Ref. 1.6

4.22 We refer you to Natural England's advice in relation to European Protected Species legislative requirements including licensing. However we do wish to stress the importance and need to consider all required consents, licences and permissions whether included within the DCO and Deemed Marine Licence or not. As discussed briefly below applications much not be broken up into separate parts thus losing the vital need to consider cumulatively and in combination all possible effects arising out of the many moving parts of the proposed development. Therefore it must be considered, when determining this Application, as to whether consents, licences and permissions also required are likely to be granted or not.

Uncertainty and the Precautionary Approach

4.23 The Precautionary Principle exists for situations where scientific data does not exist or is incomplete and therefore it is not possible to complete a full evaluation of the possible risks a plan, project or activity may cause to the environment, including possible danger to humans, animal or plant health, or to the environment in general. The European Commission's Precautionary Principle guidance[423] states that it should apply when a phenomenon, product or process may have a dangerous effect, identified by a scientific and objective evaluation, if this evaluation does not allow the risk to be determined with sufficient certainty. As such the degree of precaution applied to an evaluation, or assessment, can be seen to be directly proportional to the extent of scientific uncertainty inherent in that assessment. As the guidance goes on to recommend:

> "*The implementation of an approach based on the precautionary principle should start with a scientific evaluation, as complete as possible, and where possible, identifying at each stage the degree of scientific uncertainty***."**

The Habitats Regulations[424]

4.24 In relation to plans and projects *likely to have an effect* on a European site (SPA, SAC and/or Ramsar site[425]), the Habitats Regulations set out the sequence of steps to be taken by the competent authority when considering authorisation for that plan or project before deciding to authorise that project. These are set out in regulation 63, as follows:

- Step 1: consider whether the project is directly connected with or necessary to the management of the SPA. If not
- Step 2: consider, on a precautionary basis, whether the project is likely to have a significant effect on the SPA, either alone or in combination with other plans or projects.
- Step 3: make an appropriate assessment of the implications for the SPA in view of its conservation objectives. Regulation 48(2) empowers the competent authority to require an applicant to provide information for the purposes of the appropriate assessment. There is no requirement or ability at this stage to consider extraneous (non-conservation e.g. economics) matters in the appropriate assessment.
- Step 4: consider whether it can be ascertained that the project will not, alone or in combination with other plans or projects, adversely affect the integrity of the SPA, having regard to the manner in which it is proposed to be carried out, and any conditions or restrictions subject to which that authorisation might be given (the Integrity Test).

---

423 https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:52000DC0001&from=EN

424 Ref. 1.6

425 And due to long standing government policy – Ramsar sites too

- Step 5: In light of the conclusions of the assessment the competent authority shall agree to the project only after having ascertained that it will not adversely affect the integrity of the SPA, alone or in combination with other plans or projects.

- Step 6: If, despite not being possible to ascertain that there will not be an adverse effect on the integrity of the site, there are no possible alternative solutions to the proposed development and there are imperative reasons of overriding public interest (IROPI) (which, subject to regulation 64(2), may be of a social or economic nature), for it, consent can still be granted if…

- Step 7: any and all necessary compensation measures must be secured to ensure the overall coherence and protection of the National Sites Network[426]. (consideration of the management objectives for the National Sites Network (as set out below) should be part of these considerations).

SPA and SAC Conservation Objectives

4.25 Under the Habitats Regulations, a site's Conservation Objectives are intrinsic to the Integrity Test when considering whether to grant consent for a plan or project – see Habitats Regulations 63(1).

4.26 In order to understand the Conservation Objectives in the context of Regulation 63(1) it is important to remind oneself of the role of SPAs under the Birds Directive – as set out above. These protected sites are part of the Member State's requirement for special conservation measures in order to ensure that their contribution to national and international "conservation status" of the species[427] is maximised: as set out in the headline words at the start of all Conservation Objectives:

4.27 Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;[428]

4.28 The Conservation Objectives are to be an articulation of the contribution that it is appropriate for the SPA to make in an enduring way. It would be inconsistent with the purposes of the protection and the role of SPAs to have SPA Conservation Objectives (or the interpretation of them) aiming for lower populations.

4.29 The role of SAC Conservation Objectives are similar but slightly different to reflect the differences in SAC and SPA classification and designation.

Principles for Undertaking an Appropriate Assessment

4.30 Taking a more detailed look at first Steps 3 and 4, the English and Welsh Court of Appeal in *R (on the application of Mynydd v Gwynt Ltd) v Secretary of State for Business, Energy and Industrial Strategy* [2018] EWCA Civ 231 has recently set out the following principles for appropriate assessments under Regulation 63(1) referring to other important caselaw in this area:

> *"(1) The environmental protection mechanism in Article 6(3) is triggered where the plan or project is likely to have a significant effect on the site's conservation objectives: Landelijke: Vereniging tot Behoud van de Waddenzee v Staatsscretaris van Lanbouw (Case C-127/02) [2005] All ER (EC) 353 at [42] ("Waddenzee").*

---

426 Formerly known as the Natura 2000 Network

427 Please see points below on the management objectives of the National Sites Network and the requirements for both SPAs and SACS to ensure that the species are maintained and/or restored across their natural range

428 The SPA generic Conservation Objectives http://publications.naturalengland.org.uk/file/4811128974868480

(2) In the light of the precautionary principle, a project is "likely to have a significant effect" so as to require an appropriate assessment if the risk cannot be excluded on the basis of objective information: Waddenzee at [44].

(3) As to the appropriate assessment, "appropriate" indicates no more than that the assessment should be appropriate to the task in hand, that task being to satisfy the responsible authority that the project will not adversely affect the integrity of the site concerned. It requires a high standard of investigation, but the issue ultimately rests on the judgement of the authority: R (Champion) v North Norfolk District Council [2015] UKSC 52; [2015] 1 WLR 3710, Lord Carnwath at [41] ("Champion").

(4) The question for the authority carrying out the assessment is: "What will happen to the site if this plan or project goes ahead; and is that consistent with maintaining or restoring the favourable conservation status of the habitat or species concerned?": Sweetman v An Bord Pleanàla (Case C-258/11); [2014] PTSR 1092, Advocate General at [50].

(5) Following assessment, the project in question may only be approved if the authority is convinced that it will not adversely affect the integrity of the site concerned. Where doubt remains, authorisation will have to be refused: Waddenzee at [56-57]."

(6) Absolute certainty is not required. If no certainty can be established, having exhausted all scientific means and sources it will be necessary to work with probabilities and estimates, which must be identified and reasoned: Waddenzee, Advocate General at [107] and [97], endorsed in Champion at [41] and by Sales LJ in Smyth v Secretary of State for Communities and Local Government [2015] EWCA Civ 174 at [78] ("Smyth").

(7) The decision-maker must consider secured mitigation and evidence about its effectiveness: Commission v Germany (Case C-142/16) at [38].

(8) It would require some cogent explanation if the decision-maker had chosen not to give considerable weight to the views of the appropriate nature conservation body: R (Hart District Council) v Secretary of State for Communities and Local Government [2008] EWHC 1204 (Admin) at [49].

(9) The relevant standard of review by the court is the Wednesbury rationality standard, and not a more intensive standard of review: Smyth at [80]."

4.31 It is worth adding to this helpful review that an appropriate assessment requires all aspects of the project which could affect the site, its species and it's conservation objectives must be identified in the light of the best scientific knowledge in the field.[429] The competent authority, "taking account of the conclusions of the appropriate assessment of the implications…for the site concerned, in the light of the conservation objectives, are to authorise such activity *only if they have made certain* that it will not adversely affect the integrity of the site. That is the case where *no reasonable scientific doubt remains as to the absence of such effects*[430].

Site Integrity

4.32 The approach to the integrity question and its relationship to the SPA (and SAC) Conservation Objectives was explained by in *R (RSPB) v Defra and BAe* [2015] EWCA Civ 227 [2015] Env LR 24. It referred to the ECJ case of *Sweetman*[431] [5] which established that in judging integrity:

---

[429] *Waddenzee* CJEU Case-127/02; [2004] ECR-7405 at [61].

[430] *Waddenzee* [59].

[431] *Sweetman v An Bord Pleanàla (Case C-258/11); [2014] PTSR 1092*

"it is the essential unity of site that is relevant. To put it another way, the notion of "integrity" must be understood as referring to the continued wholeness and soundness of the constitutive characteristics of the site concerned.

The integrity that is to be preserved must be that "of the site". In the context of a natural habitat site which has been designated having regard to the need to maintain the habitat in question at (or to restore it to) a favourable conservation status….

It follows that the constitutive characteristics of the site that will be relevant are those in respect of which the site was designated and their associated conservation objectives. Thus, in determining the whether the integrity of the site is affected the essential question the decision-maker must ask is "why was this particular site designated and what are its conservation objectives?"

4.33 Therefore, the removal or disturbance of any part of the site and its supporting habitat will make the populations for which the sites are designated more vulnerable and less able to recover.

4.34 In addition, it is important to add that the integrity of an SPA requires the lasting preservation of the constitutive characteristics of the site that are connected to the presence of the species whose preservation was the purpose of the designation of the SPA: *Sweetman* [39].

Functionally linked land

4.35 We welcome the Applicant's consideration of functionally linked land for some species, consistent with the NE Guidance and previous decisions regarding functionally linked populations (Chapman and Tyldesley, 2016[432]). (see for example Noise and Visual Disturbance section above).

4.36 However this consideration is not consistently applied for all SPA species. As the NE Guidance clearly explains[433],

"Twelve SPA cases related to terrestrial or coastal habitats involving a range of waterfowl. Seven related to the marine environment and sea birds. In all cases the decision maker recognised the potential importance of functionally linked land or sea and that it should be treated as part of the Habitats Regulations Assessment."

4.37 This represents a serious gap in both the assessment and consideration of possible effects on the SPA species including whether mitigation measures are required and possible.

Mitigation Measures

4.38 Whilst we appreciate the further discussions with the Applicant offered, we did wish to briefly cover there our concerns with the mitigation proposals currently before the Examination, in particular the need for any mitigation measures proposed (*due to possible adverse effects on the integrity of an European Site*), to be clear and certain in three ways:

- ecologically effective;
- financially secured; and
- legally secured.

---

[432] Chapman, C. & Tyldesley, D. (2016) Functional linkage: How areas that are functionally linked to European sites have been considered when they may be affected by plans and projects - a review of authoritative decisions. Natural England Commissioned Reports, Number 207,

[433] see in particular electronic page 9 (unfortunately there are no page numbers in this part of the report and review of previous decisions report pages 29 -40

4.39 And it is for the Applicant to show that the mitigation it proposes will pass these certainty requirements.

4.40 The need for ecological certainty was recognised in *R (Champion) v North Norfolk District Council and another Champion [2015] UKSC 52,* paragraph 60, where the effectiveness of the mitigation measures proposed allowed the Supreme Court to determine, despite a procedural defect, that the decision should not be quashed. The information already available for the mitigation measures being sufficient and the lack of any concerns against their effectiveness is clear in the following paragraph:

> *"60 This was not a case where the environmental issues were of particular complexity or novelty. There was only one issue of substance: how to achieve adequate hydrological separation between the activities on the site and the river. It is a striking feature of the process that each of the statutory agencies involved was at pains to form its own view of the effectiveness of the proposed measures, and that final agreement was only achieved after a number of revisions. It is also clear from the final report that the public were fully involved in the process and their views were taken into account. It is notable also that Mr Champion himself, having been given the opportunity to raise any specific points of concern not covered by Natural England before the final decision, was unable to do so. That remains the case. That is not to put the burden of proof on to him, but rather to highlight the absence of anything of substance to set against the mass of material going the other way."*

Habitats Regulations General Duties

4.41 We would like to highlight, in particular, the obligation in regulation 9(3):

> *9.— Duties relating to compliance with the Directives*
>
> *(1) The appropriate authority, the nature conservation bodies and, in relation to the marine area, a competent authority must exercise their functions which are relevant to nature conservation, including marine conservation, so as to secure compliance with the requirements of the Directives.*
> *…*
> *(3) Without prejudice to the preceding provisions, a competent authority, in exercising any of its functions, must have regard to the requirements of the [Birds and Habitats] Directives so far as they may be affected by the exercise of those functions*.[434]

4.42 But the further duties in Regulation 10 are also important

> *10.— Duties in relation to wild bird habitat*
>
> *(1) Without prejudice to regulation 9(1), the appropriate authority, the nature conservation bodies and, in relation to the marine area, a competent authority must take such steps in the exercise of their functions as they consider appropriate to secure the objective in paragraph (3), so far as lies within their powers.*
> *....*
> *(3) The objective is the preservation, maintenance and re-establishment of a sufficient diversity and area of habitat for wild birds in the United Kingdom including by means of the upkeep, management and creation of such habitat, as appropriate), having regard to the*

[434] The terms of regulation 9(3) are not amended by the Conservation of Habitats and Species (Amendment) (EU Exit) Regulations although it needs to be read with the amended definitions of the relevant Directives and with the new regulation 9(4A) – regard must be had to any Secretary of State guidance – currently we do not believe this has been fully produced

requirements of Article 2 of the new Birds Directive (measures to maintain the population of bird species).

...

(7) In considering which measures may be appropriate for the purpose of securing or contributing to the objective in paragraph (3), appropriate account must be taken of economic and recreational requirements.

.....

(8) *So far as lies within its powers, a competent authority in exercising any function in or in relation to the United Kingdom must use all reasonable endeavours to avoid any pollution or deterioration of habitats of wild birds"*[435]

4.43 As mentioned above following the UK's departure from the EU these regulations have been changed and it is important to consider in particular the additions to them concerning the Management Objectives of the newly named National Sites Network[436]. Although these requirements already existed, it is helpful to have them clearly within our domestic legislation.

4.44 In summary regulation 16A, in Part 2 of the Regulations - **Conservation of Natural Habitats and Habitats of Species**, set out the requirements for the Network jointly and separately recognising the differences between SPAs and SACs (as set out above):

4.45 Authorities with relevant responsibilities must manage the National Site Network with a view to contributing to the achievement of the management objectives of it, namely

4.46 **For SACS** to maintain, or restore to favourable conservation status in their natural range

(i) the natural habitat types listed in Annex I to the Habitats Directive;
(ii) the species listed in Annex II to that Directive whose natural range includes any part of the United Kingdom's territory;

4.47 **For SPAs** to contribute, in their area of distribution, to ensuring the survival and reproduction of—

(i) the species of birds listed in Annex I to the new Wild Birds Directive;
(ii) regularly occurring migratory species of birds; and
(iii) to contribute, to securing compliance with regulation 9(1) (as set out above)

4.48 **For Both** take account of

(a) the importance of SACs and SPAs
(b) the importance of the sites for the coherence of National Site Network;
(c) the threats of degradation or destruction (including deterioration and disturbance of protected features) to which the sites are exposed; and
(d) in the case of migratory bird species, the importance of their breeding, moulting and wintering areas and staging points along their migration routes.

The Wildlife and Countryside Act 1981[437]

4.49 The Wildlife and Countryside Act 1981 (as amended) consolidates and amends existing national legislation and in part, implements the Bern Convention 1979 (Ref. 1.7), the Bonn Convention 1979 (Ref. 1.8) and the Birds Directive (Ref. 1.5). It creates the protection requirements for many species, as well as the ability to derogate from those requirements in certain limited

[435] Again the terms of regulation 10 are not amended by the Conservation of Habitats and Species (Amendment) (EU Exit) Regulations although it needs to be read with the amended definitions of the relevant Directives
[436] Formally known as the Natura 2000 Network
[437] Ref. 1.9

circumstance, helps controls the release of non-native species, and includes the need for and protection of Sites of Special Scientific Interest (SSSIs), among other things.

Sites of Special Scientific Interest

4.50 Sites of Special Scientific Interest (**SSSIs**) are the most important sites for national wildlife and natural features in England. In England, SSSIs are notified by Natural England who has a duty under Section 28 of the Wildlife and Countryside Act 1981 (as amended) (**the WCA**) to notify SSSIs where it is of the opinion that an area of land is of special interest by reason of any of its flora, fauna, or geological or physiographical features and to secure their day-to-day protection and conservation.

4.51 The purpose of SSSIs is defined in the Defra Code of Guidance[438] (paragraph 1) as being:

> *"…to safeguard, for present and future generations, the diversity and geographic range of habitats, species, and geological and physiographical features, including the full range of natural and semi-natural phenomena throughout England...".*

4.52 SSSIs make a fundamental contribution to the ecological processes upon which we all depend and to human quality of life. Individual SSSIs may also provide, or safeguard for the future, valuable research, educational and amenity resources.

4.53 Under Section 28G(2) of the WCA, public bodies must:

> *"…take reasonable steps, consistent with the proper exercise of the authority's functions, to further the conservation and enhancement of the flora, fauna or geological or physiographical features by reason of which the site is of special scientific interest".*

4.54 The Defra Code of Guidance (paragraph 73) states that the Secretary of State expects that all public bodies will take full account of their responsibilities under this duty whenever their actions may affect SSSIs.

4.55 Government Circular 06/2005[439], paragraph 61 requires all section 28G authorities, including local planning authorities, to apply strict tests when carrying out any functions within or affecting a SSSI, to ensure that they avoid or at least minimise adverse affects. It also requires public bodies to adopt the highest standards of management in relation to SSSIs in their ownership and to take positive steps wherever possible to conserve and enhance the special interest features of a SSSI where their activities may be affecting it or as opportunities arise in the exercise of their functions.

Energy Policy Background

4.56 The suite of Energy NPSs set out the Government's approach to ensuring the security of energy supplies and the policy framework within which new energy infrastructure proposals are to be considered. The presumption in favour of granting consent, as identified in NPS EN-1, *Overarching National Policy Statement for Energy*, is subject to the tests set out below in section 104 of the Planning Act (see NPS EN-1 paragraphs 4.1.2 and 1.1.2). Please see the SSSI loss section, above for consideration of the requirements in the Overarching National Policy Statement for Energy

---

438 Defra (2003): Sites of Special Scientific Interest: Encouraging Positive Partnerships.

439 Government Circular 06/2005: Biodiversity and geological conservation – statutory obligations and their impact within the planning system, 16 August 2005. https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/7692/147570.pdf.

(EN-1)[440] and the National Policy Statement for Nuclear Power Generation (EN-6)[441] in respect of proposed land take from Sizewell Marshes SSSI.

4.57 **In addition the NPPF sets** out in a number of policies about the importance of local plan making and decision making in delivering sustainable development and meeting objectively assessed needs:

4.58 Paragraph 12 of the NPPF states:

> *"This National Planning Policy Framework does not change the statutory status of the development plan as the starting point for decision making. Proposed development that accords with an up-to-date Local Plan should be approved, and proposed development that conflicts should be refused unless other material considerations indicate otherwise. It is highly desirable that local planning authorities should have an up-to-date plan in place."*

4.59 Paragraph 14 of the NPPF states:

> *"At the heart of the National Planning Policy Framework is a presumption in favour of sustainable development, which should be seen as a golden thread running through both plan-making and decision-taking.*

Adding

> *For example, those policies relating to sites protected under the Birds and Habitats Directives (see paragraph 119) and/or designated as Sites of Special Scientific Interest; land designated as Green Belt, Local Green Space, an Area of Outstanding Natural Beauty, Heritage Coast or within a National Park (or the Broads Authority); designated heritage assets; and locations at risk of flooding or coastal erosion.*

4.60 In addition the NPPF includes conserving and enhancing the natural environment policies as set out in paragraph 117 as follows:

> *"To minimise impacts on biodiversity and geodiversity, planning policies should:*
>
> - *plan for biodiversity at a landscape-scale across local authority boundaries;*
> - *identify and map components of the local ecological networks, including the hierarchy of international, national and locally designated sites of importance for biodiversity, wildlife corridors and stepping stones that connect them and areas identified by local partnerships for habitat restoration or creation;*
> - *promote the preservation, restoration and re-creation of priority habitat, ecological networks and the protection and recovery of priority species populations, linked to national and local targets, and identify suitable indicators for monitoring biodiversity in the plan;*
> - *aim to prevent harm to geological conservation interests; and*
> - *where Nature Improvement Areas are identified in Local Plans, consider specifying the types of development that may be appropriate in these Areas."*

---

[440] Department of Energy and Climate Change (2011) Overarching National Policy Statement for Energy (EN-1)

[441] Department of Energy and Climate Change (2011) National Policy Statement for Nuclear Power Generation (EN-6) Volume II of II - Annexes

4.61 And in relation to the presumption in favour of sustainable development (paragraph 14), paragraph 119 makes it clear that this presumption does not apply where development requiring appropriate assessment under the Birds or Habitats Directives is being considered, planned or determined.

The Biodiversity Duty

4.62 The Examining Authority needs to report on the duty under Section 40(1) of the Natural Environment and Rural Communities Act[442] (2006) for public authorities to have regard to conserving biodiversity. Section 40 states:

> *"Every public authority must, in exercising its functions, have regard, so far as is consistent with the proper exercise of those functions, to the purpose of conserving biodiversity."*

The EIA Requirements

4.63 We think it is important to consider the legislative requirements including the EIA Directive and its aims and objectives starting with the Directive's preamble/recitals, since the provisions of the our domestic legislation must, as far as possible, be interpreted in such a way that the purposes of the Directive are achieved.

Preamble

4.64 The Preamble highlights the need for:

> *"development consent for public and private projects which are likely to have significant effects on the environment should be granted only after prior assessment of the likely significant environmental effects of these projects has been carried out" and that "assessment must be conducted on the basis of the appropriate information supplied by the developer, which may be supplemented by the authorities and by the people who may be concerned by the project in question;"*

4.65 As well as that:

> *"the effects of a project on the environment must be assessed in order to take account of concerns to protect human health, to contribute by means of a better environment to the quality of life, to ensure maintenance of the diversity of species and to maintain the reproductive capacity of the ecosystem as a basic resource for life" (emphasis added).*

4.66 The importance of the public being informed and able to comment is key as helpfully emphasised by Lord Hoffmann in *Berkeley v SOSE* [2001] 2 AC 603 at 615c-616c[443].

The Infrastructure Planning (Environmental Impact Assessment) Regulations 2017[444]

4.67 Whilst we appreciate the Examining Authority is very familiar with these EIA requirements, it is worth highlighting the following, starting with Regulation 4, of the EIA Regulations and the need to consider environmental information:

---

442 Natural Environment and Rural Communities Act (2006) https://www.legislation.gov.uk/ukpga/2006/16/section/40

443 We of course acknowledge that Lord Hoffmann's further remarks as to exercise of discretion now have to be read in the light of the comments of the Supreme Court in *Walton v Scottish Ministers* 2013 SC (UKSC) 67. However, the reference to *Berkeley* here is in relation to the need to gather all relevant environmental information including following public engagement, as set out above, a key requirement for EIAs.

444 https://www.legislation.gov.uk/uksi/2017/572/contents

"Prohibition on granting planning permission without consideration of environmental information

4(2) Where this regulation applies, the Secretary of State or relevant authority (as the case may be) must not (in the case of the Secretary of State) make an order granting development consent or (in the case of the relevant authority) grant subsequent consent unless an EIA has been carried out in respect of that application.

4.68 And it is important to note that Regulation 2 defines environmental information as:

""environmental information" means the environmental statement (or in the case of a subsequent application, the updated environmental statement), including any further information and any other information, any representations made by any body required by these Regulations to be invited to make representations and any representations duly made by any other person about the environmental effects of the development and of any associated development;"

4.69 With an "EIA" having the meaning given by regulation 5 – namely ;

(1) The environmental impact assessment ("the EIA") is a process consisting of—

(a) the preparation of an environmental statement or updated environmental statement, as appropriate, by the applicant;

(b) the carrying out of any consultation, publication and notification as required under these Regulations or, as necessary, any other enactment in respect of EIA development; and

(c) the steps that are required to be undertaken by the Secretary of State under regulation 21 or by the relevant authority under regulation 25, as appropriate.

4.70 With an "environmental statement" having the meaning given by regulation 14;

(2) An environmental statement is a statement which includes at least—

(a) a description of the proposed development comprising information on the site, design, size and other relevant features of the development;

(b) a description of the likely significant effects of the proposed development on the environment;

(c) a description of any features of the proposed development, or measures envisaged in order to avoid, prevent or reduce and, if possible, offset likely significant adverse effects on the environment;

(d) a description of the reasonable alternatives studied by the applicant, which are relevant to the proposed development and its specific characteristics, and an indication of the main reasons for the option chosen, taking into account the effects of the development on the environment;

…and

(f) any additional information specified in Schedule 4 relevant to the specific characteristics of the particular development or type of development and to the environmental features likely to be significantly affected.

(3) The environmental statement referred to in paragraph (1) must—

….(b) include the information reasonably required for reaching a reasoned conclusion on the significant effects of the development on the environment, taking into account current knowledge and methods of assessment;…

4.71 **With Schedule 4 of the EIA Regulations** setting out in more detail the "required information for inclusion in Environmental Statements" including

> ***3.*** *A description of the relevant aspects of the current state of the environment (baseline scenario) and an outline of the likely evolution thereof without implementation of the development as far as natural changes from the baseline scenario can be assessed with reasonable effort on the basis of the availability of environmental information and scientific knowledge.*
>
> ***5.*** *A* ***description*** *of the likely significant effects of the development on the environment resulting from, inter alia—*
>
> *(a) the construction* ***and*** *existence of the development, including, where relevant, demolition works;*
>
> *(e)* ***the cumulation of effects*** *with other existing and/or approved projects,* ***taking into account any existing environmental problems relating to areas of particular environmental importance*** *likely to be affected or the use of natural resources;*
>
> *…*
>
> *The description of the likely significant effects on the factors specified in regulation 5(2) should cover the direct effects and any* ***indirect, secondary, cumulative, transboundary, short-term, medium-term and long-term, permanent and temporary, positive and negative effects of the development****. This description should take into account the environmental protection objectives established at Union level (as they had effect immediately before exit day) or United Kingdom level which are relevant to the project, including in particular those established under the law of any part of the United Kingdom that implemented Council Directive 92/43/EEC and Directive 2009/147/EC.*
>
> ***6.*** *A* ***description of the forecasting methods or evidence,*** *used to identify and assess the significant effects on the environment,* ***including details of difficulties*** *(for example technical deficiencies or lack of knowledge) encountered compiling the required information and the* ***main uncertainties*** *involved.*
>
> ***7.*** *A description of the* ***measures envisaged to avoid, prevent, reduce or, if possible, offset*** *any identified significant adverse effects on the environment and,* ***where appropriate, of any proposed monitoring arrangements*** *(for example the preparation of a post-project analysis). That description* ***should explain the extent, to which*** *significant adverse* ***effects*** *on the environment* ***are avoided, prevented, reduced or offset****, and should cover both the construction and operational phases*. (emphasis added)

The Worst Case Scenario

4.72 As caselaw[445] has made clear the challenge for the EIA will be to ensure that all realistic and worst case variations of the project have been properly considered and clearly set out in the ES and the likely significant impacts from that worst case variation have been adequately assessed.

---

[445] The 'Rochdale Envelope' arises from two cases: *R. v Rochdale MBC ex parte Milne* (No. 1) and *R. v Rochdale MBC ex parte Tew* [1999] and *R. v Rochdale MBC ex parte Milne* (No. 2) [2000].

All Aspects of the Proposed Development

4.73 The caselaw is very clear that all aspects of a project need to be considered together to ensure compliance with the EIA Regulations especially if those *other* parts are fundamental to the ability to achieve the main development – as is the case here.

4.74 We wish to stress that any assurances that possible cumulative impacts will be assessed separately during the consideration of the separate decisions is not, save in exceptional circumstances, a sufficient justification for not considering as part of the main Application and would result in a breach of the EIA requirements.

4.75 In addition the need to consider all potential cumulative effects arising from the Application as well as the potential in-combination effects from other plans and projects. Currently both these appear to be lacking in the environmental statement as set out above in several of the sections.

4.76 As discussed in each section and below – we continue to have serious concerns about the level of data available, the assessment undertaken and mitigation measures proposed including their effectiveness.

4.77 We look forward to continuing discussions with the Applicant but at this stage of the Application process the lack of details and firm commitments is of great concern

The Development Consent Order - Initial Concerns

4.78 Currently we have two broad issues in relation to the all important DCO and Deemed Marine Licence[446]

(1) Schedule 2 requirements

4.79 Article 2 grants development consent subject to the provisions of the Order and of Schedule 2 requirements (appreciating that these are akin to planning conditions). If we have understood correctly, the requirements of most relevance and concern are Requirements 2 (Code of Construction Practice) 4 (Terrestrial ecology management plan) 5 (Surface and foul water drainage) and 7 (Water Management) but also 13 (Ancillary structures, other buildings and plan) and 14 (Landscape works).

4.80 Requirement 2 requires construction (etc) of the authorised development to be carried out in "general accordance" with the Code of Construction unless otherwise agreed by the local planning authority. We understand that the Code of Construction Practice[447] is the relevant Code. However we do question why just “general accordance” rather than in accordance with and where precisely is there flexibility in that Code?

4.81 Requirement 4 - this only refers to ecology monitoring. It appears from the Mitigation Route Map [448]) that other ecological mitigation measures are to be secured through the Code of Construction Practice (Requirement 2), through scheme design (Article 3) through landscape requirement (Requirement 14) (and others) or obligations in the Section 106. However we note that the Examining Authority are seeking information in this respect from the Applicant - see EX Q1 Part 2 Bio 1.9: We will review answers provided and comment further at that stage.

---

447 ref 8.11

448 document 8.12, REP1-006

4.82 In addition there are many cases in every chapter of the ES, Volume 2, chapter 14 (for example) where it is stated that primary and tertiary mitigation with the aim of reducing or lowering levels of environmental effects (as set out in detail in the above sections). Inevitably the lists of primary and tertiary mitigation vary from site to site and receptor to receptor, however we remain extremely concerned as to how the Examining Authority can be sure that all the primary and tertiary mitigation listed is secured and will be delivered.

4.83 Therefore it is important that the Applicant clearly explains where and how the descriptions of such mitigation in the ES volumes and relevant chapters is reconciled with the mitigation secured in the DCO and the s.106 agreement

4.84 Currently, there is not, for example, a mitigation equivalent to the Terrestrial Ecology Monitoring Plan in requirement 4 nor a construction specific Ecology Management and Monitoring Plan.

4.85 We note PINS Advice Note 15is very clear in [449]this regard:

> *"16.1 An application may have significant adverse environmental effects that require mitigation; such effects will be identified in the accompanying ES and/ or relevant environmental information.* ***Any mitigation measures relied upon in the ES must be robustly secured and this will generally be achieved through Requirements in the draft DCO.*** *Mitigation that is identified in the ES as being required must also be clearly capable of being delivered."* (emphasis added)

4.86 It is not immediately apparent to us whether - or if so how - this has been done here

4.87 Requirement 7 does refer to the "the adjacent Sites of Special Scientific Interest". And in addition to the points made above (please see hydrology section) and all relevant information being required now, we also question due to the involvement of those adjacent SSSIs why Natural England is not also a required consultee. We would also request that due to the involvement of the RSPB and SWT, we too should be consulted.

4.88 We also note that there is no general requirement that the authorised development be carried out in accordance with the documents to be certified by the Secretary of State under Schedule 22 – this appears to be a fundamental oversight.

Deemed marine licence

4.89 We have two main questions at this stage

(1) What is the Marine Environmental Management Plan referred to in Schedule 20 Part 4 para 18? There appears to be no definition in Schedule 20, and

(2) When will this plan be produced to enable interested parties such as us to review and comment on it. As far as we are aware, there is not even an outline of what it is to cover, nor clarity on whether sufficient detail will be provided in the Costal Processes Monitoring and Mitigation Plan (as discussed in detail above) to check for shared issues.

[449] https://infrastructure.planninginspectorate.gov.uk/wp-content/uploads/2014/10/advice_note_15_version_1.pdf

The s.106 Agreement[450]

Schedule 9 - Implementation Plan

4.90 As far as we are aware a draft of the Implementation plan referred to within this Schedule has not been provided. This appears to be a key document including timetables proposed for secure avoidance/mitigation measures and would need to be consistent with other plans discussed above or clear how the various plans will work together as part of it

4.91 Also we note that the Applicant is to keep the Councils informed of progress (para 2.3). We would suggest that this is also relevant for the Environmental Review Group and Environmental Working Groups especially due to their role in keeping the implementation of Key Environmental Mitigation under review

4.92 We would also question whether it should be the Applicant alone who determines the appropriate course of action in the event of any delay Delays (as set out in paragraphs 2.4 - 2.8, particularly paragraph 2.6). We are particularly concerned about the potential for some delays to cause additional or further effects including due to delays in mitigation measure. As mentioned above our concerns with the adequacy of the assessments and the lack of detail currently on the proposed mitigation measures, adds to this concern.

4.93 We have further concerns namely:

4.94 Whether the drawing forward of Contingent Funds will be sufficient

4.95 What role is envisaged for Environmental Review Group and the Environmental Working Groups Why is it only the Planning Group (Schedule 17 para 5.1.2 - comprises 1 representative from each of the Councils and up to two representative from the Applicant) and Delivery Steering Group (Schedule 17 para 2 - comprises one service director (or equivalent) from each of the Councils and again up to 2 representatives from the Applicant) that are to be notified of any review and its outcomes

4.96 The make up of these groups is also concerning in relation to any changes required to the implementation of Key Environmental Mitigation as it appears this could be determined by the Applicant, appreciating the involvement of and notification to the Councils but there will be no working majority of non Applicant members.

Schedule 11 - Natural Environment

The Environment Review Group

4.97 Again we have concerns about how the different aspects covered by Schedule 11 (and Schedule 9 and 17) will work and the membership of Environmental Review Group is helpful with a working majority of non Applicant members, the issue may arise about when referred to Delivery Steering Group.

4.98 We do however query why the Environmental Review group will only meet every 6 months given that progress in carrying out Key Environmental Mitigation is to be reported to the Councils at least quarterly (Sch 11 para 2.3)

---

450 https://infrastructure.planninginspectorate.gov.uk/wp-content/ipc/uploads/projects/EN010012/EN010012-003959-Sizewell%20C%20Project%20-%20If%20needed,%20draft%20section%20106%20Agreement(s)%20(s.106),%20s.106%20Explanatory%20Memorandum%20and%20draft%20Confirmation%20and%20Compliance%20Document.pdf

Ecology Working Group

4.99 A key part of its role appears to be to review monitoring undertaken with the various Monitoring Plans (defined in para 1 to the Schedule). What appears to be lacking is provision for any technical expert input or consultation.

Legal Conclusions

4.100 We will continue to work with the Applicant on these concerns and provide comments on further information submitted to the Examination for example further details on the required management mitigation, compensation and monitoring plans and schemes as well as the details of the various funds mentioned above. We will update the Examining Authority of our position in light of any new information presented

4.101 However for now (as also covered in other section of these written representations) we have serious concerns about the adequately of information currently available and strongly recommend that without those details including the lack of clarity on the required legal, financial and ecological securing of requirements, measures, plans and schemes – confidence in them is premature.

5. BIODIVERSITY NET GAIN

Summary

5.1 Our concerns relate to the Applicant's approach to biodiversity net gain (BNG).

5.2 Whilst we welcome the Applicant including BNG within their proposals, despite the introduction of BNG within the Environment Bill not yet being a specific requirement (due to the Bill having not passed nor the further work required to establish a BNG system) we do not agree the Application can achieve net gain due to direct adverse impact on Sizewell Marshes SSSI from loss of a significant proportion of the SSSI, nor the amount claimed by the Applicant.

5.3 We are grateful to the Applicant for the discussions held and agree that the Application should take account of the requirements the new net gain system will include once established.

5.4 In addition there is a Natural England requirement for NSIPs to contribute significantly to environmental net gain[451]. As such, the Application should be demonstrating a high biodiversity metric score that does not rely on protected species mitigation and compensation measures to get over the 10% uplift requirement.

5.5 The biodiversity metric 2.0[452] used for the assessment is a consultation draft that contains software bugs and grey areas. The Applicant is currently taking full advantage of all grey areas to increase the metric score including revised baselines, use of measures that are for protected sites and species mitigation and compensation, heavy use of 'fairly good' category whilst ignoring limitations and trading down. The choices made have in each case increased the claimed BNG.

5.6 Our main concerns include:

- use of measures that are for protected sites and species mitigation and compensation

[451] The Planning Inspectorate Advice Note 11, Annex C – Natural England and the Planning Inspectorate

[452] Crosher, I. A, Gold, S. B., Heaver M.D., Heydon M.A., Moore L.D., Panks, S.A., Scott S.C., Stone D.A. and White N.A. (2019) The Biodiversity Metric 2.0: auditing and accounting for biodiversity value. User guide (Beta Version, July 2019). Natural England

- the baseline policy is directly at odds with the biodiversity gain system to be introduced by the Environment Bill
- the time for habitats to reach target condition (temporal risk) does not take account of the construction phase
- the replacement of higher biodiversity habitats with those of lower biodiversity (trading down)
- lack of evidence to support the likelihood of delivering the predicted on-site habitat conditions on post-construction soils
- lack of evidence to support the likelihood of delivering the predicted off-site habitat conditions post development
- the % net change in the metric score is calculated versus the on-site baseline but it should be calculated versus the total on-site plus off-site baseline
- the biodiversity value of existing habitats has not been adequately considered and taken account of
- heavy use of 'fairly good' category

5.7 We consider the key finding from the Applicant's BNG proposals to be at best only just over the 10% boundary by a narrow margin, and that if any one of several marginal decisions were reversed it would fall below it. Therefore it is our view that the Application is not making the ecological contribution claimed nor that is proportional to the size of it - at best it is providing no more than the minimum standard expected of any housing development[453] [454].

5.8 We also consider it important to note the biodiversity metric is not suitable for tracking ecological delivery over time - it is designed to be a one-time snapshot of future commitments at the point of the planning application and does not work as a tracking tool (e.g. the score will rise over time even if condition targets are missed).

5.9 We are also concerned the Applicant does not appear to have identified a legal mechanism for securing a 10% metric score in their mitigation strategy.

Introduction

5.10 We have engaged with the Applicant throughout the pre-application and pre-examination period. We reviewed the now superseded Biodiversity Net Gain report[455] for the main development site (MDS) submitted with the DCO application and expressed our concerns in our relevant representations [RR-1059 (RSPB) and RR-1180 (SWT)].

5.11 We have reviewed the net gain reports for the main development site[456], two village bypass[457] and Sizewell C Link Road[458] submitted at Deadline 1 and are pleased that some of our concerns around methodology have been addressed. We outline our current position below.

---

453 Ministry of Housing, Communities and Local Government (2019) National Planning Policy Framework (NPPF) paragraph 175

454 A Green Future: Our 25 Year Plan to Improve the Environment

455 Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (APP-266)

456 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

457 9.6 Biodiversity Net Gain Report - Two Village Bypass (REP1-018)

458 9.5 Biodiversity Net Gain Report - Sizewell Link Road (REP-017)

Approach to biodiversity net gain and direct adverse impact on Sizewell Marshes SSSI

5.12 Whilst the RSPB and SWT are fully aware of how the Environment Bill[459], will introduce a requirement for BNG, currently that legislation is not passed and there is a good chance it will not have done so by the time this Examination closes. In addition, the Bill purely introduces a framework for a BNG system and much more is needed before that system can get up and running.

5.13 For these reasons we would suggest that reference to the Bill (for example paragraph 1.5.2 of the Biodiversity Net Gain Report[460]) is premature. However it is useful to consider how BNG is described within it and its helpful explanatory notes. For example, at paragraph 1575[461] of the Bill's explanatory notes broadly excludes any development from BNG if it has a direct adverse impact on a protected site

> *Whilst it is generally agreed in practice that development cannot claim biodiversity net gain in cases when development results in land take from statutory protected sites (such as Sites of Special Scientific Interest, Special Protection Areas, Special Areas of Conservation, and Ramsar sites), development on such sites is not specifically exempted from the net gain requirement.*

5.14 The Bill[462] at paragraph 1575 of its explanatory notes[463] also notes the biodiversity net gain requirement for development on such sites is additional to any existing legal or policy requirements for statutory protected areas and their features

> *The biodiversity metric does not address impacts on species, recognise the significance of site designations, take account of indirect impacts, cumulative impacts or in combination impacts. In recognition of these limitations, the biodiversity net gain requirement for development on such sites is additional to any existing legal or policy requirements for statutory protected areas and their features, including restoration and conservation of designated features and the achievement of favourable conservation status and favourable condition. These requirements will need to be dealt with separately by the developer and planning authority.*

5.15 The Overarching National Policy Statement for Energy (EN-1)[464] also notes at paragraph 5.3.11 where proposed development is likely to have an adverse effect on an SSSI development consent should not normally be granted

> *Where a proposed development on land within or outside an SSSI is likely to have an adverse effect on an SSSI (either individually or in combination with other developments), development consent should not normally be granted. Where an adverse effect, after mitigation, on the site's notified special interest features is likely, an exception should only be made where the benefits (including need) of the development at this site, clearly outweigh both the impacts that it is likely to have on the features of the site that make it of special scientific interest and any broader impacts on the national network of SSSIs. The* [PINs] *should use requirements and/or planning obligations to mitigate the harmful aspects of the development and, where possible, to ensure the conservation and enhancement of the site's biodiversity or geological interest.*

461 The Environment Bill Explanatory Notes, May 2021 - https://bills.parliament.uk/publications/41448/documents/197

462 The Environment Bill, May 2021 - https://bills.parliament.uk/publications/41447/documents/196

463 The Environment Bill Explanatory Notes, May 2021 - https://bills.parliament.uk/publications/41448/documents/197

464 Department of Energy and Climate Change (2011) Overarching National Policy Statement for Energy (EN-1)

5.16 As outlined in the SSSI loss section above we do not agree the Applicant has demonstrated compliance with all legal and policy requirements for justification of the principle and scale of the proposed loss of part of Sizewell Marshes SSSI against the policy tests set out in EN-1 (Overarching NPS for Energy).

5.17 Although the National Planning Policy Framework[465] (NPPF) (2019) does not contain specific policies for nationally significant infrastructure projects it does note at paragraph 170 that planning decisions should minimise impacts on and provide net gains for biodiversity

> *Planning policies and decisions should contribute to and enhance the natural and local environment by:*
>
> *….*
>
> *d) minimising impacts on and providing net gains for biodiversity, including by establishing coherent ecological networks that are more resilient to current and future pressures;*

and at paragraph 175 notes opportunities to secure measurable net gains for biodiversity should be encouraged

> *When determining planning applications, local planning authorities should apply the following principles:*
>
> *d) opportunities to incorporate biodiversity improvements in and around developments should be encouraged, especially where this can secure measurable net gains for biodiversity.*

5.18 BNG Good Practice Principles for Development[466] notes at section 9.5 that projects affecting statutory designated sites cannot achieve BNG

> *Projects negatively affecting statutory designated sites or irreplaceable habitats cannot as a project achieve BNG.*

5.19 We do not agree the Application can achieve net gain due to direct adverse impacts on Sizewell Marshes SSSI from loss of a significant proportion of the SSSI. Despite this, we agree the Application should be meeting the requirements of the net gain system and our comments below are in relation to that achievement.

Biodiversity net gain and landscape strategy

5.20 Annex C to the Planning Inspectorate Advice Note 11[467] notes

> *Natural England will seek opportunities for positive environmental outcomes from major infrastructure developments. NSIPs can make a significant contribution to delivering the environmental ambition in the Government's 25 Year Environment Plan (25YEP). This aims to deliver an environmental net gain through development and infrastructure.*

5.21 The Defra Biodiversity Offsetting Pilots guidance[468] at paragraph 17 notes

---

465 Ministry of Housing, Communities and Local Government (2019) National Planning Policy Framework (NPPF)

466 Baker, J., Hoskin, R. and Butterworth, T. (2019) Biodiversity net gain. Good Practice Principles for Development. A practical guide.

467 Annex C to the Planning Inspectorate Advice Note 11: Working with public bodies in the infrastructure planning process – Natural England and the Planning Inspectorate

468 Defra (March 2012) Biodiversity Offsetting Pilots Technical Paper: the metric for the biodiversity offsetting pilot in England

Offsetting should:

- *contribute to enhancing England's ecological network by creating more, bigger, better and joined areas for biodiversity (as discussed in Making Space for Nature[469])*

5.22 BNG Good Practice Principles for Development[470] states at Technical Note T5 section T5.2 projects of national significance should focus on landscape scale net gains

Projects of national significance should underpin and support the delivery of UK and devolved government biodiversity commitments and should focus on landscape scale net gains and a contribution to national biodiversity targets.

5.23 Therefore the Application's BNG proposals should be focusing on landscape scale net gains and providing a functional ecological mosaic/ecotone and improving the actual ecological functionality of the surrounding area. We also query whether there may be opportunities for net gain habitat enhancements to provide habitat for protected species of bats, birds (barn owl[471], turtle dove, stone curlew, nesting terns), mammals and invertebrates.

5.24 Table 13 of the Biodiversity Net Gain Report[472] shows arable and amenity planting provide 106.8 biodiversity units, against 758.76 total for the main development site post development. It would be expected that habitat creation would focus on maximising biodiversity and we query the inclusion of significant areas of low ecological value habitats in the metric score. If arable land is to be created, we request inclusion in highest tier agri-environment scheme or a similar commitment to biodiversity enhancements such as field margins and hedgerow management.

Biodiversity net gain and protected species

5.25 We are concerned that potential loss of habitat for birds has not been adequately assessed by the Applicant particularly on the associated development sites (for example the two village bypass and link road as discussed below). We consider there should be sufficient bird surveys in accordance with best practice guidelines[473] to establish the current assemblage using the main development site and each associated development site to inform the assessment of potential losses and measures to retain and enhance the bird assemblage to ensure there is demonstrable net gain. Natural England also expressed concerns over the adequacy of breeding bird surveys[474].

5.26 We welcome any additional measures not required for mitigation and/or compensation that would be implemented to benefit specific species.

Inclusion of mitigation and compensation measures

5.27 As stated above, we do not agree the Application can achieve net gain due to direct adverse impacts on Sizewell Marshes SSSI. Despite this, we agree the Application should be meeting the requirements of the net gain system and should be providing landscape scale net gain proportionate to the scale of the project in line with planning policy. As such, the Application

---

469 Lawton, J.H., Brotherton, P.N.M., Brown, V.K., Elphick, C., Fitter, A.H., Forshaw, J., Haddow, R.W., Hilborne, S., Leafe, R.N., Mace, G.M., Southgate, M.P., Sutherland, W.J., Tew, T.E., Varley, J., & Wynne, G.R. (2010) Making Space for Nature: a review of England's wildlife sites and ecological network. Report to Defra.

471 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology (AS-033) 14.12.40 to 14.12.42

472 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

473 Bird Survey & Assessment Steering Group. (2021) Bird Survey Guidelines for assessing ecological impacts, v.0.1.0. https://birdsurveyguidelines.org

474 Natural England Relevant Representation [RR-0878] 37., 113., 114., 115., 176. and 183.

should be demonstrating a high metric score that does not rely on protected species mitigation and/or compensation habitat to get over the 10% uplift requirement.

5.28 We are concerned that protected sites and species mitigation and compensation measures have been double counted in the metric score without first demonstrating the adequacy of those mitigation and compensation measures and then providing net benefits for biodiversity over and above requirements for avoidance, mitigation and/or compensation measures.

5.29 Paragraph 2.9.1 of the Biodiversity Net Gain Report[475] notes mitigation areas are included

> *Landscape design has been carried out to maximise the benefits to a range of species, maximise biodiversity value and provide ecosystem service benefits. The design is layered in this way, for example, the reptile mitigation areas also provide benefits to a range of other species, for example bats and invertebrates. BNG as presented in the biodiversity metric guidance is a holistic landscape scale assessment of the overall long-term status of the site and the habitats within. As such, it is appropriate that where mitigation for species which results in a change of habitat (such as within the Studio Fields Complex) is assessed within the biodiversity metric.*

5.30 We consider 'no net loss' activities such as mitigation and compensation should not be relied upon to achieve the 10% metric target. We consider there should be no double counting if a mitigation or compensation area has benefit to other species unless specific measures are implemented for those other species.

5.31 Section 5.1[476] notes the marsh harrier compensation area and reptile habitat areas are included in the off-site biodiversity calculations. The marsh harrier compensation area is incorrectly described as mitigation however it provides compensatory foraging habitat for marsh harrier. The reptile habitat areas provide mitigation habitat for reptiles. One of these, Great Mount Walk, is within the marsh harrier compensation area. Therefore the Applicant is triple counting this area as reptile mitigation, marsh harrier compensation and BNG. As stated above we consider there should be no double counting (or triple counting) if a mitigation or compensation area has benefit to other species unless specific measures are implemented for those other species.

5.32 CIEEM (2018) guidelines[477] describe the key principles of ecological impact assessment at section 1.19 as

Avoidance	*Seek options that avoid harm to ecological features (for example, by locating on an alternative site).*
Mitigation	*Negative effects should be avoided or minimised through mitigation measures, either through the design of the project or subsequent measures that can be guaranteed – for example, through a condition or planning obligation.*
Compensation	*Where there are significant residual negative ecological effects despite the mitigation proposed, these should be offset by appropriate compensatory measures.*

[475] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[476] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[477] CIEEM (2018) Guidelines for Ecological Impact Assessment in the UK and Ireland: Terrestrial, Freshwater, Coastal and Marine version 1.1. Chartered Institute of Ecology and Environmental Management, Winchester

Enhancement *Seek to provide net benefits for biodiversity over and above requirements for avoidance, mitigation or compensation.*

5.33 The Applicant should correctly apply the mitigation hierarchy:

1. Avoidance: demonstrate measures to avoid impacts on protected species and habitats
2. Mitigation: demonstrate reptile mitigation measures are adequate and those within Great Mount Walk are additional to those for marsh harrier compensation
3. Compensation: demonstrate the marsh harrier compensation measures are adequate and additional to those required for reptile mitigation
4. Net gain: provide additional enhancements to benefit other species (or ecological connectivity) over and above avoidance, mitigation and compensation to provide net gain

5.34 Paragraph 4.2 of the Marsh Harrier Mitigation Area Feasibility Report[478] describes the design objectives for creation of lowland heath at Great Mount Walk (within the marsh harrier compensation area)

- *Sow short sward acid grassland mix.*
- *Spread heather brashings of local (Suffolk) provenance in suitable locations to encourage heather establishment as well as plant and invertebrate species indicative of Suffolk Sandlings heath.*
- *Create short sward acid grassland in Great Mount Walks.*
- *Provide log and brash piles to encourage populations of small mammals in the short term as vegetation develops.*
- *Allow development of small areas (less than 0.5ha) of bare ground to encourage development of a diverse assemblage of arable weeds and invertebrate species.*
- *Creation of lowland heath is a long-term process and should begin as early as is practicable to enable the establishment of vegetation and development of a good habitat structure of benefit to nesting birds and small mammals.*
- *Management of scrub and heath will be required to maximise the populations of breeding farmland bird species that are present.*

5.35 These measures are required to provide compensatory foraging habitat for marsh harrier and cannot be counted in the metric score.

5.36 The Reptile Mitigation Strategy Figure 14C2A.17[479] shows hay piles, log/brush piles and hibernacula within Great Mount Walk but it is not clear which of these are provided as reptile mitigation over and above requirements for the marsh harrier foraging area. Reptile mitigation also cannot be counted in the metric score.

5.37 The Biodiversity Net Gain Report[480] provides no indication of specific measures for other species over and above protected species mitigation and compensation measures.

---

478 Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14C5 Marsh Harrier Mitigation Area Feasibility Report (APP-259)

479 Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14C2A Reptile Mitigation Strategy Figures 14C2A.1 - 14C2A.18 (APP-255)

480 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

5.38 We consider 'no net loss' activities such as mitigation and compensation should not be relied upon to achieve the 10% metric target. We consider there should be no double counting (or triple counting) if a mitigation or compensation area has benefit to other species unless specific measures are implemented for those other species. We of course welcome any additional measures not specifically required for mitigation and/or compensation that would be implemented to benefit specific species without impeding the main purposes of the marsh harrier compensation area and the reptile mitigation areas, but their use within the metric target. Appendix B of the Biodiversity Net Gain Report [REP1-004] shows the offsite areas with some of the reptile mitigation areas annotated. We request that a map with all the mitigation and compensation areas clearly annotated is provided.

Biodiversity metric 2.0

5.39 We consider it important to note the metric is not suitable for tracking ecological delivery over time - it is designed to be a one-time snapshot of future commitments at the point of planning application and does not work as a tracking tool (e.g. the score will rise over time even if condition targets are missed).

5.40 The Outline Landscape and Ecology Management Plan (oLEMP)[481] Table 7.1 notes monitoring proposals refer to biodiversity net gain which suggests the Applicant may intend to use the metric to track ecological delivery over time

> *monitoring with regards to achieving the desired communities and quality as demonstrated in the biodiversity net gain report (ES Volume 2 Chapter 14 Appendix 14E).*

5.41 We request clarification that the Applicant does not intend to use the metric as a tracking tool.

Mechanism for securing net gain

5.42 We are concerned the Applicant does not appear to have identified a legal mechanism for securing a 10% metric score in their mitigation strategy.

5.43 The oLEMP[482] notes at paragraph 1.1.3 the Landscape and Ecological Management Plan will be secured by requirement

> *The oLEMP provides the framework for the Landscape and Ecological Management Plan (LEMP) which will provide further details of the management measures and implementation of the habitat created, along with ongoing monitoring arrangements. This is secured by a requirement within Schedule 2 of the Draft DCO.*

and at paragraph 4.1.7 notes

> *The Biodiversity Net Gain report …. demonstrates that net gain would be achieved if the habitats described within this oLEMP are delivered as proposed.*

and at Table 7.1 notes monitoring proposals refer to biodiversity net gain

> *monitoring with regards to achieving the desired communities and quality as demonstrated in the biodiversity net gain report (ES Volume 2 Chapter 14 Appendix 14E).*

[481] 8.2 Outline Landscape and Ecology Management Plan (oLEMP) (REP1-010)
[482] 8.2 Outline Landscape and Ecology Management Plan (oLEMP) (REP1-010)

5.44 Requirement 14 of the draft DCO[483] notes the landscape scheme for the permanent development site to be approved by East Suffolk Council must contain

> *(vii) a landscape and ecology management plan which will be prepared in general accordance with the measures set out in the Outline Landscape and Ecology Management Plan.*

5.45 We are however concerned that Schedule 2 of the Draft DCO[484] does not include a specific requirement for securing a 10% metric score in accordance with the draft Environment Bill [Schedule 14, 9(3) and 10(1) as currently drafted] and planning policy.

5.46 EN-1 (Overarching NPS for Energy) notes at paragraph 5.3.11 the [PINs] should use requirements and/or planning obligations to ensure enhancement of biodiversity

> *The* [PINs] *should use requirements and/or planning obligations to mitigate the harmful aspects of the development and, where possible, to ensure the conservation and enhancement of the site's biodiversity or geological interest.*

5.47 CIEEM (2018) guidelines[485] at paragraph 6.13 notes enhancements should be designed to deliver biodiversity objectives specified in relevant policy documents and evidence should be provided to support the likelihood of delivering the predicted benefit

> *Enhancement measures should be designed to deliver biodiversity objectives that are specified in relevant policy documents, and evidence should be provided to support the likelihood of delivering the predicted benefit. They should be incorporated into scheme design and assessed within the EcIA. To ensure that enhancements are enduring, their delivery and management should normally be guaranteed through a legal obligation, such as, in England and Wales, a planning obligation under section 106 of the Town and Country Planning Act 1990116 , or its equivalent provision elsewhere.*

5.48 Paragraph 7.12 notes

> *All parties should understand the actions they need to take during the implementation stages of a project. This will mean identifying and designing in detail the measures necessary to avoid, mitigate and compensate negative effects, and any measures necessary to achieve enhancements. Details of these measures will be set out in the EcIA and may be presented in an Environmental Management Plan (EMP) or similar document.*

5.49 We request the Applicant provides full details of all the measures necessary for protected species mitigation and compensation and full details of additional measures to achieve enhancements for example to benefit other species. We also request evidence is provided to support the likelihood of delivering the predicted benefits. The enhancement measures must be legally secured and we consider Schedule 2 of the Draft DCO[486] should include a specific requirement for enhancement measures to secure a 10% metric score in accordance with the draft Environment Bill (Schedule 14, 9(3) and 10(1) as currently drafted) and planning policy.

Comments on Main Development Site

5.50 Our main concerns relate to the methodology and approach to the metric calculations and include:

483 Draft Development Consent Order (Draft DCO) (AS-143)

484 Draft Development Consent Order (Draft DCO) (AS-143)

485 CIEEM (2018) Guidelines for Ecological Impact Assessment in the UK and Ireland: Terrestrial, Freshwater, Coastal and Marine version 1.1. Chartered Institute of Ecology and Environmental Management, Winchester

486 Draft Development Consent Order (Draft DCO) (AS-143)

- the baseline used is directly at odds with the biodiversity gain system to be introduced by the Environment Bill
- the time for habitats to reach target condition (temporal risk) does not take account of the construction phase
- the % net change in the metric score is calculated versus the on-site baseline but it should be calculated versus the total on-site plus off-site baseline)
- the biodiversity value of existing habitats has not been adequately considered and taken account of
- lack of evidence to support the likelihood of delivering the predicted on-site habitat conditions on post-construction soils
- lack of evidence to support the likelihood of delivering the predicted off-site habitat conditions post development
- the replacement of higher biodiversity[487] habitats with those of lower biodiversity (trading down)

Baseline

5.51 We welcome the inclusion (paragraph 2.3.2 to 2.3.8 of the Biodiversity Net Gain Report[488]) of baseline data dates for Studio Fields complex (on-site and off-site, 2011), Kenton Hills and St James Covert (off-site, 2007), Aldhurst Farm (on-site and off-site, 2015) and the remainder of the red line boundary (on-site, DCO submission). We query the baseline data date for the Marsh Harrier Habitat Improvement Area (on-site and off-site) and as have mentioned above this should be referred to as compensation.

5.52 This baseline policy is directly at odds with the biodiversity gain system set out in the Environment Bill[489], which sets the baseline at the point of the planning application for on-site delivery (Schedule 14, 5(2) as currently drafted) and the point set out in the biodiversity site gain register for off-site delivery (Schedule 10, 1(b) as currently drafted).

> *Schedule 14*
>
> *Pre-development biodiversity value*
>
> *5 (1) In relation to any development for which planning permission is granted, the pre-development biodiversity value of the onsite habitat is the biodiversity value of the onsite habitat on the relevant date.*
> *(2) The relevant date is—*
> *(a) in a case in which planning permission is granted on application, the date of the application, and*
> *(b) in any other case, the date on which the planning permission is granted.*
> *(3) But the person submitting the biodiversity gain plan for approval and the planning authority may agree that the relevant date is to be a date earlier than that specified in sub-paragraph (2)(a) or (b) (but not a date which is before the day on which this Schedule comes into force in relation to the development).*
>
> *Registered offsite biodiversity gains*
>
> *10 (1) "Registered offsite biodiversity gain" means any habitat enhancement, where—*

[487] The metric uses 'distinctiveness' as a collective measure of biodiversity and includes parameters such as species richness, diversity, rarity and the degree to which a habitat supports species rarely found in other habitats.
[488] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)
[489] The Environment Bill, May 2021 - https://bills.parliament.uk/publications/41447/documents/196

(a) the enhancement is required to be carried out under a conservation covenant or planning obligation, and
(b) the enhancement is recorded in the biodiversity gain site register (as to which, see section 93 of the Environment Act 2020).

93 Biodiversity gain site register

(1) The Secretary of State may by regulations make provision for and in relation to a register of biodiversity gain sites ("the biodiversity gain site register").
(2) A biodiversity gain site is land where—
(a) a person is required under a conservation covenant or planning obligation to carry out works for the purpose of habitat enhancement,
(b) that or another person is required to maintain the enhancement for at least 30 years after the completion of those works, and

5.53 The Applicant's policy to apply different on-site baseline data dates to each on-site delivery area (Studio Fields complex, Aldhurt Farm and the marsh harrier compensation area), all of them prior to the point of planning application (paragraph 2.3.2 to 2.3.8 of the Biodiversity Net Gain Report[490]) is at odds with Schedule 5 of the Bill which has no provision for different baseline data dates across the on-site delivery areas. The Applicant has also applied a baseline data date prior to the point of planning application to the off-site delivery areas. As there is currently no biodiversity site gain register, it would not be possible for the Applicant to claim an earlier baseline for off-site delivery under the biodiversity gain system.

The time for habitats to reach target condition (temporal risk)

5.54 Paragraphs 2.5.4 – 2.5.5 of the Biodiversity Net Gain Report[491] consider the temporal risk calculation which is aimed at accounting for the time lag for a newly created or restored habitat parcel to gain target condition, where it is created prior to, or concurrently, with the development. This multiplier is designed to take account of the time between the impact of a development on a habitat and when it is replaced by habitat of equivalent biodiversity value.

5.55 The on-site habitat creation starts post construction, and there will be a period of 8 – 12 years from the point of impact during construction where no habitat will be present. Therefore, the biodiversity unit value of these habitats will be zero, rather than the final figure with a time discount multiplier.

5.56 The Applicant's approach is directly at odds with the biodiversity gain system set out in the Environment Bill[492], which sets the post-development biodiversity value [Schedule 14, 8(1) as currently drafted] as at the time the development is completed.

8 (1) In relation to any development for which planning permission is granted, the post-development biodiversity value of the onsite habitat is the projected value of the onsite habitat as at the time the development is completed.

---

490 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

491 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

492 The Environment Bill, May 2021 - https://bills.parliament.uk/publications/41447/documents/196

5.57 Since the on-site habitat creation starts post construction, when the development is completed the value of the on-site habitats will be zero.

5.58 If any habitats are created before the end of development, the temporal risk calculation should consider the time when no habitat is present during construction and should therefore consider the time from the point of impact (when the current habitat is lost) to the estimated time the post construction habitat will reach target quality as noted in the Natural England Biodiversity Metric 2.0 user guide[493] at paragraph 5.19

> *The time period to use in applying the Time to Target Condition multiplier to a metric calculation is the length of time (in years) between the intervention and the point in time the habitat reaches the pre-agreed target quality (i.e. distinctiveness, condition, area). This time will vary between habitat types, between change scenarios (e.g. creation typically takes longer than enhancement) and due to way the habitat is managed. Time to target condition values – based on based on good practice and typical conditions are provided for all habitats used in biodiversity metric 2.0. These values are set out in detail in the Technical Supplement.*

5.59 This suggests that more offsite habitat creation should be completed to compensate for temporal losses of biodiversity in line with the Natural England Biodiversity Metric 2.0 user guide[494] which notes at paragraph 5.10

> *A typical consequence of applying risk multipliers is to increase the size (e.g. area or length for linear features) of habitat required as compensation such that it exceeds the size of habitat lost or damaged. This is necessary:*
>
> *to compensate for temporal losses of biodiversity (e.g. where there is a period of diminished biodiversity between the point in time when a habitat is impacted and it is replaced by habitat of equivalent biodiversity value);*

5.60 In addition, we recommend all habitat creation commences as soon as possible and we query whether there may be opportunities to transplant more mature trees to reduce time to reach target condition.

5.61 When considering the off-site habitat creation, the Defra Biodiversity Offsetting Pilots guidance[495] notes at paragraph 69

> *The number of years that time discounting should take into consideration is from the point of impact to the estimated time that it will take for the habitat to reach the pre-agreed target quality (i.e. the point at which the agreed number of units is delivered).*

5.62 Where off-site habitat creation starts after the impact occurs the temporal risk calculation should also consider the time from the point of impact to the estimated time to reach target quality.

494 Crosher, I. A, Gold, S. B., Heaver M.D., Heydon M.A., Moore L.D., Panks, S.A., Scott S.C., Stone D.A. and White N.A. (2019) The Biodiversity Metric 2.0: auditing and accounting for biodiversity value. User guide (Beta Version, July 2019). Natural England

495 Defra (March 2012) Biodiversity Offsetting Pilots Technical Paper: the metric for the biodiversity offsetting pilot in England

Net % change calculation

5.63 The Biodiversity Net Gain Report[496] at section 8.1.1 image 4 summarises the results of the assessment and reports 18.03% net change in the metric score. Using the figures provided there, the reported 18.03 % net change is the change in the metric score versus the on-site baseline as demonstrated below.

> Total baseline biodiversity units = on site 1244.45 + off-site 429.99 = 1,674.44
>
> Total post intervention biodiversity units = on site 918.51 + off-site 980.27 = 1,898.78
>
> Total net unit change = 1,898.78-1,674.44= 224.34
>
> Total net % change vs. on site baseline = 224.34/1244.45*100 = 18.03%
>
> Total net % change vs. total baseline = 224.34/ 1,674.44*100 = 13.40%

5.64 We note it is necessary for the net % change to be calculated versus the total baseline (on-site plus off-site baseline). In addition, any off-site habitat creation that requires planning permission would need to deliver an additional 10% net gain units in order to meet its own requirements under the biodiversity gain system.

Difficulty of creating or restoring a habitat

5.65 Paragraph 2.5.1 of the Biodiversity Net Gain Report[497] considers the difficulty of creating or restoring a habitat. We request confirmation that the recommended standard difficulty scores are used for each habitat type.

Evidence base for on-site habitat creation

5.66 We have concerns over the evidence base to support the likelihood of achieving the target on-site habitat conditions post construction, in particular the target 'lowland dry acid grassland' of 'fairly good' condition in most areas of the site.

5.67 Paragraphs 4.1.26 – 4.1.32 of the Biodiversity Net Gain Report[498] discuss creation of dry Sandlings grassland (DSG) on the construction site post construction.

5.68 Paragraph 4.1.27 notes uncertainty over the future nature of post-construction soils

> *Some flexibility is required for the creation and management of this area, since there is some uncertainty over the future nature of the post-construction soils*

and

> *The ultimate vision for the DSG (summer parched grassland) is that these develop over time into an acid grassland / heathland mosaics depending on the realities of soil pH and structure and water availability.*

---

[496] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[497] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[498] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

5.69 Paragraph 4.1.29 notes reversion of arable to acidic grassland at Aldhurst Farm can indicate future habitat creation outcomes specifically creation of 'fairly good' condition lowland dry acid grassland

> *It is considered to be achievable to target a 'Lowland dry acid grassland' sward in most areas of the site. Actions to revert arable habitat to an acidic grassland sward is already underway within Aldhurst Farm and the Studio Fields complex. These areas are off-site, but provide an indication of what can be achieved and can be learned from for future habitat creation interventions. A species-rich sward will be targeted, with wildflower cover around 30%. Positive management will target achievement of the condition assessment criteria. As such, a condition of 'fairly good' is predicted. This reflects the challenges of creating areas of such habitat and remains realistic, while targeting a positive outcome.*

5.70 We have concerns around using habitat creation from arable land at Aldhurst Farm and Studio Fields to predict creation of dry Sandlings grassland of fairly good condition on land impacted by construction.

5.71 Paragraph 5.3.28 of the Biodiversity Net Gain Report[499] discusses habitat creation in the marsh harrier compensation area and predicts creation of fairly good condition lowland dry acid grassland and fairly good condition lowland heathland from former arable land. It seems unlikely that a similar outcome will be achieved on post construction soils.

5.72 Sizewell B was constructed from 1988 to 1995[500]. Paragraphs 3.1.46 - 3.4.47 of the Biodiversity Net Gain Report[501] note the impact of Sizewell B construction

> *3.1.46 A large area of semi-improved neutral grassland is present to the east of the main platform. This area of land was impacted by construction processes associated with the Sizewell B construction works. As a result, the habitat does not have a typical dune grassland character, due to changes to the hydrology and pedology[502] caused by the construction works.*
>
> *3.1.47 The habitat to the east of the main platform is of semi-improved character, dominated by Cock's-foot and common herbs. Undesirable species and scrub are present across the area. As a result, this habitat is considered to be of moderate condition.*

5.73 This assessment concludes that land impacted by the construction of Sizewell B suffered changes in hydrology and pedology[503] and some 25 years later is semi-improved neutral grassland of moderate condition. It seems reasonable to conclude that land impacted by the 8-12 year Sizewell C construction period is likely to suffer changes that will affect the proposed habitat creation. It would be more precautionary to use habitat creation outcomes on the Sizewell B construction site as a predictor of future habitat condition on the Sizewell C construction site instead of using outcomes from habitat creation at Aldhurst Farm.

5.74 The predicted metric score is dependent on successfully creating target habitat conditions. We request evidence is provided to support the likelihood of delivering the predicted habitat conditions on land impacted by Sizewell C construction post development. We consider the target condition should take account of the difficulty of habitat creation on post construction soils.

500 Sizewell B power station

501 ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

502 Physical and chemical properties of soil

503 Physical and chemical properties of soil

Evidence base for off-site habitat creation

5.75 We also have concerns over the evidence base to support the likelihood of achieving the target off-site habitat conditions.

5.76 Paragraphs 5.3.9 - 5.3.10 of the Biodiversity Net Gain Report[504] discuss creation of acid grassland at Aldhurst Farm and notes challenges achieving the targeted level of diversity

> *it has been challenging to achieving the targeted level of diversity. As such, a precautionary approach is taken and it is assumed that the highest distinctiveness typology will not be achieved. The 'other lowland acid grassland' typology is therefore predicted. It is predicted that good condition can be achieved, through the positive management outlined in the Aldhurst Farm ELMP and due to a lower distinctiveness typology predicted.*

5.77 Paragraph 5.3.28 discusses habitat creation in the Marsh Harrier Habitat Mitigation Area and predicts creation of fairly good condition lowland dry acid grassland and fairly good condition lowland heathland from former arable land.

5.78 The predicted BNG is dependent on successfully creating the target habitat conditions. We request evidence is provided to support the likelihood of delivering the predicted off-site habitat conditions post development.

Use of 'fairly good' category

5.79 Table 13 of the Biodiversity Net Gain Report[505] notes dry Sandlings grassland of 'fairly good' condition provides 278.66 biodiversity units out of a total of 758.76 units for the on-site areas. The new metric due to be released in Summer 2021 will not include the 'fairly good' category and the condition will consequently need to be changed to moderate which will reduce the assessment for dry Sandlings grassland to 222.93 units.

5.80 Table 22 of the Biodiversity Net Gain Report[506] notes heathland and scrub, woodland forest and grassland of 'fairly good' condition provide 123.33 biodiversity units out of a total of 980.72 units for the off-site areas. The new metric due to be released in Summer 2021 will not include the 'fairly good' category and the condition will consequently need to be changed to moderate which will reduce the assessments for those habitats to 98.66 units.

Replacement of higher distinctiveness habitats with those of lower distinctiveness

5.81 The metric uses distinctiveness as a collective measure of biodiversity and includes parameters such as species richness, diversity, rarity and the degree to which a habitat supports species rarely found in other habitats.

5.82 Table 19 of the Biodiversity Net Gain Report[507] shows huge reductions in total biodiversity unit values of high distinctiveness habitat: sparsely vegetated coastal habitats (-94%) and woodland (-

---

[504] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[505] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[506] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

[507] ES Volume 2 Main Development Site Chapter 14 Terrestrial Ecology and Ornithology Appendix 14E Biodiversity Net Gain Report (REP1-004)

40%). The Defra Biodiversity Offsetting Pilots guidance [508] states at paragraph 22 that habitats of high distinctiveness would be expected to be offset with 'like for like'

> *22. One of the guiding principles for developing our approach to offsetting is that it should result in an improvement in the extent or condition of the ecological network. To do this the focus of habitat restoration or creation through offsetting should be on priority habitats. Where development is taking place on habitats in the low distinctiveness band, the offset actions should result in expansion or restoration of habitats in the medium or, preferably, high distinctiveness band. At no time should an offset result in "trading down", for instance in the replacement of habitat of high distinctiveness with creation or restoration of a habitat of medium distinctiveness. Habitats that are of high distinctiveness would generally be expected to be offset with "like for like" i.e. the compensation should involve the same habitat as was lost.*

5.83 It would be expected that habitats of high distinctiveness (such as sparsely vegetated coastal habitats and some woodland types) would not see an overall reduction in habitat unit value. In the calculations, the significant increase in grassland habitats is compensating for a loss in these habitats.

5.84 The Natural England Biodiversity Metric 2.0 user guide[509] at rule 3 (section 2.23) notes trading down must be avoided

> *'Trading down' must be avoided. Losses of habitat are to be compensated for on a 'like for like' or 'like for better' basis. Ideally, new or restored habitats should aim to achieve a higher distinctiveness or condition than habitats lost.*

5.85 And at rule 5 (section 2.23) notes it may be necessary to enhance or create a larger area of habitat than lost to fully compensate for impacts on biodiversity

> *It is not the area of habitat created that determines whether ecological equivalence or better has been achieved but the net change in biodiversity units. Risks associated with enhancing or creating habitats mean that it may be necessary to enhance or create a larger area of habitat than lost to fully compensate for impacts on biodiversity.*

5.86 BNG Good Practice Principles for Development[510] notes at section 11.4.1

> *Good practice is achieving net gains of the same or higher biodiversity value as those affected and equivalent or better levels of ecological functionality.*

5.87 More habitat creation is therefore required to fully compensate for impacts on biodiversity. If sparsely vegetated coastal habitats cannot be created on-site, then off-site enhancements would be expected. In addition to the reduction in overall biodiversity unit value of woodland, semi-natural broadleaved woodland is largely being offset by mixed woodland. It would be expected that habitats of high distinctiveness (such as semi-natural broadleaved woodland) are replaced like for like as expected in paragraph 22 of the Defra Biodiversity Offsetting Pilots guidance[511]

---

508 Defra (March 2012) Biodiversity Offsetting Pilots Technical Paper: the metric for the biodiversity offsetting pilot in England

509 Crosher, I. A, Gold, S. B., Heaver M.D., Heydon M.A., Moore L.D., Panks, S.A., Scott S.C., Stone D.A. and White N.A. (2019) The Biodiversity Metric 2.0: auditing and accounting for biodiversity value. User guide (Beta Version, July 2019). Natural England

510 Baker, J., Hoskin, R. and Butterworth, T. (2019) Biodiversity net gain. Good Practice Principles for Development. A practical guide.

511 Defra (March 2012) Biodiversity Offsetting Pilots Technical Paper: the metric for the biodiversity offsetting pilot in England

Habitats that are of high distinctiveness would generally be expected to be offset with "like for like" i.e. the compensation should involve the same habitat as was lost.

Hedgerows

5.88 Paragraph 2.2.7 of the Biodiversity Net Gain Report[512] notes hedgerows were grouped together for assessment and it is not clear if each hedgerow was surveyed for the condition assessment. We are therefore concerned hedgerows may have been undervalued and we request clarification of the evidence base for hedgerow condition assessment.

5.89 Although a hedgerow is a linear feature, it does occupy an area and we query whether there may be double counting of hedgerow and habitat areas. We request confirmation that the area of hedgerows has been removed from the area of adjacent habitat parcels.

5.90 The on-site hedgerow baseline biodiversity units reported in section 4.1.5 of the Biodiversity Net Gain Report[513] is different to the value in Table 14.

Areas excluded from the assessment

5.91 All habitat improvements funded through Sizewell B commitments should be excluded from the Sizewell C metric score calculation and we welcome the exclusion of the reversion to grassland at Retsom's Field (Sizewell B commitment) from the updated assessment (paragraph 2.10.6 of the Biodiversity Net Gain Report[514]).

5.92 We also welcome the exclusion of the Sizewell Estate Woodland Management Plan that defines the management of the existing woodlands within the site and the wider EDF Energy estate from the assessment. But Studio Fields Complex, included within the EDF Energy Estate Pre-Construction Integrated Land Management Plan, remains (Table 3.1 of the Biodiversity Net Gain Report[515]). Paragraph 3.4.1 of the oLEMP[516] helpfully explains

Management of these areas would be continued as defined by those existing plans and therefore management proposals for these areas are not considered further within this oLEMP.

5.93 As mentioned above the oLEMP[517] paragraph 4.1.7 notes

The Biodiversity Net Gain report …. demonstrates that net gain would be achieved if the habitats described within this oLEMP are delivered as proposed.

5.94 We therefore request clarification that the measures at Studio Fields Complex included in the metric calculation are additional to those in the existing management plan.

Comments on two village bypass

Baseline conditions and valuation

5.95 The baseline data date is not provided, and we assume it to be at the time of DCO submission i.e. 2020. We request confirmation of the baseline data date for the two village bypass.

5.96 Paragraph 2.11.1 of Biodiversity Net Gain Report Two Village Bypass[518] notes

> *Arcadis have used third party data as part of the assessments of the post development and off-site habitats and assumptions on the condition of the baseline habitats are inferred from existing data.*
>
> *No specific surveys or assessments were undertaken.*

5.97 We request evidence to support the baseline condition assessments. There should be sufficient surveys to ensure a demonstrable 10% increase in the metric score.

5.98 Paragraph 3.1.7 of Biodiversity Net Gain Report Two Village Bypass[519] considers the condition of semi-natural broad-leaved woodland to be lost and notes

> *The woodlands are all relatively young and comprised mainly native species such as Beech (Fagus sylvatica), Hazel (Corylus avellana) and Field Maple (Acer campestre). Locally a well-developed ground-layer with species such as Dog's Mercury (Mercurialis perennis) and Bluebell (Hyacinthoides non-scripta). The age structure is not diverse enough to classify the woods as good condition, but the precautionary method was used and fairly good condition was selected.*

5.99 Field maple, dog's mercury and bluebell are recognised as ancient woodland indicator plants in the east of England[520]. Their presence on site does suggest the semi-natural broadleaved woodland is of value and a precautionary approach would be to select good condition for habitat to be lost.

Habitat creation

5.100 The predicted metric score is dependent on achieving the target habitat conditions. Paragraph 3.2.23 onwards of Biodiversity Net Gain Report Two Village Bypass[521] note proposed broadleaved woodland, neutral grassland, lowland acid grassland, infiltration basins and ponds will achieve good condition. We request evidence is provided to support the likelihood of delivering the predicted habitat conditions.

5.101 If is important to note that the time to target condition is 15 years for the grassland habitats and 32+ years for woodland. In addition we have concerns over long-term management to achieve these target conditions. The Two Village Bypass Outline Landscape and Ecology Management Plan[522] notes at paragraph 1.1.6

---

518 9.6 Biodiversity Net Gain Report - Two Village Bypass (REP1-018)
519 9.6 Biodiversity Net Gain Report - Two Village Bypass (REP1-018)
520 Table of Ancient Woodland Indicator Plants in Rose, F. (2006) The Wild Flower Key. Warne
521 9.6 Biodiversity Net Gain Report - Two Village Bypass (REP1-018)
522 Associated Development Design Principles: Appendix A: Two Village Bypass Outline Landscape and Ecology Management Plan (AS-263)

The oLEMP and subsequent LEMP would be managed by SZC Co. for a total of five years, or until adoption by the Highways Authority. It is expected that the LEMP would contain long term management objectives for the proposed development.

5.102 We are concerned that Schedule 2 of the Draft DCO[523] does not include a specific requirement for long-term management of the habitats required for securing a 10% metric score in accordance with planning policy.

5.103 We also query whether there may be opportunities for net gain habitat enhancements to provide habitat for protected species of bats and birds. The appendices are missing from the report. We will review and comment on the baseline Phase 1 map and operational masterplans when they are submitted to the Examination. We hope the Application will include an innovatively designed green bridge linking Foxburrow Wood County Wildlife Site with the woodland to the west.

Comments on Sizewell Link Road

Baseline conditions and valuation

5.104 The baseline data date is not provided, and we assume it to be at the time of DCO submission i.e. 2020. We request confirmation of the baseline date for the Sizewell Link Road.

5.105 Paragraph 2.10.1 of Biodiversity Net Gain Report Sizewell Link Road[524] notes

Arcadis have used third party data as part of the assessments of the post development and off-site habitats and assumptions on the condition of the baseline habitats are inferred from existing data.

No specific surveys or assessments were undertaken.

5.106 We request evidence to support the baseline condition assessments. There should be sufficient surveys to ensure a demonstrable 10% increase in the metric score.

5.107 Table 8 of Biodiversity Net Gain Report Sizewell Link Road[525] describes minor changes were made to the site boundary since the previous Biodiversity Net Gain report. Many of the post development habitat descriptions use the phrase 'appear to be'. We request clarification of the post development habitats.

Habitat creation

5.108 The predicted metric score is dependent on achieving the target habitat conditions. Paragraph 3.2.22 onwards of Biodiversity Net Gain Report Sizewell Link Road[526] note proposed broadleaved woodland, neutral grassland, infiltration basins and ponds will achieve good condition. We request evidence is provided to support the likelihood of delivering the predicted habitat conditions. The time to target condition is 15 years for the grassland habitats and 32+ years for woodland and we also have concerns over long-term management to achieve the target conditions.

---

523 Draft Development Consent Order (Draft DCO) (AS-143)
524 9.5 Biodiversity Net Gain Report - Sizewell Link Road (REP-017)
525 9.5 Biodiversity Net Gain Report - Sizewell Link Road (REP-017)
526 9.5 Biodiversity Net Gain Report - Sizewell Link Road (REP-017)

5.109 We are concerned that Schedule 2 of the Draft DCO[527] does not include a specific requirement for long-term management of the habitats and securing a 10% net gain score in accordance with planning policy.

5.110 The appendices are missing from the report. We will review and comment on the baseline Phase 1 map and operational masterplans when they are submitted to the Examination.

Conclusions

5.111 In conclusion, based on our above concerns and the information available at present, we do not agree the Application can achieve net gain due to direct adverse impact on Sizewell Marshes SSSI from loss of a significant proportion of the SSSI, nor the amount claimed by the Applicant.

5.112 Despite this, we agree the Application should be meeting the requirements of the net gain system and should be providing landscape scale net gain proportionate to the scale of the project in line with planning policy. As such, the Application should be demonstrating a high metric score that does not rely on protected species mitigation and/or compensation habitat to get over the 10% uplift requirement.

5.113 Our key concerns relating to methodology and approach to the metric calculations include:

- use of measures that are for protected sites and species mitigation and compensation
- the baseline policy is directly at odds with the biodiversity gain system to be introduced by the Environment Bill
- the time for habitats to reach target condition does not take account of the construction phase
- the replacement of higher biodiversity habitats with those of lower biodiversity
- lack of evidence to support the likelihood of delivering the predicted habitat conditions
- the biodiversity value of existing habitats has not been adequately considered and taken account of
- heavy use of 'fairly good' category
- the % net change in the metric score is calculated versus the on-site baseline but it should be calculated versus the total on-site plus off-site baseline

5.114 We consider the key finding from the Applicant's BNG proposals to be at best only just over the 10% boundary by a narrow margin, and that if any one of several marginal decisions were reversed it would fall below it. We therefore conclude the Applicant will fail to meet the claimed BNG.

6. LAND AND SOCIO-ECONOMIC CONCERNS

Land

6.1 The RSPB owns land immediately adjoining the development site. The RSPB has been in discussions on the precise alignment of this boundary which is physically different to the existing fence lines on the ground. Whilst there is no specific dispute on the legal boundary, we are unclear how any new boundary will appear physically and as such how that will impact on our boundary. We are not clear on how for example the Sandlings Footpath (permissive) will be re-routed. The RSPB reserves its position on the precise boundary until these plans are made clear.

6.2 The RSPB manages RSPB Minsmere both as a nature reserve and as agricultural holding with livestock. With a development of this scale, we are concerned about the impact on the

[527] Draft Development Consent Order (Draft DCO) (AS-143)

management of our holding, whether that be through disturbance from noise, light, dust or air pollution.

6.3 We have previously worked with the Applicant to allow access to the RSPB Minsmere to carry out monitoring for the purpose of informing the Application, but we are concerned that there is no provision for monitoring for matters such as recreational displacement, coastal processes, hydrological monitoring or other ecological data currently to enable the Applicant to review assessments done and to check whether the proposed development has further, unpredicted, impacts.

Resilience Fund and Other Proposed Section 106 Funds

6.4 The RSPB is grateful to the Applicant for its proposals for a Resilience Fund for the RSPB (and others). As we understand it, this fund will be to off-set perceived impacts and risks caused by the proposed development. We have to date had outline discussions with the Applicant but the further detailed required are yet to be worked up.

6.5 We would seek to ensure that the Resilience Fund is available for the full period of the construction programme. But also are keen understand more about how precisely the Resilience Fund would practically operate.

6.6 As mentioned above the RSPB does considers that the proposed development will have impacts on visitors to RSPB Minsmere and indeed the wider area and whilst a Resilience Fund is welcome, we believe there is little evidence in the Application documents as to any acknowledgement as to how any consequential loss will be addressed.

6.7 Again as mentioned above we would also like to see additional survey work undertaken throughout the construction period on visitors both directly at RSPB Minsmere and across the wider area and to ensure the impacts of the development can monitored.

6.8 Due to its location, the proposed development will have a significant visual impact on visitor experience and the views available, with increases in noise and light pollution havin an effect on the tranquillity and character of the landscape which makes RSPB Minsmere such a special place for our visitors. We do not agree with the Applicant's position that, impacts on the landscape and visual effects are only localised, across the AONB.

6.9 For example in the Landscape and Visual Impact Assessment, the Applicant does recognises this impact but state it would localised across the AONB and the effects are not significant. The RSPB disagrees with this conclusion. The RSPB has invested heavily in its business and the visual and other impacts on visitor experience are likely to have an impact on its business. Currently we do not believe the Resilence Fund is designed to address these impacts.

6.10 Additionally, there is a concern that by agreeing to accept funding as part of a Resilience Fund that this would prevent us from being about to access other appropriate funds for mitigation for other issues measures that may be required for ongoing monitoring. It may also preclude us from being able to work in partnership with others to deliver mitigation beyond our site boundary.

6.11 We are continuing our discussions with the Applicant on these issues and concerns and will update the Examining Authority during the course of the Examination.

Second Leiston Abbey Farm Site

6.12 The RSPB is also grateful for provisions being made towards the Second Leiston Abbey Farm Site Enhancement Scheme (as referred in the draft Section 106, Schedule 8). The RSPB has not been

part of any detailed discussions surrounding this enhancement Scheme and as landowner and due to its statutory duty to maintain the Scheduled Ancient Monument we would welcome discussions on how the Scheme will operate and what enhancement measures may be possible within it. as far as we are aware these details and proposals are not currently before the Examination.

7. CONCLUSIONS

7.1 In conclusion, based on the above concerns, we do not agree that *adverse effects on integrity* can be excluded for the following sites and species for impacts from the Application alone:

- Breeding gadwall, shoveler, teal, marsh harrier, nightjar, avocet, bittern and little tern and non-breeding white-fronted goose, gadwall, shoveler and hen harrier of the Minsmere-Walberswick SPA
- Non-breeding red-throated divers of the Outer Thames Estuary SPA
- Breeding Sandwich terns of the Alde-Ore Estuary SPA
- Perennial vegetation of stony banks and European dry heaths of the Minsmere-Walberswick Heaths & Marshes SAC
- The Ramsar site - specifically criterion 1 - mosaic of marine, freshwater, marshland and associated habitats, complete with transition areas in between, criterion 2 nine nationally scarce plants and at least 26 red data book invertebrates, and the important assemblage of rare breeding birds associated with marshland and reedbeds

7.2 In relation to the Application in combination with other plans and projects, we do not agree that *adverse effects on integrity* can be excluded for the following sites and species:

- Breeding gadwall and shoveler, nightjar and little tern and non-breeding white-fronted goose, gadwall, shoveler, hen harrier of the Minsmere-Walberswick SPA
- Non-breeding red-throated divers of the Outer Thames Estuary SPA
- Breeding woodlark and nightjar of the Sandlings SPA
- Perennial vegetation of stony banks and European dry heaths of the Minsmere-Walberswick Heaths & Marshes SAC
- The Ramsar site - specifically criterion 1 - mosaic of marine, freshwater, marshland and associated habitats, complete with transition areas in between, criterion 2 nine nationally scarce plants and at least 26 red data book invertebrates, and the important assemblage of rare breeding birds associated with marshland and reedbeds

7.3 We also consider that significant impacts from the Application alone are likely on the following sites:

- Minsmere-Walberswick Heaths and Marshes SSSI
- Sizewell Marshes SSSI

7.4 We also consider that significant impacts from the Application alone are likely on the following species:

- Bats, in particular barbastelle, Natterer's
- Natterjack toad
- stone curlew
- Dartford warbler

7.5 We will continue to work with the Applicant on these concerns and provide comments on further information submitted to the Examination for example further details on the required management mitigation, compensation and monitoring plans and schemes as well as the details of the various funds mentioned above. We will update the Examining Authority of our position in light of any new information presented

7.6 However for now (as also covered in other section of these written representations) we have serious concerns about the adequately of information currently available and strongly recommend that without those details including the lack of clarity on the required legal, financial and ecological securing of requirements, measures, plans and schemes – confidence in them is premature.

8. THE LOVE MINSMERE CAMPAIGN

What is the Love Minsmere campaign?

8.1 RSPB Minsmere nature reserve is not only incredibly important to the 6000 types of birds, animals, plants, and fungi that call it home, but also the people that visit in huge numbers[528] every year to enjoy this special place.

8.2 In 2019, the RSPB was increasingly concerned about the potentially damaging impacts of the Application on RSPB Minsmere and the wildlife that lives there. The RSPB decided to create a public campaign that would allow its supporters to show that they Love Minsmere and that they want to see this incredible home for wildlife protected.

8.3 In 2020 Suffolk Wildlife Trust joined forces with the RSPB in the Love Minsmere campaign, which now campaigns to see both RSPB Minsmere nature reserve, the protected and designated sites including Sizewell Marshes SSSI (which Suffolk Wildlife Trust manage), and the surrounding wildlife that calls the Suffolk coast home, protected against potentially harmful impacts from the Application.

8.4 To date the Love Minsmere campaign has comprised of three different actions as explained in the following sections.

Stage 3 Public Consultation

8.5 During the Stage 3 public consultation in 2019, the RSPB asked supporters to submit consultation responses to the Applicant telling them why they Love Minsmere and why it must be protected. In these responses they also called on the Applicant to publicly pledge to protect RSPB Minsmere and the wildlife that calls it home.

8.6 Over the course of the consultation, 20,419 supporters submitted consultation responses to the Applicant on the importance of RSPB Minsmere and why it must be protected.

The Love Minsmere Festival

8.7 Later in 2019, on the 15 September, during the Application's fourth and final consultation, the RSPB held their first ever Love Minsmere Festival. The Love Minsmere Festival was a day to celebrate how special RSPB Minsmere is for people and wildlife. It was also an opportunity to show the Applicant once again how many people Love Minsmere and wish to see it protected.

[528] From our regular monitoring of visitor numbers we know that we have had up to 123,966 visitors per year, with an average number of visitors in the past 5 non-covid years of 110,649 visitors per year.

8.8 Over 1000 people gathered on Whin Hill, the site of the BBC Springwatch studio[529]2, and one of the reserve's most amazing viewpoints, and together they collectively declared their love for Minsmere. Supporters formed the outline of the Love Minsmere love heart logo, with Sizewell in the background, sending a visual message to the Applicant that the reserve must be protected.

Figure 2. An image of over 1000 people forming a human Love Minsmere love heart at RSPB Minsmere nature reserve as part of the Love Minsmere Festival, 15 September 2019.

Pre-examination e-action

8.9 Ahead of the formal start of the Examination, the RSPB and Suffolk Wildlife Trust came together to launch the next leg of the ongoing Love Minsmere campaign[530].

8.10 Between the 27 November 2020 and the 15 February 2021, both organisations ran a Love Minsmere e-action[531]. We called on supporters who shared our summary of concerns[532] (based on our Relevant Representations[533]) regarding the Application's potential negative impacts on

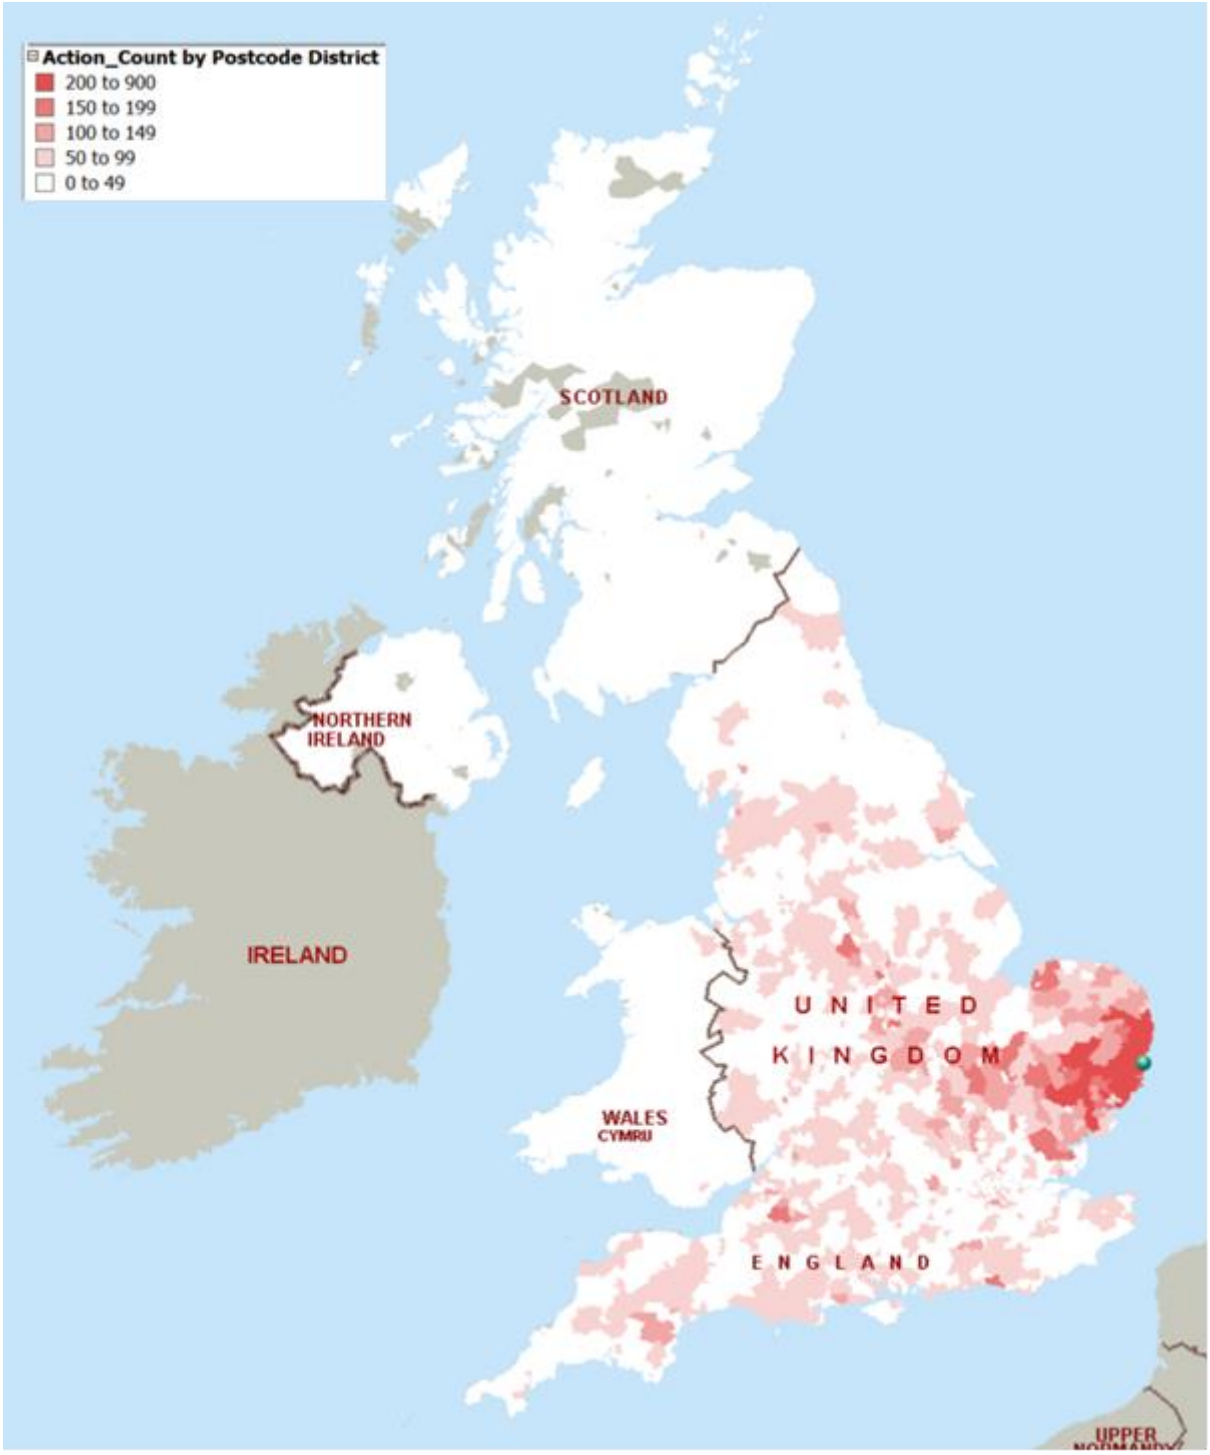
[529] BBC Springwatch was based at RSPB Minsmere nature reserve in 2014, 2015 and 2016
[530] For our latest campaign news see

[531] The Love Minsmere e-action was hosted online a website. It enabled people to add their name and address if they shared our summary of concerns (based on our Relevant Representations) regarding the Application's potential negative impacts on nature, thereby signing our e-action

[532] The RSPB and Suffolk Wildlife Trust's shared summary of concerns can be found here: https://www.rspb.org.uk/globalassets/downloads/sizewell/swt-and-rspb-shared-concerns-for-sizewell-c.pdf
[533] https://www.rspb.org.uk/globalassets/images/campaigning-and-positions/love-minsmere/rspb-relevant-representations-sizewell-c.pdf

nature, to sign our e-action and demonstrate how many people want to see RSPB Minsmere nature reserve, the protected and designated sites including Sizewell Marshes SSSI as well as the surrounding wildlife of the Suffolk coast protected.

8.11 In just 12 weeks, 104,836 people took our e-action and said they share our concerns over the Application's potential harmful impacts on nature. We told these 104,836 people that we would represent their concerns in the examination by including reference to the e-action and the number of people that shared our concerns in our Written Representations.



8.12 The number of people signing the Love Minsmere e-action has eclipsed the number of signatures and responses to all previous Sizewell C consultations and campaigns. It may also cast doubt over claimed support for Sizewell C.

8.13 The majority of our supporters who signed the Love Minsmere e-action were located on the Suffolk coast demonstrating the concern amongst local people for their local wildlife, but we saw supporters sign the e-action across the UK showing how many people Love Minsmere across the country and are concerned about the harmful impacts the Application could have on the birds, animals, plants and the ecosystems they call home.

8.14 Locally, in the Suffolk Coastal constituency[534], home to both RSPB Minsmere nature reserve, Sizewell Marshes SSSI and the Application site, 3,436 people signed the e-action – the highest number across all of the constituencies. Across the county of Suffolk this number grew with over 10,000 people sharing our concerns. However, the location of some of the people that signed the e-action is unknown so these figures could be higher.

[534] We were able to break down the location of our signatories by both parliamentary constituency and postcode district

Figure 2. A heat map showing by volume the distribution of the Love Minsmere actions (between 27 November 2020 – 15 February 2021) by Postcode District:

8.15 Support for the Love Minsmere campaign is national, not just local, and we have also seen public support from a whole host of celebrities including Chris Packham, Anthony Horowitz, Julia Bradbury, Alison Steadman, Samuel West, Deborah Meaden, Bill Turnbull, Michaela Strachan, Mike Dilger, Megan McCubbin Iolo Williams, Emma Kennedy, Miranda Krestovinkoff, Dr Amir Khan and more.

8.16 We believe that the 104,836 people signing our most recent Love Minsmere e-action, and the support for our previous campaign actions, shows just how special RSPB Minsmere, Sizewell

Marshes SSSI and the Suffolk coast is for both people, and wildlife. We also believe it shows the breadth and strength of concern regarding the Application and potential impacts on nature.

RSPB Registration Identification Ref: 20026628
Suffolk Wildlife Trust Registration Identification Ref: 20026359

1.1 Greater white-fronted goose (*Anser albifrons albifrons*)

Key Information: The white-fronted goose is a grey goose, bigger than a mallard and smaller than a mute swan. Adults have a large white patch at the front of the head around the beak and bold black bars on the belly. The legs are orange and Siberian birds have pink bills, while Greenland birds have orange bills. This species does not breed in the UK. Two subspecies visit the UK in winter - birds which breed in Greenland (*Anser albifrons flavirostris*) and birds which breed in Siberia (*Anser albifrons albifrons*); in the East of England the Siberian subspecies occurs. The current wintering areas need protection, including avoiding drainage of traditional wintering areas in southern England.

What they eat: Grass, clover, grain, winter wheat and potatoes.

UK conservation status[1]: Red

UK Wintering (Individual): 2,100[2]

Importance level: 0.18-0.21% of the biogeographic population (NW Siberia & NE/NE Europe) winters in UK

1.2 Shoveler (*Spatula clypeata*)

Key Information: Shovelers are surface feeing ducks with huge spatulate bills. Males have dark green heads, with white breasts and chestnut flanks. Females are mottled brown. In flight birds show patches of light blue and green on their wings. In the UK they breed in southern and eastern England, especially around the Ouse Washes, the Humber and the North Kent Marshes and in much smaller numbers in Scotland and western parts of England. In winter, breeding birds move south, and are replaced by an influx of continental birds from further north. The UK is home to more than 20 per cent of the NW European population.

What they eat: Small insects and plant matter sifted from the water.

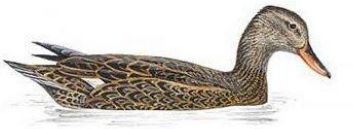
UK conservation status[3]: Amber

UK Wintering (Individual): 19,500[4] **UK Breeding (Pairs):** 1,100[5]

Importance level: 30% of the biogeographic population (NW and Central Europe) winters in UK
3.38% of the biogeographic population breeds in UK

---

1 Eaton, M., Aebischer, N., Brown, A., Hearn, R., Lock, L., Musgrove, A., Noble, D., Stroud, D. & Gregory, R. (2015) Birds of Conservation Concern 4: the population status of birds in the UK, Channel Islands and Isle of Man (App XX, Tab XX)



2 Woodward, I., Aebischer, N., Burnell, D., Eaton, M., Frost, T., Hall, C., Stroud, D.A. & Noble, D. (2020). Population estimates of birds in Great Britain and the United Kingdom. Summary. Full Report: British Birds 113: 69–104 (App XX, Tab XX)

3 Eaton et al (2015). See footnote 1

4 Woodward et al (2020). See footnote 2

5 Woodward et al (2020). See footnote 2

1.3 Gadwall (*Mareca strepera*)

Key Information: The gadwall is a very grey-coloured dabbling duck, a little smaller than the mallard, and with an obvious black rear end. It shows a white wing patch in flight. When seen close up the grey colour is made up of exquisitely fine barring and speckling. It nests in low numbers in the UK.

What they eat: Stems, leaves and seeds.

UK conservation status[6]: Amber

UK Wintering (Individual): 31,000[7] **UK Breeding (Pairs):** (1,250-3,200)[+8]

Importance level: 26% of biogeographic population (NW Europe) winters in UK
1.8 – 5.7% of the biogeographic population breeds in UK

1.4 Teal (*Anas crecca*)

Key Information: Teals are small dabbling ducks. Males have chestnut coloured heads with broad green eye-patches, a spotted chest, grey flanks and a black edged yellow tail. Females are mottled brown. Both show bright green wing patches (speculum) in flight. They are thinly distributed as a breeding species with a preference for northern moors and mires.

In winter, birds congregate in low-lying wetlands in the south and west of the UK. Of these, many are continental birds from around the Baltic and Siberia. At this time, the UK is home to a significant percentage of the NW European wintering population.

What they eat: Seeds and small invertebrates.

UK conservation status[9]: Amber

UK Wintering (Individual): 435,000[10] **UK Breeding (Pairs):** (2,700-4,750)[11]

Importance level: 87% of biogeographic population (NW Europe) winters in UK
1.0 – 1.9% of the biogeographic population breeds in UK

7 Woodward et al (2020). See footnote 2
8 Woodward et al (2020). See footnote 2
9 Eaton et al (2015). See footnote 1
10 Woodward et al (2020). See footnote 2
11 Woodward et al (2020). See footnote 2

1.5 Nightjar (*Caprimulgus europaeus*)

Key Information: Nightjars are nocturnal birds and can be seen hawking for food at dusk and dawn. With pointed wings and a long tails their shape is similar to a kestrel or cuckoo. Their cryptic, grey-brown, mottled, streaked and barred plumage provides ideal camouflage in the daytime. They have an almost supernatural reputation with their silent flight and their mythical ability to steal milk from goats. The first indication that a nightjar is near is usually the male's churring song, rising and falling with a ventriloquial quality.

What they eat: Insects - moths and beetles.

UK conservation status[12]: Amber

UK Breeding (Males): 4,600 (3,700-5,500)[13]

Importance level: 0.3 – 0.9% of the international population breeds in UK

1.6 Stone-curlew (*Burhinus oedicnemus*)

Key Information: A strange, rare summer visitor to southern England and East Anglia, the stone-curlew is a crow-sized bird with a large head, long yellow legs and relatively long wings and tail. Active at night, its large yellow eyes enable it to locate food when it is dark. It is not related to curlews and gets its name from its curlew-like call. It is listed under Schedule 1 of the Wildlife and Countryside Act.

What they eat: Invertebrates that are found on the ground.

UK conservation status[14]: Amber

UK Breeding (Pairs): 365^{+15}

Importance level: 0.12 - 0.2% of the international population breeds in UK

[12] Eaton et al (2015). See footnote 1
[13] Woodward et al (2020). See footnote 2
[14] Eaton et al (2015). See footnote 1
[15] Woodward et al (2020). See footnote 2

1.7 Avocet (*Recurvirostra avosetta*)

Key Information: The avocet is a distinctively-patterned black and white wader with a long up-curved beak. This Schedule 1 species is the emblem of the RSPB and symbolises the bird protection movement in the UK more than any other species. Its return in the 1940s and subsequent increase in numbers represents one of the most successful conservation and protection projects.

What they eat: Aquatic insects and their larvae, crustaceans and worms.

UK conservation status[16]: Amber

UK Wintering (Individual): 8,700[17] **UK Breeding (Pairs):** 1,950[18]

Importance level: 1.85 - 3.12% of biogeographic population winters in UK
0.83 – 1.39% of the international population breeds in UK

1.8 Sandwich tern (*Sterna sandvicensis*)

Key Information: The Sandwich tern is a very white tern, with a black cap on its head, a long black bill with a yellow tip and short black legs. In flight it shows grey wedges on its wings tips and it has a short forked tail. In the UK, many of the important colonies survive because they are on nature reserves.

What they eat: Fish such as sandeels, sprats and whiting.

UK conservation status[19]: Amber

UK Breeding (Pairs): 14,000 (13,000-15,000)[20]

Importance level: 14.0 – 18.8% of the biogeographic population (W Europe/W Africa) breeds in the UK

[16] Eaton et al (2015). See footnote 1
[17] Woodward et al (2020). See footnote 2
[18] Woodward et al (2020). See footnote 2
[19] Eaton et al (2015). See footnote 1
[20] Woodward et al (2020). See footnote 2

1.9 Little tern (*Sternula albifrons*)

Key Information: This delightful chattering seabird is the UK's smallest tern. It is short-tailed and has a fast flight. Its bill is a distinctive yellow with a black tip. It is noisy at its breeding colony where courtship starts with an aerial display involving the male calling and carrying a fish to attract a mate, which chases him up high before he descends, gliding with wings in a 'V'. It is listed as a Schedule 1 species in The Wildlife and Countryside Act.

What they eat: Fish.

UK conservation status[21]: Amber

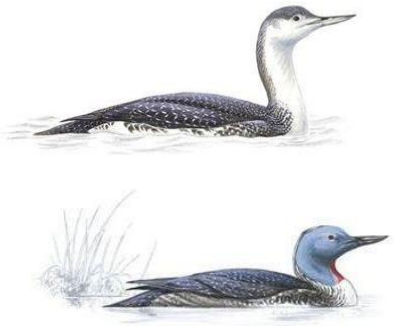
UK Breeding (Pairs): 1,450[22]

Importance level: 11.6 – 15.3% of the biogeographic population (Europe north of Mediterranean) breeds in the UK

1.10 Common tern (*Sterna hirundo*)

Key Information: These delightful silvery-grey and white birds have long tails which have earned them the nickname 'sea-swallow'. They have a buoyant, graceful flight and frequently hover over water before plunging down for a fish. They are often noisy in company and breed in colonies. The common tern is the tern species most likely to be found inland.

What they eat: Fish.



UK conservation status[23]: Amber

UK Breeding (Pairs): 11,000 (8,900-13,500)[24]

Importance level: 8.1 – 15.9% of the biogeographic population (S & W Europe) breeds in the UK

[21] Eaton et al (2015). See footnote 1
[22] Woodward et al (2020). See footnote 2
[23] Eaton et al (2015). See footnote 1
[24] Woodward et al (2020). See footnote 2

1.11 Red-throated diver (*Gavia stellata*)

Key Information: The smallest of the UK's divers, its grey-brown plumage and up-tilted bill readily distinguish it from the other species. In summer it has a distinctive red throat. They usually jump up to dive and can stay underwater for a minute and a half. They are very ungainly on land, only coming ashore to breed. They are listed as a Schedule 1 species under The Wildlife and Countryside Act.

What they eat: Fish.

UK conservation status[25]: Green

UK Wintering (Individual): 21,500[26] **UK Breeding (Pairs):** 1,250 (1,000-1,550)[27]

Importance level: 7.2% of biogeographic population (NW Europe) winters in UK
0.5 - 1.4% of the biogeographic population breeds in UK

1.12 Bittern (*Botaurus stellaris*)

Key Information: The bittern is a thickset heron with all-over bright, pale, buffy-brown plumage covered with dark streaks and bars. It flies on broad, rounded, bowed wings. A secretive bird, very difficult to see, as it moves silently through reeds at water's edge, looking for fish. The males make a remarkable far-carrying, booming sound in spring. It's very small, reedbed-dependent population make it an Amber List species. It is also a Schedule 1 species in the Wildlife and Countryside Act.

What they eat: Fish, amphibians and insects.

UK conservation status[28]: Amber

UK Wintering (Individual): 795[29] **UK Breeding (Males):** 191[+30]

Importance level: 2.1% of the international population breeds in UK
8.7% of the international population winters in UK

[25] Eaton et al (2015). See footnote 1
[26] Woodward et al (2020). See footnote 2
[27] Woodward et al (2020). See footnote 2
[28] Eaton et al (2015). See footnote 1
[29] Woodward et al (2020). See footnote 2
[30] Woodward et al (2020). See footnote 2

1.13 Marsh harrier (*Circus aeruginosus*)

Key Information: The largest of the harriers, the marsh harrier can be recognised by its long tail and light flight with wings held in a shallow 'V'. It is distinguishable from other harriers by its larger size, heavier build, broader wings and absence of white on the rump. Females are larger than males and have obvious creamy heads. Marsh harriers are a Schedule 1 listed bird on The Wildlife and Countryside Act.

What they eat: Small birds and mammals.

UK conservation status[31]: Amber

UK Breeding (Pairs): (590-695)[32]

Importance level: 0.3 – 0.7% of the international population breeds in UK

1.14 Hen harrier (Circus cyaneus)

Key Information: Of the UK's birds of prey, this is the most intensively persecuted. Once predating free-range fowl, earning its present name, its effect on the number of grouse available to shoot is the cause of modern conflict and threatens its survival in some parts of the UK, particularly on the driven grouse moors of England and Scotland.

While males are a pale grey colour, females and immatures are brown with a white rump and a long, barred tail which give them the name 'ringtail'. They fly with wings held in a shallow 'V', gliding low in search of food, which mainly consists of meadow pipits and voles. The Orkney population is famous for being polygynous, with males sometimes mating with multiple females on the island. They are listed as a Schedule 1 species under The Wildlife and Countryside Act.

What they eat: Small birds and mammals.

UK conservation status[33]: Red

UK Breeding (Pairs): 545[34]

Importance level: 1.0 – 1.8% of international population breeds in UK

---

[31] Eaton et al (2015). See footnote 1
[32] Woodward et al (2020). See footnote 2
[33] Eaton et al (2015). See footnote 1
[34] Woodward et al (2020). See footnote 2

1.15 Bearded tit (*Panurus biarmicus*)

Key Information: The bearded tit is a Schedule 1 species in the Wildlife and Countryside Act. They are brown, long-tailed birds, usually seen flying rapidly across the top of a reedbed. Males have black 'moustaches' rather than 'beards'. They are sociable and noisy, their 'ping' calls often being the first clue to their presence.

What they eat Insects, insect larvae, spiders and seeds.

UK conservation status[35]: Green

UK Breeding (Pairs): 695[36]

Importance level: 0.2 – 0.3% of the European population breeds in the UK

1.16 Woodlark (*Lullula arborea*)

Key Information: The woodlark is a streaky brown bird, with a buffy-white eye-stripe which meets across the nape. It has a well-developed crest on its crown which is not always conspicuous. In flight the peculiarly short tail and broad, rounded wings are noticeable and the deeply undulating flight with closed wing glides is characteristic. Some UK breeding birds spend the winter on the continent. Woodlarks are listed under Schedule 1 of The Wildlife and Countryside Act.

What they eat Seeds and insects.

UK conservation status[37]: Green

UK Breeding (Pairs): 2,300 (1,850-2,750)[38]

Importance level: 0.05 – 0.1% of the European population breeds in the UK

[35] Eaton et al (2015). See footnote 1
[36] Woodward et al (2020). See footnote 2
[37] Eaton et al (2015). See footnote 1
[38] Woodward et al (2020). See footnote 2

1.17 Dartford warbler (*Sylvia undata*)

Key Information: This small, dark, long-tailed warbler is resident in the UK and has suffered in the past from severe winters. The Dartford warbler's population crashed to a few pairs in the 1960s, since when it has gradually recovered, increasing in both numbers and range. It will perch on top of a gorse stem to sing, but is often seen as a small flying shape bobbing between bushes.

What they eat Insects and other invertebrates.

UK conservation status[39]: Amber

UK Breeding (Pairs): 2,200[40]

Importance level: 0.2 – 0.4% of the international population breeds in the UK

Summary

This report has been commissioned by the National Trust and the RSPB in light of concerns regarding proposals for Sizewell C Power Station and potential nature conservation impacts from recreation use. The area around Sizewell is of outstanding importance for nature conservation and contains a mix of habitats and species that are unique in the UK. The area is also popular for recreation, which includes tourists, day visitors, and local residents. There is a difficult balancing act to ensure access and conservation do not conflict in a relatively small area.

The Sizewell C proposal would result in changes in recreation use as it would involve a large construction workforce that would be living and working in the area. In addition, construction work would displace existing recreation use (for example through footpath diversions, noise, traffic, etc). We review the impacts of recreation on the nature conservation interest of relevant sites, focussing on the European sites (i.e. those that are subject to particularly strict protection) and their qualifying features.

We highlight a wide range of vulnerable features and risks to their conservation interest resulting from recreation use. Likely significant effects are clear for a range of sites and interest features and, in particular, we highlight:

- Annual vegetation of drift lines (Minsmere to Walberswick Heaths & Marshes SAC), risks from damage and contamination;
- Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC), risks from damage and contamination;
- European dry heaths (Minsmere to Walberswick Heaths & Marshes SAC), risks from fire and contamination;
- Wintering waterbirds, including White-fronted Goose (Minsmere to Walberswick SPA), risks from disturbance;
- Breeding birds, including Nightjar, Avocet, and Little Tern (Minsmere to Walberswick SPA), risks from disturbance;
- Breeding Nightjar (Minsmere to Walberswick SPA), risks from fire, and;
- Breeding Woodlark and Nightjar (Sandlings SPA), risks from disturbance and fire.

People coming to the area to live and work in the vicinity will seek nearby greenspace for recreational use that is not necessarily related or connected to the area's conservation interest, and such use will include exercise and dog walking. It may extend to sea angling, barbeques, swimming, and beach recreation. Such use is likely to be away from areas perceived as 'nature reserves' (i.e. where there are hides, wardens, and a fee to enter) and instead focus their use at more peripheral locations. These are often still part of the European site and do not have necessary infrastructure to manage access. We would expect

construction workers based in the area to utilise more informal parking and locations where they can easily access beaches, quiet areas of heath, etc. Use by construction workers is also likely to take place in the early mornings, evenings, and around shift work and therefore not necessarily fit with peak visitor use and the current visitor profile.

We provide an overview of the mitigation that is likely to be necessary, highlighting that a package of measures will be required, and this will need to include monitoring to help pick up emerging issues.

Acknowledgements

This report has been commissioned by the National Trust to provide background and help inform responses by the National Trust and the RSPB to the proposals for a new Sizewell C Power Station. Our thanks to Emma Hay (National Trust) for commissioning the work and in addition to Jacqui Miller (RSPB) and Adam Rowlands (RSPB) for useful discussion and context.

1. Introduction

Overview

1.1 The RSPB and National Trust are concerned about the potential for displacement of recreational users from the vicinity of the Sizewell C development (SZC) to neighbouring designated sites during the construction period.

1.2 Risks from recreation potentially relate to:

- Use of nearby sites for recreation by construction workers, including those potentially housed in purpose-built accommodation at Eastbridge, and;
- Displacement of visitors who would otherwise have gone to Sizewell, to access the beach and coastline around the power station and have been displaced due to the traffic, construction work and changes to access.

1.3 Displacement of visitors from Sizewell is likely to primarily relate to those using the large public car-park just to the south of Sizewell A, who might be expected to shift to other locations. There may also be some displacement in visitor routes around the general area, for example visitors at Dunwich and Minsmere may be deterred from walking as far south as they might have done otherwise due to the construction work.

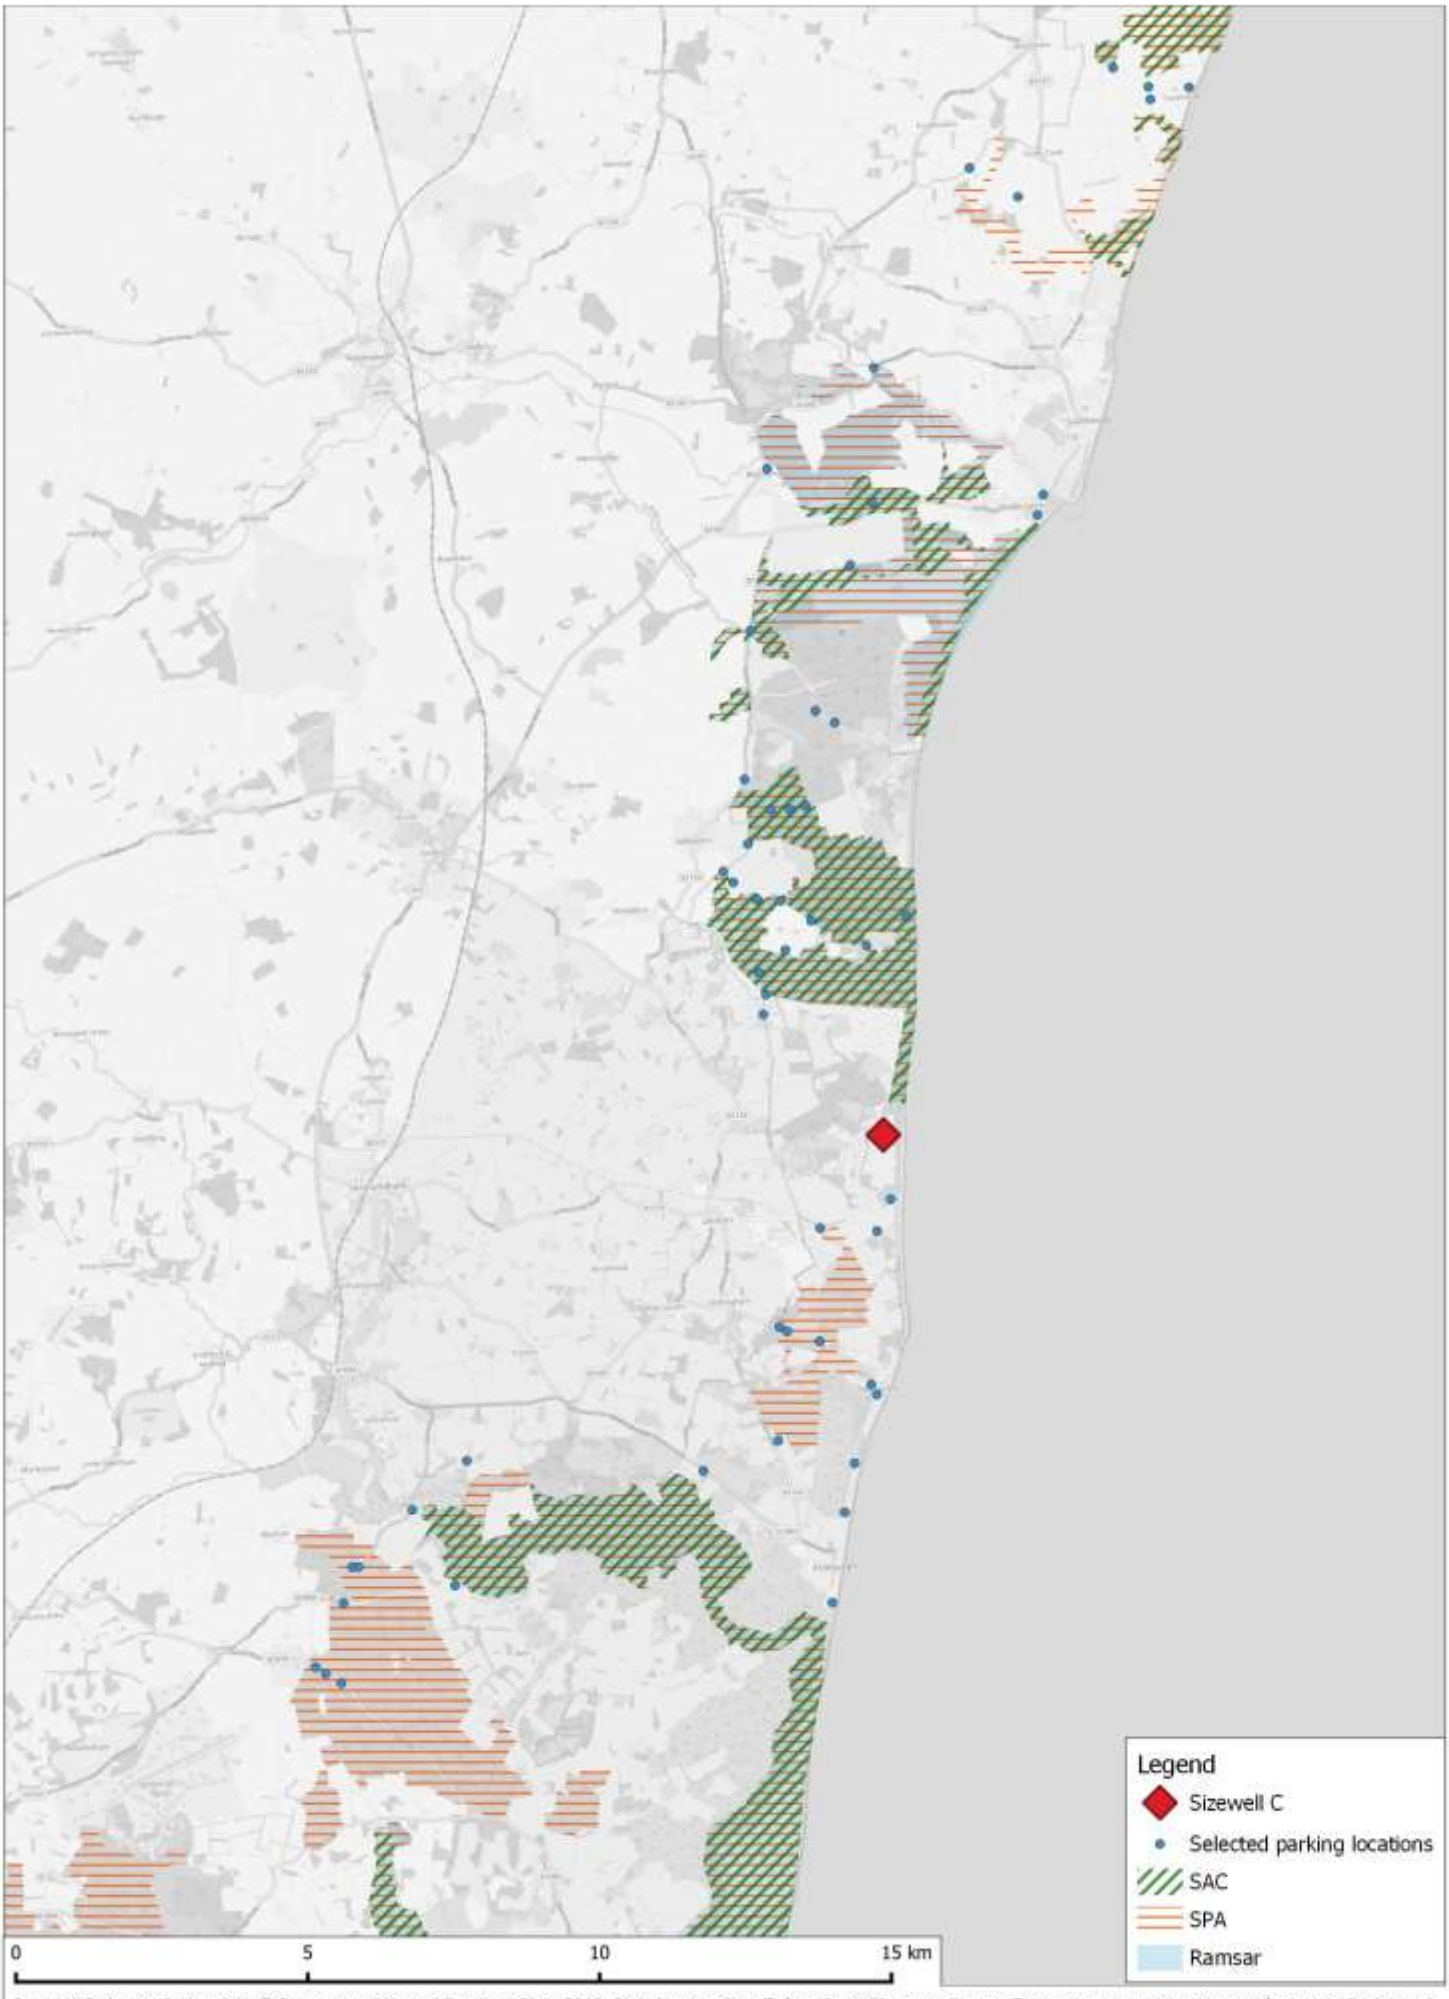
1.4 The National Trust, with the RSPB, have therefore commissioned this report to review the sensitivity of designated site features to recreation impacts and to consider the potential for suitable mitigation.

2. Relevant European sites

2.1 For recreation issues associated with new housing in Suffolk, the Recreation Avoidance Mitigation Strategy (Hoskin, Liley, & Panter, 2019) highlights how different mitigation strategies around the country define zones of influence (drawing on visitor data to show where changes in housing are likely to result in changes in access use) ranging from 5-15km. Drawing on data from the Suffolk Sandlings (Cruickshanks, Liley, & Hoskin, 2010) and the Deben Estuary (Lake, et al., 2014), the Suffolk strategy uses 13km. This is helpful as a broad guide to indicate where impacts may be expected.

2.2 Based on this guide, our knowledge of the nearby European sites and their draw for recreation and their accessibility from Sizewell/Eastbridge (taking into account the road network), we would anticipate the potential for risks at the following sites:

- Alde, Ore & Butley Estuaries SAC;
- Benacre to Easton Bavents Lagoons SAC;
- Orfordness - Shingle Street SAC;
- Minsmere to Walberswick Heaths & Marshes SAC;
- Alde-Ore Estuary SPA;
- Benacre to Easton Bavents SPA;
- Minsmere to Walberswick SPA;
- Sandlings SPA;
- Alde - Ore Estuary Ramsar, and;
- Minsmere - Walberswick Ramsar.



2.3 These European sites are shown in Map 1, where a selection of parking locations are also shown. These parking locations do not represent a comprehensive review of all potential parking locations and have not been systematically mapped from site visits. However, they are drawn on our knowledge of the sites and reflect locations where access might be expected to be deflected/change. There are a wide range of possible parking locations not mapped (see for example Cruickshanks et al., 2010) and those shown are intended as a guide only, providing a broad indication of the key areas where access might change.

2.4 We have discounted the following European sites as not relevant, even though they are potentially within the kinds of distance whereby displacement might be expected:

- Southern North Sea SAC, as this is a marine site designated for Harbour Porpoise *Phocoena phocoena*;

- Outer Thames Estuary SPA. as this is a marine site classified for foraging terns and non-breeding Red-throated Diver *Gavia stellata*;
- Staverton Park & the Thicks SAC, as this site is linearly c.15km from Sizewell, with travel distance larger still due to the barrier of the Alde-Ore Estuary. Public access at the SAC is limited to a public footpath close to the boundary of the SAC, and;
- Dew's Ponds SAC, as this is an inland site, comprising various ponds on arable land, and designated for Great-crested Newts *Triturus cristatus*. It is unlikely to draw visitors away from the coast.

3. Impacts from recreation

3.1 The nature conservation impacts of recreation are summarised in a number of general reviews (e.g. Buckley, 2004; Liddle, 1997; Liley et al., 2010; Lowen, Liley, Underhill-Day, & Whitehouse, 2008).

3.2 We group impacts from recreation under the following broad headings, which we use to structure this section:

- Disturbance;
- Damage;
- Fire;
- Contamination, and;
- Impacts on site management.

Disturbance

Overview

3.3 Disturbance occurs where human activity influences an animal's behaviour or survival. By far the majority of the literature (and there are thousands of studies), focuses on birds (Brawn, Robinson, & Thompson III, 2001; Hill et al., 1997; for general reviews see Hockin et al., 1992; Lowen et al., 2008; Showler, 2010; Steven, Pickering, & Castley, 2011; Whitfield, Ruddock, & Bullman, 2008). Disturbance can also affect mammals, herptiles (see Edgar, 2002 for review) and invertebrates.

General principles

3.4 The presence of people in the countryside will influence wildlife in many ways. For many species, people or their pets (e.g. dogs) are a potential threat and as such it is to be expected that the response will be to modify behaviour, for example fleeing. The relative trade-off as to when to change behaviour and respond to the threat will relate to the perceived scale of the threat and the costs involved (e.g. lost foraging time). This perspective can be used to understand the behavioural responses to people and led one author to describe human disturbance as predation-free predators (Beale & Monaghan, 2004).

3.5 With people (and their pets) viewed as potential predators, there is clearly a greater threat posed (and therefore a greater behavioural response) when, for example, there are more people, in larger groups (Beale & Monaghan,

2004, 2005) or when people approach directly (Smith-Castro & Rodewald, 2010) or faster (Bellefleur, Lee, & Ronconi, 2009).

3.6 The presence of people may also draw particular predators, for example a study in America showed the crow (corvid) populations were centred around campgrounds (Marzluff & Neatherlin, 2006) while Kays *et al.* (2017) used camera traps to show a range of predators actively selected human-made paths. As such the presence of people may also influence the distribution and abundance of predators with a knock-on effect for potential prey species.

Impacts

3.7 Disturbance can therefore have a range of different impacts, potentially affecting distribution, breeding success, and health. Impacts can be chronic, for example otherwise suitable nesting habitat being completely avoided (e.g. Liley & Sutherland, 2007) or more short-term in nature, for example birds becoming alert and then resuming the initial activity (e.g. Fernandez-Juricic, Jimenez, & Lucas, 2001). Birds might be temporarily displaced from particular locations and such behavioural responses will have some energetic costs, even if only very short term in duration. Impacts can also include indirect mortality, for example through increased predation associated with disturbance (e.g. Brambilla, Rubolini, & Guidali, 2004).

3.8 There are also examples of direct predation by pet dogs, for example dogs were recorded as predators of nests and incubating adult Ringed Plovers *Charadrius hiaticula* on Lindisfarne (Pienkowski, 1984). Some studies have shown evidence of accidental trampling of nests and young, including herptiles (Edgar, 2002) and birds (Liley & Sutherland, 2007). There are also studies that show direct trampling impacts by people of invertebrates (Ciach, Maślanka, Krzus, & Wojas, 2017).

3.9 Much harder to measure and record are physiological effects, for example related to stress, and these may in turn affect fitness. While studies are limited, there is evidence of physiological effects in terms of increased heart rate (Ellenberg, Mattern, & Seddon, 2013) and stress-hormones (Thiel, et al,. 2011).

Relevant qualifying features

3.10 At coastal sites, there are a range of studies that show reduced breeding success for breeding birds such as gulls and terns (Medeiros et al., 2007;

Robert & Ralph, 1975; Sandvik & Barrett, 2001). Little Terns *Sternula albifrons* are particularly vulnerable to disturbance as they nest on open sandy/shingle beaches where access is often concentrated. They will avoid nesting in otherwise suitable habitat where there are high disturbance levels (i.e. more people) (Ratcliffe, et al., 2008). Colonies will vary in size and location between years and there is likely to be interchange between different sites along the Suffolk coast over time.

3.11 Disturbance to wintering and passage waterbirds can result in:

- A reduction in the time spent feeding due to repeated flushing/increased vigilance (Bright, et al, 2003; Fitzpatrick & Bouchez, 1998; Stillman & Goss-Custard, 2002; Thomas, Kvitek, & Bretz, 2003; Yasué, 2005);
- Increased energetic costs (Nolet, et al, 2002; Stock & Hofeditz, 1997);
- Avoidance of areas of otherwise suitable habitat, potentially using poorer quality feeding/roosting sites instead (Burton, et al., 2002; Burton, Rehfisch, & Clark, 2002; Cryer, et al.1987; Gill, 1996), and;
- Increased stress (Payne et al., 2012; Sharpe, et al., 2009).

3.12 Disturbance arising from human activity has been shown to negatively affect the foraging efficiency and fat accumulation rate of diving ducks (Knapton, Petrie, & Herring, 2000), with pedestrian and cycle-based activity shown to have a greater impact in the winter than vehicular disturbance (Pease, Rose, & Butler, 2005).

3.13 For species associated with reedbeds, there is limited evidence of disturbance impacts for Bitterns (Underhill-Day, 1981), but while recreational disturbance of breeding birds at the nest is less likely, it has been suggested that human activity on the edges of reed-beds and on waterway margins may have an impact (Underhill-Day & Wilson, 1978). There is evidence of disturbance effecting breeding success for Marsh Harriers, for example. Underhill-Day (1984) found that 9% of nests were deserted as a result of human disturbance, and a range of activities were involved that included photography, walking, and fishing. Other studies have highlighted increased energetic costs imposed upon nesting Marsh Harriers by disturbance (Fernandez & Azkona, 1993).

3.14 For heathland bird species there are a range of disturbance studies. For both Nightjar and Woodlark, studies have shown recreation use affects the distribution of birds within sites, such that busy areas are avoided (Liley et al. 2006; Mallord, et al. 2007; Lowe, Rogers & Durrant, 2014). For Nightjars there

is also evidence of breeding success being lower on busier sites and busier parts of sites (Murison 2002). For Woodlarks at least, there are clear population-level impacts as a result of the presence of people on the heaths (Mallord et al. 2007).

3.15 Little work has been undertaken on disturbance impacts for wintering Hen Harrier. Traditional roost sites are identified as places where access management measures, or exclusions/restrictions, should be implemented in relation to CRoW (Brown & Langston, 2001). A well-known hen harrier roost site in Dorset was abandoned in 1997, with local counters believing that increased access by walkers and other recreational activities was the cause (Lowen et al., 2008).

3.16 Impacts for different European site qualifying features are summarised in Table 1.

Table 1: European site qualifying features identified as being susceptible to disturbance impacts from recreational activity.

Qualifying feature	European site(s)	Seasonality	References	Notes
Breeding wildfowl (i.e. Gadwall, Shoveler, and Teal)	Minsmere-Walberswick SPA; Minsmere-Walberswick Ramsar	Spring and Summer		Potential for disturbance at wetland breeding localities if walkers/dogs are able to access water's edge.
Wintering wildfowl (i.e. Gadwall, Shoveler, and White-fronted Goose)	Minsmere-Walberswick SPA	Winter		Recreational disturbance could potentially influence where birds feed, time spent feeding and flushing will have energetic consequences.
Marsh Harrier	Minsmere-Walberswick SPA; Alde-Ore Estuary SPA; Benacre to Eastern Bavents SPA; Minsmere-Walberswick Ramsar	Spring and Summer	(Fernandez & Azkona, 1993; Underhill-Day, 1984)	Both males and female spend less time near the nest, bring in fewer food items, and exhibit stress-related behaviours when disturbed.
Hen Harrier	Minsmere-Walberswick SPA	Winter	(A. Brown & Langston, 2001; Lowen et al., 2008)	Winter roost sites are likely to be susceptible to disturbance.
Bittern	Minsmere-Walberswick SPA; Benacre to Eastern Bavents SPA; Minsmere-Walberswick Ramsar	Spring and Summer	(Underhill-Day & Wilson, 1978)	Impacts more relevant to feeding birds and assumed access difficult and unlikely to nest sites
Bearded Tit	Minsmere-Walberswick SPA; Minsmere-Walberswick Ramsar	Spring and Summer		Potential scope for disturbance if accessing extensive reedbed localities.
Avocet	Minsmere-Walberswick SPA; Alde-Ore Estuary SPA; Alde-Ore Ramsar; Minsmere-Walberswick Ramsar	Spring and Summer	(Scarton, 2018)	Any access to breeding localities could lead to disturbance/abandonment. Birds respond at quite considerable distances to presence of people.
Avocet	Alde-Ore Estuary SPA	Winter		
Lesser Black-backed Gull	Alde-Ore Estuary SPA; Alde-Ore Ramsar	Spring and Summer		Potential for disturbance effects at breeding colonies, although recreational access considered unlikely on the Alde-Ore Estuary due to isolated nature of colonies.
Sandwich Tern	Alde-Ore Estuary SPA	Spring and Summer	(Brown & Grice, 2005; Garthe &	Potential for abandonment, damage to eggs/chicks, and increased levels of natural predation at colonies. Nests

Qualifying feature	European site(s)	Seasonality	References	Notes
			Flore, 2007; Lloyd, Bibby, & Everett, 1975)	in large colonies and single access events can cause whole colonies to desert.
Little Tern	Minsmere-Walberswick SPA; Alde-Ore Estuary SPA; Benacre to Eastern Bavents SPA	Spring and Summer	(Medeiros et al., 2007; Ratcliffe, Schmitt, Mayo, Tratalos, & Drewitt, 2008)	Decreased productivity, and increased levels of natural predation, arising from recreational activity. Birds also avoid nesting on beaches with high levels of access. Colonies are mobile and can shift between years, responding to habitat change and other factors.
European Nightjar	Minsmere-Walberswick SPA; Sandlings SPA	Spring and Summer (to late August)	(Liley, Clarke, Mallord, & Bullock, 2006; Lowe, Rogers, & Durrant, 2014; Murison, 2002)	Recreational activity can lead to avoidance of certain areas within a site, and also negatively impact productivity. Dunwich Forest population is likely to be functionally linked to birds within the Minsmere-Walberswick SPA and Sandlings SPA.
Woodlark	Sandlings SPA	All year (although increased impact in Spring and Summer). Potentially particularly vulnerable when settling on territories in Feb/March.	(Eyre & Baldwin, 2014; Mallord, Dolman, Brown, & Sutherland, 2007)	Recreational activity can lead to displacement or avoidance of certain areas within a site, and also negatively impact productivity. Studies with nest cameras have shown some instances where nests lost due to joggers or bikes crushing nests. We consider birds within the Minsmere-Walberswick SPA and within Dunwich Forest population to be functionally-linked to the Sandlings population.
Redshank	Alde-Ore Estuary SPA; Alde-Ore Ramsar	Winter	(Fitzpatrick & Bouchez, 1998)	Birds prone to flushing and lost feeding time following recreational disturbance
Ruff	Alde-Ore Estuary SPA	Winter		Wintering birds feeding on areas of wet grassland may be susceptible to disturbance effects.

Damage

Overview

3.17 Recreational activities can lead to changes in soil characteristics and ultimately lead to erosion. Although erosion brought about by recreational activities is small compared to natural factors it can none the less an important form of soil degradation (Holden et al., 2007). Changes to substrates can in turn lead to changes in the ecological communities they support.

3.18 At lower levels of use, the main impact is on vegetation and is largely mechanical (Bayfield & Aitken, 1992; Liddle, 1997) while higher levels of use will also affect substrates. Light use may cause a slight decrease in vegetation cover, and a decline in the incidence of flowering. Bare ground may be colonised by trampling resistant species. Heavier ground pressure leads to greater losses of vegetation. Significant erosion can be expected where the plant cover falls below 70% (Liddle, 1997), but erosion can commence before this level is reached (Kuss & Morgan, 1984). As loss of vegetation takes place, there is disruption and progressive loss of soil horizons by direct physical abrasion or loosening and indirectly by water and wind erosion. Important changes in soil structure and chemistry can result from compaction. Poor permeability to water can increase surface run-off, and reduced aeration can result in anaerobic conditions and poor root growth.

3.19 Trampling has been shown to alter the amount of litter present (Bayfield & Brookes, 1979), soil water content, soil temperature and chemistry (Liddle, 1997). There is also some evidence that trampling and resulting compaction can effect soil health and the mycorrhizae or bacteria present (with knock-on implications for plant health) (Fay, 2014).

3.20 Different recreational activities can have a significantly different impact. In general, walking is likely to be less damaging that horse riding, cycling, or motorised vehicles. For example, Weaver and Dale (1978) showed that horses were substantially more damaging, and motorcycles slightly more damaging, than hikers in grassland and woodland in the US Pacific Northwest. Thurston and Reader (2001) suggest that mountain bikes cause the same amount of damage as hikers in deciduous woodland, although MacIntyre (1991) and Rees (1990) show that mountain bikes may cause slightly more damage than foot traffic depending on the type of habitat.

Relevant qualifying features

3.21 Heather-dominated vegetation is very susceptible to trampling damage, though there may be some differences related to individual species response and soil conditions. In summer and winter trials on undamaged lowland heathland in England (Harrison, 1981), it was shown that 400 passes in the first summer of the experiment, caused heather cover to fall to about 50%, and by 800 passes it was less than 10%. The vegetation failed to recover in the period following the experimental trampling, after winter only, summer only, or all season trampling.

3.22 Seasonal and habitat response was tested in trials on heathland in Brittany (Gallet & Roze, 2001a) and though there were some differences, in all cases trampling led to a great decrease in vegetation cover, with the vegetation cover varying between 0 and 50% under 750 passes. Dry heathland was more resistant than mesophilous (humid) heath and significantly so with winter trampling, but both heath types were equally vulnerable in wet conditions. Gorse was more resilient than heathers; and younger dwarf shrubs were less vulnerable than older plants.

3.23 Though trampling can damage the dwarf shrub community of heathland, there are some aspects of the habitat that need the canopy to be broken, even to the extent of bare ground being sustained. Bare ground and early successional habitats are a very important component of the heathland ecosystem, important for a suite of plants, invertebrates and reptiles (Byfield & Pearman, 1996; Key, 2000; Lake & Underhill-Day, 1999). Typically, small, low-growing, herbs with low competitive capacity require these open conditions and lack of suppression by a taller canopy. Some may be ruderals or annuals that can only survive in such conditions.

3.24 Some kind of physical disturbance is usually required to create these bare ground habitats, and hence a certain level of physical disturbance, including erosion resulting from trampling, can be beneficial. However, the level of disturbance required is difficult to define and is likely to vary between sites (Lake, Bullock & Hartley 2001). There are likely to be optimum levels of use that maintain the bare ground habitats but do not continually disturb the substrate. Such levels of use have never been quantified, nor is it known whether sporadic use is likely to be better at maintaining bare ground habitats than low level, continuous use.

3.25 Research has shown that shingle vegetation, strandline communities, and reedbed are easily damaged by trampling, and that this can lead to a decrease in plant species diversity within shingle communities particularly (Penny Anderson Associates, 2009). This has been shown to be the case historically on the Orford Shingle (Fuller & Randall, 1988). Trampling in reedbeds is likely to be constrained by high water levels for much of the year, although may prove an issue during periods of low water and/or at the periphery of the locality. Such peripheral trampling/poaching is also of potential import for coastal lagoons and other isolated waterbodies.

3.26 Fen habitats are also highly susceptible to trampling damage, although the high water table present in tall herb fen may dissuade access away from the periphery. Nevertheless. Due to the wet, or seasonally wet, ground present within fens, the habitat is extremely susceptible to trampling damage where access is possible (Penny Anderson Associates, 2009). Experimental trampling carried out over several years within fens in Norway led to severe damage (Arneson, 1999) and results from Scotland showed that taller fen grasses were less resilient to trampling than sedges (Rees & Tivy, 1977).

3.27 Impacts of recreation upon saltmarsh have been relatively little studied, due to the often inaccessible nature of the terrain (Penny Anderson Associates, 2009), although several studies identify trampling effects (Hewitt, 1973; Schofield, 1967). The creation of distinct pathways across saltmarsh, potentially leading to changes in vegetation community structure/composition, has also been noted (Chandrasekara & Frid, 1996). In Coombes (2007) review of trampling effects on different East Anglian coastal habitats, the data show saltmarshes as more robust compared to certain other coastal habitats.

3.28 Impacts upon notable plant and invertebrate species within the qualifying habitats is likely to vary by habitat type. Some light trampling within more robust fen habitats and reedbed may prove beneficial for invertebrates especially, although notable plants/invertebrates associated with sand dune and coastal shingle are particularly susceptible to damage via trampling (Penny Anderson Associates, 2009).

3.29 Impacts for different European site qualifying features are summarised in Table 2.

Table 2: European site qualifying features identified as being susceptible to physical damage arising from recreational activity

Qualifying feature	European site(s)	Seasonality	References	Notes
H4030 European dry heaths	Minsmere-Walberswick Heaths & Marshes SAC	During the growing season. Lichens more vulnerable during the summer when dry.	(Byfield & Pearman, 1996; Gallet & Roze, 2001b; Harrison, 1981; Key, 2000; Lake et al., 2001; Lake & Underhill-Day, 1999; Penny Anderson Associates, 2009)	Some limited trampling/disturbance required to maintain important bare ground habitat components.
H1210 Annual vegetation of drift lines	Minsmere-Walberswick Heaths & Marshes SAC; Orfordness-Shingle Street SAC	During growing season.	(Doody & Randall, 2003)	Dynamic habitat type, susceptible to impact of tidal /storm action. Pioneer species susceptible to trampling impacts.
H1220 Perennial vegetation of stony banks	Minsmere-Walberswick Heaths & Marshes SAC; Orfordness-Shingle Street SAC	During the growing season. Lichens more vulnerable during the summer when dry.	(Doody & Randall, 2003; Lowen et al., 2008)	Highly susceptible to trampling effects, with often isolated/patchy nature of vegetation on shingle potentially exacerbating impact more so than in more contiguous habitat types, and making recovery and recolonization more difficult/slower. Areas with lichen cover particularly vulnerable.
H1150 Coastal lagoons	Benacre to Easton Bavents Lagoons SAC; Orfordness-Shingle Street SAC	Throughout year	(Lowen et al., 2008; Penny Anderson Associates, 2009; Saunders, Selwyn, Richardson, May, & Heeps, 2000)	Damage from pedestrian access likely to be limited to periphery of habitat, where shallow water may support specialised communities. Entry by people/dogs into deeper sections risks further physical damage to substrate. Trampling issues suggested as 'minimal' by Saunders *et al.*
H1330 Atlantic salt meadows	Alde-Ore & Butley Estuaries SAC	Throughout year	(Chandrasekara & Frid, 1996; Coombes, 2007;	Human access within saltmarsh habitats constrained by topography and tidal action, forcing creation of distinct,

Qualifying feature	European site(s)	Seasonality	References	Notes
			Hewitt, 1973; Lowen et al., 2008; Penny Anderson Associates, 2009; Schofield, 1967)	and sometimes heavily utilised, pathways within accessible locations. Trampling has been shown to cause physical damage to habitat and changes in community structure. Saltmarsh habitats potentially less vulnerable compared to other coastal habitats.
H1130 Estuaries	Alde-Ore & Butley Estuaries SAC	Throughout year	(Lowen et al., 2008; Penny Anderson Associates, 2009)	Dynamic/tidal nature of habitat means that lasting effects often concentrated in vicinity of high water mark. Possible for damage to estuarine substrate invertebrate and algal/pioneer plant communities via trampling. Many areas inaccessible or difficult to access.
H1140 Mudflats and sandflats	Alde-Ore & Butley Estuaries SAC	Throughout year	(Lowen et al., 2008; Penny Anderson Associates, 2009)	Dynamic/tidal nature of habitat means that lasting effects often concentrated in vicinity of high water mark. Possible for damage to substrate invertebrate and algal/pioneer plant communities via trampling but risks low given the difficulties with access..
Wetland habitats	Minsmere-Walberswick Ramsar	Throughout year	(Arneson, 1999; Lowen et al., 2008; Penny Anderson Associates, 2009; Rees & Tivy, 1977)	Physical damage likely to be limited to periphery during periods of high water. Drier parts of reedbeds can be readily accessible and trampling risks possible. Would require relatively high or repeated incursions for marked structural damage. Tall/waterlogged fen habitats highly susceptible to trampling impacts, including loss of less robust plant species leading to change in community structure. Potential for poaching of banks and trampling of marginal, and potentially emergent/submerged, vegetation, e.g. where dogs access water.
Nationally scarce plant species and British Red Data book invertebrates	Minsmere-Walberswick Ramsar	Throughout year		Impacts likely to relate to structural change to habitats, for which see above.

Fire

Overview

3.30 Fires in the countryside can be caused accidentally from discarded cigarettes, by sparks from a campfire, BBQs or from burning a dumped or stolen car, from fireworks, as a result of a controlled fire getting out of control, from discarded bottles in strong sunlight, from children playing with matches or similar, and from deliberate arson. Fire risks have increased with climate change (anon, 2017; Jolly et al., 2015; Moffat & Gazzard, 2019) and major fire incidents on nature reserves are becoming more common.

3.31 Based on 217 questionnaires from a sample of lowland heaths in Dorset, Kirby and Tantram (Tantram, Boobyer, & Kirby, 1999) found that 61% of fires were caused by arson, 8% from management fires getting out of control, 7% from bonfires and the remainder from camp fires, burning refuse, vehicle fires, property fire and sparks from a railway. The only natural cause of fire was from lightning. The same study noted that there was a widespread belief among the public and nature conservation professionals that most fires were deliberate and that children were often believed to be responsible (this would be most relevant on sites close to residential areas rather than remote uplands).

3.32 A number of studies have linked the incidence of fires with areas used by the public, or with the extent of urbanisation. In the Peak District National Park during 1970-1995, 84% of 324 recorded fires were next to roads, paths or within areas of open access, and many burnt areas on Exmoor are close to public roads (Miller & Miles, 1984). Kirby and Tantram (1999) noted that of the 26 lowland heathland SSSIs in Dorset with the highest number of fires, 1990-1998, 70% were located in or adjacent to urban areas, including the top nine.

Relevant qualifying features

3.33 Fires can have major impacts on the soil, vegetation, and fauna present, and recovery can take many years. After a fire where temperature and intensity are moderate, vegetation recovery will be largely influenced by the vegetation composition before the fire, although subsequent management, particularly grazing and trampling, will influence regeneration. The less palatable or better-adapted species may be favoured by grazing, so that, for example, on heathlands, cross leaved-heath and the more unpalatable

graminoids may benefit initially at the expense of heather. Pioneer communities, such as those on shingle banks, may be particularly impacted by fire, due to the small amounts of soil present and the time taken for those soils to develop (Randall, 2004). Any recovery following fire will be further hindered by the small size of the seedbank in pioneer communities.

3.34 A range of studies show impacts of fires for invertebrate populations. Recovery of the full community of unburnt areas can take as little as two years in grassland to 20 years in heathland habitats (Bell, Wheater, & Cullen, 2001; Panzer, 2002). While some species and communities can benefit from the open conditions following a fire or in regularly burned sites, others can be seriously depleted or even eliminated (Kirby, 2001). Fires is a frequently used tool in reedbed management, but if allowed to burn out of control it can damage invertebrate populations within reed stubble and litter, and potentially cause subsurface burns in areas with peat soils (Hawke & Jose, 1996).

3.35 Where fires are extensive, whole populations of invertebrates can be destroyed and large fires may cause local extinctions in less mobile species. Invertebrate groups which are most vulnerable to fire in open habitats are those present in the litter as eggs or larvae in spring when many fires take place, species with only one generation per annum and sedentary or flightless species or groups. These include molluscs, leafhoppers, grasshoppers and some butterfly and moth species (Kerney, 1999; Panzer, 2002).

3.36 Fire can also be particularly damaging to reptiles, and the occurrence of fires within heathland can also lead to habitat and/or nest destruction for important bird species (e.g. Nightjar and Woodlark).

3.37 Impacts for different European site qualifying features are summarised in Table 3.

Table 3: European site qualifying features identified as being susceptible to fires arising from recreational activity

Qualifying feature	European site(s)	Seasonality	References	Notes
H4030 European dry heaths	Minsmere-Walberswick Heaths & Marshes SAC	Can occur throughout year, particularly likely during prolonged hot/dry weather. Impact greater in spring/summer.	(Bell et al., 2001; Borghesio, 2009; Panzer, 2002; Underhill-Day, 2005)	Fire can be a useful management tool but such management is targeted to limited areas and only undertaken in the late winter. Wildfire can damage extensive areas of habitat and have devastating effects upon important bird, invertebrate, and plant species. Grazing levels can impact subsequent recovery, and long-term changes in habitat structure are possible if not carefully managed.
H1210 Annual vegetation of drift lines	Minsmere-Walberswick Heaths & Marshes SAC; Orfordness-Shingle Street SAC	Throughout year (potentially higher risk in summer months as increased access levels, use of disposable barbeques, etc)		Low risk due to patchy/tideline distribution and thin soils, impacts likely to be localised as fire unlikely to spread.
H1220 Perennial vegetation of stony banks	Minsmere-Walberswick Heaths & Marshes SAC; Orfordness-Shingle Street SAC	Throughout year (potentially higher risk in summer months as increased access levels, use of disposable barbeques, etc)	(Doody & Randall, 2003; Randall, 2004)	Higher risk than drift line communities due to more contiguous vegetation patches with more developed humus layer, but spread still unlikely and impacts possibly localised. Long-lasting impact due to time taken for soils to develop and paucity of seedbank available for recovery.
Wetland habitats	Minsmere-Walberswick Ramsar	Throughout year. Higher risk during periods of low water levels.	(Hawke & Jose, 1996)	Wildfire can destroy large areas of contiguous reedbed habitat and proved difficult to control. High water levels will preclude extensive damage to invertebrate communities within reed litter, but fires during periods of low water can lead to large die-offs of stubble and litter invertebrate populations.

Qualifying feature	European site(s)	Seasonality	References	Notes
Nationally scarce plant species and British Red Data book invertebrates	Minsmere-Walberswick Ramsar	Throughout year. Higher risk during periods of low water levels.	(Hawke & Jose, 1996)	Particular concern for drier parts of reedbeds, see above.

Contamination

Overview

3.38 Contamination risks include:

- Nutrient enrichment from dog fouling;
- Contamination of ponds and water bonds from incursions by dogs and people;
- Litter;
- Spreading of invasive species, and;
- Spreading of disease.

3.39 Air quality may also be affected via emissions from vehicles and fires, which may have resultant, diffuse, effects upon vegetation. Any changes in air quality resulting solely from increases in levels of recreational access will be difficult to isolate from changes as a result of general traffic, industry, nearby infrastructure, etc, and air quality effects are therefore not considered further within this report.

3.40 A relatively limited number of studies have addressed the impacts of dog fouling (Bull, 1998; Groome, Denton, & Smith, 2018; Taylor, Anderson, Taylor, Longden, & Fisher, 2005). Dogs will typically defecate within 10 minutes of a walk starting, and as a consequence most (but not all) deposition tends to occur within 400m of a site entrance (Taylor *et al.,* 2005). In addition, most faeces are deposited close to the path, with a peak at approximately 1m from the path edge (Shaw, Lankey, & Hollingham, 1995). Similarly, dogs will typically urinate at the start of a walk, but they will also urinate at frequent intervals during the walk too. The total volume deposited on sites may be surprisingly large. Over one year at Burnham Beeches National Nature Reserve, Barnard (2003) estimated the total amounts of urine as 30,000 litres and 60 tonnes of faeces from dogs.

3.41 Nutrient levels in soil (particularly nitrogen and phosphorous) are important factors determining plant species composition for many habitats, the typical effect will be equivalent to applying a high level of fertilizer, resulting in a reduction in species richness and the presence of species typically associated with more improved habitats. The impacts of dog fouling can often be seen in the form of grassy wedges/edges of paths on many heaths with high levels of access. This can be exacerbated by trampling, which has a lesser effect on species such as grasses (which grow from the base rather than the tip).

3.42 Ponds and small water bodies are often popular with dogs and dog walkers will often seek such features out, particularly in hot weather. Heavy use by dogs leads to turbid water, an impoverished invertebrate flora, and a loss of vegetation (Denton & Groome, 2017; Groome et al., 2018). These impacts are linked to the trampling/splashing of the dogs and are potentially exacerbated by contamination from wormer, tick, and flea treatments (Groome et al., 2018).

3.43 A further consideration is that of sunscreen and other personal care products. Personal care products containing oxybenzone and octinoxate are being banned from some areas of the world where they are thought to be contributing to the disruption of marine ecosytems. In freshwater systems, carbon-based and nano-particulate UV filters have been shown to negatively impact invertebrates (e.g. Schmitt, et al., 2008). These issues will be relevant where people enter the water.

3.44 Litter can cause direct mortality of bird, reptile, and small mammal species, and may become concentrated within certain habitats (e.g. on beaches: (Storrier, et al., 2007)). It can also be problematic for site managers if ingested by livestock.

3.45 Contamination can also include the spread of invasive species. Studies have shown that recreation can act as a vector to spread seeds over considerable distances (Wichmann et al., 2009). Additional footfall and dogs entering water bodies may increase the spread of species such as New Zealand Pigmyweed *Crassula helmsii* (Groome et al., 2018), which has been recorded near the northern boundary of the Minsmere RSPB reserve[1]. On terrestrial habitats, the occurrence of Piri-piri Burr *Acaena novae-zelandiae* has long been linked to recreation (Usher et al., 1986). The species is now widespread in the area, including around the Minsmere main RSPB car-park.

Relevant qualifying features

3.46 Relevant qualifying features are nutrient-poor habitats such as heathland and water features that are readily accessible to people and dogs. Relevant features are listed in Table 4.

[1] See RSPB website, accessed 4th July 2020

Table 4: European site qualifying features identified as being susceptible to contamination impacts from recreational activity

Qualifying feature	European site(s)	Seasonality	References	Notes
H4030 European dry heaths	Minsmere-Walberswick Heaths & Marshes SAC	Throughout year	(Denton & Groome, 2017; Marrs, 1988; Shaw et al., 1995; Underhill-Day, 2005)	Dog faeces/urine will enrich nutrient poor habitats and lead to changes in community composition. This can become concentrated car parks/access gates and can form grassy wedges alongside tracks and paths. Litter can prove a fire risk (e.g. glass, dropped cigarettes), and may prove problematic for site managers if ingested by grazing livestock. Spread of invasive species such as Piri-Piri Burr also a risk.
H1210 Annual vegetation of drift lines	Minsmere-Walberswick Heaths & Marshes SAC; Orfordness-Shingle Street SAC	Throughout year	(Storrier et al., 2007)	Risk of enrichment from dog faeces/urine. Litter (plastic in particular) often concentrated on tideline, potentially inducing physiological stress/shading if deposited over vegetation.
H1220 Perennial vegetation of stony banks	Minsmere-Walberswick Heaths & Marshes SAC; Orfordness-Shingle Street SAC	Throughout year		Risk of enrichment from dog faeces/urine.
H1150 Coastal lagoons	Benacre to Easton Bavents Lagoons SAC; Orfordness-Shingle Street SAC	Throughout year	(Saunders et al., 2000)	Risk of enrichment from dog faeces/urine. Also contamination from dog/animal skin treatments and human sunscreen. Risk of transporting disease (e.g. Chytrid) and invasive species propagules between wetland sites on footwear/clothing. Litter/waste impacts for coastal lagoons described as' observable' by Saunders *et al.*
H1330 Atlantic salt meadows	Alde-Ore & Butley Estuaries SAC	Throughout year		Risk of enrichment from dog faeces/urine, in addition to litter deposition, although severe impact considered less likely due to tidal nature of habitat.
Wetland habitats	Minsmere-Walberswick Ramsar	Throughout year		Risk of enrichment from dog faeces/urine. Also contamination from dog/animal skin treatments. Risk of transporting disease (e.g. Chytrid) and

Qualifying feature	European site(s)	Seasonality	References	Notes
				invasive species propagules between wetland sites on footwear/clothing. Litter may prove problematic for site managers if ingested by grazing livestock.
Nationally scarce plant species and British Red Data book invertebrates	Minsmere-Walberswick Ramsar	Throughout year		Risk of enrichment from dog faeces/urine. Also contamination from dog/animal skin treatments. Risk of transporting disease (e.g. Chytrid) and invasive species propagules between wetland sites on footwear/clothing. Litter may prove problematic for site managers if ingested by grazing livestock.

Impacts on site management

Overview

3.47 Damage to infrastructure can occur in a variety of ways. With more footfall, infrastructure such as car parks, paths, gates, and stiles are likely to need more maintenance and repair, and direct damage can also occur through vandalism. Increased levels of use may also lead to an increase in public opposition to management programmes associated with conservation, such as the control of invasive species (Bremner & Park, 2007). Seasonal impacts may also occur due to closures of certain paths in periods of wet weather, leading to time taken up by site managers to deal with complaints from members of the public and a potential increase in visitor numbers in novel areas of a site.

3.48 Recreational activity can be a particular problem where livestock grazing is used in conservation grazing. Dog-walkers and horse riders may be concerned about interactions with livestock, while walkers and others may be concerned about the impact of fencing and gates on open access areas or about disease. In some cases, livestock grazing (particularly sheep) is found to be untenable on sites popular with dog walkers due to worrying and death of sheep by dogs (e.g. Taylor *et al.* 2005), and displacement of livestock away from heavily utilised areas may occur. Dogs are also an issue for the welfare of livestock through the transfer of pathogens such as *Neospora* from dogs to cattle through dog faeces (causing abortion in infected cattle).

3.49 Another potential issue relates to demand for access and pressure for particular interventions, infrastructure or facilities. On sites with current recreation use visitors may well wish for better path surfacing, toilets, cafes, dog bins etc. Where access is not encouraged or there is no access there may be demand from local people and visitors for access to be provided. These issues can bring added pressure for site managers or a need to compromise between nature conservation and recreation.

Relevant qualifying features

3.50 Pressure on site managers to maintain the upkeep of recreation/access infrastructure (e.g. fencing, gates, car parks, etc) will be inherent in the face of increasing recreational activity levels, irrespective of the habitat under review. Particular focus has therefore been placed upon those habitats within which livestock are used in conservation grazing.

3.51 Ponies and cattle are used to graze areas of heathland within the SPA/SAC/Ramsar, with more robust, free-ranging, Koniks present within wetter habitats. Potential risks arise for these livestock from the ingestion of litter, worrying by dogs, and damage to fencing (leading to them accessing unsuitable areas). The presence of increased numbers, or novel, visitors within areas subject to grazing may lead to the livestock avoiding busier parts of the site (or conversely congregating if visitors begin to feed them). Any impact on the grazers could potentially impact upon the structure and quality of any of the habitats within which they are deployed.

3.52 Impacts for different European site qualifying features are summarised in Table 5.

Table 5: European site qualifying features identified as being susceptible to changes in site management arising from recreational activity

Qualifying feature	European site(s)	Seasonality	References	Notes
H4030 European dry heaths	Minsmere-Walberswick Heaths & Marshes SAC	Throughout year		Ponies, cattle and sheep used for conservation grazing on the heath and adjoining acid grassland. Damage to infrastructure and the presence of dogs/people could lead to changes in the distribution of grazers on site. Also risk of killing, injury, or disease transmission from dogs to livestock. Increased access makes some aspects of practical conservation management (e.g. tree clearance burning) more difficult.
Wetland habitats	Minsmere-Walberswick Ramsar	Throughout year		Konik ponies are used as conservation grazers in wetland areas. Damage to infrastructure and the presence of dogs/people could lead to changes in the distribution of grazers on site. Also risk of killing, injury, or disease transmission from dogs to livestock. Increased levels of access may add to pressure for water levels/flood risk to be managed differently.
Nationally scarce plant species and British Red Data book invertebrates	Minsmere-Walberswick Ramsar	Throughout year		Habitat structure will be important for these species. Konik ponies are used as conservation grazers in wetland areas. Damage to infrastructure and the presence of dogs/people could lead to changes in the distribution of grazers on site. Also risk of killing, injury, or disease transmission from dogs to livestock. Increased levels of access may add to pressure for water levels/flood risk to be managed differently.

4. Implications of Sizewell C in terms of recreation use and impact

4.1 The Suffolk coast draws visitors for a wide range of recreation use. These include a mix of tourists, day-visitors and local residents. In total, nearly 13 million visits were estimated to East Suffolk in 2018 (Destination Research, 2018), comprising a mix of day trips (just over 12 million) and staying trips (nearly 700,000).

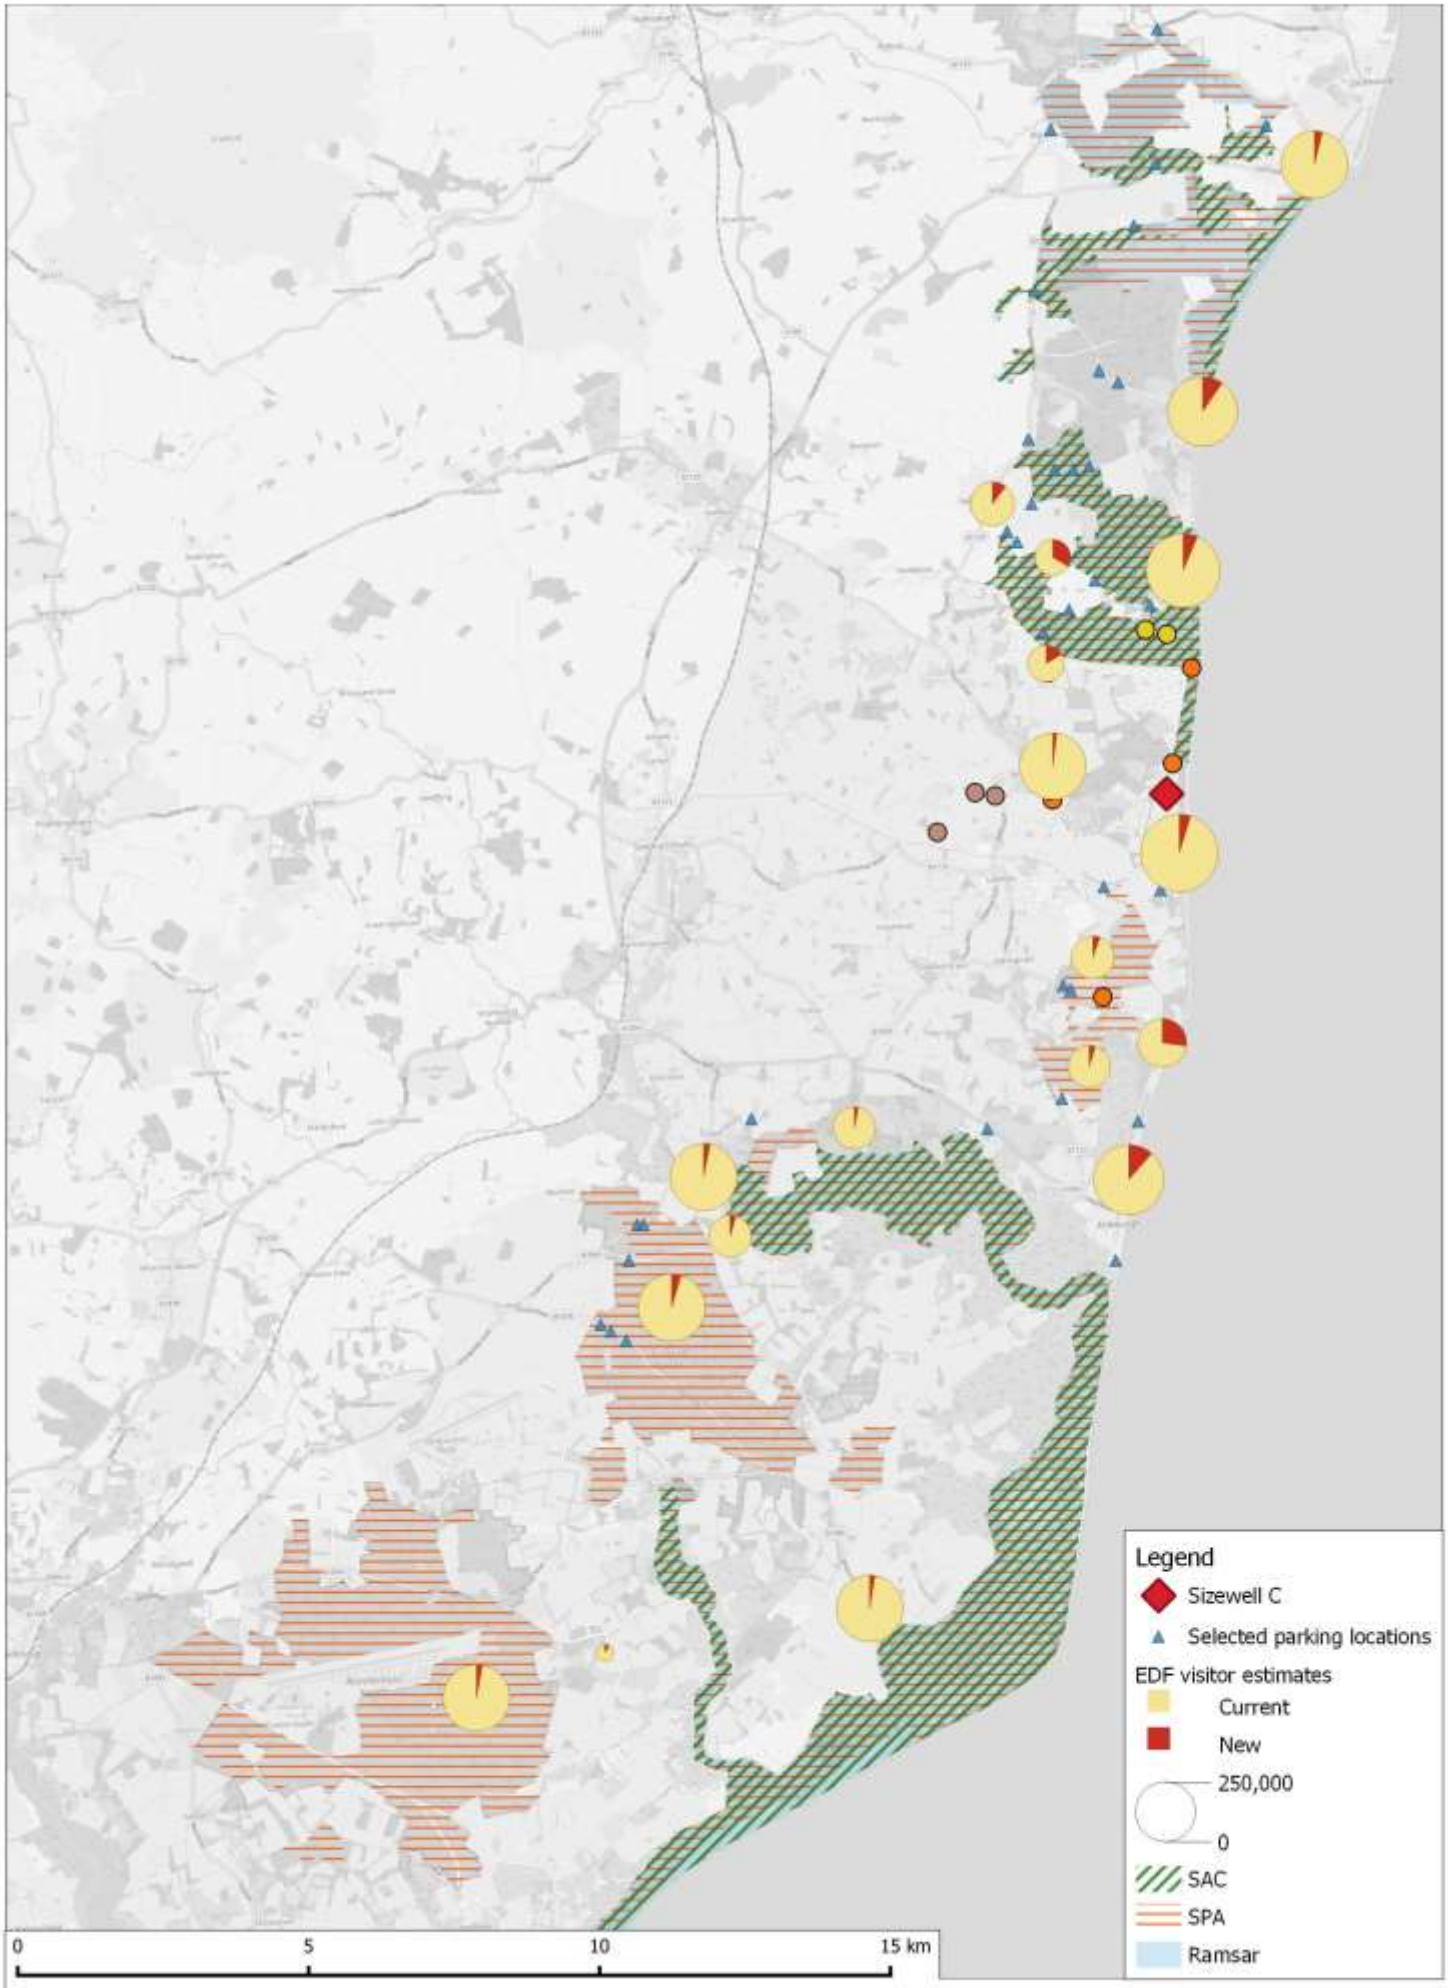
4.2 In the Sizewell area, there are a wide range of opportunities for informal recreation use of countryside sites, these include 'flagship' locations such as the main RSPB car-park at Minsmere or the National Trust car-park at Dunwich. At these locations there are visitor centres, visitor engagement staff and facilities provided for recreation use. These locations are free for members but otherwise there is a fee to access. There are also numerous much more informal locations where parking is free and there are footpaths or open access land with relatively little access infrastructure in place.

4.3 EDF have provided some estimates of visitor numbers to different locations around Sizewell and increases in use they predict associated with the proposals for Sizewell C (i.e. additional recreational use from construction workers and from displaced visitors). The data from EDF are summarised in Maps 2 and 3[2]. It is important to note that we have found errors in the EDF reports and do not agree with the methods used (see separate review for details and comment).

4.4 The EDF estimates relate to very broad areas– i.e. 'Sandlings Walk', 'Rendlesham', and 'Minsmere Outer'. These are too ambiguous and very generalised, encompassing multiple access points and a wide area. It is impossible to drill down into the data at a scale that ecological data and visitor data can be combined in a meaningful way. Many places (e.g. Dunwich Beach, Tunstall Forest, Sandlings Walk, Rendlesham, Orford, Aldeburgh, Southwold and Walberswick) are all assumed to have the same levels of current use (150,000 per annum), which is unlikely.

[2] The maps are drawn from the data in Table 2.1, and the figures based on the 500,000 visits to Sizewell area columns (page 320 of the pdf) within Appendix E: Recreational Disturbance Assessment, within the 5.10 Shadow HRA Vol. 1: Screening and appropriate assessment. PINS document reference: APP-148

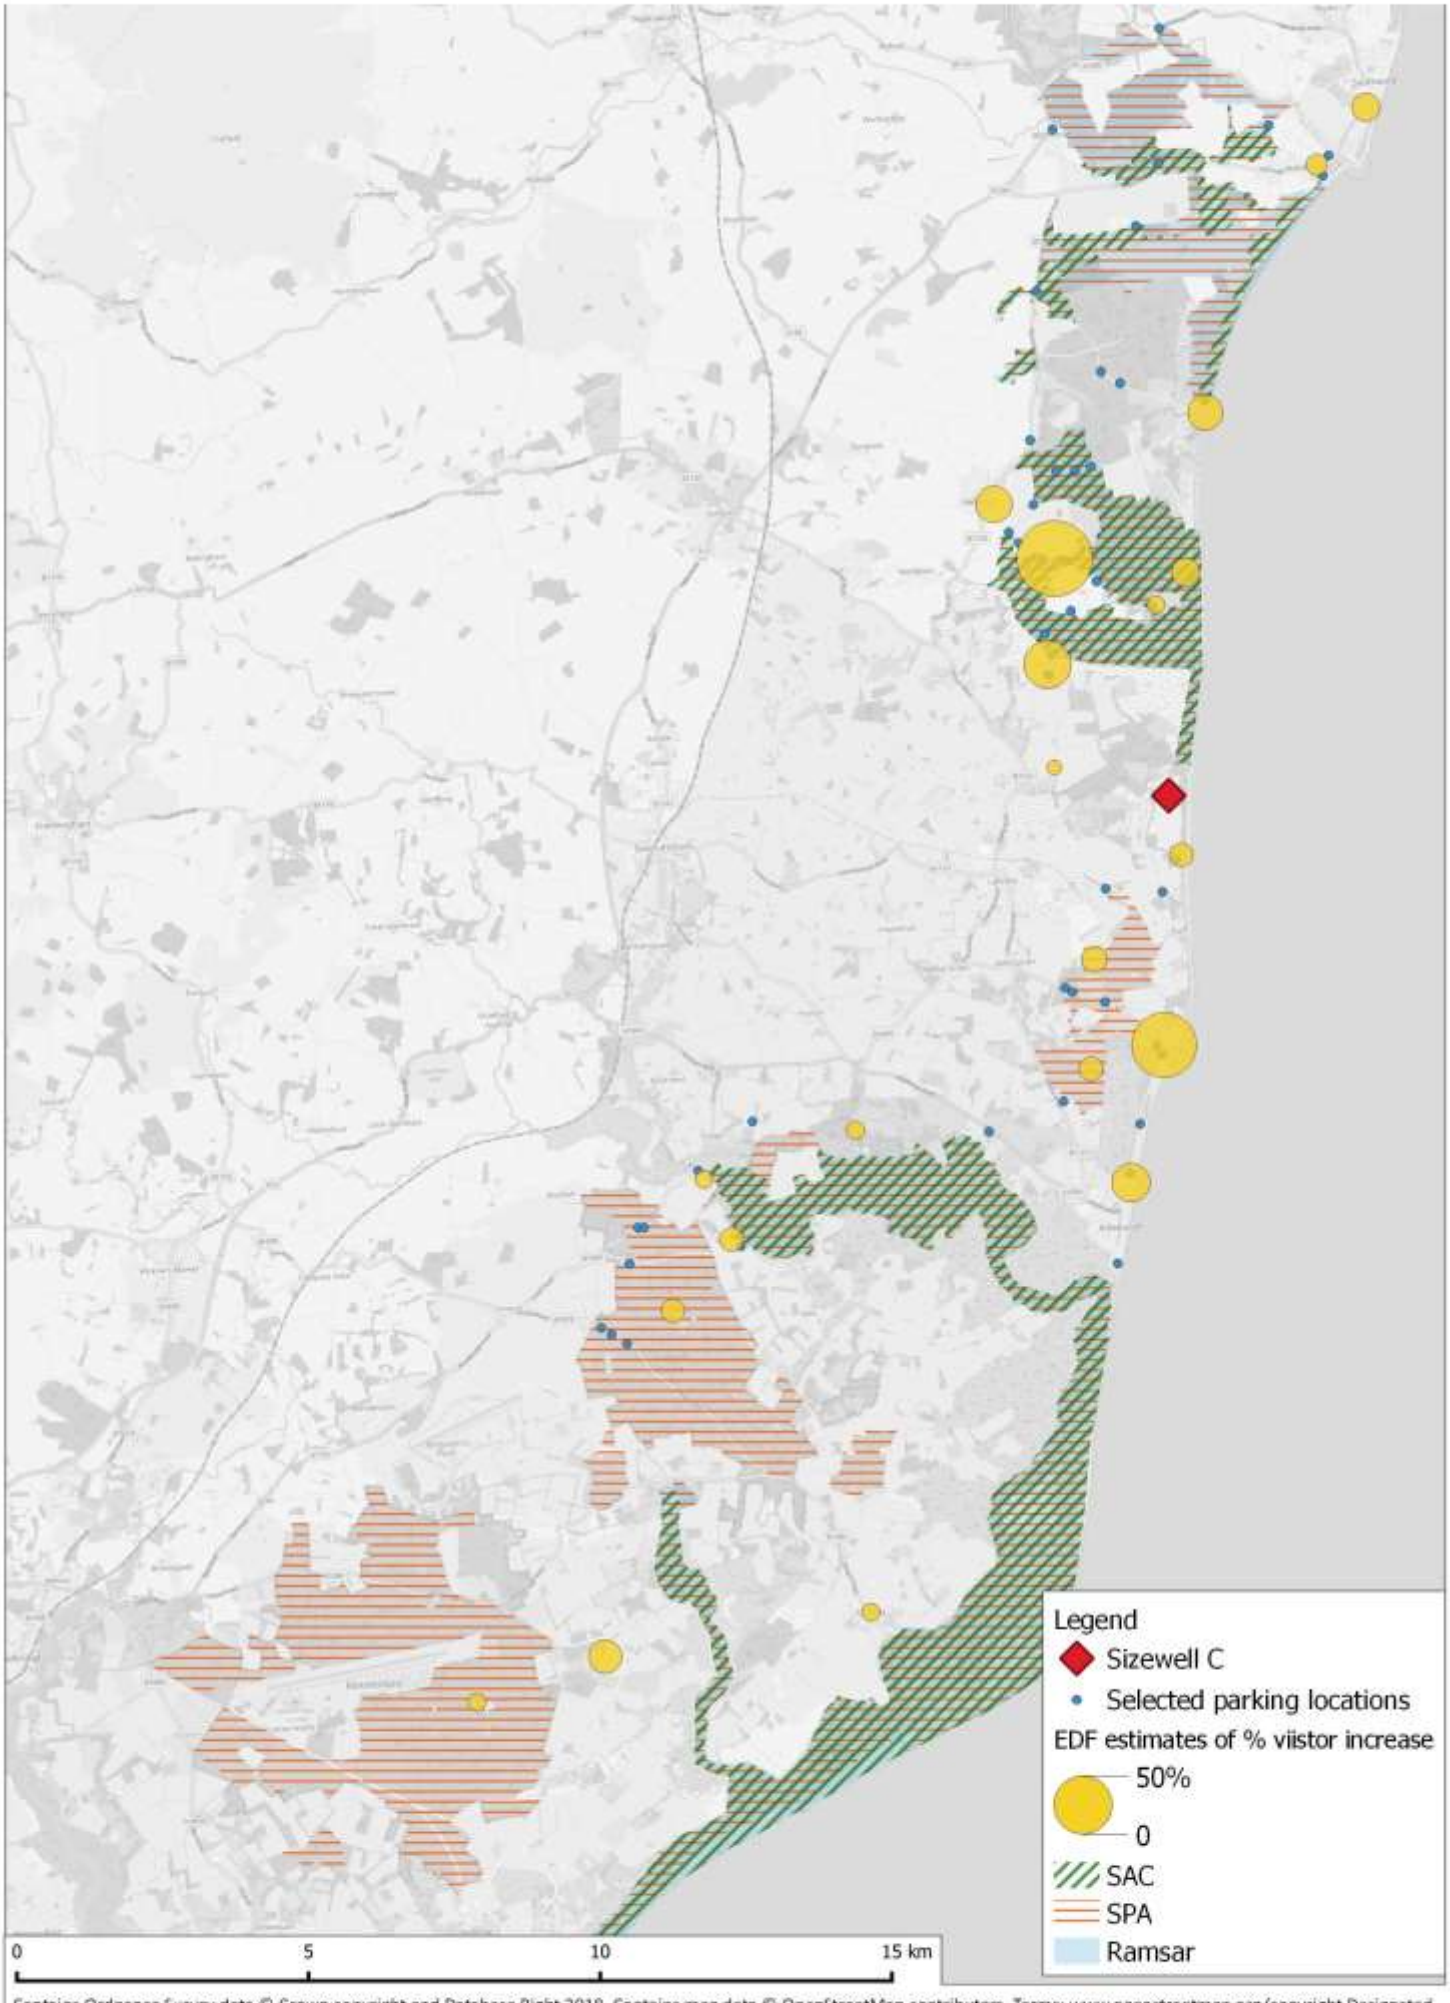
4.5 Despite these concerns, we have generated Map 2, which shows current visitor estimates by EDF and the estimates of additional use. The pie charts are graduated to reflect the total number of visitors (current and new combined) that EDF estimate. The pie charts are drawn in the approximate locations reflecting the names used by EDF and relate to a general area rather than the specific location.



4.6 Map 3 is similar and uses the same data, although the circles are graduated to show the % increase in use estimated by EDF for each general location.

4.7 In both Map 2 and Map 3 we have also shown parking locations. These are approximate and intended as a guide only, they have not been systematically mapped on the ground and checked. These blue points do highlight the range of parking locations whereby visitors can access European sites. We would have expected EDF to present visitor data at this kind of resolution, i.e. current and predicted visitor numbers at each access point. This would have allowed much more detailed analysis of visitor data alongside ecological data (habitats and species distributions). Such data gathering would then have allowed changes in access to be related to vulnerable species, providing a means by which impacts could be properly assessed and appropriate mitigation established. Unfortunately, such data are lacking, and it is not possible to gain a robust and reliable overview of current recreation use, let alone reliable predictions of future use were Sizewell C to go ahead.

European sites and qualifying features



4.8 In Table 6 we summarise the European sites and identify the qualifying features we consider potentially vulnerable to recreation impacts. We have scored each according to the likely risks from the Sizewell C proposal.

Map 2: EDF estimates of visitor use and change

Contains Ordnance Survey data © Crown copyright and Database Right 2018. Contains map data © OpenStreetMap contributors. Terms: www.openstreetmap.org/copyright Designated site boundaries download from the Natural England website © Natural England.

Map 3: EDF estimates of visitor use: percentage increase

Contains Ordnance Survey data © Crown copyright and Database Right 2018. Contains map data © OpenStreetMap contributors. Terms: www.openstreetmap.org/copyright Designated site boundaries download from the Natural England website © Natural England.

Table 6: Overview of potential impacts by site and qualifying feature. All features considered at risk are listed below, where there is overlap between Natura 2000 site features and Ramsar then we have not repeated the relevant information for the Ramsar sites. We have scored the potential impacts on a scale of 1-5. 1= risks very low, likely impact low and of relatively low concern – likely significant effects (LSE) can probably be ruled out but further checks/review necessary. 5 = risks marked, likely to occur and of major concern, may be hard to rule out adverse effects on integrity, even with mitigation. Blank cells indicate no risk identified. Shading reflects the score (from 1 (amber) to 5 (dark red)). Avian interest features are identified as breeding (br) and/or wintering (w).

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
Alde, Ore & Butley Estuaries SAC	1130 Estuaries		1				These are intertidal and subtidal habitats. Access to estuary habitat at Slaughden, Snape and Iken, potentially further afield (e.g. Orford, Boyton). Risks relate to very limited trampling damage, e.g. access to boats, paddleboards, kayaks etc. Probably can be ruled out as no LSE.
	1140 Mudflats and sandflats not covered by water at low tide		1				These are intertidal habitats. Access possible at Slaughden, Snape and Iken, potentially further afield (e.g. Orford, Boyton). Risks relate to very limited trampling damage, e.g. access to boats, paddleboards, kayaks etc. and people walking out from shore. Probably can be ruled out as no LSE due to nature of terrain relatively robust habitat. Probably can be ruled out as no LSE.
	1330 Atlantic salt meadows (Glauco-Puccinellietalia)		1				Trampling damage possible on saltmarshes, which are relatively easy to walk on. Trampling can cause loss of vegetation and lead to risks from erosion (e.g. storm surges). Risks limited to locations such as Slaughden, Snape and Iken, potentially further afield (e.g. Orford, Boyton).
Benacre to Easton Bavents Lagoons SAC	1150 Coastal lagoons		1		1		Some distance away from Sizewell and therefore unlikely to see marked changes in access. Lagoons vulnerable to damage from trampling around edge and increased turbidity and pollution from dogs and people entering the water. Benacre, Covehithe, and Easton Broad are the key locations. Access likely to have little impact given dynamic coastline and changes to these habitats in recent years. Probably can be ruled out as no LSE.
Orfordness - Shingle Street SAC	1150 Coastal lagoons		1		1		These are percolation lagoons and have changed shape markedly over time. Key location is at Shingle Street, which is a considerable travel distance from the Sizewell area. Risks relate to damage from

Impacts of recreation related to Sizewell C and implications for European sites.

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
							trampling around edge and increased turbidity, and pollution from dogs and people entering the water. Starlet Sea Anemone *Nematostella vectensis* likely to be vulnerable to trampling. LSE can probably be ruled out due to the travel distance.
	1210 Annual vegetation of drift lines		1	1	1		Accessible areas at Slaughden and Shingle Street. Risks relate to trampling leading to loss of vegetation. Localised impacts from barbeques and fires on the beach, resulting in small burnt patches. Contamination from dog fouling, and possibly from litter, fishing wire etc. as a result of increased fishing use.
	1220 Perennial vegetation of stony banks		2	1	1		Accessible areas at Slaughden and Shingle Street. Risks relate to trampling leading to loss of vegetation and damage to lichens. Contamination from dog fouling, and possibly from litter, fishing wire etc. as a result of increased fishing use.
Minsmere to Walberswick Heaths & Marshes SAC	1210 Annual vegetation of drift lines		3	1	3		Concerns would relate to a marked and prolonged spike in access, at Sizewell, from Eastbridge to the Sluice area, around Dunwich Cliffs, Dunwich and Walberswick. Potential for increased use in evenings and early mornings due to proximity to construction campus. Further trampling will lead to vegetation loss, potential for beach fires/barbeques to also cause localised vegetation damage. Contamination from dog fouling.
	4030 European dry heaths		2	4	3	2	Numerous easily accessible locations where access likely to increase markedly. Trampling damage from increased footfall likely to lead to track widening, increase in grasses, exacerbated further by nutrient enrichment from dog fouling. Risks of spread of species such as Piri-Piri Burr. Fire risk marked concern, from discarded cigarettes, barbeques and campfires and potential for major incident in area between Westleton and Eastbridge or Dunwich Heath. Given proximity of construction workers campus, barbeques etc in evenings a clear risk. Impacts to management relate to the potential for grazing to be compromised, for example through incidents with dogs.

Impacts of recreation related to Sizewell C and implications for European sites.

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
	1220 Perennial vegetation of stony banks		3	2	3		Concerns would relate to a marked and prolonged spike in access, at Sizewell, from Eastbridge to the Sluice area, around Dunwich Cliffs, Dunwich and Walberswick. Potential for increased use in evenings and early mornings due to proximity to construction campus. Further trampling will lead to vegetation loss, potential for beach fires/barbeques to also cause localised vegetation damage. Contamination from dog fouling, and possibly from litter, fishing wire etc. as a result of increased fishing use.
Alde-Ore Estuary SPA	Marsh Harrier (br)	1					Disturbance at nest a risk and birds can nest in small patches of reed and crops, potentially accessible and vulnerable, e.g. from dogs. Due to distance and habitat risks probably low.
	Lesser Black-backed Gull (br)	1					Gulls breed on Orfordness and accessibility limited and access difficult. Risks very low and LSE can probably be ruled out.
	Ruff (w)	1					Low numbers winter and use wet grassland that is difficult to access due to ditches and water table. Very low risk from dogs off lead. Relevant locations will be Hollesley Marshes, Boyton Marshes, and Town Marshes, all of which are outside the SPA (but functionally-linked).
	Avocet (br & w)	2					Breeding can occur, or is possible, at a range of locations, including Hazlewood Marshes, saltmarsh areas, Havergate Island and lagoons near Shingle Street. Most areas inaccessible and access controlled, but impacts possible at some of the breeding sites. Estuary is narrow and issues for birds feeding on intertidal areas from dogs off-lead, people straying onto saltmarsh.
	Little Tern (br)	2					Little Terns have bred at a range of locations along the coast – numbers can fluctuate and colonies shift between years. Birds will shift between different European sites and different parts of the coast. Species highly vulnerable to disturbance from dogs off lead and people on beaches. Alde-Ore sites are primarily at Orfordness, where access is difficult.
	Sandwich Tern (br)	1					Main breeding site is Havergate where nesting in recent years only sporadic. Colonies can shift markedly over time and are very vulnerable to disturbance events. LSE to the species at Havergate can probably be ruled out.

Impacts of recreation related to Sizewell C and implications for European sites.

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
	Redshank (w)	2					Increased access at Iken, Snape, Hazlewood Marshes, Town Marshes and Slaughden has potential to increase amount birds are flushed and disrupt foraging. Dogs off-leads likely to be a particular issue. Impacts during particularly cold weather perhaps most likely.
Benacre to Easton Bavents SPA	Bittern (br)	1					Nest sites unlikely to be vulnerable due to difficulties in access. Birds feeding around peripheral areas of reedbeds perhaps vulnerable to increased access, including dogs off-leads. Given distance from Sizewell, LSE can probably be ruled out.
	Marsh Harrier (br)	1					Disturbance at nest a risk and birds can nest in small patches of reed and crops, potentially accessible and vulnerable, e.g. from dogs. Due to distance and habitat risks probably low.
	Little Tern (br)	2					Little Terns have bred at a range of locations along the coast – numbers can fluctuate and colonies shift between years. Birds will shift between different European sites and different parts of the coast. Species highly vulnerable to disturbance from dogs off lead and people on beaches. Main breeding at Benacre but could nest at other locations, however in recent years main colony in area is further north still at Kessingland. While highly vulnerable to disturbance impacts, concern low due to distance from Sizewell.
Minsmere to Walberswick SPA	Shoveler (br & w)	2				1	Present on pools and waterbodies and grazing marsh across the area, and potentially vulnerable to disturbance from dogs and people in the vicinity of Eastbridge, including Minsmere Levels. Impacts from site management relate to issues with achieving necessary grazing.
	Teal (br)	2				1	Present on pools and waterbodies and grazing marsh across the area, and potentially vulnerable to disturbance from dogs and people in the vicinity of Eastbridge, including Minsmere Levels. Impacts from site management relate to issues with achieving necessary grazing.
	Gadwall (br & w)	2				1	Present on pools and waterbodies and grazing marsh across the area, and potentially vulnerable to disturbance from dogs and people in the vicinity of Eastbridge, including Minsmere Levels. Impacts from site management relate to issues with achieving necessary grazing.

Impacts of recreation related to Sizewell C and implications for European sites.

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
	European White-fronted Goose (w)	3				1	Birds wintering on Minsmere Levels and nearby grazing marsh at risk from increased use by people and dogs. Risk of birds using the area less and increased flushing when present. Impacts from site management relate to issues with achieving necessary grazing.
	Bittern (br)	2		1			Nest sites unlikely to be vulnerable due to difficulties in access. Birds feeding around peripheral areas of reedbeds perhaps vulnerable to increased access, including dogs off-leads. Potential for birds to use areas such as around Eastbridge less. Fire risk to upper parts of reedbeds and during periods of extreme dry weather. Reedbed adjoins heath/dry areas e.g. Keeble Marsh and risk of fire spreading between habitats.
	Nightjar (br)	4		3		1	Birds around Westleton, on Dunwich Heath and in Dunwich Forest vulnerable to increased disturbance, particularly from dog walking. Potential for birds to avoid nesting in some areas and risk of reduced breeding success. A major fire incident on the heaths could result in direct loss of nests and reduction in number of territories in subsequent year(s).
	Marsh Harrier (br)	2		1			Disturbance at nest a risk and birds can nest in small patches of reed and crops, potentially accessible and vulnerable, e.g. from dogs.
	Hen Harrier (w)	2		2			Increased disturbance at roost could result in roost being abandoned, access in evening (e.g. dog walkers) particularly of concern. Roosts in deep heather on the heath, which could be destroyed by fire.
	Avocet (br)	3					Birds nesting on the lagoons at Walberswick marshes and Dingle vulnerable to disturbance, particularly from dogs off leads. Risks include birds avoiding areas of otherwise suitable habitat and chicks being killed by dogs.
	Little Tern (br)	3					Little Terns have previously bred at a range of locations along the coast including in front of Sizewell A Power Station. Numbers can fluctuate and colonies shift between years. Birds will shift between different European sites and different parts of the coast. This species highly vulnerable to disturbance from dogs off lead and people on beaches. Increased access could result in birds avoiding otherwise suitable habitat, colonies deserting, breeding success being compromised and dogs killing chicks.

Impacts of recreation related to Sizewell C and implications for European sites.

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
Sandlings SPA	Nightjar (br)	4		3		1	Birds around Aldringham Walks, North Warren, and potentially Snape and Tunstall Forest vulnerable to increased disturbance, particularly from dog walking. Potential for birds to avoid nesting in some areas and risk of reduced breeding success. A major fire incident could result in direct loss of nests and reduction in number of territories in subsequent year(s).
	Woodlark (br)	4				2	Birds around Aldringham Walks, North Warren, and potentially Snape and Tunstall Forest vulnerable to increased disturbance, particularly from dog walking. Also birds around Minsmere and Dunwich Forest functionally-linked to this SPA. Potential for birds to avoid nesting in some areas and risk of reduced breeding success. A major fire incident could result in direct loss of nests and reduction in number of territories in subsequent year(s). Access may also compromise ability to graze sites effectively e.g. through dog incidents and livestock. Marked increases in dogs may affect rabbit distribution and use, which is also important for Woodlarks.
Alde - Ore Estuary Ramsar (additional to SPA/SACs)	Notable assemblage of breeding and wintering wetland birds	2					Increased access at Iken, Snape, Hazlewood Marshes, Town Marshes and Slaughden has potential to increase amount birds are flushed and disrupt foraging. Dogs off-leads likely to be a particular issue.
Minsmere - Walberswick Ramsar (additional to SPA/SAC)	Site contains a mosaic of marine, freshwater, marshland and associated habitats, complete with transitional areas in between. Contains the largest continuous stand of reedbeds in England		1	2	2	2	Trampling damage in drier areas and peripheral habitats possible. Major fire incident in reedbeds a concern. Contamination risks from dogs in ditches, pools, and wet habitats spreading invasive species such as New Zealand Pygmyweed. Dog incidents could affect ability to graze effectively.

European site(s)	Qualifying feature	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes and key concerns
	and Wales, and rare transition in grazing marsh ditch plants from brackish to fresh water						
	Nationally scarce plant species and British Red Data book invertebrates, including a population of Narrow-mouthed Whorl Snail		1	1	2	1	Trampling damage in drier areas and peripheral habitats possible. Major fire incident in reedbeds a concern. Contamination risks from dogs in ditches, pools and wet habitats spreading invasive species such as New Zealand Pygmyweed. Dog incidents could affect ability to graze effectively.
	An important assemblage of rare breeding birds associated with marshland and reedbeds	2		1		1	Risks from increased disturbance around periphery of wetland areas, from dogs off-leads and walkers. A major fire incident in reedbed could result in loss of breeding territories and species richness. Dog incidents could affect ability to graze effectively.

Vulnerable features that are not qualifying interest

4.10 Our focus in this report is on the European site interest. However, it is important to note that the area contains a wide range of habitats and species that is of outstanding importance for nature conservation and unique within the UK. There are other species and habitats in the vicinity which, while not qualifying features for the European site, are also of considerable conservation importance and potentially vulnerable. These include:

- **Stone Curlew** *Burhinus oedicnemus* breed on the acid grassland and open sandy farmland in the Walberswick/Westleton area, including the outer parts of the Minsmere RSPB reserve. The population is relatively low and the species is particularly vulnerable to disturbance, with dogs off-led a concern (Clarke & Liley, 2013; Taylor, 2006; Taylor, Green, & Perrins, 2007).
- **Ringed Plover** nest in small numbers on the beaches and are highly vulnerable to disturbance, which influences settlement pattern and breeding success (Liley & Sutherland, 2007).
- **Dartford Warbler** *Sylvia undata* nest low down in heathland vegetation and studies have shown impacts from disturbance, with reduced breeding success in disturbed territories. This species returned to Suffolk in the 1990s.
- **Adder** *Vipera berus* are found in a range of habitats in the general area, including heathland, scrub and the back of the beach. This declining reptile is vulnerable to recreation impacts, particularly dog attacks (Worthington-Hill, 2015)**.**
- **Acid Grassland** is vulnerable to impacts from fire and eutrophication (e.g. from dog fouling), while extensive grazing which is important to maintain the habitat, can be difficult where access is high.
- **Scarce invertebrates** there are a number of species, such as Antlion *Euroleon nostras*, for which the Minsmere area is important. There are risks for some of these species from access, for example through trampling and fire.

5. Mitigation

5.1 In this section we briefly consider the likely visitor profile and behaviours and set out broad approaches to mitigation that might be relevant.

Visitor profile and behaviours

5.2 The issues identified arise from increased recreation use associated with a marked increase in the local population and displacement of existing access.

5.3 It is important to recognise that there is potential for a marked change in visitor profile and the way people access the sites identified. This is because use by locally based construction workers will be very different to the use associated with recreation by tourists, day visitors travelling from a wide area, and second homeowners. Postcode analysis of visitors to the main part of the Minsmere RSPB Reserve (e.g. Hoskin et al., 2019) reveals people travelling considerable distances to visit the reserve. These visitors are likely to be drawn for the specific nature interest and wildlife spectacle.

5.4 People coming to the area to live and work in the vicinity will seek nearby greenspace for recreational use that is not necessarily related or connected to the area's conservation interest, and such use will include exercise and dog walking. It may extend to sea angling, barbeques, swimming, and beach recreation. Such people are likely to consciously avoid the areas they perceive as 'nature reserves' (i.e. where there are hides, wardens and a fee to enter) and instead focus their use at more peripheral locations. These are often still part of the European site and do not have necessary infrastructure to manage access. For example, around the Westleton and Eastbridge there are numerous public rights of way and also many areas that are 'open access' under the Countryside and Rights of Way Act (2000). The focus for increased recreational use is likely to be away from the main car-parks (such as the main Minsmere car-park and NT Dunwich Heath) where existing visitor management and engagement is focussed. We would expect construction workers based in the area to utilise more informal parking and locations where they can easily access beaches, quiet areas of heath, etc.

5.5 Use by construction workers will also be likely to take place in the early mornings, evenings, and around shift work and therefore not necessarily fit with peak visitor use and the current visitor profile.

Mitigation Options

5.6 Given the range of issues identified and the range of risks, a package of mitigation measures will be necessary. Any package will need to involve a number of different measures and be flexible in order to respond to changing access patterns or particular issues. Weather conditions, trends in access, the occurrence of rare wildlife, and a range of other factors will influence the scale of risk and the particular concerns at any one time. Different measures may be more important at some times compared to others. For example, prolonged periods of dry weather and a hot summer will bring particular fire risks, while cold winter weather may make birds more vulnerable to disturbance.

5.7 An overview of some potential mitigation options are summarised in Table 7. This indicates which measures may relate to which kinds of impact. In order to develop any mitigation package in detail, it will be necessary to draw on visitor data and liaise closely with the relevant site managers.

5.8 Any mitigation package should also include comprehensive monitoring that should be integrated alongside the mitigation and pick-up any emerging issues. Monitoring would potentially include counts of parked vehicles, counts of people, visitor interviews and regular checks on infrastructure. Unfortunately, the data collection to inform the evidence base presented by EDF is inadequate to form a foundation for such monitoring. Ideally the data collected to date would provide a baseline from which changes could be identified and locations targeted for mitigation. Unfortunately EDF have not collected such data at the relevant level of detail.

Table 7: Overview of possible mitigation options.

Mitigation option	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes
Increased warden presence	✓	✓	✓	✓	✓	Targeted to vulnerable locations. Can be flexible and responsive to emerging issues. Needs to be adequately resourced to be effective as mitigation and likely to involve anti-social hours.
Fenced exclosures on beach	✓	✓	✓			Not always effective and need to be combined with other measures (signage, warden presence). Fencing can protect vegetation and suitable habitat for breeding birds.
Access restriction	✓	✓		✓	✓	Options include enhancing fencing, ensuring gates are locked, making gates effective barriers for dogs (e.g. with mesh), blocking access to watersides etc. These measures provide potential to restrict access by dogs into sensitive watercourses, access onto grazing marsh etc. These approaches can be difficult to maintain and can be compromised by vandalism, cutting etc.
Temporary signage	✓	✓	✓	✓		Providing ability to highlight particular issues, such as high fire risk, presence of rare breeding birds, livestock.
Waymarking and permanent signage	✓	✓		✓	✓	Helps direct visitors and manipulate visitor flow.
Path management	✓	✓			✓	Boardwalks and vegetation management on path edges can help keep access to paths. Potential for less sensitive public footpaths and routes to be enhanced.

Mitigation option	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes
Dead hedging	✓	✓			✓	For example, using cut gorse and brash. Potential to close off desire lines as they form and potentially limit access by dogs. Likely to be effective only as a short term response measure and reactive.
Firebreaks			✓			Additional firebreaks, potentially targeting protection of areas at risk for changes in access. Can create new desire lines so need to be chosen carefully. Regular cutting required to maintain.
Fire management planning			✓			Reserves will have existing fire management plans. These may benefit/need reviewing in light of changes in access and visitor pressure.
Access to water/provision of new fire hydrants			✓			New fire hydrants on heath have been provided as mitigation for housing on Dorset Heaths. Clearly will not stop impact occurring but may lessen effect.
Public engagement	✓		✓	✓		Scope for messaging to target particular behaviours and issues, such as as use of disposable barbeques, dogs off-leads, dog fouling etc. Potential to react to new/emerging issues. Potential for targeted information provision at construction campus as to where to go for recreation. There is little certainty associated with these measures and they perhaps work best to reinforce other measures (e.g. wardening).
Controls on local shops selling disposable barbeques			✓			Potentially difficult to secure and limited in effectiveness if available more widely.

Mitigation option	Disturbance	Damage	Fire	Contamination	Impacts on site management	Notes
Controls on parking	✓	✓	✓	✓	✓	Potential to close off small parking locations, e.g. with bunds or dragons teeth. Also possible to reduce the number of spaces. Gates on car-parks can prevent access in late evening/early morning and help limit anti-social behaviour.
Provision of dog bins/litter bins				✓		Bins require emptying and therefore cost to maintain.
Provision of dedicated space for exercise and dog walking for construction workers	✓	✓		✓	✓	Would need to be large and could be promoted directly to workers. May be difficult to provide an adequate space to deflect people from the coast.
Gym membership for construction workers	✓	✓				Would not be effective for dog walkers but may work to direct certain activities (e.g. jogging) away from sensitive locations. Would require some research and survey work to determine whether any likelihood of effectiveness.
Screening	✓					Potential for planting/vegetation growth, use of reed/heather screens or other structures to create visual barriers for people and dogs. Likely to be an option only in limited/specific locations.
Manipulation of water levels	✓	✓				Raising water levels or retaining deep water in ditches etc. may help restrict access to some locations.
Enforcement	✓			✓		There may be scope with PSPOs in some locations to control dogs off leads and fouling. Would require enforcement and may be difficult to establish.

Version: Final
Recommended Citation: Liley, D. & Saunders, P. (2020). Review of Sizewell C application documents and evidence in relation to recreation impacts. Unpublished report by Footprint Ecology.

Summary

Footprint Ecology have been commissioned by the National Trust and RSPB to provide a review of evidence (submitted as part of the Sizewell C application) on recreation issues. The construction of the power station will require a peak workforce of 7,900 construction workers, leading to a marked increase in the number of residents in the area. In addition, construction will result in the closure of access routes and the displacement of visitors due to path closures, noise, additional traffic, etc. Marked changes in local access are therefore likely. The Sizewell C site is directly adjacent to multiple European sites where there are existing rights of access and numerous species and habitats vulnerable to recreation impacts.

Recreation impacts include disturbance, trampling, increased fire risk, and contamination (e.g. spread of invasive species, dog fouling, etc). Some of the key sensitive areas are already carefully managed, with resources in place to both manage access and allow visitors to experience the area while minimising harm. Areas such as the main car park at Minsmere draw visitors from across the country and are well-known visitor destinations, drawing visitors for the wildlife spectacle and nature interest. Here there are well marked paths, hides, screens, wardens and careful management to allow wildlife to flourish and people to be able to experience it.

Concern with respect to the Sizewell C proposals and recreation impacts therefore relates to vulnerable features within the more peripheral areas of the European sites, where public footpaths, informal parking, and open access provide opportunities for recreational use, and where any issues arising from access are much harder to manage. Access to these locations is more likely to be for dog walking, jogging, picnics, barbeques, fishing, etc. (rather than to see wildlife).

Our review highlights that:

The baseline for current visitor use is inadequate. Count data (visitor numbers) are only provided for a small number of locations (surveyed in 2014) and just for August and November. Many of the smaller, more vulnerable, locations (from an ecological perspective) have not been surveyed.

Predictions of increased use are confusingly presented, with different estimates given in different reports alongside some clear errors. Estimates appear very low compared to national data and are much lower than we would expect, based on our experience of visitor surveys and recreational use of the countryside.

Impacts are poorly assessed, and the consideration of impacts for the following are particularly poor and inadequate:

- Perennial vegetation of stony banks (Minsmere to Walberswick Heaths & Marshes SAC);
- European Dry Heaths (Minsmere to Walberswick Heaths & Marshes SAC);
- Little Tern (Minsmere-Walberswick SPA);
- Nightjar (Minsmere-Walberswick SPA);
- Hen Harrier (Minsmere-Walberswick SPA);
- Wintering waterbirds (Shoveler, Gadwall, White-fronted Goose) (Minsmere-Walberswick SPA);
- Breeding waterbirds (Shoveler, Gadwall, Teal) (Minsmere-Walberswick SPA), and;
- Woodlark (Sandlings SPA).

Mitigation measures are scant and fail to address the nature conservation issues that are likely to arise.

Ultimately the Suffolk Coast is of unique importance for nature conservation and supports a diversity of habitats and species that is unparalleled in the UK, particularly in the area between Slaughden and Southwold. The area also draws high numbers of visitors, resulting in a difficult balancing act to manage both access and nature conservation; it is a crowded area.

Sizewell C would disrupt the balance and the application documents do not provide the robust assessment and mitigation package that we expected. The assessment of impacts is inadequate, and predictions of changes in visitor use are full of inaccuracies, confusing, and poorly put together. Necessary mitigation, targeted to the vulnerable locations, is virtually non-existent. Ultimately, the information as presented in the Shadow HRA does not allow a conclusion of no adverse effect on integrity, from recreation impacts, to be drawn for a range of different species and habitats across multiple European sites.

We are grateful to Emma Hay (National Trust) for commissioning and overseeing this work. In addition, we are grateful to Graham Brown (National Trust), Jacqui Miller (RSPB), and Adam Rowlands (RSPB) for useful background information and discussion.

1. Introduction

1.1 This document has been commissioned by the National Trust and RSPB to assist both organisations with their response to the application for a new power station at Sizewell C. Both organisations are concerned about impacts from recreation, for example through displacement of recreational users from the vicinity of the Sizewell C development to neighbouring sites during the construction period.

1.2 This report involves a review of specific ecological reports with the aim of checking the robustness of EDF's conclusions. We structure the report addressing the following questions, set by the National Trust/RSPB:

- What is Footprint Ecology's view on the adequacy of EDF's assessment of recreational disturbance impacts (particularly in the HRA) and the robustness of the data on which this is based? Please qualify this view.
- Is any monitoring strategy proposed by EDF sufficient to detect ecological impacts of increased recreational disturbance, with appropriate triggers to secure further mitigation if adverse effects are shown, and assess the effectiveness of mitigation? This may be included in the DCO application or be developed as an Examination requirement.
- Is any mitigation strategy proposed by EDF sufficient to address ecological impacts of increased recreational disturbance? Again, this may be included in the DCO application or be developed as an Examination requirement.
- What would be valuable questions and points that National Trust and RSPB should raise in relation to recreational disturbance impacts with EDF and why?

1.3 More general points or concerns are set out in a table at the end of the report, which picks up any additional points that result from our review.

1.4 Our focus is on the recreation impacts to the nature conservation interest, particularly that relating to European sites. Table 1 lists the documents referred to in this report.

About Footprint Ecology

1.5 Footprint Ecology are a specialist consultancy with particular expertise in the assessment of recreation impacts on nature conservation sites. Our work includes Local Plan HRAs, writing mitigation plans for European sites, visitor survey work, reserve management plans, and visitor management strategies for nature conservation sites.

1.6 Our work on visitor management, recreation assessment, and visitor surveys has included sites such as the New Forest National Park, Epping Forest, Burnham Beeches, the North Kent coast, Wicken Fen, Hatfield Forest, the Humber, Morecambe Bay, the Severn Estuary, Poole Harbour, the Exe Estuary, the Solent, the Dorset Heaths, the Wealden Heaths and the Thames Basin Heaths.

1.7 We have provided advice to Natural England on open access provision under CRoW and on coastal access and we have acted for Natural England, RSPB and local authority clients at public inquiry. Previous work in Suffolk has included visitor surveys on the southern part of the Suffolk Sandlings, a visitor survey of the River Deben, Local Plan HRA work for Ipswich Borough Council, Suffolk Coastal District Council, and Waveney District Council (and now East Suffolk Council). We wrote the Suffolk Coast Recreational Disturbance Avoidance and Mitigation Strategy (RAMS).

2. Adequacy of EDF's assessment of recreation impacts

Overview

2.1 The assessment by EDF is not adequate to rule out the conclusions of no adverse effect on integrity set out in the HRA.

2.2 We expected to see detailed visitor survey work that provided an accurate description of the current use, showing numbers of visitors and footfall across the relevant European sites and supporting habitat. This would have provided the detail of levels of use along different paths and the number of vehicles parked in different locations, allowing maps of current recreation use to be produced. Change could then be predicted to show how construction work and visitor displacement would change access and maps produced to show change alongside ecological data (species and habitats). This would then clearly indicate which locations and which interest features would be vulnerable to change and ensure mitigation measures were fit for purpose and appropriately targeted.

2.3 Instead we find a number of errors and muddled information, with conflicting information scattered across different reports. There is a lack of detail as to what levels of change are to be expected in which precise locations and a failure to apply this to the ecological interest at the appropriate level of detail.

Baseline on visitor use

Existing visitor data

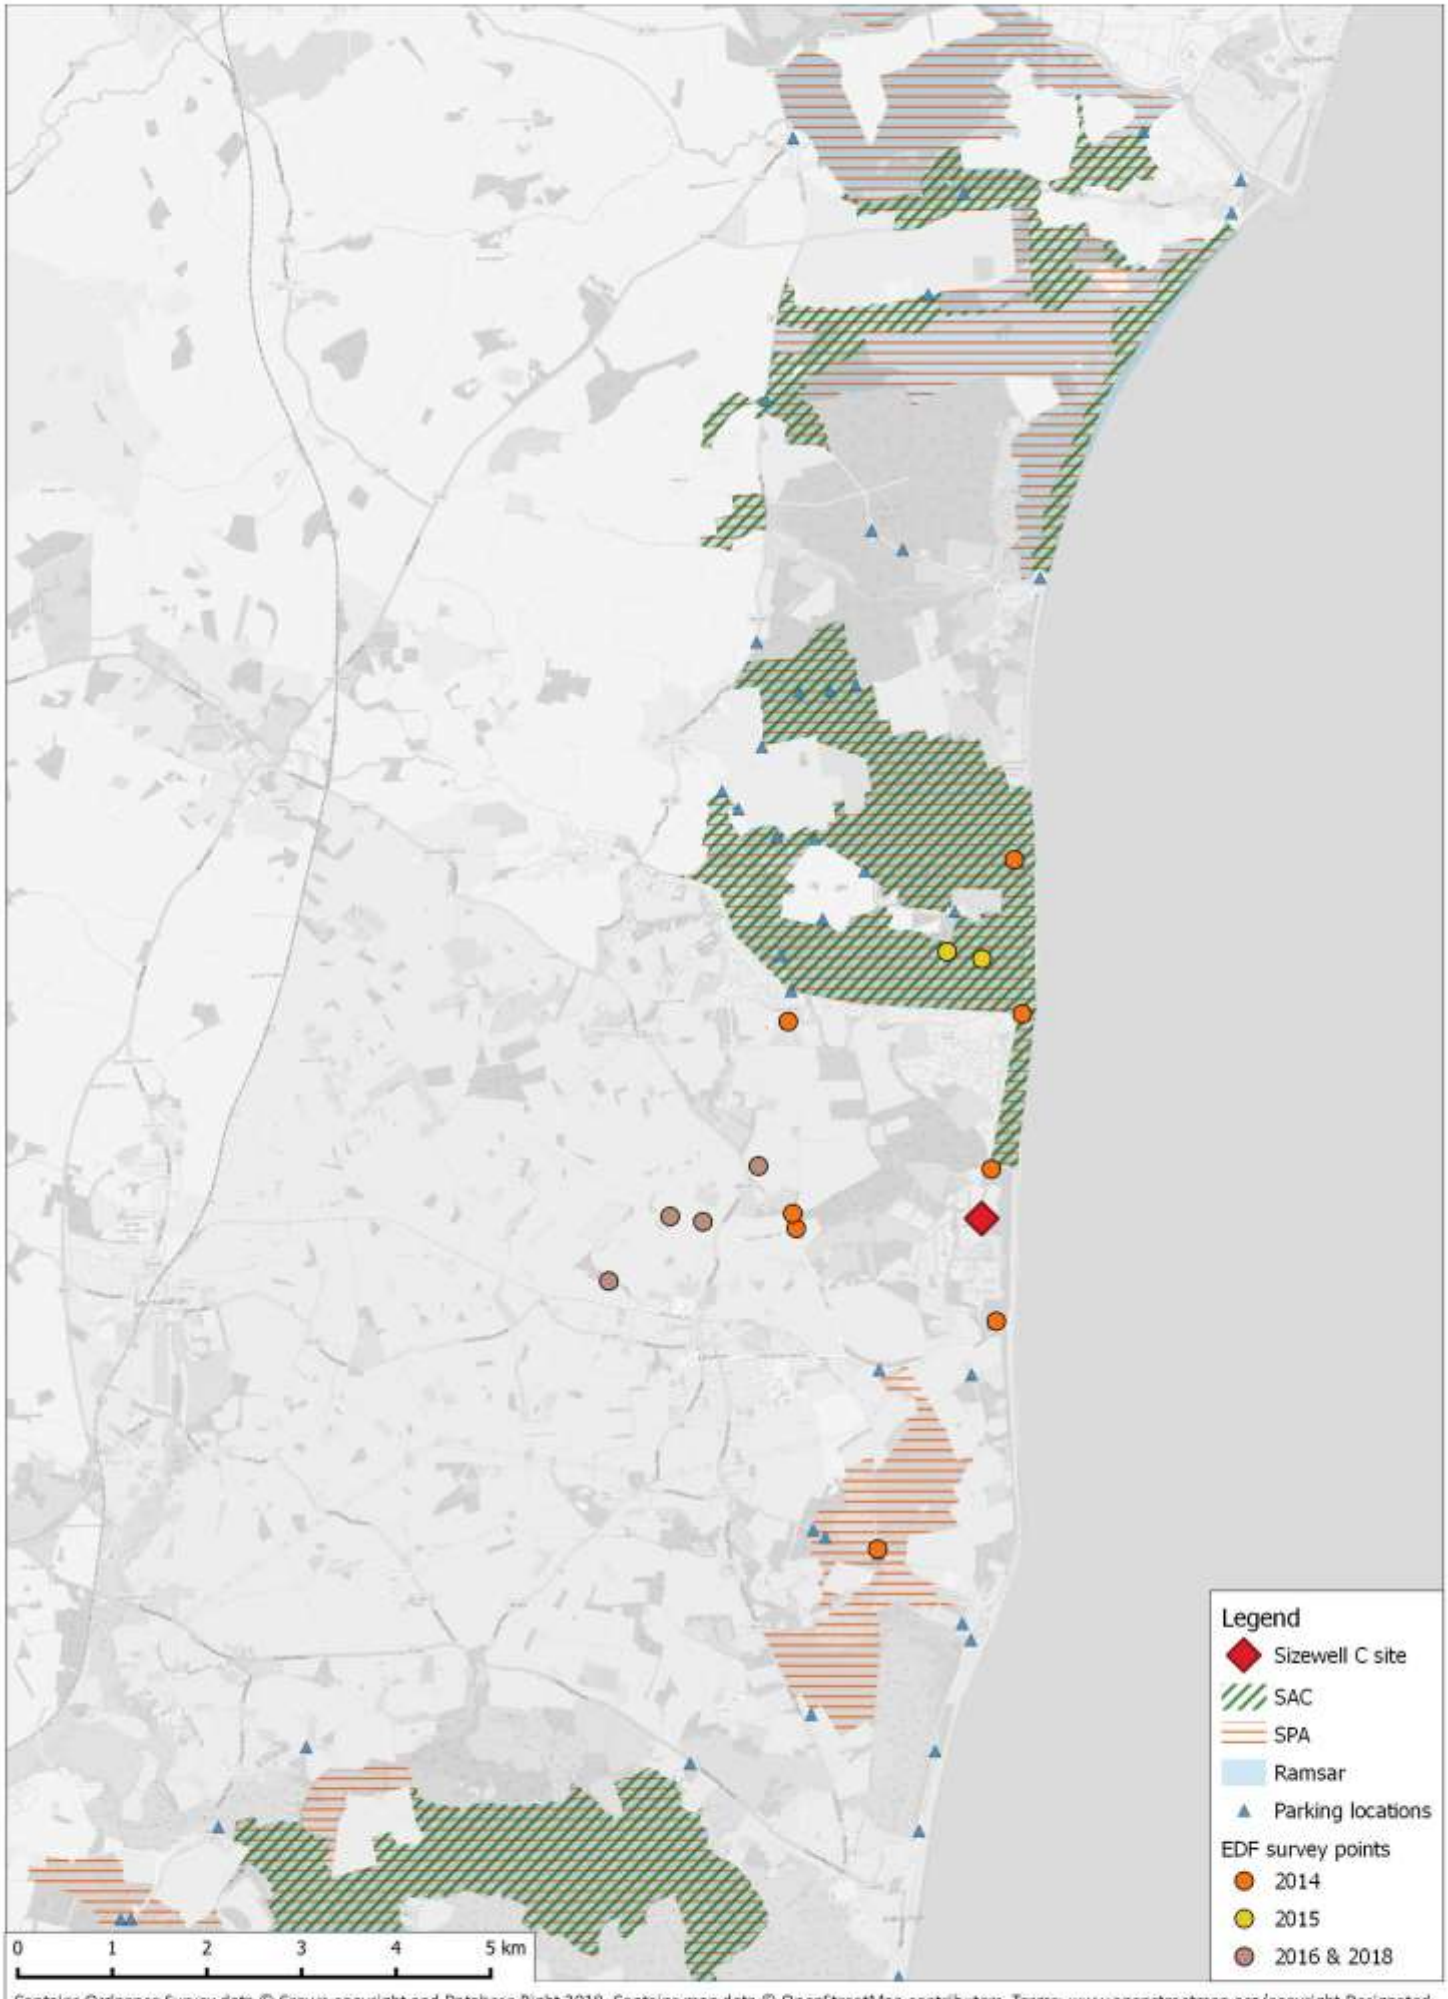
2.4 The **Amenity and Recreation Baseline Report** (para 1.2.2) and **Shadow HRA recreational disturbance evidence base** (para 2.4.1) both list a range of studies as relevant baseline visitor survey information.

2.5 It is noteworthy that while the list in the Shadow HRA recreational disturbance evidence base and the Amenity and Recreation Baseline in the ES are superficially similar, they differ, with 13 studies listed in the Shadow HRA recreational disturbance evidence base and 11 in the Amenity and Recreation Baseline Report, and a different mix in each. While the Shadow HRA recreational disturbance evidence base supposedly includes reports to 2019 and the Amenity and Recreation Baseline only to 2018, it is only the list

in the Amenity and Recreation Baseline that includes a report from 2019. These errors highlight that material is repeated in different places and shoddily collated and does not provide confidence of a robust assessment.

2.6 The **Amenity and Recreation Baseline Report** (para 1.2.4) describes this as a 'good resource'. However, most of the studies listed are very specific (e.g. RSPB data for the core part of Minsmere Reserve) or are general (e.g. Suffolk County Council's Green Access Strategy) with limited relevance. Most are dated (e.g. 2010, 2011, even 2004) and most cover locations well away from Sizewell (e.g. Deben Estuary). As a baseline there is scant information on visitor numbers, activities at different locations relevant to Sizewell C, or how use varies at the different sites.

Surveys commissioned by EDF



2.7 EDF commissioned visitor surveys to gain a more detailed understanding. These involved:

- 2014: 7 locations surveyed in August and November (514 questionnaires) summarised in 2014 **Sizewell C Visitor Surveys**;
- 2015: focussed on the Minsmere Reserve (133 questionnaires) summarised in **2015 Sizewell C RSPB Minsmere Visitor Surveys**;
- Additional surveys undertaken at 5 locations (surveyed in both August 2016 and November 2018, **2016-2018 Sizewell C Visitor Surveys**). These are however not referred to in the Shadow HRA recreational disturbance evidence base and are located away from European sites.

2.8 Map 1 details the locations for all the EDF surveys carried out in 2014, 2015, 2016 and 2018 in relation to the European sites. The map also shows a selection of parking locations around the European sites – locations where visitors might park when visiting them. These are shown as blue triangles and are not intended to be exhaustive. The map highlights that the survey coverage by EDF is minimal. In particular, there are no survey data from locations to the west of the Minsmere Reserve, around Westleton, or north of Dunwich Coastguards. Given the scant information in the existing baseline, we have little confidence that the survey effort is adequate to provide an understanding of visitor use and how that might change. We would have expected better spatial coverage. We would also have expected routes to be mapped and maps produced to show visitor numbers along different paths, allowing visitor data to be overlaid with ecological data. This is missing.

2.9 Surveys were conducted during August and November. While these months allow some comparison across the year, they are a poor choice. During August the coast is very busy with tourists and it might be expected that use by local residents would be reduced during this time. By contrast, November is likely to be more focussed towards local use, but likely to be quite limited. There is a notable gap of survey data from the spring. During the spring we would expect increased local use, making use of the warmer weather and longer days, with people coming from slightly further afield. Many countryside sites see marked peaks in visitors around the Easter period. The spring is also a time when breeding bird interest and other ecological interest is vulnerable to recreation impacts.

Predictions of changes in visitor use

Visits from the construction workforce

2.10 The **Shadow HRA recreational disturbance evidence base** (para 3.3.3) states that the approach taken to estimate recreational use by the construction workforce is based on the best available data and is precautionary. From a review of the data this does not seem to be the case.

2.11 EDF state in para 15.6.42 onwards of the **Amenity and Recreation Report** that the peak workforce would use different types of accommodation and provide the numbers in each:

- 7,900 workers;
  - 2,000 drawn from the existing population;
  - 5,900 non-home based ('NHB');
    - 880 buy homes;
    - 2,400 campus;
    - 600 caravans, and;
    - 2,000 renting (private rented sector or using tourist accomodation).

2.12 However, no evidence is given as to how these estimates are broken down and we suspect there is likely to be considerable guess work in estimating relative proportions. While these are 'peak' figures, it is clear that the workforce will number over 7,000 for 2 years (**Shadow HRA recreational disturbance evidence base** para 3.3.5).

2.13 We have constructed Figure 1 below to try and understand the numbers provided by EDF and understand their related estimates of countryside visits.

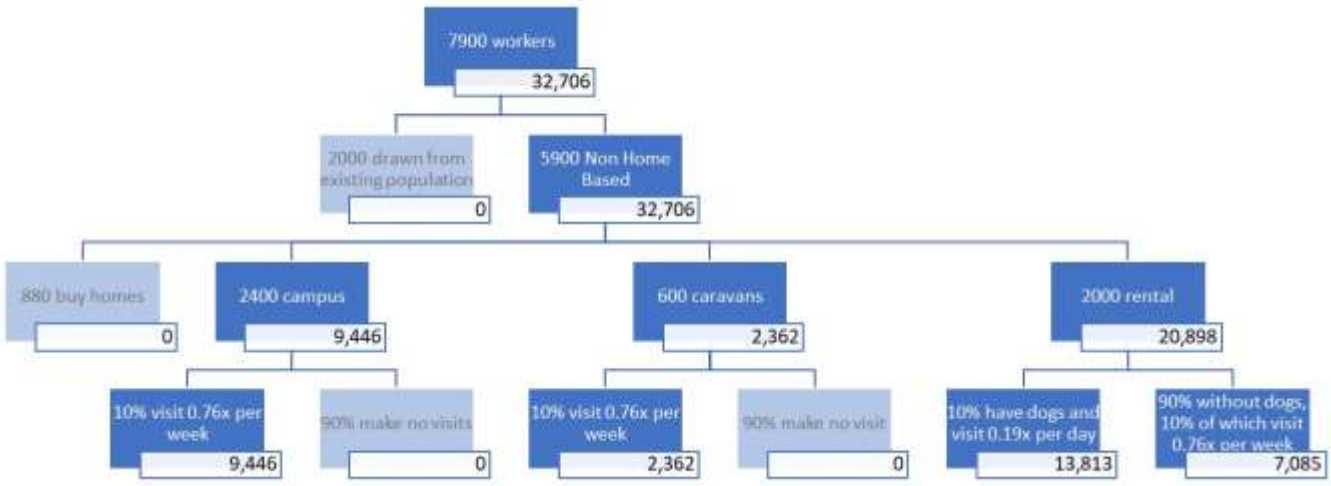

Figure 1: Chart summarising construction workforce and the estimates made of visits to the countryside by each segment. Pale boxes are those where no net increase in visits assumed by EDF. Numbers in bottom right indicate EDF estimates of countryside visits per year for each segment.

2.14 The 2,000 workers who are estimated to come from the existing population, and the 880 who buy their own homes, are discounted by EDF in terms of any recreational impact. EDF suggest they would not be net additional people to the area and therefore have no net additional effect on recreation activity (e.g. para 3.3.6). However, these workers should not be discounted, as they are more likely to visit the area around Sizewell C as they will be based there for work. Some of this workforce might travel independently to, and undertake recreational visits after, work – for example going fishing in the vicinity, walking the dog, or meeting friends or family when their shift has finished.

2.15 For the remaining 5,020 non home-based workers the assumption is made that 10% of those in rental accommodation (10% of 2,000 is 200) will have a dog or dogs and walk their pet daily. This 10% is apparently derived from a mystery shopper survey of rental providers to check how many properties allowed dogs. This rental shopper survey revealed marked variation and was very limited in scope. Many tourist lets, etc, may well have restrictions on pet ownership, but those workers living in rented accommodation are nevertheless considered more likely to own dogs than those living on the campus or in caravans (where dogs are not allowed) and as such are likely to seek out accommodation where pets are allowed. No consideration of this is made.

2.16 The number of dog walks is adjusted down to account for shift work (87%) and holidays (87%). It is not clear how the 87% figures have been derived and it would appear that the assumption is that dog walking would only take place on days when construction workers were doing shifts. The number of dog walks to local countryside sites is then reduced by a further 75% to account for 'short walks local to accommodation before and after shifts, often at night'. Again no justification is made for the application of the 75%.

2.17 For the rest of the 5,020 (i.e. those without dogs), 10% are assumed to undertake informal recreation in the countryside around Sizewell once a week (para 3.3.15 of the **Shadow HRA**). This appears to highly speculative, drawing on tourist board surveys from 2004 for visits by residents of Suffolk Coastal while discounting much more recent, national survey data (MENE) that gives typical visit rates to the countryside.

2.18 The resulting estimates for use of the countryside by the workforce are exceptionally low and far from precautionary. 7,900 workers are predicted to make 32,706 recreation visits to the countryside per year – this equates to around 4 visits per worker. The 32,706 visits are made up of 18,893 visits by those without dogs and 13,813 dog walks.

2.19 Whilst the 32,706 figure is given in the Shadow HRA, a very different estimate is confusingly given in the **Plants and Habitats Synthesis Report** which, on page 20, para 1.3.52, states that there will be 60,000 additional countryside visits per year from the construction workforce. In para 1.3.53 a total of 39,000 are anticipated for the key sites of Sizewell Beach/Sizewell Estate (20,000 annual visits), Aldeburgh (7,000 annual visits), Thorpeness (4,000 annual visits), Dunwich Heath (2,000 annual visits), Dunwich Beach (4,000 annual visits) and Minsmere (2,000 annual visits).

2.20 Further discrepancies are evident in the **Amenity and Recreation Report**. Table 15.7 gives a figure for 18,893 annual countryside visits made by workers without dogs. However, table 15.8 suggests construction workers with dogs would make 55,254 annual visits (after allowing for shift patterns and holidays).

2.21 EDF argue that the levels of recreational use of the countryside among construction workers will be low because: they will work long shifts; they may visit their family, etc/return to a permanent home at weekends; and they are likely to use gyms and sports facilities instead of the countryside, etc. These arguments are made with little justification or support. Market segmentation/demographic profiles produced by Sport England are referred

to (e.g. para 3.3.11 of the **Shadow HRA recreational disturbance evidence base**, see also the **Sport and Leisure Audit)** to justify assumptions about low levels of countryside recreation use. It is important to note that these profiles relate to organised sports, not countryside recreation use.

2.22 The **Shadow HRA recreational disturbance evidence base** totally fails to address that:

- The construction workforce will be based in a highly attractive area with lots of countryside recreation opportunities;
- The campus at Eastbridge is directly adjacent to numerous footpaths that provide access directly to the beach, woodland, heathland, and marshes – with multiple opportunities for activities such as mountain biking, jogging, fishing, photography, picnics, and walking;
- Some workers are likely to be drawn to work in the area and particular accommodation types due to recreation opportunities;
- Shift workers and those in temporary accommodation may use their weekends and non-shift time to explore the new area, and;
- There are increasing trends for informal recreational use of the countryside and that, following Covid, access patterns have changed markedly.

2.23 It is possible to drill into survey data and figures from other studies to highlight just how low the estimates from EDF are, with some consideration of relevant studies provided below.

2.24 Natural England's Monitoring Engagement with the Natural Environment (MENE) dataset provides national data on recreation use, with MENE data cited in the Shadow HRA recreational disturbance evidence base (para 2.4.18). Here, EDF's own report states that 3 in 5 adults in England make visits to the natural environment once a week and 51% of these visits were to the countryside or coast.

2.25 Drawing on the most recent MENE data (O'Neill, 2019), the average number of visits to the natural environment taken per person per week in 2018/19 was 1.7. This visit rate has been rising steadily (it was 1.3 in 2009). If this rate of 1.7 were applied to the entire workforce (7,900) across the whole year (52 weeks), this gives a figure of 698,360 visits per annum. Even if it is applied to just 45 weeks of the year, and to the 5,000 workers in private rental accommodation, and in caravans or on campus, the figure would be 382,500 visits to the natural environment. This figure is well over 10x as much as the 'precautionary' estimates made by EDF. While we concur this may still be an

overestimate, it does provide context as to how low the EDF estimates appear.

2.26 Sport England data (Gordon, et al., 2015) shows:

- 58% of the population 'Enjoy the outdoors';
- Out of the UK population of 43.7 million (aged over 16), some 32.4 million are 'active', i.e. take part in any kind of sport or outdoor activity, with 8.96 million (i.e. 20.5% of all those aged over 16) participants in outdoor activities;
- Males tend to be more active outdoors compared to females and activities such as mountain biking and running all have a male bias, and;
- 44% of gym users prefer to access outdoors, i.e. would prefer to be outside.

2.27 The Sports England Active Lives survey data can be accessed online with the online tool[1] and is able to provide information for particular sectors. The figures below are the percentage of people who walked for leisure/cycled (all cycling types) at least twice in the 28 days prior to the survey:

- National Statistics Socio-economic classes 6-8 (lower), i.e. those undertaking semi-routine occupations, routine occupations, or the long-term unemployed: 35.9%/12.7%;
- All adult males: 41.9%/21.1%;
- Those aged 16-34: 34.2%/17.9%;
- Those currently employed: 44%/19.4%, and;
- Single people: 36.8%/16.2%.

2.28 While these figures clearly do not single out those likely to be undertaking construction work at Sizewell C, they clearly indicate well over a third of individuals would likely walk for leisure (which includes dog walking) at least twice a month, and somewhere around 15-20% might be cycling (i.e. road cycling, mountain biking, etc). These are two activities which would be relevant to the construction workforce at Sizewell C.

Displaced visitors

2.29 The **2014 Sizewell C Visitor Surveys** (from 2014) indicate in para 4.1.17 that 65% of interviewees overall would not stop using the area around Sizewell C during construction, 29% would stop using it, and 2.5% said that they were not sure. Broadly about a third of visitors would choose to visit another

[1] https://activelives.sportengland.org/ accessed 06/08/2020

location, with the data suggesting that most would not be deflected very far and across a wide variety of locations.

2.30 The effect of displacement is estimated (in terms of additional visitor use) within the **Shadow HRA recreational disturbance evidence base (**paras 3.2.28 – 3.2.31**)**. The approach is fundamentally flawed. The screen shot below is taken from the **Shadow HRA recreational disturbance evidence base** (page 39 of the report), and, for example, calculates (erroneously) a figure of 4,380 visits to Aldeburgh. The errors in the calculation are set out below the screenshot. It should be noted that similar figures are used in other documents – for example the **Plants and Habitats Synthesis Report** (which gives a value of 4,377 for Aldeburgh in Table 1.5).

Table 3.5: Extrapolated visitor numbers for locations given by survey respondees as sites to which they would relocate during construction of SZC

			Most 'realistic' approach			'Precautionary' approach		
Column No.	1	2	3	4	5	6	7	8
Location	% of survey visitors displaced to location	Existing visitor numbers to location	Extra visits / year	Extra visits / day	% extra over existing visits	Extra visits / yr based on 500,000 visits in Sizewell area	Extra visits / day	% extra over existing visits
Aldeburgh	2.92%	150000	4380	12.0	2.9	14600	40	9.7
Butley	0.19%	10000	19	0.05	0.2	950	2.6	9.5

2.31 Below we use blue text to explain how the values in the table have been calculated by EDF and the black text describes why this is wrong, using the numbers given for Aldeburgh.

Column 1: 15 interviewees from the 2014 survey stated they would be displaced to Aldeburgh. 514 people were interviewed, giving the value of 2.92%. In the 2014 survey there were 15 interviewees who stated they would be displaced to Aldeburgh however 151 interviewees said they would be displaced somewhere and only 95 of those could name a location, presumably because they weren't sure. Therefore the % actually displaced to Aldeburgh could be higher.

Column 2: This is how many people EDF estimate visit Aldeburgh per year. The figure is essentially a rough guess, and the same value is applied to most sites. It highlights the poor quality of the data used.

Column 3: This figure is the 2.92% figure applied to column 2, i.e. 2.92% of 150,000. This step does not make sense and is where the fundamental error has crept in. It is not 2.92% of the people that visit Aldeburgh that are displaced, but 2.92% of the people visiting locations further north around Sizewell. The application of 2.92% to the number of visitors already visiting Aldeburgh makes no sense.

Column 4: This is simply 4380 divided by 365.

Column 5: This is simply column 1 repeated (and rounded down). This is the same as column 1 because the wrong numbers have been used in earlier columns.

Column 6: This is 2.92% of 500,000.

2.32 It would have been better to take the percentage of interviewees at each location where surveys were conducted that were displaced to different locations and then scale those figures up, based on the observation data at the relevant survey locations. In order to understand what that uplift might then mean, accurate visitor totals for the receptor sites is necessary and that is entirely missing from the EDF reports. The calculations given in columns 6-8 are more reasonable and make much more sense.

2.33 Within the 2014 visitor survey reports there is no breakdown of the percentages that would be displaced by survey point. This is critical information as it is necessary to understand the variation between locations.

2.34 The general approach of asking people whether they might be displaced and where they might go is useful, because there are few alternative means to ascertain such information. There are however concerns about such preference surveys and actual likely behaviour. This issue is discussed in the **Shadow HRA evidence base report** (para 3.2.5-3.2.12) but not really addressed. The text suggests some visitors may state they would be displaced but not actually change their behaviour, whereas no consideration is made that the opposite could occur. It is quite possible that some interviewees might not appreciate the scale of works and disruption and as such believe they wouldn't be displaced – but once work has started they may well be put off.

2.35 The **Shadow HRA evidence base report** (para 3.4.1) suggests that a precautionary approach is used and 29% of visitors are considered likely to be displaced. This is not precautionary, as it excludes those who indicated they weren't sure and does not address the concerns about preferences.

2.36 In summary, the figures for displacement are inaccurate, have been miscalculated, and the quality of the data in terms of the receptor sites and number of current visitors is very poor (meaning it is hard to be confident of what any uplift might mean). There has been a lack of survey work to accurately identify current visitor use around the area and current levels of use. The visitor surveys focus on a small number of locations but there are many more that have not been surveyed and for which no data exists.

Other visitor assumptions

2.37 There is no information provided to indicate how often and for how long the coast path will be closed and therefore how long the diversion is likely to be in place for. This is a key omission as the diversion will direct the coast path

and visitors through Eastbridge and across the Levels towards the Minsmere Sluice. This is a sensitive area in terms of disturbance and can be very wet and muddy, particularly during the winter. Displacement from here further north (e.g. when the path is waterlogged) would also deflect recreational use to sensitive locations. Without a clear understanding of how often the diversion will be required, and the duration and time of year it will be in place, it is impossible to assess the scale of impact.

2.38 Several assumptions are made within Tables 5.2 and 5.3 of the **Shadow HRA** concerning the behaviour of displaced site users. Item 9 in both tables suggests that new visitors to sites will exhibit the same behaviour and use the same access infrastructure as current site users, and that visitors specifically displaced from Sizewell and Minsmere to Aldeburgh would restrict their activities to the beach frontage around the town. Elsewhere in the same volume of the **Shadow HRA** (Para 8.3.64), it states that any recreational users displaced to Aldeburgh will focus their activities upon the main beach frontage, rather than spread out to nearby European Sites (e.g. the Alde-Ore Estuary). No evidence is provided to back up these assumptions.

2.39 The **Shadow HRA** also seeks to downplay the level of recreational activity occurring either side of the peak construction period, by contrasting it with that period (Para 7.4.73). Nevertheless, the period either side of peak construction will still have increased levels of recreational requirement above the current baseline. The same document also suggests that once construction has ceased many displaced site users will revert back to using Sizewell (Para 7.7.36) although no evidence is provided to support this, and it is considered just as likely that visitors will continue to use their newly adopted recreation sites post-construction.

Overall predictions of visitor numbers

2.40 Predictions of visitor use as a result of both the displacement of existing users and from additional construction workers are set out in the **Recreational Disturbance Assessment** Table 2.1. These should therefore be combined figures for both the construction workers and the displaced visitors. The numbers given bear little resemblance to those in other documents and it is not clear how the totals have been derived.

Screenshots of the top lines of different tables are provided on the following pages and all sites include estimates for Aldeburgh:

Recreational Disturbance Assessment. This claims to give figures for displaced recreational use and visits by construction workers – i.e. the overall increase in recreation use:

Table 2.1: Estimated additional visits to locations in the study area (two scenarios) as a result of displacement of existing users from the Sizewell area and the construction workforce.

Location and estimated number of annual visits	Access point(s) reference	% of survey visitors who gave as alternative location	Based on % of displaced visitors			Based on 500,000 visits to Sizewell area		
			Inc. visits / year	Inc. total visits / day	% inc. over existing visits	Inc. visits / year	Inc. total visits / day	% inc. over existing visits
Alde-Ore Estuary SPA								
Aldeburgh – 150,000	U,V,W	2.92%	9292	25.5	6.2	19,512	53.4	13
Butley – 10,000	DD	0.19%	19	0.05	0.2	950	2.6	9.5

Shadow HRA Recreational Disturbance Evidence Base. This table gives displacement of existing visitors

Table 3.5: Extrapolated visitor numbers for locations given by survey respondees as sites to which they would relocate during construction of SZC

			Most 'realistic' approach			'Precautionary' approach		
Column No.	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**
Location	**% of survey visitors displaced to location**	**Existing visitor numbers to location**	**Extra visits / year**	**Extra visits / day**	**% extra over existing visits**	**Extra visits / yr based on 500,000 visits in Sizewell area**	**Extra visits / day**	**% extra over existing visits**
Aldeburgh	2.92%	150000	4380	12.0	2.9	14600	40	9.7
Butley	0.19%	10000	19	0.05	0.2	950	2.6	9.5

Shadow HRA Recreational Disturbance Evidence Base. This table provides the displacement of construction workers

Table 3.9: Estimated numbers of construction worker visits to locations per year

Locations most likely to visit					Construction workers who have dogs
	*Estimated % who visit location	No. campus or caravan site based workers visits to location/yr**	No. PRS & tourist based worker visits to location/yr***	Total construction worker visits to location/yr	No. PRS & tourist based worker visits to location/yr****
Sizewell Estate and beach (not European Sites)	18%	2125	1275	3401	2486
Aldeburgh	26%	3070	1842	4912	3591
Thorpeness	15%	1771	1063	2834	2072

2.41 It can be seen that Table 2.1 of the **Recreational Disturbance Assessment** gives an increase of either 9,292 visits or a ('precautionary') 19,512. These are apparently displaced visitors and construction workers combined.

2.42 Table 3.5 of the **Shadow HRA Recreational Disturbance Evidence Base** gives totals for visitors that would be displaced: 4,380 and a ('precautionary') 14,600 per annum.

2.43 Table 3.9 of the **Shadow Recreational Disturbance Evidence Base** gives figures for use by construction workers: 8,503 per annum, this is the sum of 4,912 visits by non-dog walkers and 3,591 from dog walkers.

2.44 It can be seen that the figures do not add up. According to the EDF figures the total for Aldeburgh should be 23,103 (i.e.14,600 + 8,503) not the 19,512 referred to in Table 2.1 of the Recreational Disturbance Assessment. The errors are made for all sites, not just Aldeburgh. Even accepting our concerns regarding the approach, level of surveys etc., there are also different figures quoted in different reports with clear errors that undermine the conclusions drawn.

Impacts on nature conservation interest

2.45 Various locations ('amenity and recreation receptors') have been identified in the **Description of non-significant effects** report as experiencing non-significant effects. These include:

- Walberswick and Dingle Marshes;
- Middleton, Westleton and Darsham;
- South of Westleton, and;
- The areas around Thorpeness, Aldeburgh, and Knodishall.

2.46 EDF propose that for these locations, which include European sites, the effect on amenity (i.e. visitor experience) will not be diminished, i.e. for these locations the impacts from noise, use by construction workers, etc, will not affect visitor enjoyment.

2.47 The **Shadow HRA** appears to suggest in the early parts of the document (Table 2.2) that displacement of visitors is not one of the scenarios that is assessed and the only recreational effect listed is that from construction workers (at the bottom of the table).

Sandlings SPA

2.48 Table 5.3 (Item 9) within the **Shadow HRA** also suggests that any adverse effect arising from recreational disturbance upon Sandlings SPA is unlikely to impact SPA bird populations due to the extensive and spatially disparate nature of the habitats within the SPA. However, when considered in combination with the smaller size and number of parking spaces available within proximity to the SPA, it is considered that even a relatively small increase in visitor numbers could lead to a proportionately larger effect upon the fragmented habitat parcels comprising the SPA.

2.49 The percentage populations of Nightjar and Woodlark found within Sandlings SPA is presented as 3% and 9%, respectively, within the **Shadow HRA** (Para 6.3.198), although this has been calculated using the most recent 4-year average rather than the most recent (2018) counts. The recalculated percentages using the 2018 counts are 6% and 10%, respectively. Elsewhere in the document (Para 8.8.435) it is stated that Dunwich Forest, which lies outside of the Minsmere-Walberswick SPA but which supports a Nightjar population considered to be functionally linked with the SPA population, *has the capacity to accommodate a significant level of recreational use without any adverse effects on this species.* No evidence is provided to explain why this is considered to be the case.

2.50 Throughout the **Shadow HRA**, and the majority of supporting documents, recreational impacts upon Woodlark are only considered within the Sandlings SPA, despite the species being distributed across several localities (as evidenced by the desk study information provided within para 1.3.69 of the **Terrestrial Ecology and Ornithology Report – Ornithology Appendix**). Woodlark populations outside of Sandlings SPA (e.g. within Minsmere-Walberswick SPA) are considered likely to be functionally linked to the Sandlings SPA population and any impact upon them should therefore be considered.

Minsmere to Walberswick Heaths and Marshes SAC

2.51 **The Shadow HRA** argues that because there is already a high level of visitor use, any increase will not have an adverse effect. Para 7.7.34 states that there are already 1,114,206 visitors to the SAC. The paragraph then suggests that an additional 20,000 displaced visitors to the SAC would be small and the text also states "*this pressure would be diffuse and spread across a large*

number of potential car-park access points". There are many problems with this approach.

2.52 Firstly, the figure of 20,000 displaced visitors does not match that used elsewhere. For example, the **Recreational Disturbance Assessment**, in Table 2.1 on page 16, gives a total of displaced visitors of 23,172 or 88,623 visiting the Minsmere to Walberswick Heaths and Marshes SAC. These two totals are the sum of the increased visits per year given in the table and calculated by the two methods described.

2.53 To then argue that the increase is small in proportion to the total visitor numbers to the SAC, such that adverse effects can be ruled out, is flawed. Most visitors to the SAC visit the Minsmere RSPB Reserve car-park, Dunwich Cliffs, and other such destination car-parks that are promoted by the RSPB and National Trust. Wardens are present at these locations to meet and greet visitors, and considerable access infrastructure is already in place to manage recreation. The displaced visitors, and indeed the construction workforce, are likely to be pushed to inland car-parks and more informal parking around the periphery of the reserve (for example, across Dunwich Heath, around Westleton, or near Eastbridge). Here access is harder to manage as parking, etc, is not necessarily in the control of the conservation organisations and there are numerous footpaths and bridleways that provide access to areas with sensitive habitats.

Minsmere – Walberswick Heaths and Marshes SPA

2.54 Adverse effects are ruled out for Little Tern in the **Shadow HRA** (para 8.8.334) on the basis that management measures are in place to protect Little Terns (through the Little Tern Recovery Project) and subject to this management continuing. The Little Tern Recovery Project was funded through EU Life funds and funding is not secured indefinitely. It is therefore not a sound conclusion to rule out adverse effects on integrity on the basis that existing conservation management by organisations such as the RSPB will continue indefinitely. Given the highly mobile nature of the species, with colonies shifting over time, this assumption is even more open to question. Historically Little Terns have bred in front of Sizewell A and birds will exploit available habitat in areas with low levels of disturbance. Ensuring areas of beach with suitably low levels of recreation use is a challenge which will not be helped by the construction work and deflection of access.

2.55 Adverse effects on Hen Harrier are ruled out in the **Shadow HRA** (para 8.8.458), apparently because the roost sites are not known and confidential and because there is apparently ample habitat for birds to roost in within the SPA where no disturbance is likely. This is hardly a robust conclusion. Roost sites have been monitored for many years and have been in areas with public access. Locating roost sites would have been possible as part of the assessment (while ensuring they remained confidential) and more detailed consideration should have been undertaken.

2.56 Impacts upon Dartford Warbler are not considered in the EIA nor in any of the supporting ornithological survey reports. It is not a qualifying species within any of the SPAs, although this may potentially be seen as historical oversight in light of the important population now established in Suffolk (it is a SPA qualifying species elsewhere in its UK range). The species is also listed on Schedule 1 of the Wildlife and Countryside Act 1981 and is an Amber-listed Bird of Conservation Concern. Under these criteria alone the species should be considered alongside the other bird species identified in para 1.4.70 and Table 1.3 of the **Ornithology Synthesis Report**. It is likely to be present within areas of heath within which site users will potentially be displaced and the populations affected may be of value at the regional, or even national, level. Other non-SPA qualifying species (e.g. Stone-curlew) are considered within designated sites (e.g. Para 14.12.155 to 14.12.156 of the **Terrestrial Ecology and Ornithology Report**), and it is therefore not clear why Dartford Warbler has been excluded from assessment.

2.57 An overarching thread within the ornithological baseline surveys supporting the **Shadow HRA** is the age of the data. Table 1.7 in the **Terrestrial Ecology and Ornithology Report – Ornithology Appendix** provides the survey periods for the most recent ornithological surveys undertaken by Arcadis. Little Tern surveys have not been carried out since 2013, the last Nightjar surveys were in 2014, and breeding and wintering bird surveys have not been undertaken since 2015. Several historic species-specific ornithological surveys carried out in the period 2008 to 2012, and categorised as secondary data within the Ornithology Appendix, are also used to inform the assessment. It is therefore considered that update surveys would be required to accurately inform any impact assessment upon several of the important ornithological receptors identified.

3. The monitoring strategy proposed by EDF and adequacy

3.1 The **Shadow HRA** (e.g. para 7.7.37) states that "*The Rights of Way and Access Strategy for the EDF Energy estate would be developed to minimise the displacement of people away from the Sizewell C area and to nearby European sites to minimise trampling of vegetation. In addition, the strategy outlines a monitoring programme for recreational displacement to identify local mitigation measures, to be agreed with local land managers, which could be introduced to further reduce recreational disturbance*."

3.2 The above quote would appear to suggest that the strategy includes a monitoring programme. Elsewhere in the **Shadow HRA** the text regarding monitoring is more ambiguous and would suggest that a monitoring programme is yet to be produced. For example para 8.8.434: "*It is proposed that existing recreational management measures at Westleton Heath and other heathland areas within the Minsmere (southern) section of the Minsmere-Walberswick SPA, are enhanced to minimise the potential for any increase in recreational disturbance pressure on breeding nightjar and other breeding birds of heathland habitats. This would be a monitoring and mitigation plan, to be agreed with land managers and would be aligned with the proposed Rights of Way and Access Strategy*."

3.3 Further confusion results from para 8.8.111 which states: "*Mitigation measures have been identified to minimise the ecological effects of increased recreational pressure on habitats and associated species in the Minsmere RSPB Reserve area. A Rights of Way and Access Strategy is being developed to minimise the displacement of existing recreational users from Sizewell C and the likelihood that displaced visitors and construction workers would access the Minsmere-Walberswick SPA for recreation. In addition, the strategy outlines a monitoring programme for recreational displacement to identify local mitigation measures, to be agreed with local land managers, which could be introduced to further reduce recreational disturbance."* This seems to suggest that a strategy is being produced but is not yet available, and that the strategy includes the monitoring programme.

3.4 The **Rights of Way and Access Strategy** does exist; we have checked it for a monitoring programme and there is no programme set out. As such, it would appear that the monitoring of recreation issues has not been

programmed and that no monitoring strategy has so far been produced. It is therefore not possible to rely on monitoring as a means to deliver mitigation.

3.5 We would have expected more detailed visitor survey work as part of the assessment, with for example counts of parked cars at every parking location across the relevant European sites and supporting habitat. This would have provided basic baseline data on visitor numbers which would then provide the foundation for a monitoring strategy. Monitoring data could then be used to identify where changes occur and therefore where mitigation needs to be targeted.

4. The mitigation strategy proposed by EDF and its adequacy.

4.1 The Sizewell C Project would have an impact on various public rights of way (PRoW), including temporary and permanent closures and diversions. A **Rights of Way and Access Strategy** is proposed to resolve these issues. The **Rights of Way and Access Strategy** is referred to in the **Shadow HRA** (e.g. para 8.8.415) as the means by which mitigation will minimise the ecological effects of increased recreational pressure on habitats and associated species.

4.2 The Suffolk Coast Path, the future England Coast Path, and Sandlings Walk will need to be diverted inland for 'temporary periods'. The strategy does not give any indication of how frequently this will happen, the duration, etc. Without this information it is impossible to assess the adequacy of any mitigation to resolve disturbance impacts at Eastbridge and the surrounding vicinity.

4.3 The **Shadow HRA** is ambiguous about the state of mitigation proposals for recreation impacts. For example para 8.8.434: "*It is proposed that existing recreational management measures at Westleton Heath and other heathland areas within the Minsmere (southern) section of the Minsmere-Walberswick SPA, are enhanced to minimise the potential for any increase in recreational disturbance pressure on breeding nightjar and other breeding birds of heathland habitats. This would be a monitoring and mitigation plan, to be agreed with land managers and would be aligned with the proposed Rights of Way and Access Strategy*."

4.4 Exactly what the recreational management measures might be and how they would work to enable a conclusion that adverse effects on integrity can be ruled out is not clear. There appears to be scant detail on such mitigation and nothing in the **Rights of Way and Access Strategy**.

4.5 The **Shadow HRA** (para 8.8.438) seems to indicate that monitoring and mitigation will be linked and triggers have been set to deliver enhanced recreational management: "*mitigation in the form of enhanced recreational management measures is identified for heathland areas within the southern (Minsmere) block of the SPA during the construction period. If the changes in visitor use predicted during construction continue into the operational phase, then it is considered that these mitigation measures should be continued. Subject*

to the above enhanced recreational management, no adverse effects associated with increased recreational pressure are predicted on breeding nightjar using the Minsmere-Walberswick SPA, either directly or indirectly via habitat change."

4.6 It seems therefore that mitigation measures are being relied on and linked to monitoring, without the necessary detail provided to support the application and the conclusions in the **Shadow HRA**.

4.7 There are some mitigation measures described in the **Amenity and Recreation Report** (Section 15.5). These predominantly relate to retaining access provision, diversions to footpaths, and so on, rather than addressing impacts on habitats or species. Measures in the **Amenity and Recreation Report** that have some relevance include:

- A new off-road combined bridleway, cycleway, and footpath linking Sizewell and Gap to the construction accommodation campus (para 15.5.23-15.5.24);
- The provision of 27ha of new access land at Aldhurst Farm. The land here will include a small car park and informal and surfaced footpaths (para 15.5.26-15.5.28);
- Some enhancements to the Kenton Hills car park (para 15.5.25);
- Provision of formal sports facilities to the south of the Alde Valley Academy, including sports pitches (para 15.5.36), and;
- A footpath around the perimeter of the accommodation campus to allow workers to exercise within the campus boundary.

4.8 The **Mitigation Route Map** has been reviewed and does not provide any further detail on additional mitigation to the above that is relevant to recreation impacts upon European sites.

4.9 Additional (and conflicting) information on mitigation for recreational disturbance are provided in the **Terrestrial Ecology and Ornithology Report.** Para 14.12.161 states that it is considered prudent to develop appropriate mitigation for recreational disturbance issues. Para 14.12.162 states that Aldhurst Farm would provide 43ha of open space for informal recreation. In addition to this (para 14.12.163) indicates that local site-based measures "*would be developed as part of a Rights of Way and Access Strategy, in partnership with relevant stakeholders. This strategy would complement measures already outlined in the Suffolk Coast Recreational Disturbance Mitigation Strategy (RAMS) developed by Natural England and local planning authorities in Suffolk*". Such measures appear to be missing from the Rights of Way and Access Strategy.....

4.10 Further confusion arises in the **Planning Statement**, para 6.10.3 of which states: "*SZC Co. will monitor impacts on European Sites relating to recreational displacement during the construction phase as a result of the Sizewell C Project. SZC Co. will provide a European Sites access contingency fund to support measures to access points to European Sites where monitoring identifies a potential risk of harm occurring as a result of additional use of these areas. Measures to be funded could include additional signage and information boards, fencing, as well as training and support for wardens. The European Sites access contingency fund would not be available to support measures at RSPB Minsmere, or National Trust Dunwich Heath and Coastguard Cottages which will be funded through separate resilience funds (see section 6.14)*."

4.11 There appears to be no further detail on these measures. In order to be effective they must be timely, reliable, and achievable. There is no evidence given as to the level of funding that might be provided, what might trigger particular mitigation elements, and how they might be implemented. It is not really clear what training or support for wardens might look like – is this additional staff (and if so how will it be hosted) or simply a training course?

4.12 There is no detailed consideration or assessment as to how effective these measures might be, or how they will serve to allow a conclusion of no adverse effects on integrity to be made, in any of the reports. For example, we would expect to see information on the levels of use, types of visitors, and clear evidence that the mitigation is sufficient to address impacts from recreation use. In fact, the measures seem poorly conceived and inadequate to address the scale of impact that might occur. For example, new greenspace is provided in some parts of the country, such as the Thames Basin Heaths, at 8ha per 1,000 new residents, in order to resolve the issues from increased recreation associated with new development. While this metric is not necessarily transferable to the Suffolk Coast, it would suggest that – for the 7,900 construction workers alone – some 63ha of new greenspace might be necessary. Aldhurst Farm is merely 27ha and no evidence is given as to how it might function as new greenspace.

4.13 Furthermore, in the Thames Basin Heaths, and indeed many other parts of the country where there are new residents (from house building), on-site access management measures are provided alongside new greenspace. For example, increased wardening, fire-fighting resources, education, and awareness raising initiatives, and so on. These appear to be lacking for Sizewell C. There are many areas, such as around Eastbridge, from Eastbridge towards Westleton, and parts of Dunwich Heath and Dunwich

Forest where such measures could help address impacts from increased recreation.

5. Questions for National Trust/RSPB to raise in relation to recreation impacts.

5.1 Recreational disturbance impacts have not been properly assessed, evidence is lacking, and the suggested mitigation is confusing. Given the poor quality of the work done, it seems that a conclusion of no adverse effects on integrity cannot be justified. In some respects, we would advocate that EDF need to review, update, and redo much of the work on recreation impacts, with more original surveys necessary. Possible points to clarify/address include the following:

1. There are errors in the calculations of visitor estimates and discrepancies between the different reports. These need to be explained and clear analysis of the recreation impact issues and necessary mitigation presented. Without this information it is not possible to rule out adverse effects on integrity.

2. There is a lack of detail on assessment of ecological impacts. For example Little Tern, Hen Harrier, and trampling of shingle seem to be poorly addressed. For some of the coastal features there is little indication of how mobile species of dynamic habitats can be protected from disturbance. We would have expected to see much more detailed mapping of visitor flows and numbers (both current and predicted), providing heat maps of footfall. These maps would then be overlaid with ecological data and checked with site managers/local organisations[2].

3. Further information is required concerning the coast path diversion. How often will the diversion of visitors to Eastbridge be in place? How will parking issues be addressed in Eastbridge and how will the diverted path cope with increased use, given that it is prone to waterlogging in the winter?

4. There is a lack of mitigation to resolve recreation impacts at the following locations:

- Eastbridge area (including path to coast);

[2] We understand some checks were made early on in the assessment with relevant organisations, but the expertise of site managers in checking model predictions and pin-pointing where there are concerns with recreation impacts and how they should be addressed has been missed entirely.

- Periphery of Minsmere Reserve, particularly between Eastbridge and Westleton;
- Dunwich Heath;
- Beach at Dunwich, including vegetated shingle below the cliffs and marshes to north;
- Dunwich Forest;
- Walberswick Marshes;
- Beach area at Minsmere and south towards Sizewell;
- Beach area between Thorpeness and Aldeburgh (vegetated shingle);
- North Warren, and;
- Aldringham Walks.

5. As part of a robust mitigation package we would expect to see provision for an increased wardening presence, public education and awareness raising (including a focus on dog fouling and dogs running off-lead), protocols to resolve fire risks, etc. These seem to be alluded to in the **Planning Statement** but nowhere else.

6. There is no comprehensive monitoring programme to address visitor numbers and use. This needs to be drawn up and integrated into mitigation delivery.

6. Conclusions

6.1 We have reviewed the information provided by EDF in relation to visitor use and nature conservation impacts. This information is scattered across numerous reports and we have struggled to find a clear, coherent narrative that identifies the changes in recreation use might be expected were the proposal to go ahead, the scale of impact and the necessary mitigation that would be required.

6.2 The coastal strip in the vicinity of Sizewell is outstanding in its nature conservation interest and the area supports a range of habitats and species – within a relatively small geographic area – that is unique within the UK. The area is also a popular destination for recreation and draws visitors from the local area and more widely. There are visitor facilities and infrastructure in place at some key locations where, for example, tourist use is focussed. There are also numerous more informal locations where access is currently low key and difficult to manage. The Sizewell C proposal will change the recreation use through the increase in construction workers (some 7,900 workers at peak period) living locally and the displacement of existing visitors, for example as a result of footpath closures, diversions, traffic etc.

6.3 The area around Sizewell includes SAC, SPA and Ramsar sites and a range of qualifying features. There are a number of ways in which recreation impacts could undermine the conservation objectives for the relevant European sites. For example, through increased fire risk, disturbance, trampling, contamination and spread of invasive species. As such there are likely significant effects from recreation and appropriate assessment is necessary.

6.4 The purpose of the appropriate assessment is to undertake an objective scientific assessment of the implications for the European site's qualifying features potentially affected by the project in light of their conservation objectives. The competent authority should conclude that a project would not adversely affect the integrity of a European site, only if it is convinced that this is the case, such that there is no reasonable scientific doubt. In order to reach such a conclusion we would expect detailed survey work to show current levels of recreation, predictions of change and these overlaid with ecological data to show which locations (i.e. particular car-parks and paths) and which species/habitats would affected. Such a granular and detailed level of evidence has not been gathered. Were such information

available, it would allow mitigation measures and long-term monitoring to be designed and targeted to allow adverse effects on integrity to be ruled out.

6.5 Guidance on HRAs is clear that all mitigation measures should be effective, reliable, timely, guaranteed to be delivered and as long-term as they need to be to achieve their objectives (Tyldesley, Chapman, & Machin, 2020). It is for the competent authority, as part of the appropriate assessment, to assess the mitigation measures and the difference they would make to the anticipated project. The information provided by EDF does not provide the necessary level of precision in the baseline data or predictions of change. As a consequence, there is insufficient detail on the mitigation needed. Mitigation measures are not adequately set out or secured.

2	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 4 – Section 2 - Para 2.1.8	*In addition, all 600 associated development workers are assumed to be 'home based'.*	Use of the word assumption. If not home-based then these workers will need to be accommodated elsewhere.	
3	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 27 – Table 2.2		Repeat of 'assumed' home worker numbers.	
4	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 84 – Table 5.2 – Item 9	*Additional visitors to these locations would be expected to follow similar behaviours to existing visitors and use the defined path network/beach. Further incursion by people into areas supporting sensitive shingle vegetation would not be expected and additional loss of vegetation as a result of trampling is therefore considered unlikely to arise.*	No indication as to why novel/increased numbers of visitors would be expected to follow the same pattern.	
5	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 84 – Table 5.2 – Item 9	*It is considered that the majority of additional visits undertaken by people displaced from Sizewell, or potentially the RSPB Minsmere Reserve, to Aldeburgh would involve activities on the immediate beach frontage around the town, rather than the estuarine habitats and landscape of the Alde-Ore Estuary Ramsar site.*	No indication as to why people visiting Minsmere (a "wild" site) would swap to the town seafront if displaced. Different pull factors at work potentially.	
6	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 93 – Table 5.3 – Item 9	*Many of these areas, in particular the coastal frontage/beach at Dunwich and Walberswick, are already subject to intense visitor use.*	Leading statement which suggests that no cumulative ecological effect can occur at a heavily used site with	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
				the advent of increased visitor numbers.	
7	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 94 – Table 5.3 – Item 9	Same wording to Footprint ref 5	No indication as to why people visiting Minsmere (a "wild" site) would swap to the town seafront if displaced. Different pull factors at work potentially.	
8	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 94 – Table 5.3 – Item 9	*Such increased recreational pressure is likely to involve activities on the immediate beach frontage at Aldborough, rather than on the estuarine habitats of the Alde-Ore Estuary SPA*	No indication given as to why this would be the case.	
9	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 94 – Table 5.3 – Item 9	*However, despite all this, the potential for an increase in the number of visits to some locations around the Alde-Ore Estuary cannot be discounted and further studies need to be carried out to remove this pathway of effect.*	Cannot rule out disturbance effects on the SPA.	
10	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 95 – Table 5.3 – Item 9	*Sandlings SPA includes a number of discrete areas of heathland, acid grassland and coniferous plantations. Within the 8km displacement buffer zone the SPA component area comprises Aldringham Walks, to the south of Sizewell, and North Warren Nature Reserve located to the west of Thorpeness and north of Aldeburgh. Both of these sites are located away from the immediate coast and are more discrete than the sites at Minsmere and Dunwich. As a result, they have fewer visitor facilities and are accessed via a series*	No explanation of 8km displacement buffer. Suggestion that sites won't be visited because they are not coastal. Smaller size/smaller amount of parking suggests potential for increased impacts arising from relatively	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
			of smaller and informal car parks. Given the extensive and spatially disparate nature of the habitat comprising the SPA is that an adverse effect from Sizewell C at the level of designated SPA populations is considered to be unlikely.	small increase in visitor numbers.	
11	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 125 – Section 6 - Para 6.3.3	*The citation and most recently available population estimates for the SPA show declines in numbers for the breeding qualifying features, other than marsh harrier, whilst recent population estimates for the wintering populations are higher than at citation (Table 6.1). Declines are particularly notable amongst the breeding seabirds, with neither of the two tern species which are qualifying features of the SPA currently being present as breeding species.*	Phrasing here is leading, intimating that quality of designated site has declined. No indication as to why this may be (e.g. increased recreation) or the issues posed to recovery by increased visitor numbers arising from Sizewell C project.	
12	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 127 – Section 6 - Para 6.3.11	Said of Little Tern: *The peak count was eight birds at VP10 (Sudbourne Beach) in early June 2013, at which point a colony attempted to establish. However, this was deserted by the time of the nest survey in late June.*	No indication given as to why colony abandoned. If due to recreation then evidence of potential impact on re-colonising feature of SPA.	
13	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 127 – Section 6 - Para 6.3.13	Said of Little Tern: *Based on the mean maximum alongshore foraging range (3.9km) suggested by Parsons et al. (Ref. 6.43), breeding birds from a colony at Slaughden could be expected to generally forage no further south than Orford Ness and no further north than Thorpeness.*	Mean value is being misinterpreted here. Could easily have birds regularly foraging at distances past this point.	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
14	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 143 – Section 6 - Para 6.3.48	*Given that the mean maximum foraging distance from breeding colonies in the SPA is expected to be around 3.9km alongshore (Ref. 6.43), the nearest VP is likely to be outside the maximum foraging range for little terns in this SPA. However, the greater distance of the Benacre to Easton Bavents SPA little tern colony from the main development site also means that there would be less potential for effects to arise on this SPA little tern population than on those at SPAs closer to the main development site.*	Same misinterpretation of mean foraging range (see Footprint ref 13).	
15	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 143 – Section 6 - Para 6.3.49	*Based on the mean maximum alongshore foraging range (3.9 km) estimated by Parsons et al. (2015 – Ref. 6.43), breeding birds from the colony at Covehithe Broads could be expected to generally forage no further south than Southwold and no further north than Kessingland.*	Same misinterpretation of mean foraging range (see Footprint ref 13).	
16	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 145 – Section 6 - Para 6.3.54	*However, there have been marked declines in the breeding populations of little tern, teal and nightjar, and in the wintering population of hen harrier.*	No indication of why these decreases have occurred. Potentially due (at least partly) to increased levels of recreational pressure/disturbance?	
17	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 148-149 – Section 6 - Para 6.3.66	*Although these survey data are relatively old, there has been relatively little change in the relevant habitats in the Minsmere South Levels and Sizewell Marshes and no substantive increase in bittern numbers within the RSPB Minsmere Reserve since*	Stated change in habitat use. No way of confirming that behaviour and distribution hasn't	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
			these surveys. Therefore, it is likely that these findings remain representative of the current situation.	changed without update surveys.	
18	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 149 – Section 6 - Para 6.3.67	*Other evidence on the use of the Sizewell Marshes by bittern derives from radio-tracking studies undertaken by RSPB in 2000 and 2001, which showed that the Sizewell Marshes were used by first winter birds from the SPA (Ref. 6.73).*	20 year old data from a population which was just starting to recovery. Behaviour/movements potentially different now due to increased population/distribution of territories on site.	
19	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 168 – Section 6 - Para 6.3.107	*The Minsmere South Levels and Sizewell Marshes (which occur outside the SPA – Figure 6.2) comprise habitat that may be used by breeding gadwall, so there is the potential for functional linkage with the SPA gadwall population.*	Misleading wording. Following paragraph makes it clear that both localities are used by breeding Gadwall.	
20	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 168 – Section 6 - Para 6.3.110	*The Minsmere South Levels and Sizewell Marshes (which occur outside the SPA – Figure 6.2) comprise habitat that may be used by breeding shoveler, so there is the potential for functional linkage with the SPA shoveler population.*	Misleading wording. Following paragraph makes it clear that both localities are used by breeding Shoveler.	
21	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 170 – Section 6 - Para 6.3.115	*Thus, surveys of the Kenton Hills and Goose Hill plantations, undertaken specifically for nightjar, recorded no birds in any of the three visits (i.e. 19th May and 23rd June 2014 and 17th May 2015).*	Are 3 visits enough to confirm probable absence? Also these surveys are 5 years old…	
22	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 171 – Section 6 - Para 6.3.118	*Two surveys (each of three hours duration) were undertaken on each survey day, with two hen harrier sightings obtained over the wintering period (in October and November survey) and both involving*	Evidence of Hen Harriers favouring South Levels (for foraging at least).	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
			birds hunting over the Minsmere South Levels (Ref. 6.45)... Four of the records were from the Minsmere South Levels and six from the Sizewell Marshes.		
23	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 182 – Section 6 - Para 6.3.154	*Greater numbers of shoveler were recorded during WeBS counts within the WeBS Sizewell Belts count sector (with peak counts of 10 or more birds in six of the seven years for which data were obtained) than during project-specific surveys of the Sizewell Marshes, which recorded only two birds in this area during the two winters of survey (Table 6.14 and Table 6.15). Such a marked discrepancy between the respective counts is difficult to explain, although it is notable that shoveler were recorded in a relatively low proportion (i.e. 60%) of the WeBS Sizewell Belts counts.*	Potentially evidence of too low a survey effort in project-specific surveys?	
24	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 203 – Section 6 - Para 6.3.197	*Although the SPA is within 0.7km of the main development site at its closest point, the largest blocks of land which comprise the SPA are considerably further from the main development site, at over 9km.*	Still a material consideration though!	
25	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 203 – Section 6 - Para 6.3.198	*Over this period the number of nightjar territories on the Reserve increased from two in 2010 to five in 2018 (with an average of 1.4 territories per year from 2010 to 2014 and of 2.6 from 2014 to 2018), whilst for woodlark they increased from three in 2010 to seven in 2018 (with an average of 4.6 territories per year from 2010 to 2014 and of 6.8 from 2014 to 2018) (RSPB, unpublished data). Therefore, the discrete block of the SPA which is closest to the main*	The author is being disingenuous and using the most recent 4-year average rather than the most recent (2018) counts to calculate percentage of population. Using most recent counts the	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
			development site seems likely to hold approximately 3% and 9% of the total SPA nightjar and woodlark populations, respectively.	percentages come out at 6% and 10% for Nightjar and Woodlark, respectively.	
26	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 258 to 259 – Section 7 - Para 7.4.73	*There is the potential for an increase in visitor numbers or changes in the patterns of use of recreational areas (such as the Alde-Ore Estuary Ramsar site) due to the presence of the Sizewell C Project construction workers. For the purposes of assessment, it is assumed that 7,900 workers would be present for the peak construction period of the Sizewell C Project. They are likely to be on-site for approximately 20% of the overall construction timeline (2.5 years of the 9 to 12 year construction period) and increase the pressure associated with recreational activity. Either side of peak construction the workforce would be lower and, therefore, would generate less demand for informal recreation.*	Assumptions of worker distribution again, and suggestion that either side of peak construction that recreational pressure will still be higher than it is now.	
27	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 259 – Section 7 - Para 7.4.74	*In addition, the construction period could lead to the displacement of a number of existing recreational users through their avoidance of particular areas, e.g. Sizewell Beach, during the construction period. When considered together, these effects are expected to generate an additional 60,000 recreational visits per annum overall, of which 7,000 may be to Aldeburgh, where it is possible to access the Alde-Ore Estuary Ramsar site.*	No indication of where these figures have come from.	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
28	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 259 – Section 7 - Para 7.4.76	*Appendix E of this report indicates that the car park locations that give access to the Ramsar site already receive an estimated 580,000 recreational visits per year, and that any increase due to recreational users displaced from Sizewell would be small (estimated to be an additional 29,000 recreational visits in this case per annum). In addition, this total increase in pressure would be diffuse and spread across a large number of potential car park access points.*	Previously stated that displacement will lead to use of existing heavily used sites – not sure that this fits with diffuse? The numbers stated still comprise a 5% increase in visitor numbers.	
29	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 259 to 260 – Section 7 - Para 7.4.79	*The number of workers for the operation phase would represent a substantial reduction from the levels during construction. The assessment for recreational disturbance during construction concluded that adverse effects would not arise and, as less recreational visits would be generated, it can be concluded that recreational disturbance during the operation of the Sizewell C Project would not have an adverse effect on the vegetated shingle of the Alde-Ore Estuary Ramsar site.*	The workers are still an increase in "population" above current levels, just fewer than in the construction phase…	
30	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 273 – Section 7 - Para 7.7.31	*The Plants and Habitats Synthesis Report as provided in Volume 2, Chapter 14, Appendix 14B1 concludes that any trampling effects are likely to be reversible in time, with vegetation recovering once the trampling pressure is removed.*	Assumption that trampling pressure will be removed and that people's behaviour doesn't change as a result of displacement during construction. Also no confirmation that trampling effects are reversible in reality,	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
				if damage to underlying seedbank/invasive spread/eutrophication occurs as an allied impact. All of this is subsequently highlighted in the remainder of the same paragraph.	
31	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 273 to 274 – Section 7 - Para 7.7.34	*In addition, this pressure would be diffuse and spread across a large number of potential car-park access points. It is estimated that perhaps 20% of the predicted increase in visitor numbers would visit the main RSPB nature reserve (where dog walking is not permitted) and 80% of the predicted increase in visitor numbers would visit the outer areas of the reserve, where dog walking is permitted.*	It's not clear in the shadow HRA how these visits will be spread across numerous car parks, or how this spread has been calculated. Likely to be a few busier and many quieter sites.	
32	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 274 – Section 7 - Para 7.7.35	*There is no automatic correlation between an increase in the number of recreational visits and the potential for the qualifying features of European sites to be detrimentally affected.*	It's arguable that published evidence suggests there is a correlation with "potential for" (even if impacts do not ultimately occur).	
33	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 274 – Section 7 - Para 7.7.35	*It is envisaged that, overall, managed sites with a well-defined path network, such as the core area of the RSPB reserve, where people are easily observed, new recreational users are likely to keep to existing*	How is this justified? Is there any evidence to prove that this is in fact the case?	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
			path networks and would be unlikely to lead to an increase in trampling.		
34	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 274 – Section 7 - Para 7.7.36	*The displacement of existing recreational users is likely to last for the duration of the construction phase, although as people establish new patterns of behaviour and access alternate sites, the changes could become permanent for a proportion of users. For the majority, once construction activities have ceased, a substantial proportion of displaced users are likely to reuse the Sizewell area and be joined by new users.*	No evidence is provided to suggest how likely any of these scenarios are. Increased recreational pressure could remain indefinitely.	
35	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 274 – Section 7 - Para 7.7.37	*As set out earlier, mitigation measures have been established to minimise the requirement for both construction workers and existing recreational users from Sizewell to access the SAC for recreation.*	Assume this refers to the Suffolk RAMS (alongside proposed Rights of Way and Access Strategy for the EDF Energy estate?	
36	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 285 to 290– Section 7 – Table 7.8	Table cumulatively lists 1,100 new dwellings in outline planning applications within 13.7km of Sizewell C, and a minimum of 815 new dwelling allocations within various relevant Plans within 8.6km.	Table identifies potential for in-combination effect with Sizewell C, but not for adverse in-combination effect. This is presumably due to existing RAMS Strategy (mitigation??)	
37	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 301 to 306 – Section 7 – Table 7.10	See Footprint ref 37	See Footprint ref 36.	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
38	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 344 – Section 8 – Para 8.3.64	*Aldeburgh was identified as the most likely site near to the Alde-Ore Estuary SPA that users could be displaced to, with smaller predicted increases to other locations. Increased visitor use in and around Aldeburgh would be unlikely to impinge directly upon the estuary, with the focus of any additional activity likely to be the main beach frontage.*	No evidence provided here to confirm limitation to Aldeburgh beachfront.	
39	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 346 – Section 8 – Para 8.3.73	*Any residual effects of visitor displacement from Sizewell C post-construction, and recreational use of the local area by operational workers, are predicted to be so small as to be undetectable in the context of the likely future drivers of trends in recreational use of the Suffolk Coast (population growth, initiatives to promote tourism and the increasing popularity of outdoor recreation) and the predicted numbers of annual visitor trips to the Suffolk Coast in the vicinity of the main development site.*	Is this a material consideration when assessing the impact of the Sizewell Project?	
40	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 494 – Section 8 – Para 8.8.422	*It is also unlikely that SPA birds rely on suitable habitat near to the main development site for foraging because the main breeding sites within the SPA are over 1km from the main development site. Although nightjar have been recorded foraging at distances of up to 3.1km from their nests, most foraging is generally much closer to the nest and studies of radio-tracked birds in southeast England recorded a mean maximum distance of 747m from the territory centres*	Would argue that it is less likely, but not unlikely.	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
41	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 496 – Section 8 – Para 8.8.434	*It is proposed that existing recreational management measures at Westleton Heath and other heathland areas within the Minsmere (southern) section of the Minsmere-Walberswick SPA, are enhanced to minimise the potential for any increase in recreational disturbance pressure on breeding nightjar and other breeding birds of heathland habitats. This would be a monitoring and mitigation plan, to be agreed with land managers and would be aligned with the proposed Rights of Way and Access Strategy.*	Not currently clear what this would entail.	
42	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 496 – Section 8 – Para 8.8.435	*It is considered that Dunwich Forest – outside the SPA but with a functionally linked breeding population of nightjar - has the capacity to accommodate a significant level of recreational use without any adverse effects on this species.*	Why? No evidence for this statement provided.	
43	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 565 – Section 8 – Para 8.11.23	*Estimated increases in visitor numbers to locations associated with the SPA are shown in Table 8.31. The largest estimated increase is at Thorpeness Village. Most visitors relocating here might be expected to access the beach and village. Although there is access to the Sandlings SPA to the west (Aldringham Walks) this is a 4-5km round trip.*	Confirmation that people will not access areas away from the beach?	
44	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 566 – Section 8 – Para 8.11.26	Said of Nightjar*: It is also stated that the population size at classification may have been unusually high due to the extensive area of open habitat suitable for nesting that was created following a gale in 1987 that felled most trees; and a more realistic target is being modelled.*	If this is the case, then it increases the importance/proportion of the population within those parcels closest to the Sizewell C site.	

Footprint ref	DCO Document name & reference	Page, Section, Paragraph reference	Quote of text from document	Issue or concern	Response
45	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 566 – Section 8 – Para 8.11.26	*Disturbance due to human activity is identified as a potential issue for nightjar if an increase in development locally leads to an increase in recreational pressure (Ref. 6.109), suggesting it is not currently considered to be a limiting factor.*	This interpretation is open to question.	
46	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 566 – Section 8 – Para 8.11.27	*The Sizewell C visitor survey data and presence of several entry points to open access land indicate that the Sandlings SPA is already subject to considerable visitor use. There are extensive path networks and access to woodland and open habitats. The main activity undertaken by visitors is dog-walking (Ref. 8.139). Nevertheless, as described above RSPB data show that the nightjar population within the RSPB's Aldringham Walks and North Warren reserve has increased in recent years*.	Not clear that visitor survey data shows high levels of use within Aldringham Walks and North Warren Reserve, specifically?	
47	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 566 – Section 8 – Para 8.11.28	*No change in the behaviour of users or the pattern of use is considered likely to arise.*	Based on what data? Increased site use may cause existing users to spread out more within the site.	
48	5.10 Shadow Habitats Regulations Assessment Volume 1: Screening and Appropriate Assessment 1 of 5 (revision 1.0)	Page 568 – Section 8 – Para 8.11.36	*Subject to the implementation of enhanced management measures for recreational access at Aldringham Walks and North Warren, an increase in recreational pressure during the construction of Sizewell C is not predicted to adversely affect the ability of the Sandlings SPA to achieve the conservation objectives for breeding nightjar, either directly or indirectly, via effects on habitats.*	How will these be enforced? Increasing population is a sign of recovery and increased disturbance should therefore be avoided.

1. Introduction

This report contains comments from the Amphibian and Reptile Conservation Trust (hereafter, ARC) on the proposals for mitigating the impacts of the proposed Sizewell C new nuclear power station on natterjack toad *Epidalea calamita*. The report was commissioned by Suffolk Wildlife Trust (SWT), and written by Jim Foster (Conservation Director, ARC) with support from Yvette Martin (Amphibian Conservation Officer, ARC). The comments are based on the following information sources:

(a) Sizewell C proposal documents submitted by the developer (EDF) to the Planning Inspectorate, as available at the Sizewell C Development Consent Order (DCO) Document Portal, (sizewellcdco.co.uk). Hereafter these are referred to as the "EDF proposals". In particular, we have reviewed the following documents in depth (identified here by their filenames):

- SZC_Bk6_ES_V2_Ch14_Terrestrial Ecology Ornithology
- SZC_Bk6_ES_V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14A5_Amphibians
- SZC_Bk6_ES_V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species
- SZC_Bk6_ES_V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C7A_Natterjack_Toad_Mitigation_Strategy_Fig14C7A.1_14C7A.5
- SZC_Bk8_8.2_Outline_Landscape_and_Ecology_Management_Plan

(b) information on natterjack toads in Suffolk collected as part of the national monitoring programme co-ordinated by ARC.

The report also takes into account experience gained by the authors on natterjack toad conservation and management across their range in Great Britain.

2. Review of natterjack toad survey data and impact assessment

The natterjack toad survey data used as a basis for the EDF proposals are largely sufficient for this type of impact assessment and mitigation planning, and are generally well presented with the exception of surveys in terrestrial habitat. We agree with some of the conclusions about the origin and status of the natterjack toad population adjacent to the development footprint, i.e. the Retsom's Field population managed by SWT on behalf of EDF. The EDF proposals adequately summarise long-term monitoring data, and the suggestion of a population size of around 30 adults[1] is reasonable. However, it would have been appropriate to caveat this with a note about the fact that monitoring effort has not been consistent and intensive enough for a precise and reliable population estimate. We do not think it likely that the adults found in Pond N1 in 2006 and 2007 originated from Minsmere as suggested (1.2.13)[2], given that the Minsmere population has been in

[2] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14A5_Amphibians – pdf pg 10, para 1.2.13 (doc pg:

a long-term decline and given the distance to that population. We do not think that the use of terrestrial habitat in Retsom's Field and surrounding areas has been well described in the EDF proposals.

Some of the statements in the EDF proposals about natterjack toads are unusual and call into question the author's level of expertise with this species. For instance, there are peculiar comments implying that natterjack toads might be considered poor swimmers (1.1.12)[3]; the intention of the comment about natterjack toads not being found during reptile surveys is unclear and requires further context (1.3.5)[4]. The mitigation proposals (see below for detailed comments) indicate at several points that conventions used in great crested newt mitigation have simply been applied to natterjack toads, despite the fact that there are marked differences in the ecology of these two species.

There are significant shortcomings with the impact assessment in the EDF proposals. The impacts stated in section 1.3 are all appropriate, but some possible impacts are not mentioned, and some are mentioned but are not adequately described.

The range of impact types (1.3) [5] is incomplete, as it apparently does not include consideration of the following:

- The likelihood that rabbit grazing would be reduced or possibly re-distributed by Water Management Zone (WMZ) construction activities such as noise and lighting, meaning that (a) ongoing maintenance of a low sward would be compromised, which is known to be a significant issue for natterjack toads; (b) the provision of bare ground and underground voids through rabbit warren excavations would be compromised, leading to a reduction in refuge availability.

- The possibility that WMZ construction and operation would result in significant changes to the hydrology of Retsom's Field and surrounding areas. If the field were to be either inundated, or conversely made significantly drier by the works, this would likely have an adverse effect on the natterjack toad population. We do not agree with the simplistic conclusion (1.3.8)[6] that hydrology is not an issue simply because the existing breeding pond (N1) is lined and the substrate is sandy. Were the Field to be inundated during the winter, there might be overwintering

mortality, for example. If the field were to become significantly drier, this might impact the suitability of the substrate for natterjack toads, which require some water content in the substrate to avoid desiccation when taking refuge. Hydrological changes might affect prey availability. In addition, the possibility that hydrological changes might affect N4, which is unlined, has not been investigated.

The scale of the following impact is inadequately characterised:

- Loss of terrestrial habitat (1.3.6)[7]. We believe the impact of the "temporary" loss of terrestrial habitat during WMZ construction and operation has been significantly under-estimated and is not adequately explained. Natterjack toads are highly terrestrial, with most adults spending the majority of time on land and only a small fraction of the year in aquatic habitat; post-metamorphic immature individuals rarely if ever enter aquatic habitat. The exclusion of 3.5 ha of good quality terrestrial habitat close to the breeding pond for 3 generations could have a noticeable impact on the population through reduced foraging and refuge opportunities. The small size of the population, and its isolation, may exacerbate any negative effects.

Other comments on the impact assessment:

It is concerning that the wording regarding the location of WMZ boundary and to what extent it will actually impact on habitat in Retsom's Field is imprecise. There is mention of changes at the detailed design stage, but this makes it difficult to comment meaningfully on impacts now, since there is a degree of uncertainty.

There is a parcel of heathland to the far west of Retsom's Field, which would be lost to the WMZ. This area is likely to be used by natterjack toads, but the impact of its loss is not considered in the EDF proposals.

The particular vulnerabilities of this population, in conservation status terms, are not sufficiently addressed. This population is currently based on a single breeding pond, and if that were compromised the population would perish, resulting in a loss of range of significance at a much wider spatial scale. This needs to be considered in the context of the "FCS test" in the proposed mitigation licence.

We note that there is an error in the section describing the legislation applying to natterjack toads. At 1.1.2[8] the text indicates that that killing, injuring or taking

[7] ES V2 Ch14 Terrestrial Ecology Ornithology Appx14C Protected Species – pdf pg 341, para 1.3.6 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 10) (APP-252)

[8] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 350, para 1.1.2 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 19) (APP-252)

natterjack toads is an offence under the Wildlife and Countryside Act 1981 (as amended), but this is not the case. In fact, most provisions of Section 9 of that Act do not apply to natterjack toads, with the main protection being offered by The Conservation of Habitats and Species Regulations 2017 (as amended). We would expect factual matters like this to be correct in a mitigation report.

3. Review of natterjack toad mitigation and compensation proposals

The mitigation proposals appear largely to be based on methods and standard levels of effort used for great crested newts. Unfortunately they do not take into account some important ecological characters of natterjack toads, nor have they been sufficiently adjusted to account for this particular population. There is a disconnect between the section of the EDF proposals which discusses natterjack toad ecology (Appendix 14C.7A.3)[9], and the proposals for mitigation and compensation: the former do not appear to have sufficiently informed the latter. For example, it is unlikely that 30 days of capture effort would be sufficient to adequately deplete the population in the fenced area (Table 1.3)[10], and the apparent reliance on pitfall trapping is insufficient.

The post-development works are not adequately explained. For example, Table 1.4 is blank aside from row headings[11].

The proposed compensation for the loss of terrestrial habitats is inadequate. Presently the proposal is that a single new pond would be created, and that this would effectively generate new terrestrial habitat. However, the terrestrial habitat in the field is currently poor for natterjack toads, largely because the vegetation is rank. There is no meaningful mention of how the new breeding pond and terrestrial habitat would be maintained in suitable condition for natterjack toads after construction. Therefore there is a lack of confidence that sufficient terrestrial habitat would in fact be created and maintained.

It is notable that N3 has not yet been colonised; this is likely because of the small source population, distance to that source, and the poor surrounding terrestrial habitat. These issues would not be sufficiently addressed by the EDF proposals for the new pond, N5. However, it is in principle a sensible idea to create a “stepping stone” pond between N1 and N4.

In setting out any plans for new lined ponds, it has not been recognised that they have a finite lifespan, typically 20 years, though this can be much shorter depending on materials and local conditions. Pond liners may be punctured by

[9] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 353 App 14C.7A.3 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 22) (APP-252)
[10] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 346-347, Table 1.3 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 15-16) (APP-252)
[11] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 348, Table 1.4 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 17) (APP-252)

grazing animals and need repairing or replacing, for example. In addition, ponds need to be well designed, with shallow margins, and be maintained so that aquatic vegetation, competitors and predators do not proliferate. Measures have not been suggested as to how there will be continued provision of suitable breeding habitat.

The proposed linear feature (1.4.8, second bullet)[12] is unlikely to have any effect on connectivity. Natterjack toads are more likely to disperse over flat grassland, were
it to be of a suitable sward, than to use a linear mound for dispersal. This seems an odd statement to make. The feature would, however, create terrestrial refuge opportunities as stated, if well constructed.

The scale of the proposed compensation habitat is inadequate given the potential impacts. Given the significance of the population, its vulnerability in terms of size and isolation, and the risks posed by the development, it would be appropriate to create a larger extent of quality habitat, with the aim of extending the local distribution of the species and increasing its viability. That could buffer against any residual impacts caused by the construction and operational phase.

A cluster of ponds of slightly differing profiles would be more appropriate than a single pond. This would increase the chance that in any one year suitable breeding habitat would be available, buffering against changes in environmental conditions. The natterjack toad is a pioneer species and populations can decline rapidly if habitat (both terrestrial and aquatic) conditions are not adequately maintained. The EDF proposals do not give reassurance that there would be measures in place to ensure a sufficient extent and quality of habitat in the long term.

4. Review of natterjack toad monitoring proposals

The monitoring proposals are inadequate. It is not explained precisely what would be monitored, and the methods, effort and timing to achieve this. The lack of detail here makes it difficult to comment. For example, there is mention of monitoring being delivered annually during WMZ operation and biannually over a 6 year period afterwards[13], but in order to obtain a mark recapture estimate we would expect annual monitoring. Table 1.4 has blank spaces[14], it is unclear who has responsibility for monitoring, and there is no link to remedial work should monitoring identify an issue.

[12] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 343, para 1.4.8 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 13) (APP-252)
[13] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 345, para 1.4.12 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 14) (APP-252)
[14] ES-V2_Ch14_Terrestrial_Ecology_Ornithology_Appx14C_Protected_Species – pdf pg 348, Table 1.4 (doc pg: V2, C14, App 14C7A Natterjack Toad Mitigation Strategy pg 17) (APP-252)

5. Suggested changes to mitigation and compensation proposals

We suggest that the mitigation methods, effort and timing are revised to better take into account natterjack toad ecology, and the particular circumstances of this population. For example, during the capture phase, we would expect active capture by searching at night with a powerful torch, rather than a reliance on pitfall traps which appears to be the case with current proposals.

The compensation proposals should be prefaced by a clear ambition. We would like to see a commitment to securing a resilient population in the long term, based on the availability of several breeding ponds set in good quality terrestrial habitat, with a local distribution expansion to the north.

Habitat creation should involve a network of at least four new ponds, with slightly differing profiles and designed to provide good breeding habitat for natterjack toads. These should be sited in Retsom's Field, around the location currently proposed for N5, providing breeding opportunities between the existing breeding pond and N4.

When setting out habitat creation, management and monitoring proposals, the particular constraints of the area should be fully explored and explained. In particular, the soils and presence of waders may influence the type and location of new ponds.

There should be a comprehensive plan for the short-term and long-term management of both breeding ponds and terrestrial habitat, clearly showing objectives, routine management, remedial measures (e.g. pumping out of ponds), triggers for remedial measures, and an inspection regime. There should be clear responsibility for the actions listed, and a commitment for resourcing the actions.

6. Suggested changes to monitoring proposals

We would like to see significantly more detail on the monitoring proposals, in terms of objectives, methods, effort, timing, responsibility for delivery, use of monitoring results, and sharing of data.

In terms of monitoring objectives, we suggest that the following should be covered:

- Assessing the efficacy of mitigation measures put in place to reduce harm to natterjack toads during WMZ construction and operation
- Assessing the efficacy of habitat creation and enhancement measures in the short and long term.

In terms of field survey methods used, we suggest two broad categories are included:

> (1) standard monitoring methods for this species: counts of spawn strings laid, assessment of metamorph production, counts of adults in ponds during the breeding season, assessment of habitat quality;
>
> (2) a finer resolution of population status assessment: an estimate of adult population size through repeat surveys of adults and applying standard mark-recapture statistics, using natural markings to identify individuals (see, e.g. Smith et al 2018; McMurray undated).

Routine monitoring during the construction phase should be undertaken annually with at least 7 survey visits per year, as recommended for standard natterjack toad monitoring (e.g. see guidance on ARC's website at: https://www.arc-trust.org/targeted-surveys-for-natterjack-toads).

Monitoring should be undertaken annually for at least 6 years following completion of WMZ operation, in order to detect any residual impacts of the development and to trigger remedial actions. Monitoring should cover all the existing ponds (N1-4) and newly created ponds. There should be a clear statement of investigations and potential remedial actions should monitoring detect problems such as a failed pond liner; these investigations and remedial actions should be costed and secure resourcing plans put in place.

Assessment of habitat quality should include a note of management operations (e.g. grazing) and natural factors (e.g. rabbit activity, weather) likely to be influencing habitat condition.

Monitoring should be carried out by personnel meeting standard criteria (CIEEM, 2013).

Constraints on monitoring should be explored and explained. For example, the presence of waders may require restrictions on access.

Monitoring results should be shared with those with an interest or involvement in managing the natterjack toad population, and with the national monitoring programme operated by ARC.

7. Summary

EDF's proposals for mitigating and compensating the impacts of the proposed Sizewell C new nuclear power station on a population of natterjack toads *Epidalea calamita* are assessed. This species is strictly protected by law. The current status of the population is adequately described in EDF proposals. However, we find significant shortcomings in the proposals for mitigating and compensating impacts, and for monitoring the population. The framing of impacts as "temporary" when they would in fact last for three natterjack toad generations is a notable misinterpretation. There is insufficient reassurance that habitat creation and management proposals would generate and maintain a resilient population of natterjack toads and put in place suitable monitoring oversight. In general, the proposals do not adequately take into account the ecology and local conservation status of the population. Amendments to the proposals are suggested. In particular, we suggest that proposals need to be much clearer in relation to methods, effort, timing, responsibility for actions, remedial operations, and long-term resourcing.

EC Directive 79/409 on the Conservation of Wild Birds: Special Protection Areas

Alde-Ore Estuary (Suffolk)

The Alde-Ore Estuary proposed Special Protection Area (pSPA) is situated on the east coast of Suffolk between Aldeburgh in the north and Bawdsey in the south. The site comprises the estuary complex of the rivers Alde, Butley and Ore, including Havergate Island and Orfordness. The variety of habitats important for breeding and wintering birds includes vegetated shingle, intertidal mudflats, semi-improved grazing marsh, saltmarsh and saline lagoons.

The site includes the entire Alde-Ore Estuary SSSI, notified in 1985 (revised in 1992 under the Wildlife and Countryside Act, 1981). The Alde-Ore Estuary SSSI includes the Orfordness-Havergate NNR, the English Nature owned part of which has already been designated as Orfordness-Havergate SPA.

The site qualifies under Article 4.1 of the EC Birds Directive by sustaining nationally important numbers of the following Annex 1 species, marsh harrier *Circus aeruginosus* (breeding), avocet *Recurvirostra avosetta* (wintering and breeding) ruff *Philomachus pugnax* (wintering), sandwich tern *Sterna sandvicensis* (breeding) and little tern *Sterna albifrons* (breeding). Further Annex 1 species winter on site, including, bittern *Botaurus stellaris*, Bewick's Swan *Cygnus columbianus*, hen harrier *Circus cyaneus*, golden plover *Pluvialis apricaria*, and short-eared owl *Asio flammeus*. Mediterranean gull *Larus melanocephalus*, common tern *Sterna hirundo* and Arctic tern *Sterna paradisaea* breed on Havergate Island.

The site qualifies under Article 4.2 of the Directive by regularly supporting internationally important numbers of two migratory species. The Orfordness colony of breeding lesser black-backed gull *Larus fuscus graellsii*, represented in 1995, 12% of the British population and 8% of the world population of the *graellsii* race. The five year wintering peak mean 1989/90 to 1993/94 for redshank *Tringa totanus*, was 1,662 birds, representing 1.5 % of the British population and 1.1% of the east Atlantic flyway population.

The site supports over 1% of the British wintering population of the following (calculated from five year winter peak means 1989/90 to 1993/94), shelduck *Tadorna tadorna*, wigeon *Anas penelope*, teal *Anas crecca*, black-tailed godwit *Limosa limosa*. In addition, the site supports over 1% of the British breeding population of, Gadwall *Anas strepera*, shoveler *Anas clypeata* and herring gull *Larus argentatus*.

The site also supports a notable assemblage of breeding and wintering wetland birds, in addition to the species mentioned above. Breeding species include, oystercatcher *Haematopus ostralegus*, ringed plover *Charadrius hiaticula*, lapwing *Vanellus vanellus* (also winter) black headed gull *Larus ridibundus* and barn owl *Tyto alba*. Wintering species include, cormorant *Phalacrocorax carbo*, European white-fronted goose *Anser abifrons albifrons*, brent goose *Branta bernicla*, pintail *Anas acuta*, grey plover *Pluvialis squatarola*, dunlin *Calidris alpina* and curlew *Numenius arquata*.

European Site Conservation Objectives for Alde–Ore Estuary Special Protection Area Site Code: UK9009112

With regard to the SPA and the individual species and/or assemblage of species for which the site has been classified (the 'Qualifying Features' listed below), and subject to natural change;

Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;

- **The extent and distribution of the habitats of the qualifying features**
- **The structure and function of the habitats of the qualifying features**
- **The supporting processes on which the habitats of the qualifying features rely**
- **The population of each of the qualifying features, and,**
- **The distribution of the qualifying features within the site.**

This document should be read in conjunction with the accompanying *Supplementary Advice* document, which provides more detailed advice and information to enable the application and achievement of the Objectives set out above.

Qualifying Features:

A081 *Circus aeruginosus*; Eurasian marsh harrier (Breeding)
A132 *Recurvirostra avosetta*; Pied avocet (Non-breeding)
A132 *Recurvirostra avosetta*; Pied avocet (Breeding)
A151 *Philomachus pugnax*; Ruff (Non-breeding)
A162 *Tringa totanus*; Common redshank (Non-breeding)
A183 *Larus fuscus*; Lesser black-backed gull (Breeding)
A191 *Sterna sandvicensis*; Sandwich tern (Breeding)
A195 *Sterna albifrons*; Little tern (Breeding)

This is a European Marine Site

This SPA is a part of the Alde Ore & Butley European Marine Site (EMS). These Conservation Objectives should be used in conjunction with the Conservation Advice document for the EMS. Natural England's formal Conservation Advice for European Marine Sites can be found via GOV.UK.

Explanatory Notes: European Site Conservation Objectives

These Conservation Objectives are those referred to in the Conservation of Habitats and Species Regulations 2017 (as amended) ('the Habitats Regulations'). They must be considered when a competent authority is required to make a 'Habitats Regulations Assessment' including an Appropriate Assessment, under the relevant parts of this legislation.

These Conservation Objectives, and the accompanying Supplementary Advice (where this is available), will also provide a framework to inform the management of the European Site and the prevention of deterioration of habitats and significant disturbance of its qualifying features

These Conservation Objectives are set for each bird feature for a Special Protection Area (SPA).

Where these objectives are being met, the site will be considered to exhibit a high degree of integrity and to be contributing to achieving the aims of the Wild Birds Directive.

Publication date: 21 February 2019 (version 3). This document updates and replaces an earlier version dated 30 June 2014 to reflect the consolidation of the Habitats Regulations in 2017.

Alde-Ore Estuary SPA

Last updated: 13th September 2019

Supplementary advice

The Supplementary Advice on Conservation Objectives (SACOs) present attributes which are ecological characteristics or requirements of the classified species within a site. The listed attributes are considered to be those which best describe the site's ecological integrity and which if safeguarded will enable achievement of the Conservation Objectives.

Conservation Objectives relating to extent and distribution of habitat and population abundance are reflected in single attributes within the Supplementary Advice. Structure and function of habitats, and supporting processes for those habitats, are reflected in multiple attributes describing integrity of these ecological characteristics.

The Conservation Objective relating to the distribution of qualifying features (individual species or assemblages) may apply to most or all of the attributes listed in the SACOs and should be considered against them. Ensuring integrity of attributes relating to supporting habitats and processes should allow birds to distribute themselves optimally within (and, sometimes, outside) the SPA boundary. This is perhaps particularly relevant for food availability; extent and distribution of supporting habitat; quality of supporting habitat; predation; and disturbance caused by human activity.

Attributes have a target which is either quantified or qualified depending on the available evidence. The target identifies as far as possible the desired state to be achieved for the attribute. In many cases, the attribute targets show if the current objective is to either 'maintain' or 'restore' the attribute. The targets given for each attribute do not represent thresholds to assess the significance of any given impact in Habitats Regulation Assessments. You will need to assess this on a case-by-case basis using the most current information available.

Where there is no evidence to determine a marine feature's condition, a vulnerability assessment, which includes sensitivity and exposure information for features and activities in a site, has been used as a proxy for condition. Evidence used in preparing the SACO has been cited with hyperlinks included where possible. Where references have not been provided, Natural England has applied ecological knowledge and expert judgement.

Some, but not all, of these attributes can also be used for regular monitoring of the condition of the classified features. The attributes selected for monitoring the features, and the standards used to assess their condition, are listed in separate monitoring documents, which will be available from Natural England. As condition assessment information becomes available, the conservation advice package will be reviewed accordingly.

When to use

You should use this information, along with the conservation objectives and case-specific advice issued by Natural England when developing, proposing or assessing an activity, plan or project that may affect the site.

Any proposals or operations which may affect the site or its features should be designed so they do not adversely affect any of the attributes in the SACO or achievement of the conservation objectives.

Features:
Choose one or more features and/or their sub-features below by selecting the applicable boxes in the tree. This will show the relevant targets. Where a feature has sub-features this will be indicated with a greyed out triangle below, which can be expanded.

- ☐ Avocet (Recurvirostra avosetta), Breeding
- ☐ Avocet (Recurvirostra avosetta), Non-breeding
- ☐ Lesser black-backed gull (Larus fuscus), Breeding
- ☐ Little tern (Sternula albifrons), Breeding
- ☐ Marsh harrier (Circus aeruginosus), Breeding
- ☐ Redshank (Tringa totanus), Non-breeding
- ☐ Ruff (Calidris pugnax), Non-breeding
- ☐ Sandwich tern (Thalasseus sandvicensis), Breeding

Reset | Select all | Show attributes and targets for selected features

Attributes:
You can filter to show only targets for certain attributes by selecting one or more attributes from the list below (use ctrl click to select multiple). Note that only attributes for the features you have chosen are shown.

Feature target

'Maintain' targets do not preclude the need for management, now or in the future, to avoid a significant risk of damage or deterioration to the feature. The supporting and/or explanatory notes in the SACOs set out why the target was chosen and any relevant site based supporting information. This is based on the best available information, including that gathered during monitoring of the feature's current condition.

Please select a feature.

See further guidance on how to undertake an HRA for a plan or project on a European site (https://www.gov.uk/guidance/habitats-regulations-assessments-protecting-a-european-site).

These tables bring together the findings of the best available scientific evidence which may be updated or supplemented in further publications from Natural England and other sources. You may decide to use other additional sources of information.

These tables do not give advice about SSSI features or other legally protected species which may also be present within the European site.

Information Sheet on Ramsar Wetlands (RIS)

Categories approved by Recommendation 4.7 (1990), as amended by Resolution VIII.13 of the 8th Conference of the Contracting Parties (2002) and Resolutions IX.1 Annex B, IX.6, IX.21 and IX. 22 of the 9th Conference of the Contracting Parties (2005).

Notes for compilers:

1. The RIS should be completed in accordance with the attached *Explanatory Notes and Guidelines for completing the Information Sheet on Ramsar Wetlands*. Compilers are strongly advised to read this guidance before filling in the RIS.

2. Further information and guidance in support of Ramsar site designations are provided in the *Strategic Framework for the future development of the List of Wetlands of International Importance* (Ramsar Wise Use Handbook 7, 2nd edition, as amended by COP9 Resolution IX.1 Annex B). A 3rd edition of the Handbook, incorporating these amendments, is in preparation and will be available in 2006.

3. Once completed, the RIS (and accompanying map(s)) should be submitted to the Ramsar Secretariat. Compilers should provide an electronic (MS Word) copy of the RIS and, where possible, digital copies of all maps.

1. Name and address of the compiler of this form:

Telephone/Fax: +44 (0)1733 – 562 626 / +44 (0)1733 – 555 948
Email: RIS@JNCC.gov.uk

2. Date this sheet was completed/updated:

Designated: 05 January 1976

3. Country:

UK (England)

4. Name of the Ramsar site:

Minsmere–Walberswick

5. Designation of new Ramsar site or update of existing site:

This RIS is for: Updated information on an existing Ramsar site

6. For RIS updates only, changes to the site since its designation or earlier update:

a) Site boundary and area:

** Important note: If the boundary and/or area of the designated site is being restricted/reduced, the Contracting Party should have followed the procedures established by the Conference of the Parties in the Annex to COP9 Resolution IX.6 and provided a report in line with paragraph 28 of that Annex, prior to the submission of an updated RIS.

b) Describe briefly any major changes to the ecological character of the Ramsar site, including in the application of the Criteria, since the previous RIS for the site:

7. Map of site included:

Refer to Annex III of the *Explanatory Notes and Guidelines*, for detailed guidance on provision of suitable maps, including digital maps.

a) A map of the site, with clearly delineated boundaries, is included as:

i) **hard copy** (required for inclusion of site in the Ramsar List): *yes* ✓ -or- *no* □;
ii**) an electronic format** (e.g. a JPEG or ArcView image) Yes
iii) **a GIS file providing geo-referenced site boundary vectors and attribute tables** *yes* ✓ -or- *no* □;

b) Describe briefly the type of boundary delineation applied:

e.g. the boundary is the same as an existing protected area (nature reserve, national park etc.), or follows a catchment boundary, or follows a geopolitical boundary such as a local government jurisdiction, follows physical boundaries such as roads, follows the shoreline of a waterbody, etc.

The site boundary is the same as, or falls within, an existing protected area.

For precise boundary details, please refer to paper map provided at designation

8. Geographical coordinates (latitude/longitude):

52 18 55 N 01 38 02 E

9. General location:

Include in which part of the country and which large administrative region(s), and the location of the nearest large town.

Nearest town/city: Southwold

Composite site situated on the coast of Suffolk, between Southwold in the north and Sizewell in the south.

Administrative region: Suffolk

10. Elevation (average and/or max. & min.) (metres): 11. Area (hectares): 2018.92

Min. -1
Max. 24
Mean 9

12. General overview of the site:

Provide a short paragraph giving a summary description of the principal ecological characteristics and importance of the wetland.

This composite, Suffolk coastal site contains a complex mosaic of habitats, notably, areas of marsh with dykes, extensive reedbeds, mudflats, lagoons, shingle and driftline, woodland and areas of lowland heath. The site supports the largest continuous stand of reed in England and Wales and demonstrates the nationally rare transition in grazing marsh ditch plants from brackish to fresh water. The combination of habitats create an exceptional area of scientific interest supporting nationally scarce plants, British Red Data Book invertebrates and nationally important numbers of breeding and wintering birds.

13. Ramsar Criteria:

Circle or underline each Criterion applied to the designation of the Ramsar site. See Annex II of the *Explanatory Notes and Guidelines* for the Criteria and guidelines for their application (adopted by Resolution VII.11).

1, 2

14. Justification for the application of each Criterion listed in 13 above:

Provide justification for each Criterion in turn, clearly identifying to which Criterion the justification applies (see Annex II for guidance on acceptable forms of justification).

Ramsar criterion 1

The site contains a mosaic of marine, freshwater, marshland and associated habitats, complete with transition areas in between. Contains the largest continuous stand of reedbeds in England and Wales and rare transition in grazing marsh ditch plants from brackish to fresh water.

Ramsar criterion 2

This site supports nine nationally scarce plants and at least 26 red data book invertebrates.

Supports a population of the mollusc *Vertigo angustior* (Habitats Directive Annex II; British Red Data Book Endangered), recently discovered on the Blyth estuary river walls.

An important assemblage of rare breeding birds associated with marshland and reedbeds including: *Botaurus stellaris, Anas strepera, Anas crecca, Anas clypeata, Circus aeruginosus, Recurvirostra avosetta, Panurus biarmicus*

15. Biogeography (required when Criteria 1 and/or 3 and /or certain applications of Criterion 2 are applied to the designation):

Name the relevant biogeographic region that includes the Ramsar site, and identify the biogeographic regionalisation system that has been applied.

a) biogeographic region:

Atlantic

b) biogeographic regionalisation scheme (include reference citation):

Council Directive 92/43/EEC

16. Physical features of the site:

Describe, as appropriate, the geology, geomorphology; origins - natural or artificial; hydrology; soil type; water quality; water depth, water permanence; fluctuations in water level; tidal variations; downstream area; general climate, etc.

Soil & geology	acidic, neutral, shingle, sand, peat, nutrient-poor, mud, alluvium
Geomorphology and landscape	lowland, coastal, valley, floodplain, shingle bar, intertidal sediments (including sandflat/mudflat), open coast (including bay), estuary, lagoon
Nutrient status	mesotrophic
pH	circumneutral
Salinity	brackish / mixosaline, fresh, saline / euhaline
Soil	no information
Water permanence	usually permanent
Summary of main climatic features	Annual averages (Lowestoft, 1971–2000) (www.metoffice.com/climate/uk/averages/19712000/sites/lowestoft.html) Max. daily temperature: 13.0° C Min. daily temperature: 7.0° C Days of air frost: 27.8 Rainfall: 576.3 mm Hrs. of sunshine: 1535.5

General description of the Physical Features:

Minsmere – Walberswick comprises two large marshes, the tidal Blyth estuary and associated habitats. This composite coastal site contains a complex mosaic of habitats, notably areas of marsh with dykes, extensive reedbeds, mudflats, lagoons, shingle, woodland and areas of lowland heath. It supports the largest continuous stand of common reed *Phragmites australis* in England and Wales, and demonstrates the nationally rare transition in grazing marsh ditch plants from brackish to fresh water.

17. Physical features of the catchment area:

Describe the surface area, general geology and geomorphological features, general soil types, general land use, and climate (including climate type).

Minsmere – Walberswick comprises two large marshes, the tidal Blyth estuary and associated habitats. This composite coastal site contains a complex mosaic of habitats, notably areas of marsh with dykes, extensive reedbeds, mudflats, lagoons, shingle, woodland and areas of lowland heath.

18. Hydrological values:

Describe the functions and values of the wetland in groundwater recharge, flood control, sediment trapping, shoreline stabilization, etc.

No special values known

19. Wetland types:

Marine/coastal wetland

Code	Name	% Area
Other	Other	30
U	Peatlands (including peat bogs swamps, fens)	30
G	Tidal flats	12.9
E	Sand / shingle shores (including dune systems)	12.4
H	Salt marshes	7.2
M	Rivers / streams / creeks: permanent	4
F	Estuarine waters	2.5
J	Coastal brackish / saline lagoons	1

20. General ecological features:

Provide further description, as appropriate, of the main habitats, vegetation types, plant and animal communities present in the Ramsar site, and the ecosystem services of the site and the benefits derived from them.

This composite Suffolk coastal site contains a complex mosaic of habitats notably, areas of marsh with dykes, extensive reedbeds, mud flats, lagoons, shingle, woodland and areas of lowland heath. The site supports the largest continuous stand of reed *Phragmites australis* in England and Wales and nationally rare transition in grazing marsh ditch plants from brackish to fresh water. The combination of habitats create an exceptional area of scientific interest supporting nationally scarce plants, RDB invertebrates and nationally important numbers of breeding and wintering birds.

Ecosystem services

21. Noteworthy flora:

Provide additional information on particular species and why they are noteworthy (expanding as necessary on information provided in **12**. Justification for the application of the Criteria) indicating, e.g. which species/communities are unique, rare, endangered or biogeographically important, etc. *Do not include here taxonomic lists of species present – these may be supplied as supplementary information to the RIS.*

Nationally important species occurring on the site.

Higher Plants.

This is one of few sites nationally for red-tipped cudweed *Filago lutescens* (RDB2) which occurs on light, sandy soils.
The nationally rare species *Corynephorus canescens* (RDB3) occurs on coastal dune habitat.

The site supports a range of nationally scarce plant species characteristic of heathland, wetland and coastal habitats, and the transitions between them. *Althaea officinalis, Myriophyllum verticillatum, Ruppia cirrhosa, Sium latifolium, Sonchus palustris, Ceratophyllum submersum, Ranunculus baudotii,* and *Carex divisa* (all nationally scarce) are associated with reedbeds, grazing marsh or ditches. *Hordeum marinum* occurs on sea-walls, *Lathyrus japonicus* on coastal shingle, and *Crassula tillaea* on heathland.

22. Noteworthy fauna:

Provide additional information on particular species and why they are noteworthy (expanding as necessary on information provided in **12**. Justification for the application of the Criteria) indicating, e.g. which species/communities are unique, rare, endangered or biogeographically important, etc., including count data. *Do not include here taxonomic lists of species present – these may be supplied as supplementary information to the RIS.*

Birds

Species currently occurring at levels of national importance:

Species regularly supported during the breeding season:

Eurasian marsh harrier , *Circus aeruginosus*, Europe	16 pairs, representing an average of 10.5% of the GB population (5 year mean 1993-1997)
Mediterranean gull , *Larus melanocephalus*, Europe	2 apparently occupied nests, representing an average of 1.8% of the GB population (Seabird 2000 Census)
Black-headed gull , *Larus ridibundus*, N & C Europe	2558 apparently occupied nests, representing an average of 1.9% of the GB population (Seabird 2000 Census)
Little tern , *Sterna albifrons albifrons*, W Europe	20 apparently occupied nests, representing an average of 1% of the GB population (Seabird 2000 Census)

Species with peak counts in spring/autumn:

Great bittern , *Botaurus stellaris stellaris*, W Europe, NW Africa	3 individuals, representing an average of 3% of the GB population (5 year peak mean 1998/9-2002/3 - spring peak)
Eurasian teal , *Anas crecca*, NW Europe	3083 individuals, representing an average of 1.6% of the GB population (5 year peak mean 1998/9-2002/3)
Ruff , *Philomachus pugnax*, Europe/W Africa	10 individuals, representing an average of 1.4% of the GB population (5 year peak mean 1998/9-2002/3)
Black-tailed godwit , *Limosa limosa islandica*, Iceland/W Europe	846 individuals, representing an average of 5.4% of the GB population (5 year peak mean 1998/9-2002/3 - spring peak)
Spotted redshank , *Tringa erythropus*, Europe/W Africa	15 individuals, representing an average of 11% of the GB population (5 year peak mean 1998/9-2002/3)
Common greenshank , *Tringa nebularia*, Europe/W Africa	9 individuals, representing an average of 1.5% of the GB population (5 year peak mean 1998/9-2002/3)

Species with peak counts in winter:

Greater white-fronted goose , *Anser albifrons albifrons*, NW Europe	212 individuals, representing an average of 3.6% of the GB population (5 year peak mean for 1996/7-2000/01)

Gadwall , *Anas strepera strepera*, NW Europe	261 individuals, representing an average of 1.5% of the GB population (5 year peak mean 1998/9-2002/3)
Northern shoveler , *Anas clypeata*, NW & C Europe	238 individuals, representing an average of 1.6% of the GB population (5 year peak mean 1998/9-2002/3)
Hen harrier, *Circus cyaneus*, Europe	15 individuals, representing an average of 2% of the GB population (5 year peak mean 1985/6-1989/90)
Water rail , *Rallus aquaticus*, Europe	5 individuals, representing an average of 1.1% of the GB population (5 year peak mean 1998/9-2002/3)
Pied avocet , *Recurvirostra avosetta*, Europe/Northwest Africa	329 individuals, representing an average of 9.6% of the GB population (5 year peak mean 1998/9-2002/3)
European golden plover , *Pluvialis apricaria apricaria*, P. a. altifrons Iceland & Faroes/E Atlantic	4503 individuals, representing an average of 1.8% of the GB population (5 year peak mean 1998/9-2002/3)
Common redshank , *Tringa totanus totanus*,	1386 individuals, representing an average of 1.1% of the GB population (5 year peak mean 1998/9-2002/3)
Lesser black-backed gull , *Larus fuscus graellsii*,	905 individuals, representing an average of 1.4% of the GB population (5 year peak mean 1998/9-2002/3)

Species Information

Nationally important species occurring on the site.

Invertebrates.

Ethmia bipunctella, Aleochara inconspicua, Philonthus dimidiatipennis, Deltote bankiana, Cephalops perspicuus, Erioptera bivittata, E. meijerei, Gymnancycla canella, Pisidium pseudosphaerium, Archanara neurica, Heliothis viriplaca, Pelosia muscerda, Photedes brevilinea, Senta flammea, Herminea tarsicrinalis, Haematopota grandis, Tipula marginata, Podalonia affinis, Arctosa fulvolineata, Eucosma catroptana, E.maritima, Melissoblaptes zelleri, Pima boisduvaliella, Acrotophthalmus bicolor, Limonia danica, Telmaturus tumidulus, Vertigo angustior (a Habitats Directive Annex II species (S1014)).

---

23. Social and cultural values:

Describe if the site has any general social and/or cultural values e.g. fisheries production, forestry, religious importance, archaeological sites, social relations with the wetland, etc. Distinguish between historical/archaeological/religious significance and current socio-economic values.

Aesthetic
Aquatic vegetation (e.g. reeds, willows, seaweed)
Environmental education/ interpretation
Livestock grazing
Non-consumptive recreation
Scientific research
Tourism

b) Is the site considered of international importance for holding, in addition to relevant ecological values, examples of significant cultural values, whether material or non-material, linked to its origin, conservation and/or ecological functioning? No

If Yes, describe this importance under one or more of the following categories:

i) sites which provide a model of wetland wise use, demonstrating the application of traditional knowledge and methods of management and use that maintain the ecological character of the wetland:

ii) sites which have exceptional cultural traditions or records of former civilizations that have influenced the ecological character of the wetland:

iii) sites where the ecological character of the wetland depends on the interaction with local communities or indigenous peoples:

iv) sites where relevant non-material values such as sacred sites are present and their existence is strongly linked with the maintenance of the ecological character of the wetland:

24. Land tenure/ownership:

Ownership category	On-site	Off-site
Non-governmental organisation (NGO)	+	+
Local authority, municipality etc.	+	
National/Crown Estate	+	
Private	+	+
Other	+	

25. Current land (including water) use:

Activity	On-site	Off-site
Nature conservation	+	+
Tourism	+	+
Recreation	+	+
Current scientific research	+	
Cutting of vegetation (small-scale/subsistence)	+	
Permanent arable agriculture		+
Grazing (unspecified)	+	
Flood control	+	
Transport route	+	+
Non-urbanised settlements	+	+

26. Factors (past, present or potential) adversely affecting the site's ecological character, including changes in land (including water) use and development projects:

Explanation of reporting category:

1. *Those factors that are still operating, but it is unclear if they are under control, as there is a lag in showing the management or regulatory regime to be successful.*
2. *Those factors that are not currently being managed, or where the regulatory regime appears to have been ineffective so far.*

NA = Not Applicable because no factors have been reported.

Adverse Factor Category	Reporting Category	Description of the problem (Newly reported Factors only)	On-Site	Off-Site	Major Impact?
Erosion	2	Coastal squeeze within the Blyth Estuary	+		+
Recreational/tourism disturbance (unspecified)	2	Trampling damage to vegetated shingle and driftline communities, and disturbance of little tern nesting habitat	+		+

For category 2 factors only.
What measures have been taken / are planned / regulatory processes invoked, to mitigate the effect of these factors?
Erosion - English Nature provides advice to the Environment Agency and coastal local authorities in relation to flood and coastal protection management. This will inform the development of the Suffolk Estuaries strategies and the second generation shoreline management plan.

Recreational/tourism disturbance (unspecified) - English Nature to work with owners/occupiers and regulatory authorities to develop a strategy to manage visitor pressure on Suffolk vegetated shingle. These measures are likely to include temporary fencing and provision of boardwalks as well as measures to increase visitor awareness about the sensitivity of the shingle habitat, for example by interpretation, wardening.

Is the site subject to adverse ecological change? YES

27. Conservation measures taken:

List national category and legal status of protected areas, including boundary relationships with the Ramsar site; management practices; whether an officially approved management plan exists and whether it is being implemented.

Conservation measure	On-site	Off-site
Site/ Area of Special Scientific Interest (SSSI/ASSI)	+	
National Nature Reserve (NNR)	+	
Special Protection Area (SPA)	+	
Land owned by a non-governmental organisation for nature conservation	+	
Management agreement	+	
Site management statement/plan implemented	+	

Area of Outstanding National Beauty (AONB)	+	+
Environmentally Sensitive Area (ESA)	+	+
Special Area of Conservation (SAC)	+	

b) Describe any other current management practices:
The management of Ramsar sites in the UK is determined by either a formal management plan or through other management planning processes, and is overseen by the relevant statutory conservation agency. Details of the precise management practises are given in these documents.

28. Conservation measures proposed but not yet implemented:

e.g. management plan in preparation; official proposal as a legally protected area, etc.

No information available

29. Current scientific research and facilities:

e.g. details of current research projects, including biodiversity monitoring; existence of a field research station, etc.

Fauna.
Numbers of migratory and wintering wildfowl and waders are monitored annually as part of the national Wetland Birds Survey (WeBS) organised by the British Trust for Ornithology, Wildfowl & Wetlands Trust, the Royal Society for the Protection of Birds and the Joint Nature Conservation Committee.

Flora.
NVC and vegetation monitoring, bird and invertebrate surveys/monitoring carried out on EN's NNRs, NT, SWT, RSPB reserves.

30. Current communications, education and public awareness (CEPA) activities related to or benefiting the site:

e.g. visitor centre, observation hides and nature trails, information booklets, facilities for school visits, etc.

Facilities at National Trust and Royal Society for the Protection of Birds reserves.

31. Current recreation and tourism:

State if the wetland is used for recreation/tourism; indicate type(s) and their frequency/intensity.

Activities, Facilities provided and Seasonality.
A popular area for tourists as it is an AONB and contains Minsmere bird reserve and Dunwich heath, both with toilets/shop/cafe. There are more visitors in the summer, however it well used throughout the year by walkers and bird watchers.

32. Jurisdiction:

Include territorial, e.g. state/region, and functional/sectoral, e.g. Dept. of Agriculture/Dept. of Environment, etc.

Head, Natura 2000 and Ramsar Team, Department for Environment, Food and Rural Affairs, European Wildlife Division, Zone 1/07, Temple Quay House, 2 The Square, Temple Quay, Bristol, BS1 6EB

33. Management authority:

Provide the name and address of the local office(s) of the agency(ies) or organisation(s) directly responsible for managing the wetland. Wherever possible provide also the title and/or name of the person or persons in this office with responsibility for the wetland.

Site Designations Manager, English Nature, Sites and Surveillance Team, Northminster House, Northminster Road, Peterborough, PE1 1UA, UK

34. Bibliographical references:

Scientific/technical references only. If biogeographic regionalisation scheme applied (see **15** above), list full reference citation for the scheme.

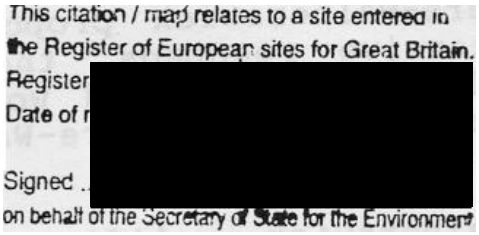
EC Directive 79/409 on the Conservation of Wild Birds:
Special Protection Area

MINSMERE-WALBERSWICK (SUFFOLK)

The Minsmere-Walberswick proposed SPA contains areas of grazing marsh, extensive reedbeds, the estuary of the River Blyth, and areas of lowland heath and woodland. The boundaries of the site follows those of the Minsmere-Walberswick Heath and Marshes.SSSI.

Minsmere-Walberswick qualifies under Article 4.1, by supporting, in summer, nationally important breeding populations of the following Annex 1 species: 5 booming male bitterns *Botauris stellaris* (presumed to represent 5 breeding pairs; 22% of the British breeding population) ; 15 breeding female marsh harriers *Circus aeruginosus* (20% of British) ; 47 pairs of avocet *Recurvirostra avosetta* (12% of British) ; 32 pairs of little tern *Sterna albifrons* (1% of British): and 24 pairs of nightjar *Caprimulgus europaeus* (1% of British).

The site qualifies also under Article 4.1 by regularly supporting, in winter, a nationally important wintering population of hen harrier *Circus cyaneus* (15 individuals, 2% of the British wintering population).



Minsmere-Walberswick qualifies under article 4.2 by supporting, in summer, in recent years, nationally important breeding populations of three regularly occurring migratory species: 24 pairs of gadwall *Anas strepera* (4% of British); 73 pairs of teal *A. crecca* (1% of British): and 23 pairs of shoveler *A. clvpeata* (2% of British) . Also notable is a nationally important breeding population of bearded tit *Panurus biarmicus* (50 pairs, 8% of British).

The site qualifies also under Article 4.2 by supporting nationally important wintering populations of three migratory waterfowl. (average peak counts for the five year period 1985/86 to 1989/90): 100 European white-fronted geese *Anser albifrons albifrons* (2% of the British wintering population); 90 gadwall *Anas strepera* (1% of British) , and 100 shoveler *Anas clypeata* (1% of British).

Minsmere-Walberswick is also of importance for an outstandingly diverse assemblage of breeding birds of marshland and reedbed habitats, including bittern, garganey *Anas querquedula*, marsh harrier, water rail *Rallus aquaticus*, Cetti's warbler *Cettia cetti* and Savi's warbler *Locustella lusciniodes*. Also notable is an assemblage of wintering waterfowl including, in addition to species listed above, Bewick's swan *Cygnus columbianus*, wigeon *Anas penelope*, teal *Anas crecca*, avocet; spotted redshank *Tringa erythropus*; and redshank *Tringa totanus*.

During severe winter weather Minsmere-Walberswick can assume even greater national and international importance as wildfowl and waders from many other areas arrive, attracted by relatively mild climate, compared with continental areas, and the abundant food resources available.

European Site Conservation Objectives for Minsmere–Walberswick Special Protection Area Site Code: UK9009101

With regard to the SPA and the individual species and/or assemblage of species for which the site has been classified (the 'Qualifying Features' listed below), and subject to natural change;

Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;

- **The extent and distribution of the habitats of the qualifying features**
- **The structure and function of the habitats of the qualifying features**
- **The supporting processes on which the habitats of the qualifying features rely**
- **The population of each of the qualifying features, and,**
- **The distribution of the qualifying features within the site.**

This document should be read in conjunction with the accompanying *Supplementary Advice* document, which provides more detailed advice and information to enable the application and achievement of the Objectives set out above.

Qualifying Features:

A021 *Botaurus stellaris*; Great bittern (Breeding)
A051 *Anas strepera*; Gadwall (Non-breeding)
A051 *Anas strepera*; Gadwall (Breeding)
A052 *Anas crecca*; Eurasian teal (Breeding)
A056 *Anas clypeata*; Northern shoveler (Breeding)
A056 *Anas clypeata*; Northern shoveler (Non-breeding)
A081 *Circus aeruginosus*; Eurasian marsh harrier (Breeding)
A082 *Circus cyaneus*; Hen harrier (Non-breeding)
A132 *Recurvirostra avosetta*; Pied avocet (Breeding)
A195 *Sterna albifrons*; Little tern (Breeding)
A224 *Caprimulgus europaeus*; European nightjar (Breeding)
A394 *Anser albifrons albifrons*; Greater white-fronted goose (Non-breeding)

This is a European Marine Site

This SPA is a part of the Minsmere–Walberswick European Marine Site (EMS). These Conservation Objectives should be used in conjunction with the Conservation Advice document for the EMS. Natural England's formal Conservation Advice for European Marine Sites can be found via GOV.UK.

Explanatory Notes: European Site Conservation Objectives

These Conservation Objectives are those referred to in the Conservation of Habitats and Species Regulations 2017 (as amended) ('the Habitats Regulations'). They must be considered when a competent authority is required to make a 'Habitats Regulations Assessment' including an Appropriate Assessment, under the relevant parts of this legislation.

These Conservation Objectives, and the accompanying Supplementary Advice (where this is available), will also provide a framework to inform the management of the European Site and the prevention of deterioration of habitats and significant disturbance of its qualifying features

These Conservation Objectives are set for each bird feature for a Special Protection Area (SPA).

Where these objectives are being met, the site will be considered to exhibit a high degree of integrity and to be contributing to achieving the aims of the Wild Birds Directive.

Publication date: 21 February 2019 (version 3). This document updates and replaces an earlier version dated 30 June 2014 to reflect the consolidation of the Habitats Regulations in 2017.

Minsmere-Walberswick SPA

Last updated: 13th September 2019

Supplementary advice

The Supplementary Advice on Conservation Objectives (SACOs) present attributes which are ecological characteristics or requirements of the classified species within a site. The listed attributes are considered to be those which best describe the site's ecological integrity and which if safeguarded will enable achievement of the Conservation Objectives.

Conservation Objectives relating to extent and distribution of habitat and population abundance are reflected in single attributes within the Supplementary Advice. Structure and function of habitats, and supporting processes for those habitats, are reflected in multiple attributes describing integrity of these ecological characteristics.

The Conservation Objective relating to the distribution of qualifying features (individual species or assemblages) may apply to most or all of the attributes listed in the SACOs and should be considered against them. Ensuring integrity of attributes relating to supporting habitats and processes should allow birds to distribute themselves optimally within (and, sometimes, outside) the SPA boundary. This is perhaps particularly relevant for food availability; extent and distribution of supporting habitat; quality of supporting habitat; predation; and disturbance caused by human activity.

Attributes have a target which is either quantified or qualified depending on the available evidence. The target identifies as far as possible the desired state to be achieved for the attribute. In many cases, the attribute targets show if the current objective is to either 'maintain' or 'restore' the attribute. The targets given for each attribute do not represent thresholds to assess the significance of any given impact in Habitats Regulation Assessments. You will need to assess this on a case-by-case basis using the most current information available.

Where there is no evidence to determine a marine feature's condition, a vulnerability assessment, which includes sensitivity and exposure information for features and activities in a site, has been used as a proxy for condition. Evidence used in preparing the SACO has been cited with hyperlinks included where possible. Where references have not been provided, Natural England has applied ecological knowledge and expert judgement.

Some, but not all, of these attributes can also be used for regular monitoring of the condition of the classified features. The attributes selected for monitoring the features, and the standards used to assess their condition, are listed in separate monitoring documents, which will be available from Natural England. As condition assessment information becomes available, the conservation advice package will be reviewed accordingly.

When to use

You should use this information, along with the conservation objectives and case-specific advice issued by Natural England when developing, proposing or assessing an activity, plan or project that may affect the site.

Any proposals or operations which may affect the site or its features should be designed so they do not adversely affect any of the attributes in the SACO or achievement of the conservation objectives.

Features:
Choose one or more features and/or their sub-features below by selecting the applicable boxes in the tree. This will show the relevant targets. Where a feature has sub-features this will be indicated with a greyed out triangle below, which can be expanded.

- ☐ Avocet (Recurvirostra avosetta), Breeding
- ☐ Bittern (Botaurus stellaris), Breeding
- ☐ Gadwall (Mareca strepera), Breeding
- ☐ Gadwall (Mareca strepera), Non-breeding
- ☐ Greater white-fronted goose (Anser albifrons albifrons), Non-breeding
- ☐ Hen harrier (Circus cyaneus), Non-breeding
- ☐ Little tern (Sternula albifrons), Breeding
- ☐ Marsh harrier (Circus aeruginosus), Breeding
- ☐ Nightjar (Caprimulgus europaeus), Breeding
- ☐ Shoveler (Spatula clypeata), Breeding
- ☐ Shoveler (Spatula clypeata), Non-breeding
- ☐ Teal (Anas crecca), Breeding

Reset | Select all | Show attributes and targets for selected features

Attributes:
You can filter to show only targets for certain attributes by selecting one or more attributes from the list below (use ctrl click to select multiple). Note that only attributes for the features you have chosen are shown.

Feature target

'Maintain' targets do not preclude the need for management, now or in the future, to avoid a significant risk of damage or deterioration to the feature. The supporting and/or explanatory notes in the SACOs set out why the target was chosen and any relevant site based supporting information. This is based on the best available information, including that gathered during monitoring of the feature's current condition.

Please select a feature.

See further guidance on how to undertake an HRA for a plan or project on a European site (https://www.gov.uk/guidance/habitats-regulations-assessments-protecting-a-european-site).

These tables bring together the findings of the best available scientific evidence which may be updated or supplemented in further publications from Natural England and other sources. You may decide to use other additional sources of information.

These tables do not give advice about SSSI features or other legally protected species which may also be present within the European site.

EC Directive 92/43 on the Conservation of Natural Habitats and of Wild Fauna and Flora

Citation for Special Area of Conservation (SAC)

Name:	Minsmere to Walberswick Heaths and Marshes
Unitary Authority/County:	Suffolk
SAC status:	Designated on 1 April 2005
Grid reference:	TM468682
SAC EU code:	UK0012809
Area (ha):	1265.52
Component SSSI:	Minsmere to Walberswick Heaths and Marshes SSSI

Site description:
Lowland dry heaths occupy an extensive area of this site on the east coast of England, which is at the extreme easterly range of heath development in the UK. The heathland is predominantly heather – western gorse (*Calluna vulgaris – Ulex gallii*) heath, usually more characteristic of western parts of the UK. This type is dominated by heather, western gorse and bell heather *Erica cinerea*.

Shingle beach forms the coastline at Walberswick and Minsmere. It supports a variety of scarce shingle plants including sea pea *Lathyrus japonicus*, sea campion *Silene maritima* and small populations of sea kale *Crambe maritima*, grey hair-grass *Corynephorus canescens* and yellow horned-poppy *Glaucium flavum*. A well-developed beach strandline of mixed sand and shingle supports annual vegetation. Species include those typical of sandy shores, such as sea sandwort *Honckenya peploides* and shingle plants such as sea beet *Beta vulgaris* ssp. *maritima*.

Qualifying habitats: The site is designated under **article 4(4)** of the Directive (92/43/EEC) as it hosts the following habitats listed in Annex I:

- Annual vegetation of drift lines
- European dry heaths
- Perennial vegetation of stony banks. (Coastal shingle vegetation outside the reach of waves)

This citation relates to a site entered in the Register of European Sites for Great Britain.
Register reference number: UK0012809
Date of registration: 14 June 2005
Signed: [redacted]
On behalf of the Secretary of State for Environment, Food and Rural Affairs

European Site Conservation Objectives for Minsmere to Walberswick Heaths and Marshes Special Area of Conservation Site Code: UK0012809

With regard to the SAC and the natural habitats and/or species for which the site has been designated (the 'Qualifying Features' listed below), and subject to natural change;

Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the Favourable Conservation Status of its Qualifying Features, by maintaining or restoring;

- **The extent and distribution of qualifying natural habitats and habitats**
- **The structure and function (including typical species) of qualifying natural habitats, and**
- **The supporting processes on which qualifying natural habitats rely**

This document should be read in conjunction with the accompanying *Supplementary Advice* document, which provides more detailed advice and information to enable the application and achievement of the Objectives set out above.

Qualifying Features:

H1210. Annual vegetation of drift lines

H1220. Perennial vegetation of stony banks; Coastal shingle vegetation outside the reach of waves

H4030. European dry heaths

This is a European Marine Site

This site is a part of the Minsmere–Walberswick European Marine Site. These Conservation Objectives should be used in conjunction with the Conservation Advice document for the EMS. Natural England's formal Conservation Advice for European Marine Sites can be found via GOV.UK.

Explanatory Notes: European Site Conservation Objectives

These Conservation Objectives are those referred to in the Conservation of Habitats and Species Regulations 2017 as amended from time to time (the "Habitats Regulations"). They must be considered when a competent authority is required to make a 'Habitats Regulations Assessment', including an Appropriate Assessment, under the relevant parts of this legislation.

These Conservation Objectives and the accompanying Supplementary Advice (where available) will also provide a framework to inform the measures needed to conserve or restore the European Site and the prevention of deterioration or significant disturbance of its qualifying features.

These Conservation Objectives are set for each habitat or species of a Special Area of Conservation (SAC). Where the objectives are met, the site will be considered to exhibit a high degree of integrity and to be contributing to achieving Favourable Conservation Status for that species or habitat type at a UK level. The term 'favourable conservation status' is defined in regulation 3 of the Habitats Regulations.

Publication date: 27 November 2018 (version 3). This document updates and replaces an earlier version dated 30 June 2014 to reflect the consolidation of the Habitats Regulations in 2017.

COUNTY: SUFFOLK SITE NAME: MINSMERE-WALBERSWICK HEATHS AND MARSHES

Date Notified (Under 1981 Act): 1989 Date of Last Revision: 1993

Other Information:
This site amalgamates Minsmere Level SSSI (notified in 1954), Walberswick SSSI (notified in 1954) and Brick Kiln Walks SSSI (notified in 1972).

Much of this site has been designated a Special Protection Area under EC Directive 79/409 on the Conservation of Wild Birds, and as a Wetland of International Importance under the Ramsar Convention.

Much of the site is included within 'A nature conservation review' by Ratcliffe (1977). It is within the Suffolk Coast and Heaths Area of Outstanding Natural Beauty.

Parts of the site are owned and/or managed as nature reserves and are listed below

Walberswick National Nature Reserve (English Nature)
Westleton Heath National Nature Reserve (English Nature)
Minsmere Reserve (Royal Society for the Protection of Birds)
Dunwich Heath (National Trust)
Norman Gwatkin Reserve (Suffolk Wildlife Trust)

Description and Reasons for Notification:
This composite site is situated on the coast of Suffolk between Southwold in the north and Sizewell in the south. It contains a complex series of habitats, notably mudflats, shingle beach, reedbeds, heathland and grazing marsh, which combine to create an area of exceptional scientific interest.

The tidal mudflats of the River Blyth estuary form sheltered feeding grounds for wildfowl and shorebirds, notably wigeon, shelduck, redshank and dunlin. Saltmarsh, dominated by sea purslane *Halimione portulacoides*, but also composed of sea

lavender *Limonium vulgare*, sea aster *Aster tripolium* and common cord-grass *Spartina anglica* fringes the southern shore of the estuary. Other saltmarsh species include glasswort *Salicornia* spp., sea rush *Juncus maritimus*, common saltmarsh grass *Puccinellia maritima* and sea couch-grass *Elymus pycnanthus*.

Shingle beach forms the coastline at Walberswick and Minsmere. This is subject to sea erosion and human disturbance but, nevertheless, it supports a variety of scarce shingle plants including sea pea *Lathyrus japonicus*, sea campion *Silene maritima* and small populations of sea kale *Crambe maritima*, grey hair-grass *Corynephorus canescens* and yellow horned-poppy *Glaucium flavum*. A narrow strip of yellow dune extends southwards at Minsmere behind which is a strip of dune grassland. A series of shallow, brackish lagoons and saltmarsh occurs behind the shingle beach between Walberswick and Dunwich.

Extensive reedbeds, consisting largely of pure stands of reed *Phragmites australis*, occur at Minsmere and Walberswick. These developed on former grazing marshes which were flooded as a war-time defence measure in 1940. Both marshes contain shallow pools of open water and are intersected by deep water channels. The reedbeds are an important habitat for birds and insects. There are large breeding populations of reed warbler and bearded tit. Other notable breeding species include marsh harrier, bittern, cetti's warbler, garganey and water rail. The marshes have a rich insect fauna; particularly moths, which includes a number of rare species: notably *Archanara neurica*, *Photedes brevilinea* and *Senta flammea*.

At Minsmere, a 20 hectare area of shallow lagoons and islands has been created for wading birds and wildfowl. This area is renowned for its breeding colony of avocets; shoveler, gadwall, teal and shelduck also breed.

Large blocks of grazing marsh are found near Eastbridge and Southwold. These marshes support a high number of species of breeding waterfowl such as snipe, redshank, gadwall, shoveler and black-tailed godwit. Dykes within the marshes contain very diverse aquatic plant communities, with brackish and freshwater types represented. Many nationally rare and scarce invertebrates such as the soldier fly *Odontomyia ornata* are found east of Eastbridge, as are a number of nationally scarce plants including sea barley *Hordeum marinum* and whorled water-milfoil *Myriophyllum verticillatum*. The marshes west of Eastbridge support a mosaic of different unimproved wetland communities including fen-meadow characterised by blunt-flowered rush *Juncus subnodulosus* and marsh thistle *Cirsium palustre*, reed beds, swamps dominated by lesser pond sedge *Carex acutiformis*, marshes dominated by meadowsweet *Filipendula ulmaria* with some angelica *Angelica sylvestris*, and alder *Alnus glutinosa* woodland.

High land at Minsmere, Westleton and Walberswick forms part of the East Suffolk Sandlings and is composed of infertile sands and gravels. This supports large areas of lowland heath, bracken, dry acidic grassland, woods and scrub.

Lowland heath, dominated by ling *Calluna vulgaris* but also containing bell heath *Erica cinerea* and cross-leaved heath *E. tetralix*, occupies a large continuous tract of about 400 ha at Minsmere, Dunwich and Westleton Heath with smaller areas at

Walberswick. This heathland provides a valuable habitat for two nationally decreasing birds, the. nightjar and woodlark.

Patches of unimproved acid grassland in which red fescue *Festuca rubra* and common bent *Agrostis capillaris* predominate, occur through the site but areas dominated by wavy hair-grass *Deschampsia flexuosa*, purple moor-grass *Molinia caerulea* and sand sedge *Carex arenaria* also occur. A variety of other acid grassland plants is also present, of which heath bedstraw *Galium saxatile* and sheep's sorrel *Rumex acetosella* are common. Scarce species include bird's-foot clover *Trifolium ornithopodioides* and mossy stonecrop *Crassula tillaea* together with a small colony of red-tipped cudweed *Filago lutescens*. There are also substantial areas dominated by bracken *Pteridium aquilinum* or gorse *Ulex europaeus* and *U. gallii*.

Mature plantation woodland, chiefly of oak *Quercus robur* or Scots pine *Pinus sylvestris* but also including sycamore *Acer pseudoplatanus* and sweet chestnut *Castanea sativa*, occur at Minsmere and Walberswick. Naturally regenerated woods of birch *Betula pendula* and Scots pine have arisen on former heathland and alder *Alnus glutinosa*, sallow *Salix* spp. and birch woodlands are also present on wet ground. This woodland and scrub provides important additional habitat diversity for birds and invertebrates.

Views About Management

ENGLISH NATURE

A statement of English Nature's views about the management of Minsmere-Walberswick Heaths & Marshes Site of Special Scientific Interest (SSSI).

This statement represents English Nature's views about the management of the SSSI for nature conservation. This statement sets out, in principle, our views on how the site's special conservation interest can be conserved and enhanced. English Nature has a duty to notify the owners and occupiers of the SSSI of its views about the management of the land.

Not all of the management principles will be equally appropriate to all parts of the SSSI. Also, there may be other management activities, additional to our current views, which can be beneficial to the conservation and enhancement of the features of interest.

The management views set out below do not constitute consent for any operation. English Nature's written consent is still required before carrying out any operation likely to damage the features of special interest (see your SSSI notification papers for a list of these operations). English Nature welcomes consultation with owners, occupiers and users of the SSSI to ensure that the management of this site conserves and enhances the features of interest, and to ensure that all necessary prior consents are obtained.

Management Principles

Blyth Estuary

Estuaries are relatively natural habitats which generally require little direct intervention to maintain them. Their proper management requires an understanding of the inputs and processes, both natural and otherwise, which affect them, and needs to be responsive to these factors.

The Blyth Estuary needs to be considered as a single functional unit that will respond to a variety of influences such as sea level rise, coastal squeeze and changing sediment regimes. The location and extent of habitats such as saltmarshes and mudflats depends upon the extent to which the estuary is constrained from responding to these influences. In the absence of constraints such as flood banks and hard defences, the estuary would adjust to sea level rise by inland translocation of intertidal habitats. Where constraints occur, space to accommodate greater volumes of water is compressed and the extent and quality of intertidal habitats declines.

The maintenance of high quality estuarine habitats such as saltmarshes and mudflats is essential if the associated plant and animal communities are to be maintained. In addition there are a variety of wetland habitats on the coastal flood plain that contribute to the overall importance of the estuary, including coastal grazing marshes,

brackish and freshwater pools and ditches. This combination of wetland and intertidal interest features, which may be dynamic over time, provides the feeding, roosting and nesting sites for the large numbers of breeding, wintering and passage wildfowl and waders.

Littoral sediments (mud and sand flats) of the Blyth Estuary

Intertidal mud and sand flats include a range of generally muddy or sandy low-gradient shores that are exposed to air during low tide and submerged during the higher tides. High energy shores, such as those on open coasts, are generally sandy in nature whilst more sheltered, low energy flats are muddier. They support a wide variety of marine invertebrates that represent an important food source for many fish and bird species.

Good water quality and sediment quality should be maintained, and the sediment budget within the estuarine or coastal system should not restricted by anthropogenic influences.

The birds that use mud and sandflats for feeding and roosting are vulnerable to disturbance from human activities, for example, bait digging, dog walking and wildfowling. These activities can lead to reduced time spent feeding, or individuals being restricted to areas with a poor food supply. Disturbance should therefore be minimised, especially at times when bird populations may be stressed, such as during severe winter weather.

The location and extent of mud or sandflats is dependent on the extent to which the estuary or coast where they occur is constrained from responding to sea level rise and changing sediment regimes. Management needs to create space to enable landward roll-back to take place in response to sea-level rise, and should also allow the system to be dynamic and retain the flexibility to respond to associated changes such as the movement of physical features within the system, e.g. migrating subtidal sandbanks.

Coastal saltmarsh

Saltmarshes form the upper vegetated portions of intertidal mudflats in sheltered coastal locations, such as estuaries, lagoons and beach plains. There is typically a zonation of vegetation, from plants adapted to regular immersion by the tides (halophytes), through to more widespread plant species in the areas less frequently covered by the sea. The halophyte plant species are confined to this type of habitat, and areas of structurally diverse vegetation provide good invertebrate habitat. Saltmarshes are also important nursery sites for several fish species, and important refuge, feeding and breeding grounds for wading birds and wildfowl.

Where saltmarshes require management this has traditionally been achieved by grazing, and previously used regimes should be continued. Grazing provides a variety of different habitats, particularly for wintering bird species, and if grazing were to cease there may be a loss of botanical diversity. The precise timing and intensity will vary according to local conditions and requirements, for example the type or availability of stock, or the need to avoid trampling ground nesting birds. However on many sites, the aim of will be to create a short turf that can be attractive to over-wintering wildfowl, with a reduction in stock density in the early summer for the

benefit of ground-nesting birds. Indeed, careful reduction of grazing can increase the number of breeding birds, without significantly altering the plant species composition. Care should be taken not to overgraze the site, as this may reduce the diversity of animal and plant species that the saltmarsh is able to support, as well as potentially impact the sediments supporting the saltmarsh.

Not all saltmarsh habitats require active management to retain their conservation interest. Where there has not been a history of grazing, the saltmarsh will be able to maintain itself and grazing-sensitive species are likely to be present, therefore grazing should not be introduced.

There are a number of factors that are contributing to saltmarsh change that management may need to take into consideration. These include coastal erosion as a result of coastal flood-defence works, rising sea-levels, variations in sediment deposition, and land claim for development.

Coastal lagoons

Coastal lagoons which occur behind the shingle beach between Dunwich and Walberswick are saline water bodies separated from the sea by a barrier (e.g. sand, shingle or rock sill), This separation from the sea makes them unique among coastal habitats and means that saline lagoons are either tideless, or where inlets occur, the tide has only a restricted effect on the lagoon. They retain part of their water-body at low tide, and this water may be either saline or brackish. They often support unusual assemblages of marine, estuarine and aquatic plants and animals, including lagoonal specialist species.

Any management needs to be carefully tailored to the needs of each individual lagoon and should be based on an understanding of the natural features of importance and the external factors affecting the lagoon. Indeed, where a lagoon is in a good and stable condition, active management is unlikely to be necessary. Maintaining salinity and water depths can be a key management priority, particularly where some lagoons become increasingly separated from the sea as a result of natural coastal processes - the balance between freshwater (e.g. from rainfall, streams or artificial outputs) and saline (i.e. sea water) inputs may change as a result. It may be necessary to actively manage freshwater and seawater input to favour certain species or communities. Whilst freshwater input is not essential to the conservation of lagoons, some connectivity with seawater is.

The water depth is also critical to many of the lagoonal specialist species with a depth between 0.5 and 1m being desirable. Some deeper water refuges are also beneficial. Siltation from surrounding land run-off may need to be addressed.

Water quality, and any direct and/or diffuse inputs from the surrounding land, can have a profound effect upon the productivity of lagoons and well-being of specialist species. Saline lagoons can show extreme reactions to a build up of some types of nutrients and therefore it may be necessary to actively manage inputs, especially where in close proximity to farmland.

In some cases, it may be desirable to allow vegetation to encroach into the lagoon to increase the diversity of habitats present, particularly for some breeding and migratory bird species. However vegetation should not be allowed to encroach to such an extent that it significantly reduces the areas of open water and shallow water, thus reducing the variety of habitats available to specialist species within the lagoon itself.

Islands in saline lagoons can be important for breeding birds and some management of the vegetation on these islands may be necessary to provide the best conditions for breeding birds. Two typical methods of vegetation control include flooding and hand clearance.

Vegetated shingle

Shingle is defined as sediment with particle sizes from 2-200mm. Shingle beaches form where sediment is first deposited on the shore by wave action. These deposits can then build up into more stable spits, bars or forelands. The types of vegetation that occur on shingle depend on the stability and structure of the shingle itself, but all must be able to cope with the unique physical and hydrological conditions typical of this habitat. This results in some communities being unique to shingle; including unusual moss- and lichen-rich communities that are of great conservation value. Shingle structures also provide important habitats for invertebrates and breeding birds.

A key management requirement is to avoid or minimise surface disturbance, especially in the more open communities. Many of the vegetation types and species associated with shingle are fragile and vulnerable to damage from trampling. This breaks up the fine humus that develops in the upper layers of the shingle that is vital for the plants to survive. Where recreational pressures are significant enough to result in the loss of vegetation cover, or prevent its recovery, it may be necessary to take steps to manage access. Disturbance of areas important for breeding birds should be minimised during the breeding season.

Where there is more closed vegetation cover, light grazing, by rabbits for example, may be all that is needed to prevent scrub encroachment on areas of grassland and heath. However, if there is a tradition of sheep grazing; it may be beneficial to continue this practice at a low intensity. In some cases grazing is not necessary, because of the low rates of plant growth on shingle structures, and can even be damaging, due to the fragility of shingle habitats. The introduction of grazing where it has not been traditionally practiced would not be beneficial.

Sand-dunes

Sand-dune habitats support a diverse range of species and communities. Sand-dunes develop where sand is blown landwards from the intertidal beach plain and is deposited above the high water mark. This is then colonised by dune building grasses which can continue to grow up as new layers of sand are deposited. A process of succession takes place as sand-dunes develop first into embryo dunes which can be ephemeral, then into semi-fixed dunes dominated by marram grass, and eventually into fixed dunes. Depending on the location of the dune in the system, different types of specialist vegetation occur. For example, the key features of the early-successional dunes are marram and lyme grass, with areas of bare sand. These more open communities can be important for amphibians and reptiles and some breeding birds

including several species of terns. The fixed dunes tend to be characterised by a more continuous sward of vegetation which may include dune grassland, low scrub, heath and lichen-dominated communities, which are often important for a variety of breeding and passage birds. Low-lying areas within dune systems are referred to as slacks, which can be either wet or dry and may be created by blowouts. These slacks are also important for amphibians, including rare species such as the natterjack toad.

The management of dune systems should take into account the need to maintain the range of habitats and associated species reflecting the different stages of succession, by maintaining (or restoring where necessary) the natural processes and dynamics of dune development and succession.

Dune management should aim to allow for all stages of the succession to be present on the site. Management of amenity beaches can affect the early stages of dune formation by removing the strandline that helps to trap blown sand and helps to develop new dune ridges. Dune systems exhibit a degree of dynamism, for example change from blowouts or newly deposited sand, which helps to retain a variety of successional stages within the site. Without management intervention, a mix of dune scrub and woodland may eventually replace the habitats on stable areas of the dune. Selective scrub management and grazing or mowing may be necessary. Where light grazing has traditionally been practised, this prevents the invasion of scrub and it should be continued. The effects of non-domestic grazing animals, such as rabbits, should also be taken into account. Other management options that might be appropriate include mowing to remove rank vegetation and in extreme situations can include turf stripping, which is useful for recreating the younger stages of slack formation.

Many of the vegetation types supported by sand dunes are fragile and vulnerable to erosion from heavy trampling. Where recreational pressures are significant enough to result in the loss of vegetation cover and prevent recovery, it may be necessary to take steps to manage access by putting boardwalks in or controlling activities in vulnerable areas such as the foredunes. It may also be necessary to manage access to limit the impacts of disturbance on breeding birds. Where recreation pressure is not severe, the impact of trampling can help to retain diversity on some sites – sandy tracks break up the vegetation sward and provide areas of bare sand thus increasing the diversity of habitats available.

Reedbed and Swamp

Reedbed and Swamp habitats develop on the fringes of open water, or in shallow depressions with permanent standing water. The plants may be rooted in the submerged soil or form a floating mat of inter-twined roots, rhizomes and stems. Swamps usually consist of a dominant single species of plant (e.g. reeds, tussock sedges, reedmace, reed sweet grass, reed canary grass and bull rushes) with a few other species thinly distributed among them. In common with most other types of wetland, swamps represent a transient stage in the change from open water to dry land.

Management should either seek to retain swamp communities in the same place or should acknowledge the dynamics of succession by ensuring there is always a new

niche for the swamp communities to develop in. The succession from swamp into floodplain fen, for example, as the diversity of species present increases, may be slowed by raising the water table and by periodically removing any encroaching scrub. If the vegetation surface of the whole wetland appears to be building up or drying out for some other reason it may be necessary to lower the ground level by creating scrapes or ponds. A programme of rotational cutting to maintain the reedbed may be necessary to encourage the vigorous growth of reed whilst preventing excessive build up of litter. Cutting should take place during the winter (November – March) and all cut material should be removed.

Management should ensure that appropriate water quality is maintained according to the requirements of the wetland communities present. Where swamp is in continuity with a waterbody, the water quality in the waterbody will affect the swamp. While some communities, such as reed swamp are unlikely to be very sensitive to nutritional enrichment, others, such as tussock sedge and narrow leaved reedmace, will be out-competed by other species (e.g. reed or reed sweet grass) where any increase in the amount of nutrients present occurs.

Swamp habitats have often survived where the vegetation has traditionally been cut for a variety of purposes, including use as building materials or animal bedding. It may be beneficial to consider re-instating these traditional management practices where they are not in conflict with other nature conservation objectives, such as the specific requirements of certain birds or invertebrates.

Wet grassland with breeding and wintering bird interest

Wet grasslands occur on land that is subject to periodic flooding or has a seasonally high water table and is waterlogged for much of the year. Wet grassland often supports a wide variety of plants and animals, in particular birds and invertebrates, and is an important habitat for breeding waders and wintering wildfowl.

Wet grassland requires active management if it is to retain its conservation interest. Generally, each year's growth of vegetation must be removed. Otherwise the sward becomes dominated by tall, vigorous grasses and rushes which, together with an associated build up of dead plant matter, suppress less vigorous species and lower the botanical richness of the sward. Traditionally, this management is achieved by grazing. Cattle are often the preferred stock, being relatively tolerant of wet conditions and able to control tall grasses and rank vegetation. Cattle also tend to produce a rather uneven, structurally diverse sward. However, ponies, or even hill sheep, can be used if necessary. Grazing usually takes place at times between late spring and early autumn, but the precise timing and intensity will depend on local conditions and requirements, such as the need to avoid trampling ground-nesting birds. Heavy poaching should be avoided but light trampling can be beneficial in breaking down leaf litter and providing areas for seed germination. Agricultural operations in general should be avoided before mid-June to minimise disturbance to breeding birds or the destruction of nests. An element of managed scrub, both within and fringing a field can be of importance to birds and invertebrates, as can a surrounding hedge.

Partial winter flooding is important in maintaining suitable habitat conditions for wintering birds. A mosaic of winter flooded grassland and permanently un-flooded grassland is desirable, with both temporary and permanent pools present. The maintenance of a mosaic of shallow surface pools and un-flooded areas during the winter will provide roosting and feeding habitat for wintering wildfowl and waders. From April onwards, the area of standing surface water should be reduced to increase the area available for nesting waders and also by concentrating aquatic invertebrates in small pools to provide suitable feeding areas for their young. Some shallow areas of flooding should be maintained until late June to provide patches of bare muddy ground on which the birds and their young can feed as raised sward height makes feeding on the drier areas more difficult. The birds using these features are directly vulnerable to disturbance, which can cause them to lose time spent feeding or drive them to areas with a poorer supply of food. Management should seek to minimise any harmful disturbance, especially at times when bird populations are under stress, such as severely cold conditions. Predators, especially crows and related species, should be controlled and this may be best achieved by limiting their nesting sites.

Careful maintenance of existing ditches and drains is usually acceptable practice, but abandonment or deepening of ditches can be harmful.

Ditches

Ditches are artificial habitats created by land drainage, or occasionally by the channelisation of small streams. They may represent the only remaining freshwater habitat within former wetland areas, and often support a wide range of aquatic plant and animal (in particular invertebrate) species that would have previously been more widespread in ponds and wetlands.

If left unmanaged, silt accumulates in the bottom of the ditches, and emergent plants such as reeds are able to colonise across the width of the ditch, leading to a loss of aquatic plant diversity and a gradual drying out of the ditch. To prevent this, periodical removal of sediment and vegetation may be necessary to return the ditch to an early stage of the management cycle. Ideally, ditch management should be undertaken on a rotation, creating a series of different management stages across a site at any one time. All stages of the management cycle have wildlife interest; recently cleared ditches are good for plants and animals which favour newly created habitats and cannot tolerate competition with other species; middle-stage ditches support a rich aquatic plant flora; and late-stage ditches may be important for a variety of invertebrates. The removal of both sediment and vegetation is usually better than simply cutting the vegetation, which does not recreate the earliest stages of the ditch management cycle. Where possible, management should aim to create shallow shelving margins rather than steep ditch sides. Where water voles are known to be present, the relevant good practice guidelines for ditch management and conservation should be followed.

Most ditch systems are subject to water level control, which should be managed to ensure that there is a sufficient depth of water (0.3-0.5m) in ditches throughout the year. Rapid or extreme changes in water level should be avoided unless they are known to be important to plant or animal communities relying on such fluctuations.

Ditches are susceptible to increased levels of nutrients which can cause a loss of aquatic plants and increases in algal growth. Other activities that can lead to this include the control or removal of aquatic plants, or the introduction of species such as bottom feeding coarse fish which uproot plants and disturb ditch sediments. Ditches are also susceptible to invasion by non-native aquatic plants such as floating pennywort and water fern, which are able to grow rapidly taking up available habitat and smothering other plants. Some native plants including a number of duckweed species are also able to take over in this way (although such growths are usually exacerbated by increased nutrients in the water) and management may be necessary to control such invasions where they cause a problem.

An important feature of many coastal ditch systems relating to water quality is the transition between freshwater and brackish water conditions, which often results in interesting changes in plant and animal species along ditch lengths or across the site. Management should aim to maintain such freshwater-brackish transitions where they occur.

Dry and wet lowland heath

On this site both wet and dry heath communities occur, however wet heath is restricted to a few isolated fragments, such as at Walberswick Common.. Heathland supports the greatest diversity of plants and animals (including a diverse invertebrate fauna and a number of characteristic bird species) where management maintains the open nature of the heath and by promoting a varied structure of uneven-aged stands of native heathers and other characteristic plants. It is generally beneficial if all stages of the heather life cycle are present. Without such management, heathland becomes progressively dominated by bracken, gorse and, on wet ground, purple moor grass tussocks. Eventually scrub and trees will invade. The precise management requirements will vary both between and within sites according to the needs of the different heathland interests present and site conditions.

Low intensity grazing is a suitable means of managing areas of dry heath. Generally areas of wet heath require limited management but light grazing may also be useful for maintaining the variation in vegetation composition and structure, and for controlling invasive grasses such as purple-moor grass. By feeding selectively in different areas and on different plants, free-roaming livestock help to maintain variation in the vegetation composition and structure. They can also suppress scrub encroachment and provide some light poaching to create small pockets of bare peat and sandy ground that are of benefit to a variety of specialised plants, invertebrates and reptiles. Sheep grazing is an acceptable method of management but cattle or hardy ponies may also be used, although care must be taken to avoid damage to the heather by trampling. An appropriate stocking rate should take into account local conditions and the timing and length of grazing, but an off-take of between 30-40% of the current growth increment is desirable. Heavy grazing should be avoided on wet heath as it can lead to a decline in characteristic dwarf shrub cover in favour of grass and sedge species, as well as excessive poaching and erosion of the underlying peat.

Alternatively, cutting or mowing may be useful options for managing dry heath where a mosaic of patches of heather of different ages is desired. The cut material should be removed to avoid nutrient accumulation on site and to allow the cut plants to re-sprout

successfully. However, mowing or cutting may not be suitable on wet heath or on mature stands of dry heath of importance for rare reptiles.

The rare silver-studded blue butterfly present on this site requires the maintenance of a very short heather turf and warm ground conditions associated with pioneer heath communities. Grazing is usually a suitable means of managing dry heath and can extend the time that the heath is in the pioneer phase. However, it is not usually capable on its own of maintaining the open conditions required by the silver-studded blue. These conditions are best achieved by either regular mowing to prevent the build up of mature vegetation, or by cutting patches or strips of vegetation on rotation. The cut material should be removed to avoid nutrient accumulation on site and to allow the cut plants to re-sprout successfully. Heathland supporting this rare butterfly should not be burnt.

Prescribed burning can be a useful tool for maintaining the structural diversity of some dry heathlands and for re-establishing areas of pioneer heath required by certain species, but special care is required when sensitive species are present (see above) and burning should not be used on wet heath vegetation. Burning must be used with caution, as inappropriate burning can be very damaging to both plant and animal communities and careful consideration should be given to the timing of the burn.

There is some benefit in retaining a few scattered individual trees and some small patches of scrub. For example, the maintenance of scattered mature Scots pine in undisturbed locations will provide suitable nest sites for hobbies. However, this should not encroach on the open nature of the habitat, and mechanical control or manual cutting followed by the careful application (spot application on areas of wet heath) of a suitable herbicide may be necessary to prevent this. Bracken invasions may need to be controlled in the same way.

Where gorse is present, scattered stands with a bushy structure rather than large continuous blocks are of greater benefit to the characteristic bird and invertebrate species associated with gorse scrub. For example, Dartford warbler require areas of open heath (with less than 25 trees per hectare) with over 50% cover of mature heather (preferably over 30 cm tall) and patches of dense, compact, mature gorse bushes (0.5-3 m tall) to be maintained. Winter cutting of ‘leggy’ stands of gorse and the removal of cut material will maintain gorse at different stages of re-growth and avoid nutrient accumulation in the soil.

Although careful maintenance of existing ditches and drains is usually acceptable, the abandonment or deepening of ditches or drains should be avoided. Water levels within areas of wet heath should be maintained to avoid adverse changes to the characteristic plant composition of the habitat. In some instances it may be appropriate to restore natural drainage where this is possible.]

Lowland acid grassland

Free-draining, acidic soil is the key requirement of the grassland communities at this site, but their maintenance also depends on active management. If neglected, the sward becomes dominated by tall, vigorous grasses or bracken which, together with an associated build up of dead plant matter, suppress less vigorous species and reduce

the botanical richness of the site. Eventually the sward reverts to scrub and even woodland. Traditionally, management has consisted of stock grazing and this remains the most appropriate management tool. Grazing, through the removal of plant matter and nutrients, helps to maintain an open sward of small tussocky grasses. It also, through disturbance and trampling, creates areas of open ground suitable for colonization by the lichens, ephemeral plants and invertebrates that are often characteristic of this type of grassland. However, rabbit grazing, though difficult to control, can also be a useful management tool in some situations. Occasional management of invasive scrub and bracken may be necessary.

Lowland wet woodland
Wet woodland includes a range of different woodland types but usually is dominated by ash, alder and willow species. It often supports important invertebrate species and assemblages.

Areas usually benefit from minimum intervention and are often best left undisturbed to limit damage to their fragile soils. This allows the development of old stands where individual trees reach maturity and die naturally to create gaps in the canopy, leading to a diverse woodland structure. However, works to remove dangerous trees in areas of public access may be necessary.

Where particularly important light-demanding or glade species interests are present, including where the woodland is spreading on to valuable open wetland habitat, it may be necessary to periodically clear areas of vegetation. In some woods a more active programme of management by coppice may be appropriate, where this has been the historical management and the conditions are such that it will not lead to heavy ground disturbance.

Broadleaved semi-natural woodland
There are many different ways in which broadleaved woodland can be managed to conserve its value for wildlife. The following gives broad views on a range of regimes that may be appropriate on your site.

A diverse woodland structure, with open space, a dense understory, and a more mature overstory is important. A range of ages and species within and between stands is desirable. Some dead and decaying wood, such as fallen logs, can provide habitats for fungi and invertebrates. However, work may be needed to make safe dangerous trees in areas of high public access. Both temporary and permanent open spaces benefit groups of invertebrates such as butterflies. They may require cutting to keep them open, and should be of sufficient size to ensure that sunny conditions prevail for most of the day.

Felling, thinning or coppicing may be used to create or maintain variations in the structure of the wood, and non-native trees and shrubs can be removed at this time. To avoid disturbance to breeding birds the work is normally best done between the beginning of August and the end of February. Work should be avoided when the ground is soft, to prevent disturbing the soil and ground flora. Normally successive felling, thinning or coppicing operations should be spread through the wood to promote diversity, but where there is open space adjacent plots should be worked to

encourage the spread of species that are only weakly mobile. Natural regeneration from seed or stump regrowth is preferred to planting because it helps maintain the local patterns of species and the inherent genetic character of the site.

Deer management and protection from rabbits or livestock are often necessary. Whilst light or intermittent grazing may increase woodland diversity, heavy browsing can damage the ground flora and prevent successful regeneration. Invasive species, such as *Rhododendron* or Himalayan balsam, should be controlled.

Parts of a wood should be left unmanaged to benefit species that do best under low disturbance or in response to natural processes. Within these areas some trees will eventually die naturally and dead wood accumulate.

All habitats

The habitats within this site are highly sensitive to inorganic fertilisers and pesticides, applications of which should be avoided both within the site itself and in adjacent surrounding areas. Herbicides may be useful in targeting certain invasive species, but should be used with extreme care. Access to this site, and any recreational activities within, may also need to be controlled.

NATURA 2000 – STANDARD DATA FORM

Special Protection Areas (SPAs) classified under Directive 2009/147/EC of the European Parliament and of the Council of 30 November 2009 on the conservation of wild birds (codified version), also known as the 'Birds Directive'

and

Special Areas of Conservation (SACs) (includes candidate SACs, Sites of Community Importance (SCIs) and designated SACs) designated under Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora, also known as the 'Habitats Directive'

Each Natura 2000 site in the United Kingdom has its own Standard Data Form containing site-specific information.

The information provided here follows the officially agreed site information format for Natura 2000 sites, as set out in the Official Journal of the European Union recording the Commission Implementing Decision of 11 July 2011 (2011/484/EU).

The Standard Data Forms are generated automatically for all of the UK's Natura 2000 sites using the European Environment Agency's Natura 2000 software. The structure and format of these forms is exactly as produced by the EEA's Natura 2000 software (except for the addition of this coversheet and the end notes). The content matches exactly the data submitted to the European Commission.

Please note that these forms contain a number of codes, all of which are explained either within the data forms themselves or in the end notes.

Further technical documentation may be found here:
http://bd.eionet.europa.eu/activities/Natura_2000/reference_portal

In December 2015, several sections of the UK's previously published Standard Data Forms were updated. For details of the approach taken by the UK in this submission please refer to the following document:
http://jncc.defra.gov.uk/pdf/Natura2000_StandardDataForm_UKApproach_Dec2015.pdf.
These changes formed part of the UK Submission to the European Commission on 22/12/2015.

More general information on Special Protection Areas (SPAs) and Special Areas of Conservation (SACs) in the United Kingdom, including in Gibraltar, is available from the SPA homepage and SAC homepage on the JNCC website. These webpages also provide links to Standard Data Forms for all Natura 2000 sites in the UK.

Date Standard Data Form generated by the Joint Nature Conservation Committee:	14th November 2017 (UK Tranche 56)

EXPLANATION OF CODES USED IN THE NATURA 2000 STANDARD DATA FORMS

The codes in the table below are also explained in the official European Union guidelines for the Standard Data Form. The relevant corresponding page number is shown in the table below.

1.1 Site type

CODE	DESCRIPTION	PAGE NO
A	SPA (classified Special Protection Area)	53
B	cSAC, SCI or SAC (candidate Special Area of Conservation, Site of Community Importance, designated Special Area of Conservation)	53
C	SPA area/boundary is the same as the cSAC/SCI/SAC i.e. a co-classified/designated site (Note: in the UK Natura 2000 submission, this is only used in Gibraltar)	53

3.1 Habitat representativity

CODE	DESCRIPTION	PAGE NO
A	Excellent representativity	57
B	Good representativity	57
C	Significant representativity	57
D	Non-significant presence	57

3.1 Habitat code

CODE	DESCRIPTION	PAGE NO
1110	Sandbanks which are slightly covered by sea water all the time	57
1130	Estuaries	57
1140	Mudflats and sandflats not covered by seawater at low tide	57
1150	Coastal lagoons	57
1160	Large shallow inlets and bays	57
1170	Reefs	57
1180	Submarine structures made by leaking gases	57
1210	Annual vegetation of drift lines	57

European Site Conservation Objectives for Outer Thames Special Protection Area Site Code: UK9020309

With regard to the SPA and the individual species and/or assemblage of species for which the site has been classified (the 'Qualifying Features' listed below), and subject to natural change;

Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;

- **The extent and distribution of the habitats of the qualifying features**
- **The structure and function of the habitats of the qualifying features**
- **The supporting processes on which the habitats of the qualifying features rely**
- **The population of each of the qualifying features, and,**
- **The distribution of the qualifying features within the site.**

This document should be read in conjunction with the accompanying *Supplementary Advice* document, which provides more detailed advice and information to enable the application and achievement of the Objectives set out above.

Qualifying Features:

A001 Gavia stellata; Red-throated diver (Non-breeding)

A193 Sterna hirundo; Common tern (Breeding)

A195 Sternula albifrons; Little tern (Breeding)

This is a European Marine Site

This SPA is a part of the Outer Thames European Marine Site (EMS). These Conservation Objectives should be used in conjunction with the Conservation Advice document for the EMS. Natural England's formal Conservation Advice for European Marine Sites can be found via GOV.UK.

Explanatory Notes: European Site Conservation Objectives

These Conservation Objectives are those referred to in the Conservation of Habitats and Species Regulations 2017 (as amended) ('the Habitats Regulations'). They must be considered when a competent authority is required to make a 'Habitats Regulations Assessment' including an Appropriate Assessment, under the relevant parts of this legislation.

These Conservation Objectives, and the accompanying Supplementary Advice (where this is available), will also provide a framework to inform the management of the European Site and the prevention of deterioration of habitats and significant disturbance of its qualifying features

These Conservation Objectives are set for each bird feature for a Special Protection Area (SPA).

Where these objectives are being met, the site will be considered to exhibit a high degree of integrity and to be contributing to achieving the aims of the Wild Birds Directive.

Publication date: 21 February 2019 (version 3). This document updates and replaces an earlier version dated 20 December 2017 to reflect the consolidation of the Habitats Regulations in 2017.

Outer Thames Estuary SPA

Last updated: 13th September 2019

Supplementary advice

The Supplementary Advice on Conservation Objectives (SACOs) present attributes which are ecological characteristics or requirements of the classified species within a site. The listed attributes are considered to be those which best describe the site's ecological integrity and which if safeguarded will enable achievement of the Conservation Objectives.

Conservation Objectives relating to extent and distribution of habitat and population abundance are reflected in single attributes within the Supplementary Advice. Structure and function of habitats, and supporting processes for those habitats, are reflected in multiple attributes describing integrity of these ecological characteristics.

The Conservation Objective relating to the distribution of qualifying features (individual species or assemblages) may apply to most or all of the attributes listed in the SACOs and should be considered against them. Ensuring integrity of attributes relating to supporting habitats and processes should allow birds to distribute themselves optimally within (and, sometimes, outside) the SPA boundary. This is perhaps particularly relevant for food availability; extent and distribution of supporting habitat; quality of supporting habitat; predation; and disturbance caused by human activity.

Attributes have a target which is either quantified or qualified depending on the available evidence. The target identifies as far as possible the desired state to be achieved for the attribute. In many cases, the attribute targets show if the current objective is to either 'maintain' or 'restore' the attribute. The targets given for each attribute do not represent thresholds to assess the significance of any given impact in Habitats Regulation Assessments. You will need to assess this on a case-by-case basis using the most current information available.

Where there is no evidence to determine a marine feature's condition, a vulnerability assessment, which includes sensitivity and exposure information for features and activities in a site, has been used as a proxy for condition. Evidence used in preparing the SACO has been cited with hyperlinks included where possible. Where references have not been provided, Natural England has applied ecological knowledge and expert judgement.

Some, but not all, of these attributes can also be used for regular monitoring of the condition of the classified features. The attributes selected for monitoring the features, and the standards used to assess their condition, are listed in separate monitoring documents, which will be available from Natural England. As condition assessment information becomes available, the conservation advice package will be reviewed accordingly.

When to use

You should use this information, along with the conservation objectives and case-specific advice issued by Natural England when developing, proposing or assessing an activity, plan or project that may affect the site.

Any proposals or operations which may affect the site or its features should be designed so they do not adversely affect any of the attributes in the SACO or achievement of the conservation objectives.

Features:
Choose one or more features and/or their sub-features below by selecting the applicable boxes in the tree. This will show the relevant targets. Where a feature has sub-features this will be indicated with a greyed out triangle below, which can be expanded.

- ☐ Common tern (Sterna hirundo), Breeding
- ☐ Little tern (Sternula albifrons), Breeding
- ☐ Red-throated diver (Gavia stellata), Non-breeding

Reset | Select all | Show attributes and targets for selected features

Attributes:
You can filter to show only targets for certain attributes by selecting one or more attributes from the list below (use ctrl click to select multiple). Note that only attributes for the features you have chosen are shown.

Feature target

'Maintain' targets do not preclude the need for management, now or in the future, to avoid a significant risk of damage or deterioration to the feature. The supporting and/or explanatory notes in the SACOs set out why the target was chosen and any relevant site based supporting information. This is based on the best available information, including that gathered during monitoring of the feature's current condition.

Please select a feature.

See further guidance on how to undertake an HRA for a plan or project on a European site (https://www.gov.uk/guidance/habitats-regulations-assessments-protecting-a-european-site).

These tables bring together the findings of the best available scientific evidence which may be updated or supplemented in further publications from Natural England and other sources. You may decide to use other additional sources of information.

These tables do not give advice about SSSI features or other legally protected species which may also be present within the European site.

EC Directive 79/409 on the Conservation of Wild Birds

Citation for Special Protection Area (SPA)

Name: Sandlings

Unitary Authority/County: Suffolk

Consultation proposal: All or parts of Blaxhall Heath Site of Special Scientific Interest (SSSI), Leiston - Aldeburgh SSSI, Sandlings Forest SSSI, Snape Warren SSSI, Sutton & Hollesley Heaths SSSI and Tunstall Common SSSI have been recommended as a Special Protection Area because of their European ornithological importance. In particular, for their breeding populations of Nightjars *Caprimulgus europaeus* and Woodlarks *Lullula arborea*.

Site description: The Sandlings SPA lies near the Suffolk Coast between the Deben Estuary and Leiston. In the 19th century, the area was dominated by heathland developed on glacial sandy soils. During the 20th century, large areas of heath were planted with blocks of commercial conifer forest and others were converted to arable agriculture. Lack of traditional management has resulted in the remnant areas of heath being subject to successional changes, with the consequent spread of bracken, shrubs and trees, although recent conservation management work is resulting in their restoration. The heaths support both acid grassland and heather-dominated plant communities, with dependant invertebrate and bird communities of conservation value. Woodlark *Lullula arborea* and Nightjar *Caprimulgus europaeus* have also adapted to breeding in the large conifer forest blocks, using areas that have recently been felled and recent plantation, as well as areas managed as open ground.

Size of SPA: The SPA covers an area of 3,391.80 ha.

Qualifying species:
The site qualifies under **article 4.1** of the Directive (79/409/EEC) as it is used regularly by 1% or more of the Great Britain populations of the following species listed in Annex I in any season:

Annex 1 species	Count and Season	Period	% of GB population
Nightjar *Caprimulgus europaeus*	109 males - breeding	Count as a 1992	3.2% GB
Woodlark *Lullula arborea*	154 pairs - breeding	Count as at 1997	10.3% GB

Bird figures from:

Morris, A., Burges, D., Fuller, R.J., Evans, A.D. & Smith, K.W. 1994. The status and distribution of nightjars *Caprimulgus europaeus* in Britain in 1992. A report to the British Trust for Ornithology. *Bird Study* **41**: 181-191.

Wotton, S.R. & Gillings, S. 2000. The status of breeding woodlarks in Britain in 1997. *Bird Study* **47**: 212-224.

Status of SPA
Sandlings was classified as a Special Protection Area on 10 August 2001.

European Site Conservation Objectives for Sandlings Special Protection Area Site Code: UK9020286

With regard to the SPA and the individual species and/or assemblage of species for which the site has been classified (the 'Qualifying Features' listed below), and subject to natural change;

Ensure that the integrity of the site is maintained or restored as appropriate, and ensure that the site contributes to achieving the aims of the Wild Birds Directive, by maintaining or restoring;

- **The extent and distribution of the habitats of the qualifying features**
- **The structure and function of the habitats of the qualifying features**
- **The supporting processes on which the habitats of the qualifying features rely**
- **The population of each of the qualifying features, and,**
- **The distribution of the qualifying features within the site.**

This document should be read in conjunction with the accompanying *Supplementary Advice* document, which provides more detailed advice and information to enable the application and achievement of the Objectives set out above.

Qualifying Features:

A224 *Caprimulgus europaeus*; European nightjar (Breeding)

A246 *Lullula arborea*; Woodlark (Breeding)

Explanatory Notes: European Site Conservation Objectives

These Conservation Objectives are those referred to in the Conservation of Habitats and Species Regulations 2017 (as amended) ('the Habitats Regulations'). They must be considered when a competent authority is required to make a 'Habitats Regulations Assessment' including an Appropriate Assessment, under the relevant parts of this legislation.

These Conservation Objectives, and the accompanying Supplementary Advice (where this is available), will also provide a framework to inform the management of the European Site and the prevention of deterioration of habitats and significant disturbance of its qualifying features

These Conservation Objectives are set for each bird feature for a Special Protection Area (SPA).

Where these objectives are being met, the site will be considered to exhibit a high degree of integrity and to be contributing to achieving the aims of the Wild Birds Directive.

Publication date: 21 February 2019 (version 3). This document updates and replaces an earlier version dated 30 June 2014 to reflect the consolidation of the Habitats Regulations in 2017.

COUNTY: SUFFOLK SITE NAME: SIZEWELL MARSHES

DISTRICT: SUFFOLK COASTAL

Status: Site of Special Scientific Interest (SSSI) notified under Section 28 of the Wildlife and Countryside Act 1981 as amended

Local Planning Authority: SUFFOLK COUNTY COUNCIL, Suffolk Coastal District Council

National Grid Reference: TM 466638 Area: 104.33 (ha.) 257.80 (ac.)

Ordnance Survey Sheet 1:50,000: 156 1:10,000: TM 46 SE

Data Notified (Under 1949 Act): – Date of Last Revision: –

Date Notified (Under 1981 Act): 1987 Date of Last Revision: 1992

Other Information:
The site has been extended at the 1992 revision.

Description and Reasons for Notification:
Sizewell Marshes are important for their large area of lowland, unimproved wet meadows which support outstanding assemblages of invertebrates and breeding birds. Several nationally scarce plants are also present.

The site occupies a low-laying basin of deep fen peat. The water table is permanently high, with the area being prone to flooding, and there is an extensive network of ditches across the site.

In the areas of unimproved wet meadow the principal grass species are Sweet Vernal-grass *Anthoxanthum odoratum*, Crested Dog's-tail *Cynosurus cristatus*, Rough-stalked Meadow-grass *Poa trivialis* and Yorkshire-fog *Holcus lanatus*. There are many other typical species including Marsh Pennywort *Hydrocotyle vulgaris*, Ragged Robin *Lychnis flos-cuculi*, Large Bird's-foot-trefoil *Lotus uliginosus*, Marsh-orchids *Dactylorhiza* spp., Bogbean *Menyanthes trifoliata*, Bog Pimpernel *Anagallis tenella*, Yellow Iris *Iris pseudacorus*, sedges *Carex spp*. and rushes *Juncus spp*. The nationally scarce Marsh Dock *Rumex palustris* and Greater Water-parsnip *Sium latifolium* are also present. It is considered that these communities are representative of the *Juncus subnodulosus – Cirsium palustre* fen-meadow and the *J. effusus/acutiflorus – Galium palustre* rush-pasture, as described in the National Vegetation Classification. In addition, several areas of reedbed dominated by Common Reed *Phragmites australis* and alder carr occur.

The extensive ditch system supports a diverse aquatic flora which includes the nationally scarce Soft Hornwort *Ceratophyllum submersum*, Fen Pondweed *Potamogeton coloratus* and Whorled Water-milfoil *Myriophyllum verticillatum*. The variety of ditch depths and widths, together with their fringing vegetation provide an important contribution to the site's habitat value for invertebrates and birdlife.

Sizewell Marshes are of exceptional interest for their invertebrate fauna, supporting a wide range of taxa and many nationally rare or scarce species. These include terrestrial and aquatic beetles (Coleoptera), flies (Diptera), moths (Lepidoptera), dragonflies (Odonata) and spiders (Araneae).

The breeding bird assemblage is also of national significance with many species that are typical of wet grassland and associated habitats, including Shoveler, Gadwall, Teal, Snipe and Lapwing.

Operations likely to damage the special interest

Site name: Sizewell Marshes, Suffolk

OLD1003416

Ref. No.	Type of Operation
1	Cultivation, including ploughing, rotovating, harrowing, and re-seeding.
2	Grazing and changes in the grazing regime (including type of stock or intensity or seasonal pattern of grazing and cessation of grazing).
3	The introduction of stock feeding and changes in stock feeding practice.
4	The introduction of mowing and changes in the mowing or cutting regime (including hay making to silage and cessation).
5	Application of manure, fertilisers and lime.
6	Application of pesticides, including herbicides (weedkillers).
7	Dumping, spreading or discharge of any materials.
8	Burning.
9	The release into the site of any wild, feral or domestic animal*, plant or seed.
10	The killing or removal of any wild animal*, including pest control.
11	The destruction, displacement, removal or cutting of any plant or plant remains.
12	The introduction of tree and/or woodland management+ and changes in tree and/or woodland management+.
13a	Drainage (including the use of mole, tile, tunnel or other artificial drains).
13b	Modification of the structure of watercourses (eg streams, springs, ditches, dykes, drains), including their banks and beds, as by re-alignment, re-grading and dredging.
13c	Management of aquatic and bank vegetation for drainage purposes (see also 11).
14	The changing of water levels and tables and water utilisation (including irrigation, storage and abstraction from existing water bodies and through boreholes).
15	Infilling of ditches, dykes, drains and marshes.
16a	The introduction of freshwater fishery production and/or management** and changes in freshwater fishery production and/or management.
20	Extraction of minerals, including peat, shingle, sand and gravel, topsoil, subsoil, and spoil.
21	Construction, removal or destruction of roads, tracks, fences, banks ditches or other earthworks, or the laying, maintenance or removal of pipelines and cables, above or below ground.
22	Storage of materials.
23	Erection of permanent or temporary structures, or the undertaking of engineering works, including drilling.
26	Use of vehicles or craft likely to damage or disturb features of interest.
27	Recreational or other activities likely to damage features of interest.
28	Game and waterfowl management and hunting practices and changes in game and waterfowl management and hunting practice.

---

* ‘animal’ includes any mammal, reptile, amphibian, bird, fish or invertebrate.

\+ including afforestation, planting, clear and selective felling, thinning, coppicing, modification of the stand or underwood, changes in species composition, cessation of management.

** including sporting fishing and angling.

Views About Management

ENGLISH NATURE

A statement of English Nature's views about the management of Sizewell Marshes Site of Special Scientific Interest (SSSI).

This statement represents English Nature's views about the management of the SSSI for nature conservation. This statement sets out, in principle, our views on how the site's special conservation interest can be conserved and enhanced. English Nature has a duty to notify the owners and occupiers of the SSSI of its views about the management of the land.

Not all of the management principles will be equally appropriate to all parts of the SSSI. Also, there may be other management activities, additional to our current views, which can be beneficial to the conservation and enhancement of the features of interest.

The management views set out below do not constitute consent for any operation. English Nature's written consent is still required before carrying out any operation likely to damage the features of special interest (see your SSSI notification papers for a list of these operations). English Nature welcomes consultation with owners, occupiers and users of the SSSI to ensure that the management of this site conserves and enhances the features of interest, and to ensure that all necessary prior consents are obtained.

Management Principles

Ditches

Ditches are artificial habitats created by land drainage, or occasionally by the channelisation of small streams. They may represent the only remaining freshwater habitat within former wetland areas, and often support a wide range of aquatic plant and animal (in particular invertebrate) species that would have previously been more widespread in ponds and wetlands.

If left unmanaged, silt accumulates in the bottom of the ditches, and emergent plants such as reeds are able to colonise across the width of the ditch, leading to a loss of aquatic plant diversity and a gradual drying out of the ditch. To prevent this, periodical removal of sediment and vegetation may be necessary to return the ditch to an early stage of the management cycle. Ideally, ditch management should be undertaken on a rotation, creating a series of different management stages across a site at any one time. All stages of the management cycle have wildlife interest; recently cleared ditches are good for plants and animals which favour newly created habitats and cannot tolerate competition with other species; middle-stage ditches support a rich aquatic plant flora; and late-stage ditches may be important for a variety of invertebrates. The removal of both sediment and vegetation is usually better than simply cutting the vegetation, which does not recreate the earliest stages of the ditch

management cycle. Where possible, management should aim to create shallow shelving margins rather than steep ditch sides. Where water voles are known to be present, the relevant good practice guidelines for ditch management and conservation should be followed.

Most ditch systems are subject to water level control, which should be managed to ensure that there is a sufficient depth of water (0.3-0.5m) in ditches throughout the year. Rapid or extreme changes in water level should be avoided unless they are known to be important to plant or animal communities relying on such fluctuations.

Ditches are susceptible to increased levels of nutrients which can cause a loss of aquatic plants and increases in algal growth. Other activities that can lead to this include the control or removal of aquatic plants, or the introduction of species such as bottom feeding coarse fish which uproot plants and disturb ditch sediments. Ditches are also susceptible to invasion by non-native aquatic plants such as floating pennywort and water fern, which are able to grow rapidly taking up available habitat and smothering other plants. Some native plants including a number of duckweed species are also able to take over in this way (although such growths are usually exacerbated by increased nutrients in the water) and management may be necessary to control such invasions where they cause a problem.

Wet grassland with breeding and wintering bird interest

Wet grasslands occur on land that is subject to periodic flooding or has a seasonally high water table and is waterlogged for much of the year. Wet grassland often supports a wide variety of plants and animals, in particular birds and invertebrates, and is an important habitat for breeding waders and wintering wildfowl.

Wet grassland requires active management if it is to retain its conservation interest. Generally, each year's growth of vegetation must be removed. Otherwise the sward becomes dominated by tall, vigorous grasses and rushes which, together with an associated build up of dead plant matter, suppress less vigorous species and lower the botanical richness of the sward. Traditionally, this management is achieved by grazing. Cattle are often the preferred stock, being relatively tolerant of wet conditions and able to control tall grasses and rank vegetation. Cattle also tend to produce a rather uneven, structurally diverse sward. However, ponies, or even hill sheep, can be used if necessary. Grazing usually takes place at times between late spring and early autumn, but the precise timing and intensity will depend on local conditions and requirements, such as the need to avoid trampling ground-nesting birds. Heavy poaching should be avoided but light trampling can be beneficial in breaking down leaf litter and providing areas for seed germination. Agricultural operations in general should be avoided before mid-June to minimise disturbance to breeding birds or the destruction of nests. An element of managed scrub, both within and fringing a field can be of importance to birds and invertebrates, as can a surrounding hedge.

Partial winter flooding is important in maintaining suitable habitat conditions for wintering birds. A mosaic of winter flooded grassland and permanently un-flooded grassland is desirable, with both temporary and permanent pools present. The maintenance of a mosaic of shallow surface pools and un-flooded areas during the

winter will provide roosting and feeding habitat for wintering wildfowl and waders. From April onwards, the area of standing surface water should be reduced to increase the area available for nesting waders and also by concentrating aquatic invertebrates in small pools to provide suitable feeding areas for their young. Some shallow areas of flooding should be maintained until late June to provide patches of bare muddy ground on which the birds and their young can feed as raised sward height makes feeding on the drier areas more difficult. The birds using these features are directly vulnerable to disturbance, which can cause them to lose time spent feeding or drive them to areas with a poorer supply of food. Management should seek to minimise any harmful disturbance, especially at times when bird populations are under stress, such as severely cold conditions. Predators, especially crows and related species, should be controlled and this may be best achieved by limiting their nesting sites.

All habitats

The habitats within this site are highly sensitive to inorganic fertilisers and pesticides, applications of which should be avoided both within the site itself and in adjacent surrounding areas. Herbicides may be useful in targeting certain invasive species, but should be used with extreme care. Access to this site, and any recreational activities within, may also need to be controlled.

HABITAT USE AND SELECTION OF THE MARSH HARRIER *CIRCUS AERUGINOSUS* IN AN AGRICULTURAL-WETLAND MOSAIC

USO Y SELECCIÓN DE HÁBITAT DEL AGUILUCHO LAGUNERO *CIRCUS AERUGINOSUS* EN UN MOSAICO DE AGRICULTURA Y HUMEDAL

Michelle Alves[1, 2], Joaquim Pedro Ferreira[1], Inês Torres[1], Carlos Fonseca[1] and Milena Matos[1] *

Summary.—Studying various aspects of the biology of a species of conservation concern allows us to improve our understanding of, for example, how the particularities of the landscape matrix influence its occurrence. The Lower Vouga Lagoon in central-western Portugal offers an unusual diversity of natural and humanised biotopes in an agricultural-wetland complex mosaic. This study aimed to identify the factors that may influence the occurrence and abundance of a diurnal raptor, the marsh harrier *Circus aeruginosus*, in this kind of landscape. The marsh harrier is a top predator that is considered as an umbrella species, i.e. one whose conservation may also help preserve and promote biodiversity in general in its community. This study provides potentially valuable information on management and conservation strategies in both natural and agricultural areas. We found that natural habitats, such as reedbeds, are a key habitat for this predator, providing shelter, food and suitable nesting sites. Despite the general negative effect of human pressure on the occurrence of marsh harriers, the species seems to tolerate and even benefit from humanised environments, such as rice fields, which constituted the preferred foraging habitat during the non-breeding period. Nevertheless, the degree of disturbance should be carefully considered, since road density and agricultural machinery negatively influenced the presence of the species in the landscape, particularly during the breeding period. The preservation of the distinctive features of the studied mosaic is very important. It is also necessary to establish a conservation programme involving the local human community.

Key words: conservation, humanised landscape, Lower Vouga Lagoon, reed beds, spatial heterogeneity.

Resumen.—El estudio de varios aspectos de la biología de una especie con problemas de conservación nos permite comprender mejor cómo, por ejemplo, las particularidades del hábitat pueden influir en la distribución de esa especie. El Baixo Vouga Lagunar, centro-oeste de Portugal, ofrece una diversidad inusual de biotopos naturales y humanizados, en un complejo mosaico de agricultura y humedal. El objetivo de este estudio es comprender qué factores pueden estar influenciando la presencia y abundancia de una rapaz diurna, el aguilucho lagunero *Circus aeruginosus*, en este particular mosaico. El aguilucho lagunero es un predador considerado una especie paraguas, esto es, una especie cuya conservación puede también ayudar a preservar y promover la biodiversidad en general. Este estudio propor-

ciona información potencialmente valiosa para la gestión y las estrategias de conservación en las zonas naturales y agrícolas. Encontramos que los hábitats naturales, como los carrizales, son un hábitat clave para este predador, proporcionando refugio, alimentos y lugares de nidificación adecuados. A pesar del efecto negativo general de la presión humana sobre la presencia de aguilucho lagunero, la especie mostró que también puede tolerar, e incluso beneficiarse, de los ambientes humanizados, como los arrozales, que constituyen el hábitat preferido de alimentación durante el período no reproductivo. Sin embargo, el grado de perturbación debe ser considerado cuidadosamente, ya que la densidad de carreteras y máquinas agrícolas influyen negativamente en la presencia de la especie, sobre todo durante la época de cría. La preservación de las características distintivas del paisaje estudiado debería ser prioritaria, así como el establecimiento de un programa de conservación para ser llevado a cabo a nivel local.

Palabras clave: Baixo Vouga Lagunar, conservación, carrizales, heterogeneidad espacial, paisaje humanizado.

Introduction

The presence of animals in specific landscapes indicates that species have priorities, preferring some places over others, in order to establish their populations (Alcock and Farley, 2009), which leads species to be more abundant in certain environments than in others (Morris, 1987). In nature, top predators such as raptors play a key role in the resilience of biodiversity, determining the patterns of the composition of the ecosystem (Terborgh, 1988; Luo *et al*., 2010).

The concept of habitat selection implies a preference of a species for a specific habitat type, whereas recording habitat use only notes the presence/occupation of the species without considering habitat availability within the landscape (Sutherland and Green, 2008). Habitat use and selection can be influenced by several factors, such as vegetation structure and composition, food resources, human disturbance, microclimate and biotic factors (e.g. presence of predators or conspecifics), making these important features to consider when evaluating habitat quality for a particular species (Cardador *et al*., 2012a; Rotenberry, 1985; Firkowski, 2006). In particular, habitat use and selection within humanised landscapes are important aspects to consider in wildlife studies, since habitats provide food, shelter and breeding sites, which are essential for species survival (Johnson, 1980; Morris, 1987; Firkowski, 2006). Changes in landscapes can induce habitat loss and fragmentation, by reducing the size of optimal habitat patches and increasing the distance between them respectively, and may contribute to the development of new environments. As these new conditions may or may not be usable by animals (Andren, 1994; Williams *et al*., 2013), the species composition within communities may potentially be changed. Human activities strongly affect the landscape, generally reducing the amount and the quality of available habitat for many species (Murcia, 1995). The transition from natural habitats to anthropogenic habitats such as monocultural exotic forests, farmlands or pastures, are examples of some severe landscape changes (Saunders *et al*., 1991; Herkert, 1994).

The marsh harrier *Circus aeruginosus* is a medium-sized raptor that occurs in a wide range of open habitats, including agricultural landscapes (Cardador *et al*., 2001; Cardador and Mañosa, 2011), and requires large areas of land to hunt and breed (Cramp and Simmons, 1983). In Portugal, it is a resident species that occurs mostly in the western coastal strip, especially in wetlands and in some agricultural areas (Cabral *et al*., 2005). In recent decades the species has undergone a moderate increase across Europe (Cramp and Simmons, 1994; BirdLife International,

2004; Cardador *et al*., 2012b). However, in Portugal, the increase in the abundance was not accompanied by an expansion in its distribution area, and the species is still classified as 'Vulnerable' (Cabral *et al*., 2005). The main threats to its survival or reproduction include habitat loss, degradation of wetlands, urbanisation and other disturbances caused by human activities (Del Hoyo *et al*., 1994; Fernandes *et al*., 1996). In some wetlands, water pollution with heavy metals and pesticides from industrial and agricultural effluents is another pertinent factor (Pedrocchi, 1994; Rodrigues, 1998). However, with respect to agriculture, recent studies demonstrate that the species seems to tolerate a certain degree of intensification and may even benefit from it (Cardador *et al*., 2011; Sternalski *et al*., 2013). The marsh harrier has a preference for marshland vegetation, especially reed beds of *Phragmites australis*, where it forms winter dormitories, nests and hunts. Reeds provide good thermal conditions and reduce the effects of human disturbance and of predation by terrestrial mammals (Costa *et al*., 1993; Rosa *et al*., 2001; Oliver, 2005; Verma and Prakash, 2007), these latter factors being main causes of reproductive failure (Underhill-Day, 1984).

Given that high quality habitats, offering feeding, nesting and resting opportunities, are essential for the maintenance of the species, understanding the patterns of occurrence of the marsh harrier within human-transformed mosaics is of vital importance for the success of any attempt to reconcile development and conservation. The aim of this study was to assess the habitat use and selection of the marsh harrier in a complex agricultural-wetland mosaic, defining the most important aspects of its spatial ecology. Despite the conservation status of this species, the threats to its survival and its ecological importance, it remains relatively poorly studied among raptor species, especially in Portugal. Thus, we believe that this study will add valuable knowledge about its ecology. We also aim at contributing to the general conservation of the biodiversity of wetlands that are under human pressure.

Material and methods

Study Area

The Lower Vouga Lagoon is included in the Vouga River Estuary, located in the District of Aveiro, central-western Portugal, approximately between 8º 32' 57" W and 8º 41' 32" W; and 40º 49' 43" N and 40º 41' 32" N (fig. 1). The region presents characteristics of the Mediterranean climate with strong Atlantic influences, with an annual mean temperature of about 15ºC. The average annual humidity is 77% and the average annual rainfall is 1,387 mm, limited rainfall occurring in the summer. This agricultural-wetland complex occupies approximately 12,205 ha, and encompasses important ecosystems integrated in the Natura 2000 Network (Special Protection Area of Ria de Aveiro, PTZPE0004, and Site of Community Importance, PTCON006), featuring one of the most important Portuguese wetlands. The system integrates a variety of natural and humanised habitats, such as pastures (2.35% of the area), fields of rice *Oryza sativa* (0.98%) and maize *Zea mays* (28.13%); and "Bocage" (7.09%), a typical and rare landscape type that consists of hedgerows of trees (e.g. *Salix alba*), shrubs (e.g. *Rubus ulmifolius*) and ditches that compartmentalise farmlands and pastures. The wetlands are composed of reed beds of *Phragmites australis* (4.50%), saltmarshes of *Spartina maritima* (12.79%) and rush beds of *Juncus maritimus* (6.67%) (Alves, 2013; Pinho *et al*., 2003). This region also houses high faunal richness, from all taxonomical groups. According to national bird censuses, the study area shelters 11 to 12 breeding resident pairs of marsh harriers, some 17% of the national breeding population (Rosa *et al*., 2006). The number of marsh harriers in the study area almost doubles in autumn and winter in some years (IDAD, 2008).

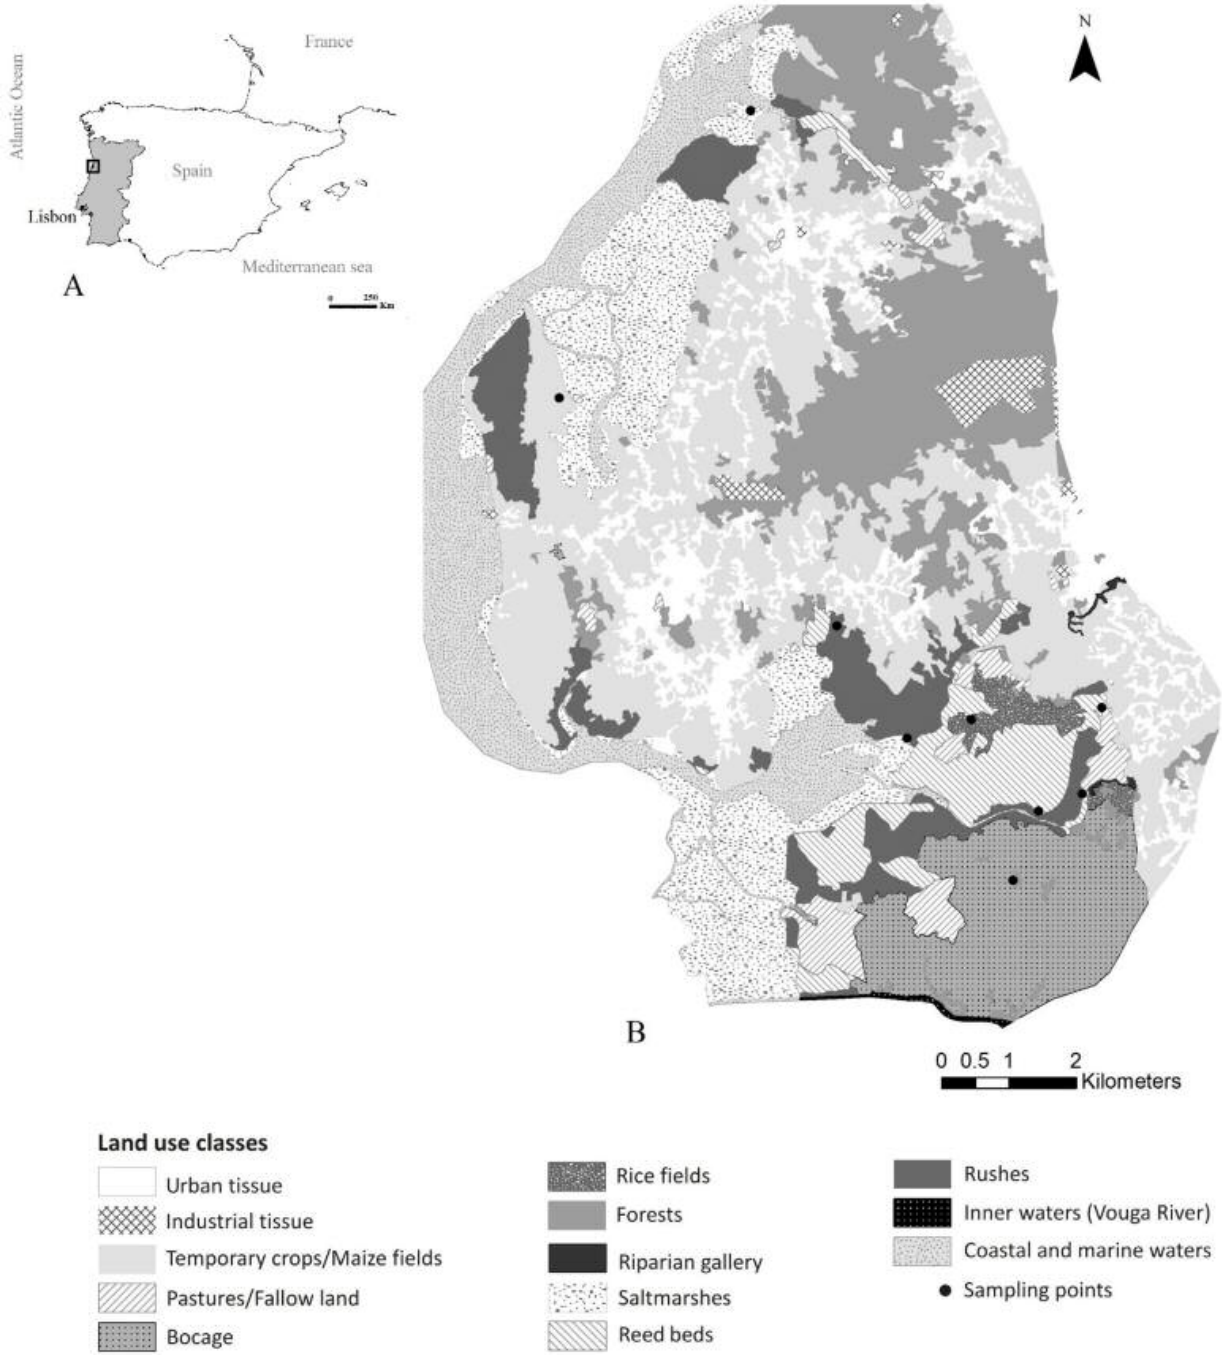

FIG. 1.—Location of the study area in the Iberian Peninsula and in Portugal (A). Distribution of land use within the study area, with sampling points (B).
[Situación del área de estudio en la península Ibérica y en Portugal (A). Cobertura del suelo en el área de estudio, con los puntos de muestreo (B).]

Habitat use and selection

Fieldwork was conducted using direct observation of birds from November 2011 to October 2012. A set of 25 random areas, at least 1 km apart, was generated in ArcGIS 9.3®ESRI. After field prospection, we selected nine fixed observation points based on: the existence of high observation points such as fire watch-towers or landscape observatories,

their reasonable distance from urban areas and their accessibility. The land cover of the entire study area was mapped and characterised through a Geographic Information System (GIS). The habitats considered in the study were reed beds, saltmarshes, rushes, "Bocage", rice fields and maize fields.

The frequency and duration of sampling sessions are presented in table 1. April 2012 was only sampled once due to heavy rain. Sampling was always performed by the same observer (MA), from each point in turn. Throughout the year, efforts were made to alternate the sampling hour at each observation point, in order to reduce potential bias related to daily activity patterns. During each sampling session, an area of about 1.5 km radius was covered using binoculars and telescope. This radius delimits the sampling area around the observation points that allowed the correct identification of the species and habitat. Each time a marsh harrier was observed, the displayed behaviour -such as flight, mating, nest building, hunting and resting– was recorded, as well as the habitat over which it took place. For each sampling session, weather conditions –temperature, relative humidity, wind speed, visibility– were measured using a portable weather station (Kestrel® 4000). Relevant human activities in the landscape, such as cropping, agricultural machinery working at the site or the presence/absence of livestock, were also recorded.

Statistical analyses

Habitat use and selection

The evaluation of the habitat use was based on the number of observations recorded in each habitat type. For the analysis, we considered

TABLE 1

Frequency and duration of sampling sessions per month.
[Frecuencia y duración de las sesiones de muestreo por mes.]

three different types of behaviours, namely 'presence' (birds flying or resting), 'foraging' (confirmed hunting behavior and successful hunting attempts) and 'reproduction' (all activities related to reproduction, from courtship and nest building to chick feeding). Observation data were also seasonally grouped (under breeding and non-breeding periods) and were standardised for sampling effort. To assess habitat selection we used the Savage selectivity index (e.g. Tella and Forero, 2000; Ursúa *et al*., 2005; Catry *et al*., 2013): $wi = Ui/pi$, where Ui is the proportion of observations recorded in a given habitat and pi is the proportion of that habitat related to the total habitat available. This index varies from 0 (maximum negative selection) to infinity (maximum positive selection), 1 indicating no selection (Manly *et al*., 1993). The statistical significance of this index was obtained by comparing the statistic $(wi - 1)^2/\mathrm{se}(wi)^2$ with the corresponding critical value of a Chi-square distribution with one degree of freedom. The standard error $(\mathrm{se}(wi))$ was calculated using the formula $\sqrt{[(1 - pi)/(u_+ * pi)]}$, where u_+ is the total number of observations in a given habitat. All comparisons were corrected for multiple tests using the Bonferroni criteria.

Presence and abundance of marsh harriers

We modelled two dependent variables: presence (presence/absence data) and abundance (number of individuals) of marsh harriers during the breeding and non-breeding periods. We grouped the independent variables into categories related to: 1) landscape, 2) food availability, 3) abiotic factors and 4) human disturbance (table 2). Landscape variables included six classes of land cover, corresponding to the habitats considered in this study (reed beds, saltmarshes, rushes, "Bocage", rice fields and maize fields). We measured the length of water ditches, as well as their occupancy within the considered sampling areas (each sampling area was divided into four quadrants and those with ditches were counted) from our GIS database. We measured seasonal changes within the landscape in terms of the number of times each habitat experienced a structural alteration, *e.g*. from cultivated to fallow land or vice versa. We calculated spatial heterogeneity using the Shannon diversity index (Magurran, 2004), based on the area of each habitat within the considered sampling areas.

Studies of small mammal communities and the diet of marsh harriers were also conducted in the study area during fieldwork (Alves, 2013). Small mammals were the most important prey, accounting for 68% frequency of occurrence in the diet. Thus, food availability for this study consisted of the field abundance of the four most important prey species represented within the diet (small mammal species *Apodemus sylvaticus*, *Crocidura russula*, *Mus* spp., *Microtus* spp.), in the habitats of the respective sampling area.

Abiotic factors were tested using the meteorological variables measured during sampling sessions. Variables related to human disturbance were established based on the extent of constructions (e.g. buildings, industry), on the presence of livestock and agricultural machinery working during sampling sessions, and on the length of roads within each sampling area. As with ditches, the occupancy of roads and constructions was also evaluated according to their presence in the quadrants of the sampling area.

We also included 'behaviour' as a factor to control variability in models, to avoid some overrepresented behaviors affecting the results. While foraging was included in breeding and non-breeding periods, by definition reproduction was only considered in the breeding period.

Generalised linear mixed models (GLMM) were used to identify the factors determining the presence and abundance of marsh harriers. We considered sampling points as random factors for each observation data. We analyzed the presence of marsh harriers with a binomial distribution and a logit link function and the

abundance data with a Poisson distribution with a log link. We used the R software (R Core Team, 2013), function 'glmer', package 'lme4' (Bates *et al*., 2011).

We assessed the correlation between independent variables with Spearman's Correlation Coefficient (Sokal and Rohlf, 1995). If two variables were highly correlated ($r_s > 0.70$) only one data set was selected. The variable showing the lowest correlation with the dependent variable or, under special circumstances, the variable with less justified biological interpretation, was eliminated (Mladenoff *et al*., 1999). We used the Akaike Information Criterion (AIC) to rank models according to their capacity to describe the data parsimoniously (Burnham and Anderson, 2002).

Results

In total, 324 hours of observations were conducted during 180 sampling sessions throughout an annual cycle (table 1), and 267 observations of marsh harriers were recorded. Marsh harriers were observed in 85% of the sampling sessions. Field observations and previous censuses (Rosa *et al*., 2006) agree on an estimate of 11 to 12 resident breeding pairs in the study area.

Habitat use and selection

We observed that marsh harriers positively selected reed beds, saltmarshes and rice fields, during both the breeding and non-breeding periods (table 3). Whereas they preferred reed beds for foraging during the breeding season, they selected both reed beds and rice fields during the non-breeding period. Maize fields were avoided during the breeding period and never used for foraging during the non-breeding period, despite being the most extensive habitat in the study area. No foraging activities were observed in Bocage. Reproductive behaviours were observed solely in reed beds. Rushes showed consistent negative selection throughout the year (table 3).

Presence and abundance of marsh harriers

The best model describing the presence of marsh harriers in the Lower Vouga Lagoon, during the breeding period (table 4) includes variables related to landscape, food availability and human presence. Spatial heterogeneity, reed beds, saltmarshes and maize fields presented a significant positive association with the species presence, whereas roads and human constructions were significant and negatively associated with the species presence (table 5). During the non-breeding period, the best model describing the species presence included variables related to landscape, food availability, abiotic factors and human presence (table 4). The most significant variables were reed beds and roads, with a positive influence, and the abundance of *Crocidura russula* and agriculture machinery with a negative influence (table 5).

Reed beds were the only variable explaining the abundance of marsh harriers during the breeding period, with a significant positive influence (tables 4 and 5). In the non-breeding period, the species abundance was best explained by the model including reed beds, food availability (*Mus* spp.) and human presence (table 4), with reed beds presenting the most significant positive influence and road occupancy presenting the most significant negative influence (table 5). Foraging behaviour was strongly associated with the abundance of marsh harriers during the non-breeding season (tables 4 and 5).

Discussion

Habitat use and selection

In general, the pattern of use and selection of habitats can be explained by two important factors: provision of a suitable nesting location

TABLE 3

Proportion of habitat available and used by marsh harriers (presence, foraging and nesting) during breeding and non-breeding periods, Savage Selectivity Index (w*i*) of the different habitats in those periods, and standard error (s.e.). Threshold for significance was set at 0.05; 0.008 and 0.0125 for presence and foraging, respectively, in both breeding and non-breeding periods, after correction for multiple comparisons. NS: non-significant; *: significant. Habitat availability in sampling areas (%) = rice fields (6.05), Bocage (18.39), reed beds (20.82), rushes (18.35), maize fields (23.87) and saltmarshes (12.50).
*[Proporción de hábitat disponible y utilizado por los aguiluchos laguneros (presencia, alimentación y nidificación) durante los periodos de reproducción y sin reproducción, Índice de Selectividad de Savage (w*i*) de los diferentes hábitats en esos periodos y error estándar (s.e.). El nivel de significación se estableció en 0,05; 0,008 y 0,0125 para presencia y alimentación, respectivamente, tanto durante el periodo de reproducción como sin reproducción, después de corrección a causa de comparaciones múltiples. NS: no significativo; *: significativo. Disponibilidad de hábitats en áreas muestreadas (%) = arrozales (6,05), Bocage (18,39), carrizales (20,82), juncales (18,35), maizales (23,87) y marismas salobres (12,50).]*

and food availability (Martin, 1993; Němečková *et al*., 2008). Several studies report that marsh harriers use marshland vegetation in flooded areas, demonstrating a preference for reed beds (Thiollay, 1967; Schipper, 1978; Underhill-Day, 1985; Bavoux *et al*., 1990; Costa *et al*., 1993). Such a preference was also confirmed in the Lower Vouga Lagoon throughout the year, as reed beds were positively selected for foraging and during both the breeding and non-breeding periods and were also used for nesting. As stated by Cardador and Mañosa (2001) and Cardador *et al*. (2009), the patterns of foraging habitat selection of the marsh harriers may result from a compromise between the quality of the different patches and their distance from nesting sites. In our study, during the breeding season, both nesting and foraging occurred in reed beds. Thus we conclude that this habitat is very important for the species in this region. Factors contributing to the quality of reed bed habitat should include the seasonal flooding, which protects the nests against terrestrial predators; the density and height of the reeds, which protect from the wind; and food availability (small mammals (Alves, 2013) and birds (IDAD, 2008) in our study area). During the non-breeding period, rice fields, which actually offer higher food availability than reed beds (Alves, 2013), are correspondingly the preferred foraging habitat (table 3). In general, the habitat selection results demonstrated that in addition to reed beds and saltmarshes (natural wetlands), rice fields (during the non-breeding period) are the most important habitat for the occurrence of marsh harriers at the Lower Vouga Lagoon. Farmlands, with their typically high food availability for both prey and predators, short vegetation in the case of crops and irrigation may increase the accessibility of small mammals to marsh harriers (Cardador *et al*., 2011). However, maize fields were avoided by marsh harriers (table 3), despite being the most extensive habitat in the study area. Since crop height may influence foraging by raptors (Rodríguez *et al*., in press), at least during early stages of the crop development, one could expect that young maize could also provide good foraging conditions. However, maize fields offered low small mammal abundance (Alves, 2013), failing to provide food for harriers. These results agree with previous findings showing that although farming intensification is generally a major threat for open-habitat bird species (Benton *et al*., 2003), some intensive agricultural lands are still able to provide adequate foraging conditions for some species –such as the marsh harrier (Cardador *et al*., 2011)– at least outside the sensitive breeding season, and if food availability is not compromised (Ursúa *et al*., 2005). Moreover, field observations indicated that human disturbance, resulting from agricultural machinery, was greater and more continuous in maize than in rice fields, which may also have contributed to maize avoidance.

Presence and abundance of marsh harriers

We found that landscape and human disturbance variables were in general the most important variables influencing the presence and abundance of marsh harriers in the study area. Not only individual habitats, such as reed beds, saltmarshes and maize fields were important, but also the landscape heterogeneity presented a significant positive effect on the presence of the species during the breeding period. This suggests that the diversity of habitat opportunities may favour the occurrence of marsh harriers in the region, as demonstrated for other species (Rodríguez *et al*., in press) or taxonomical groups (Mendes *et al*., 2014). The consistent positive effect of reed beds throughout the year confirmed this natural habitat as a key element for the species in this region. Indeed, the importance of wetlands, and reed beds in particular, was already acknowledged in previous studies (e.g. Báldi, 1999; Cardador *et al*., 2011; Verma and Prakash, 2007).

Human disturbance variables, such as agricultural machinery, constructions, road occupancy and cattle, presented a general negative effect on marsh harriers. Previous studies (Cardador *et al*., 2011) found no relationship between human pressure and nesting-site occupancy, but our field observations showed clear disturbance and avoidance behaviour of birds when, for instance, farmers and machines were operating in the area. Roads had a significant negative influence on the presence of marsh harriers during the breeding period, but a positive effect during the non-breeding period (table 5), suggesting that this population may be sensitive to this type of human pressure only during reproduction. Roads can increase the presence of diurnal raptor species in a given area, thereby causing possible competition (Lambertucci *et al*., 2009). The presence of other diurnal raptor species, such as the black-shouldered kite *Elanus caeruleus*, common kestrel *Falco tinnunculus*, black kite *Milvus migrans* and Common Buzzard *Buteo buteo*, resting or hunting near or over roads, was in fact confirmed during fieldwork, but no territoriality or other competition behaviours towards marsh harriers was observed, so this hypothesis was not confirmed in this study.

The degree of disturbance caused by other human constructions, such as houses or warehouses, showed little or no relevance in the results, but we believe they must also be considered. In fact, the consequences of this type of disturbance are often difficult to detect and quantify, especially because they are not immediate. Yet, birds may be affected indirectly by them, for instance in terms of reproductive success (Fernández and Azkona, 1993).

Relevance for conservation

In general, the results lead to the conclusion that in the Lower Vouga Lagoon, the marsh harrier utilises anthropogenic landscapes such as rice fields to forage. However, human disturbance that influences the presence and abundance of the species may reach harmful levels if there is no proper management of the agricultural and wetland areas. The level of disturbance may determine the use or avoidance of certain habitats, despite the availability of favourable nesting or hunting conditions there. Due to high human pressure, individuals may be forced to seek less favourable locations, which may ultimately have a negative impact on reproductive success and thus lead to a population decrease.

The availability of food resources in agricultural areas may also be altered as a result of their intensive use (*e.g*. Burel *et al*., 2004), eventually leading to lower diversity and availability of prey for the marsh harrier. This condition emphasises the importance of preserving natural habitats, such as reed beds and saltmarshes, which are used by the species throughout the year. Since wetlands and water quality are strongly related, particularly within agricultural complexes (Verhoeven *et al*., 2006), this study also highlights the importance of protecting water resources in this humanised landscape. All factors that may influence water quality and availability, such as pollution and the use of chemicals associated with agricultural and industrial activities in the region, should be considered in a well-structured, integrated management plan. Since the marsh harrier is an umbrella species (e.g. Kaboli *et al*., 2006), its conservation may favour local biodiversity and nature conservation as a whole. However, the management of a humanised area may not be viable without the collaboration of the local residents. For instance, it would be relevant to make local landowners aware of the ecological dynamics of the Lower Vouga Lagoon, and the importance of preserving biodiversity. The sustainability of their agriculture, namely through the application of correct timings and practices (e.g. logging, ploughing, harvesting and reed cutting) that

are compatible with natural equilibria should urgently be promoted. We thus suggest the creation of a management plan aiming at sustainability and so favouring both economic activities and the conservation of natural values, while simultaneously promoting public awareness.

ACKNOWLEDGEMENTS.— This work was co-supported by European Funds through COMPETE and by National Funds through the Portuguese Science Foundation (FCT) within project PEst-C/MAR/LA0017/2013. The authors would like to thank the Câmara Municipal de Estarreja and OHM Estarreja for logistical and financial support. We also thank Sara Marques for kindly offering field data on small mammal captures; Eduardo Mendes for support in field work; and Maria João Pereira for helpful comments on statistical analysis. Milena Matos and Joaquim Pedro Ferreira were financed by post-doctoral grants from the Fundação para a Ciência e Tecnologia (SFRH / BPD / 74071 / 2010 and SFRH / BD / 16114 / 2004, respectively). Field observations were made under the ICNF licence 95/2012/PERTURBAÇÃO, as required by Portuguese law.

Table 21 Displacement effects for divers and auks from other offshore wind farms taken from Welcker & Nehls (2016) with the addition of Mendel *et al.* (2019) and Heinänen *et al.* (2020): '-' and '0' indicates statistically significant negative effect on abundance and no effect detected respectively. Symbols in parentheses indicate no significant effect, but response suggested by authors. 95

1. Executive Summary

- This report provides a summary of the results of surveys undertaken from 2009 until 2016, evaluating them against the requirements of the Marine Licence and its stated objectives in order to determine whether these requirements have been discharged.
- A process, informed by the conclusions of the Environmental Statement (ES) and consultation with the Marine Management Organisation (MMO), Natural England and the Royal Society for the Protection of Birds (RSPB; organised through the Ornithological Review Panel [ORP]), determined the key species in relation to each monitoring objective. This report primarily presents analysis and conclusions with respect to the following effects and key species:
    - Barrier effects on divers;
    - Collision risk in relation to divers, gannet, large gulls, and small gulls; and
    - Displacement of divers and auks.
- Since 2009 APEM, on behalf of London Array Ltd., has conducted digital aerial surveys over the London Array Offshore Wind Farm (LAW) and associated control zones over the winter months November to February.
- The monitoring period began in November 2010 and concluded in February 2016. Zone 1 (which contained the LAW) and Zone 2 (surveyed as the 'reference' site), were consistently surveyed from 2010 until 2016.
- The period 2010 until 2016 was classified as the monitoring period with three phases: pre-construction (2010 to 2011), during construction (2011 to 2013), and post-construction (2013 to 2016). Annual monitoring reports were produced for the programme of surveys conducted each winter across this period.
- The survey months were selected to coincide with the key season for the occurrence of non-breeding red-throated divers, as agreed as part of the ORP process.
- The most abundant species group recorded was divers (peak density: 15.86 birds km^{-2} recorded for red-throated divers) and the second most abundant was auks (peak density: 5.58 birds km^{-2} recorded for guillemot / razorbills).
- Non-parametric analysis was undertaken for gannets, small gulls and large gulls to investigate if there was any significant difference in densities between the development phases for Zone 1 and Zone 2. A significant difference was observed for common gull (P=0.01) in Zone 1 and herring gull in Zone 2 (P=0.01).
- Analysis was not undertaken for species recorded sporadically (scaup, common scoter, unidentified seaduck species, fulmar, shearwater, grebes, waders and skuas) during the monitoring period (2010 to 2016) as too few individuals were recorded to provide a meaningful result.

1.1 Assessment of Barrier Effect Summary

- To assess barrier effects, the relative bearing of each diver to the closest turbine was estimated. Directions were subdivided in to four quadrants: towards, away, and two for flying parallel in relation to the nearest turbine based on the relative angle.
- Two approaches were used to test the relative direction of flying divers in relation to the nearest turbine of the LAW. The null hypothesis that divers were likely to fly in all directions was tested using first a chi-squared (χ^2) test and second a randomisation approach.
- The first analysis found no significant difference in the proportion of divers flying towards the nearest turbine of the LAW between two regions: the LAW to 4 km region and greater than 4 km region (P >0.05). However, the number of flying divers recorded was low, especially in the buffer regions nearest to the LAW.

- To further investigate, additional analysis of flight directions was undertaken based on data bootstrapping. The results of this analysis showed that in the 2 to 4 km buffer region, significantly fewer divers than expected by chance were recorded flying toward the wind farm ($P < 0.05$). For the remaining buffer regions, LAW to 2 km and greater than 4 km, no significant difference was found between the number of divers flying towards the OWF and in other directions
- No flying divers within the footprint and a trend for increasing densities of flying divers away from the LAW post-construction suggest avoidance that could be in part brought about by a possible barrier effect. The evidence that divers avoided flying towards the LAW when between 2 km and 4 km of it provides stronger evidence of a possible barrier effect created by the LAW.
- This analysis was specifically conducted in relation to individual flight direction relative to the nearest turbine, rather than in relation to areas of suitable habitat (e.g. within the Outer Thames Estuary Special Protection Area [OTE SPA]). The area covered by the OTE SPA consists of large areas of favourable habitat for divers and any effect on energy expenditure created by a barrier would be expected to be negligible as rather than flying around any obstruction the divers may be able to utilise other feeding or roosting areas in other directions.

1.2 Assessment of Collision Risk Summary

- The density of flying individuals within the LAW was calculated for each species for each survey month based on the number of individuals in flight and the area surveyed. The peak density estimates per development phase of each key species were identified and qualitatively compared between pre-construction and post-construction.
- The expected number of collisions in the LAW was extrapolated from the estimated number of collisions in the ES. Assuming that the flight behaviour of each species did not change between the pre- and post-construction phases, and that comparable survey data have been gathered for the two phases the change in the estimated number of collisions for each species in the LAW from that predicted in the ES would be directly proportional to (1) the change in the species' densities used for the ES and those recorded post-construction, and (2) the ratio of the total rotor swept zones used in the built wind farm to that estimated in the ES. If these assumptions are correct the following should be exact.
- Red-throated divers were not recorded in flight during the post-construction phase of the LAW and therefore the species is not expected to be at collision risk from the turbines. For gannet, lesser black-backed, herring gull, and great black-backed gull the estimated number of collisions is lower than that predicted in the ES primarily due to the reduced number of turbines installed at LAW compared to the number used in the ES predictions. The lower flying bird densities measured in the post-construction surveys compared to that included in the ES predictions also contributes to lower collisions estimates for all but great black-backed gull. These results do not support the need for further collision monitoring.

1.3 Assessment of Displacement Summary

- APEM Ltd was commissioned by Natural England in 2016 with permission from London Array Ltd to undertake spatial modelling of diver and auk density based on relevant environmental variables following the first year of post-construction surveys.

- The purpose of the modelling was to identify any potential displacement impacts and to set up a suitable model framework for any subsequent analysis of the data collected at the LAW.
- Using the same spatial modelling approach but including the final two years of post-construction surveys, the Centre for Research into Ecological and Environmental Modelling (CREEM) repeated the assessment of displacement using the MRSea package in the R statistical program. The modelling outputs were summarised and presented graphically according to distance from the LAW.
- The density profile of divers increased gradually throughout the buffer regions with a peak at 9 km pre-construction. Year-to-year fluctuations in diver numbers and distribution should be an important consideration when interpreting the results. The displacement distance estimated for divers was up to approximately 12 km based on changes in the modelled absolute densities of divers between pre- and post-construction survey periods..
- Complete displacement was not detected at any distance, but the area of influence on diver densities was greater than what was originally predicted in the ES. This was primarily due to the limited evidence for potential effect distances available in the literature at the time the ES was issued
- The modelling showed that an estimated 1,111 divers (approximately 6% of the population which is approximately twice the percentage assumed in the ES) have been displaced from an area within the OTE SPA centred around the LAW.
- A decreasing proportion of auks were estimated to be displaced up to approximately 5 km from the LAW but, as for divers, complete displacement was not detected at any distance.
- The modelling showed that an estimated 536 auks were displaced from an area within the OTE SPA centred around the LAW, with an area of influence of up to approximately 5 km.
- The areas surveyed, Zone 1 and Zone 2, formed an irregular buffer around the LAW. This means only the smaller buffer regions were completely surveyed and larger buffer distances would have been incompletely surveyed. It is not possible to state with any certainty what the displacement effects would be for the surrounding areas that were not surveyed.

Importance of ecological compensation areas for small mammals in intensively farmed areas

Janine Aschwanden, Otto Holzgang & Lukas Jenni

Aschwanden, J., Holzgang, O. & Jenni, L. 2007: Importance of ecological compensation areas for small mammals in intensively farmed areas. - Wildl. Biol. 13: 150-158.

Small mammals make up an important link in the food chain as many predator species feed on them. There are indications that small mammal populations in Europe are declining due to the intensification of agriculture. According to national legislation, farmers in Switzerland have to cultivate at least 7% of their land as ecological compensation areas and, thus, some alternative habitats that are possibly beneficial for small mammals have been created. In this study, we estimated the diversity and density of small mammals on two types of conventional farmland field types (artificial grassland and autumn-sown wheat) and three types of ecological compensation areas (wild-flower strips, herbaceous strips and low-intensity meadows) by use of capture-recapture in March, May and July 2003. The common vole *Microtus arvalis* was the most abundant and predominant species in all habitat types except in herbaceous strips, which harboured the highest diversity with six species caught. In March the density of small mammals was generally very low, but significantly higher in wild-flower (mainly due to common vole) and herbaceous strips than in the other habitat types. In wild-flower and herbaceous strips, densities increased strongly from March to May and in July. On autumn-sown wheat fields, a strong increase occurred only from May to July and was caused by common vole. On artificial grassland and low-intensity meadows, densities of small mammals (mainly common vole) increased only marginally with low-intensity meadows supporting slightly higher densities. Thus, habitats that were not mown each year supported the highest densities of small mammals. This demonstrates that ecological compensation areas, such as wild-flower and herbaceous strips, make up an important refuge for small mammals. They probably also have positive effects on populations of many predator species that depend on small mammals, particularly if a mosaic with mown surfaces is created.

Key words: density of small mammals, ecological compensation area, intensive agriculture, Microtus arvalis, vole

Small mammals constitute an important food resource for many avian and mammalian predator species. In Europe, the fossorial form of water vole *Arvicola terrestris* and many vole *Microtus* species are common and typical inhabitants of agricultural landscapes, yet many farming practices have negative short-term effects on these animals. Mowing and harvesting, for example, remove shelters and food (Tew & MacDonald 1993), and tillage destroys burrows. The intensification of agriculture in western Europe during the last decades may thus have resulted in a decline in vole populations and their predators. Indeed, there are indications that since the beginning of the 1980s the abundance of voles declined in agricultural landscapes of Germany and France (Kostrzewa & Kostrzewa 1993, Butet & Leroux 2001, Reichholf 2004). In these countries agricultural intensification is thought to have resulted in a decrease in the frequency and amplitude of the typical vole population cycles. A similar decline in vole populations may be assumed for agricultural areas in lowland Switzerland, although, to our knowledge, there is no study describing population dynamics of voles in this part of the country.

In order to counteract the loss of biodiversity in intensively farmed areas, farmers in Switzerland are bound by law to cultivate at least 7% of their land as 'ecological compensation areas', and they get subsidies for their ecological contribution (Harder 1998). Additional subsidies can be applied for if areas show a high ecological quality or are connected to each other (Oppermann & Gujer 2003). Legally approved ecological compensation areas, each with specific guidelines of cultivation and a subsidy, include for example: low-intensity meadows, litter meadows, hedgerows, wild-flower strips and traditional orchards.

Some ecological compensation areas like wild-flower strips and herbaceous strips are not mown or tilled each year. Potentially, such areas constitute a suitable habitat for small mammals typical of the farmland. On a farmland in northern Yorkshire UK, the total small mammal biomass in autumn, for example, was found to be three times higher on 6-m wide field margins than on conventional arable field edges (Shore et al. 2005). Untilled land strips serve as a refuge for small mammals during harvest of adjacent agricultural fields (Tew & MacDonald 1993, Baumann 1996, Tattersall et al. 1997). However, we are not aware of any study in which the density of small mammals in different types of ecological compensation areas and agriculturally used fields in their vicinity has been monitored over several months.

In our study, we examined whether ecological compensation areas support higher densities of small mammals than artificial grassland and autumn-sown wheat fields over the vegetation period from March to July. While most previous studies concentrated on one species or on one habitat type (Baumann 1996, Tattersall et al. 1997, Briner 2002, Shore et al. 2005) or applied different trapping designs for different habitat types, we used the same trapping design and a coherent capture-recapture analysis to estimate the densities of small mammals simultaneously on three different types of ecological compensation areas, on artificial grassland and autumn-sown wheat fields.

Material and methods

Study area and vegetation

We collected data in an intensively farmed plain (17 km^2) near Wauwil (47°10'N 8°02'E, 500 m a.s.l.) in central Switzerland during the summer of 2003. Since 1995, the ecological compensation areas in the whole region have been increased from 3.2 to 8% of the cultivated area (Graf 1999). In the study area, ecological compensation areas amounted to 4.3% of the agricultural acreage (low-intensity meadows 3.6%, wild-flower strips 0.4% and herbaceous strips 0.3%), while artificial grassland (49%), autumn-sown wheat (8.5%) and other cultures (38.2%) dominated the area.

The abundance of small mammals was studied on five different habitat types, three of which were ecological compensation areas (low-intensity meadows, wild-flower strips and herbaceous strips),

Downloaded From: https://bioone.org/journals/Wildlife-Biology on 29 Mar 2021
Terms of Use: https://bioone.org/terms-of-use

and two were conventional farmland field types (artificial grassland and autumn-sown wheat). Wild-flower strips are arable fallows sown with seed mixtures of native plants. They were on average 15 m wide and 185 m long (i.e. covering 0.28 ha). Herbaceous strips consisted of different species of herbaceous plants: thistles *Cirsium* spp., common teasel *Dipsacus sylvestris*, St John's Wort *Hypericum perforatum*, common mallow *Malva sylvestris* and mulleins *Verbascum* spp. (5 × 320 m, i.e. covering on average 0.16 ha). They were bordered by hedgerows on one side and conventional field types on the other side (e.g. artificial grassland, maize fields or potato fields). Low-intensity meadows (64 × 100 m, i.e. covering on average 0.64 ha) in the study area are typical *Arrhenatheretum* (i.e. meadows dominated by tall oat grass). They are usually cut twice a year with the first cutting no sooner than 15 June. Application of liquid manure or other fertilizers is not allowed. Artificial grassland (0.88 ha on average) is dominated by white clover *Trifolium repens* and ryegrass *Lolium* sp. and form part of the ordinary crop rotation practice. It is cut at least five times between April and October and liquid manure is applied regularly. One artificial grassland was situated between a herbaceous strip, a maize field and two farm tracks. The second artificial grassland was bordered by farm tracks on three sides and by a potato field on the fourth side, and the third artificial grassland was situated between two farm tracks, another artificial grassland and a wetland reserve. Autumn-sown wheat fields which are harvested at the end of July covered an average area of 1.3 ha. They were machine harvested leaving little standing stubble. The wheat fields were mostly bordered by artificial grassland, potato fields and farm tracks.

For each of the five habitat types, three fields were chosen. During each trapping session (in March, May and July), the vegetation structure of each field was described on five randomly chosen squares (each of 1 m^2) as follows: a) vegetation height (in cm) was determined by measuring the 10th highest plant (to avoid measuring unusually high plants), b) vegetation density was determined by measuring the height (in cm) at which only 50% of a horizontal ruler, 1.7 cm wide and 100 cm long, was visible by watching vertically from above, c) percent cover of green vegetation, and d) dead plant material was estimated visually (at an accuracy of 5%).

Trapping of small mammals

The density of small mammals in each of the 15 fields (five habitat types with three replicates each) was determined using capture-recapture during three trapping sessions; one in March, one in May and one in July. In each field, we set 40 traps (Trip Trap with a nest box; we glued two metal washers to the outside of the trap door to ensure door shutting even during wet conditions). Because wild-flower and herbaceous strips were narrower than 10 m, we could not set traps in a square grid design. Therefore, the traps were placed along two straight lines 5 m apart. Along each line, 10 pairs of traps were set at 5-m intervals. Thus, the trapping rectangle covered an area of 45 × 5 m. In low-intensity meadow, artificial grassland and autumn-sown wheat, the borders of the trapping rectangle were at least 40 steps away from adjacent habitat types. In wild-flower and herbaceous strips, we were forced to set the trapping lines close to the edge of the strips.

We never set traps in freshly mown patches, and the vegetation height usually exceeded 20 cm, except for artificial grassland and low-intensity meadows in March when vegetation height was just below 20 cm. If there were indications of small mammal activity such as corridors or holes within a circle of a 50-cm radius around a trapping point, the traps were placed directly at such a sign. The openings of each trap pair were orientated into different directions. Each trapping session consisted of continuous trapping during 60 hours, starting in the evening (for three consecutive days and nights). Traps were checked every eight hours, starting at 23:00. Small mammals were lured with a piece of apple and a piece of mixed rolled oats, peanut butter and minced meat (Holzgang & Pfunder 2002), and a paper tissue was offered as nesting material. The animals were marked by locally cutting of the guard hair on the shoulder or on the back. Because the underhair is darker than the guard hair, the marking was visible as a dark spot in the fur. For every recapture round, the fur cutting was made at a different place (e.g. on the left shoulder, right lower back). By doing this, the time of the first and subsequent captures, respectively, were known for every recapture, and resulted in capture histories of eight time points for each trapping session.

Data analysis

The trapped individuals were assumed to live on a surface of 500 m^2 (50 × 10 m), which results from

Downloaded From: https://bioone.org/journals/Wildlife-Biology on 29 Mar 2021
Terms of Use: https://bioone.org/terms-of-use

multiplying the length and width of the trapping rectangle after addition of a margin of 2.5 m on each side (Gurnell & Flowerdew 1994, Williams et al. 2002). The population size on each single field for each trapping session was estimated using closed capture-recapture models by use of the computer software CAPTURE (Otis et al. 1978). These models assume a closed population during the 60 hours of each trapping session, thus only capture probabilities needed to be calculated to estimate the number of individuals. We believe that the assumption of a closed population is valid, as it is quite improbable that there is much immigration or emigration within only three days. Separate analyses were performed for each field and trapping session. For 22 out of the 45 samples it was not possible to calculate population sizes by the use of CAPTURE due to too few recaptures. In these cases, the population sizes were estimated by use of the formula $N = C/(1 - (1 - P)^8)$ where C is the number of captures, P is the average of the capture probabilities (calculated using CAPTURE) of all samples of one trapping session and eight as exponent is the number of trap checks per trapping session. From the population estimates, we calculated the densities of small mammals (ha^{-1}) and the average density of the three fields sampled for each of the five habitat types with its standard error.

The common vole was the only species for which sufficient captures were obtained to estimate densities at a species-specific level. We estimated the proportion of common voles from the pooled overall density of all species of small mammals (see above) from the proportion of common voles caught and corrected for the species-specific capture probabilities as corrected proportion of common vole = (number of common vole/p (common vole))/(number of species 1/p (species 1)) + … + (number of species n/p (species n)), where p is the capture probability of each species pooled for May and July, respectively. This corrected proportion of common voles multiplied with the overall density of small mammals yielded the density of common voles and was calculated for each field.

Small mammal densities were analysed for their dependence on habitat type, month (trapping session), the interaction between habitat type and month and the four parameters of vegetation structure (height, density, cover of green vegetation and dead plant material) with an analysis of variance. Because the error variance did not show an equal distribution among the habitat types, an important criterion for the application of an analysis of variance was violated. Therefore, we used a weighted multifactorial analysis of variance (weighted least squares) according to Neter et al. (1990). The weight factor in such an analysis corresponds to the reciprocal value of the error variance.

Results

In total, we caught 349 different small mammal individuals at 738 occasions; thus an animal was on average captured twice. We caught the following six small mammal species: yellow-necked mouse *Apodemus flavicollis*, wood mouse *A. sylvaticus*, bank vole *Clethrionomys glareolus*, field vole *Mi-*

crotus agrestis, common vole *M. arvalis* and some individuals of the common shrew *Sorex araneus* complex. Herbaceous strips were the only habitat type in which all six species were captured (60% voles, 38% *Apodemus* spp. and 2% shrews; Fig. 1). In all other habitat types, > 75% of the catches were common voles together with one additional species, the field vole on low-intensity meadows, or the wood mouse on wild-flower strips, artificial grassland and autumn-sown wheat.

Vegetation parameters had no significant effect on small mammal density (Table 1) or common vole density (Table 2), even when entered into the model before month (trapping session) and habitat type. But both small mammal and common vole density differed significantly between months and habitat types (see Tables 1 and 2), and these two effects were not independent of each other. The significant interaction term habitat type*month shows that the increase in small-mammal density over the three months differed between habitat types.

In March, the density of small mammals was low (averaging 27.0 ha^{-1} ± 22.0 SE) over all habitat types (Fig. 2). Nevertheless, wild-flower and herbaceous strips had a higher density (57.6 ha^{-1} ± 22.3 and 88.4 ha^{-1} ± 68.7, respectively) than low-intensity meadows (0 ha^{-1}), artificial grassland (8.2 ha^{-1} ± 8.1) and autumn-sown wheat (8.2 ha^{-1} ± 8.1). In all habitat types, the common vole was the only species that we caught at this time of year, except for herbaceous strips where the small-mammal density was made up by wood mouse and yellow-necked mouse. In May, a substantial increase to 486.6 ha^{-1} ± 292.4 and 630.2 ha^{-1} ± 289.6 was observed on wild-flower and herbaceous strips, respectively, whereas in the artificial grassland, autumn-sown wheat and low-intensity meadows, the increase was clearly less prominent (to 61.8 ha^{-1} ± 67.4, 78.8 ha^{-1} ± 11.9 and to 113.3 ha^{-1} ± 50.0, respectively; see Fig. 2). The common vole was the most abundant species on wild-flower strips (92% common voles), low-intensity meadows (85%) and artificial grassland (100%), whereas it was only a by-catch on herbaceous strips (7.5%) and autumn-sown wheat (21%). Even larger differences in small mammal densities between habitat types were estimated for July. On low-intensity meadows and artificial grassland, the density had increased slightly from 113.3 ha^{-1} to 140.0 ha^{-1} (± 82.6) and from

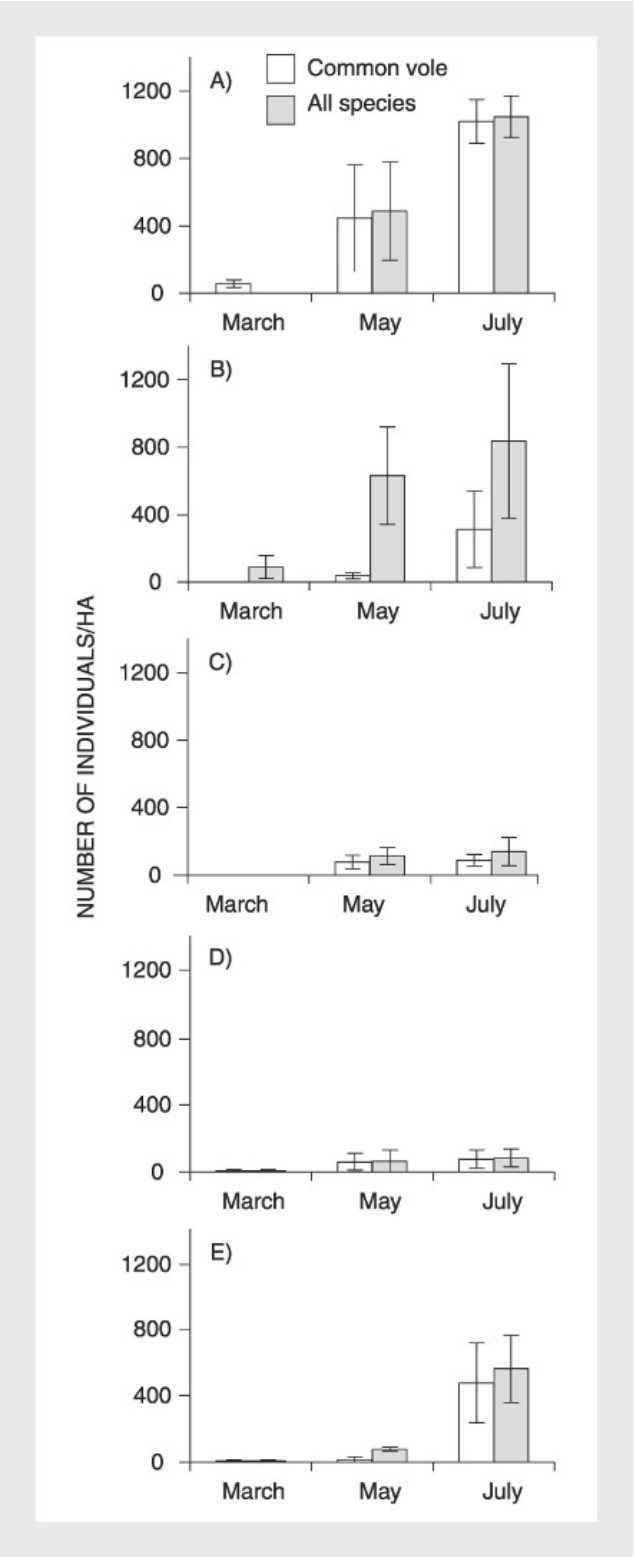

Figure 2. Mean densities of small mammal species (± SE) and mean densities of common voles (± SE), corrected for different capture probabilities, in the five habitat types (A) wild-flower strips, B) herbaceous strips, C) low-intensity meadows, D) artificial grassland and E) autumn-sown wheat) for March, May and July 2003. Capture probabilities: *M. arvalis* = 0.22, *M. agrestis* = 0.39, *A. sylvaticus* = 0.22, *A. flavicollis* = 0.25, *C. glareolus* = 0.19.

61.8 ha^{-1} to 84.0 ha^{-1}(± 54.0), respectively. In contrast, the densities of small mammals had increased further on wild-flower and herbaceous strips from May to July (from 486.6 ha^{-1} to 1046.6 ha^{-1} ± 123.5 and from 630.2 ha^{-1} to 836.4 ha^{-1} ± 457.6, respectively). During this period, an increase in density was also observed on autumn-sown wheat fields from 78.8 ha^{-1} to 561.3 ha^{-1} (± 201.7; see Fig. 2). In July, the proportion of common voles was > 80% of the total small mammal density in all habitat types, except in herbaceous strips where it amounted to 40%.

Discussion

Our study demonstrated large differences in species composition and seasonal abundance of small mammals between habitat types. The highest species diversity occurred in herbaceous strips with six species trapped. In all other habitat types, only two species were captured, with the common vole being the predominant species. Herbaceous strips are typical ecotones between hedges (including hedges along streams or channels) or woodland and agriculturally used land. This mosaic of different habitat types holds a diverse small-mammal community, and in the herbaceous strips we captured all the species typical for this habitat (Holzgang & Pfunder 2002). Clearly, bank vole, yellow-necked mouse and individuals of the common shrew complex, which prefer trees, bushes or dense undergrowth (Corbet & Ovenden 1982, Hausser 1995), moved from the adjacent hedge into the herbaceous strips where they were trapped. Also Baumann (1996) caught bank voles only in herbaceous strips adjacent to woodland. In wild-flower strips surrounded only by arable land, the common vole, typical of open land, was caught as well as the wood mouse, which moves also into open land with a good cover.

As expected, both the density of common voles and of all small mammals taken together generally increased over the study period from March to July. The common vole was the most abundant species on wild-flower strips, low-intensity meadows, artificial grassland and autumn-sown wheat, whereas it was only a bycatch on herbaceous strips. Although many tracks, particularly vole corridors, were observed in March, only a few individuals were caught. The estimated low density for March (27 ha^{-1}) corresponds to the findings of other studies, although the methods used differed. On fallows

Downloaded From: https://bioone.org/journals/Wildlife-Biology on 29 Mar 2021
Terms of Use: https://bioone.org/terms-of-use

and orchards in West Germany, Boyce & Boyce (1988) estimated a vole density of 24 ha^{-1} for April 1982 (based on Minimum Number Alive). In western France, Butet & Leroux (2001) found vole densities between 0.8 and 87.6 ha^{-1} for April during 1986-1998 (pooled data based on the trap-night index for abandoned pastures, grazed and mown grassland and cereal crops). Gromadzki & Trojan (1971) estimated spring densities between 4.1 ha^{-1} and 33.8 ha^{-1} on cultivated fields and in refuge habitats in Poland in 1966 and 1967 (based on capture-marking-release).

The short vegetation might have offered only poor protection against predators (e.g. long-eared owl *Asio otus*, kestrel *Falco tinnunculus*, common buzzard *Buteo buteo*, red fox *Vulpes vulpes* and stoat *Mustela erminea*) and may have influenced the spatial behaviour of the small mammals resulting in reduced captures. Small mammals perceive tall vegetation as good protection (Tchabovsky et al. 2001). Under predation risk, which is high in short vegetation (Korpimäki et al. 1996, Longland & Price 1991, Jacob & Brown 2000, Sheffield et al. 2001), small mammals move faster, cover shorter distances (Lagos et al. 1995) and may reduce their home-ranges (Jacob & Hempel 2003). A reduced number of captures would influence the density of small mammal estimates negatively. For May and July, the effects of low vegetation cover can be excluded, as traps were only placed on fields with vegetation heights > 20 cm.

Compared to wild-flower and herbaceous strips, small mammal densities in autumn-sown wheat were very low in March and May, and increased only from May to July. The small mammals were probably exploiting this huge food resource shortly before harvest (i.e. at the end of July).

Densities of small mammals in artificial grassland remained at very low levels throughout the summer. Apparently, the regular cutting (first cut in April and afterwards about every five weeks until October) and subsequent application of liquid manure prevented the establishment of higher small-mammal densities. Populations of gray-tailed voles *Microtus canicaudus* on alfalfa fields are known to decline by about 50% after mowing (Edge et al. 1995).

Small-mammal and common-vole densities remained low for the whole study period in low-intensity meadows compared to wild-flower and herbaceous strips. Compared to artificial grassland, though, densities of small mammals and of common vole in May and July were twice as high. This may be the result of the lower frequency of mowing (only twice, first cut after 15th of June).

Many studies have shown that vole density is influenced by vegetation height, cover and litter (e.g. Ostfeld et al. 1985, Tattersall et al. 1997, Sheffield et al. 2001, Olson & Brewer 2003). Unexpectedly, we found no significant correlations between small mammal or common vole densities and parameters of vegetation structure in our study. Apparently, it was not vegetation structure, but habitat type that determined small-mammal densities in our study area. The habitat types differed in agricultural activities (mainly in the frequency of mowing and the application of liquid manure) and food availability (i.e. autumn-sown wheat). Therefore, it is likely that the density patterns of small mammals seen in our study area were mainly determined by the adverse effects of agricultural practices (i.e. mowing and liquid manure) and food availability.

Our study clearly demonstrated that ecological compensation areas not tilled or mown every year, such as wild-flower and herbaceous strips, support high densities of small mammals and can serve as a refuge in intensively farmed areas. Similarly, grassy field margins were found to harbour a higher small mammal biomass than conventional arable field edges in the UK (Shore et al. 2005). If connected to other semi-natural habitats (e.g. hedgerows), such ecological compensation areas may also increase the species diversity of small mammals. Regularly mowed ecological compensation areas (low-intensity meadows) support a lower diversity and density of small mammals.

The density of small mammals, in particular of the genera *Microtus* and *Arvicola*, directly determines the occurrence and abundance of many avian and mammalian predators. While some predators exploit small mammals opportunistically when their densities are high (e.g. red fox; Ferrari & Weber 1995, badger *Meles meles* and beech marten *Martes foina*; Niethammer & Krapp 2002), certain bird and mammal species are specialised predators that depend almost exclusively on them (e.g. stoat and weasel *Mustela nivalis*; Niethammer & Krapp 2002, long-eared owl; Mebs & Scherzinger 2000). Such specialised predators have a higher reproductive output or reproduce exclusively during periods of elevated small mammal densities (e.g. Wendland 1957, Niethammer & Krapp 2002). However, as shown in a study of the hunting behaviour of common kestrel and long-eared owl, it is not the

Downloaded From: https://bioone.org/journals/Wildlife-Biology on 29 Mar 2021
Terms of Use: https://bioone.org/terms-of-use

absolute density of voles, but their accessibility, that determines where they hunt. Indeed, they mostly hunted on freshly mown grassland and also preferred freshly mown grassland bordering wild-flower and herbaceous strips (Aschwanden et al. 2005). Therefore, both refuge areas with high densities and a mosaic of freshly mown surfaces (preferably adjacent to high density areas) are important to support avian vole predators. Wild-flower and herbaceous strips are not only indirectly important for avian predators during summer, but also directly during winter as kestrels preferred wild-flower strips for hunting activities during the winter (Buner 1998).

In intensively farmed landscapes, ecological compensation areas, such as e.g. herbaceous and wild-flower strips, are of high value. As well as supporting highly productive and diverse small mammal communities, they support also a rich diversity and density of plants, insects and birds (Lys & Nentwig 1994, Jenny et al. 1998, Kleijn & Sutherland 2003, Walter et al. 2004) and thus are important to maintain biodiversity in agricultural landscapes.

Acknowledgements - we thank the Wauwiler Moos prison and local farmers for their information about the work planned on their fields (mowing and harvesting dates) and for allowing access to their farmland. Furthermore, we thank Thilo Tschersich, Vreni Mattmann and Marco Thoma for their assistance in the field and Marc Kéry and Michael Schaub for their support in data analysis. We also thank Verena Keller, Niklaus Zbinden, Roman Graf and Simon Birrer and two anonymous reviewers for commenting on an earlier draft of the manuscript. This study was part of the diploma thesis by Janine Aschwanden at the Zoological Institute, University of Zurich. We thank Heinz-Ulrich Reyer for his supervision and comments on the thesis.

Executive summary

Biodiversity is essential to sustain our society and economy. Enhancing biodiversity is integral to sustainable development, and BNG is an approach to embed and demonstrate biodiversity enhancement within development. It involves first avoiding and then minimising biodiversity loss as far as possible, and achieving measurable net gains that contribute towards local and strategic biodiversity priorities.

This guide offers practical advice to achieve BNG in the UK's land and freshwater environment. It applies to:

- building, infrastructure and extractive industries, as well as sites used by developers, such as construction compounds
- all sizes of development from a single home build to large-scale projects in rural and urban locations
- developments requiring consents such as planning permission, and those not requiring consent such as those under permitted development rights
- developments with limited or no adverse effects on biodiversity to projects in sensitive environments
- individual projects, a portfolio of projects or management of a land-holding or an estate
- new projects, those already underway and routine maintenance activities.

The guide is for:

- those involved with commissioning, planning, assessing, designing, constructing and operating development projects, whether in a policy, regulatory or advisory capacity
- those exploring possibilities to adopt BNG within their business
- local planning authorities (LPAs) seeking to incorporate BNG within local plans and planning decisions
- landowners and managers, including companies undertaking development on or managing an estate, as well as organisations supporting developers to achieve BNG.

This guide focuses on how to achieve BNG by following good practice, but it is not prescriptive in terms of approaches or tools. Rather, the advice is relevant to all development while its application will be proportionate to the scale of a project and its effects on biodiversity.

Developments involving Environmental Impact Assessments (EIAs), Ecological Impact Assessments (EcIAs) or Preliminary Ecological Assessments (PEAs) will already be undertaking many activities in this guide. Links with these assessments are identified throughout with reference to guidelines from IEMA (Ricketts *et al*, 2016) and CIEEM (2018) on EcIAs and PEAs. They are also summarised in **Technical notes T6 and T7**.

The guide does not contain technical advice on enhancing individual habitats or specific features, but should be read with such technical references.

BNG does not apply to statutory designated sites or irreplaceable habitats. This guide advises that impacts on statutory designated sites or irreplaceable habitats are avoided where possible. Any impacts should be addressed as fully as possible by adhering to the mitigation hierarchy, as well as legislative and policy requirements on a case-by-case basis, usually in collaboration with the planning decision maker and statutory nature conservation advisor.

Part C The business case for biodiversity net gain 41

5 Business case for developers ... 42
5.1 Gaining a competitive advantage ... 43
5.2 Increasing financial value ... 44
5.3 Securing efficiencies ... 45
5.4 Selling the business case and additional information ... 46
Part D Implementing the biodiversity net gain good practice principles ... 49
6 Developing corporate strategies ... 50
6.1 Assess risks and opportunities ... 51
6.2 Identify gaps ... 51
6.3 Phase implementation ... 51
6.4 Commit to good practice ... 52
6.5 Establish KPIs ... 53
6.6 Monitor progress and review performance ... 56
6.7 Plan external communications ... 56
7 Engaging stakeholders throughout a project life cycle ... 57
8 Quality assurance ... 60
8.1 Embedding biodiversity net gain within quality assurance ... 61
8.2 Strategic audits and project-level quality assurance ... 61
8.3 Overarching themes for quality assurance ... 62
8.4 Quality assurance throughout the project life cycle ... 63
8.5 Strategic-level auditing of biodiversity net gain ... 65
8.6 Good practice for auditing by local planning authorities ... 66
9 Feasibility and scoping ... 68
9.1 Planning for biodiversity net gain early ... 69
9.2 Identify local and strategic priorities for biodiversity ... 69
9.3 Apply the mitigation hierarchy ... 72
9.4 Engage stakeholders ... 72
9.5 Assess feasibility ... 74
9.6 Set a goal ... 75
9.7 Finalise reports ... 76
10 Impact assessment ... 77
10.1 Assess the project's biodiversity baseline ... 78
10.2 Measure the project's biodiversity baseline ... 79
10.3 Assess negative effects ... 81
10.4 Measure negative effects ... 82
10.5 Apply the mitigation hierarchy ... 83
11 Designing biodiversity net gain ... 84
11.1 Apply the mitigation hierarchy ... 86
11.2 Clarify the starting point ... 86
11.2.1 Describe measures ... 86
11.2.2 Define the reference scenario ... 86
11.3 Set the outcomes ... 86
11.4 Design for net gains in biodiversity ... 87
11.4.1 Should the net gains be in the same or a different type of habitat? ... 88
11.4.2 Where should biodiversity net gain be located? ... 89
11.4.3 Should biodiversity net gain enhance existing or create new habitat? ... 90
11.4.4 How can biodiversity net gain create more, bigger, better and joined-up areas for wildlife? ... 91
11.4.5 How can a biodiversity net gain design optimise wider benefits? ... 92
11.5 Avoid or minimise risks ... 93
11.5.1 Avoid or minimise time-lags ... 93
11.5.2 Avoid, minimise or safeguard against risks ... 94
11.6 Measure the predicted net gains ... 95
11.6.1 Clarify whether information is a prediction or actual ... 95
11.6.2 Use the same measurement ... 95
11.6.3 Add contingency ... 95
11.6.4 Measure individual features ... 96
11.6.5 Reporting ... 96
11.7 Plan for the long term ... 97

11.7.1 Be specific on timescales 97
11.7.2 Develop a management and monitoring plan 97
11.7.3 Define responsibilities 99
11.7.4 Determine accountability 99
11.7.5 Put mechanisms in place 100
11.8 Finalise the design outputs 102
12 Construction 103
12.1 Update the biodiversity baseline 104
12.2 Include biodiversity net gain within construction documents 104
12.3 Train key staff 105
12.4 Avoid or reduce the time-lag between losses and gains 106
12.5 Act on risks and opportunities 106
12.6 Collect data 106
13 Maintenance and monitoring 108
13.1 Monitor progress and outcomes 109
13.2 Employ adaptive management 109
13.3 Report on progress and outcomes 110
Part E Technical notes 113

Case study 9.2
Engaging stakeholders on biodiversity net positive pilot for the Midland Mainline programme

The Midland Mainline Programme (MMP) involves permanent clearance of vegetation to enable the delivery of its electrification, building and civils projects (see Figure 9.2). Carillion, representing the MMP, recognised the need to address this loss by achieving biodiversity net positive (BNP). It ran the first engagement workshop with key stakeholders including Natural England, RSPB, the Environment Agency, Wildlife Trusts and representatives from the farming community (see Figure 9.3). The workshop included discussions on critical aspects of BNP, including local wildlife priorities that MMP could contribute towards. By holding the workshop at an early stage of MMP, the programme benefitted from being able to target its BNP activities and from establishing good working relations with key stakeholders.

Fore more details see Case study 9 in C776b.

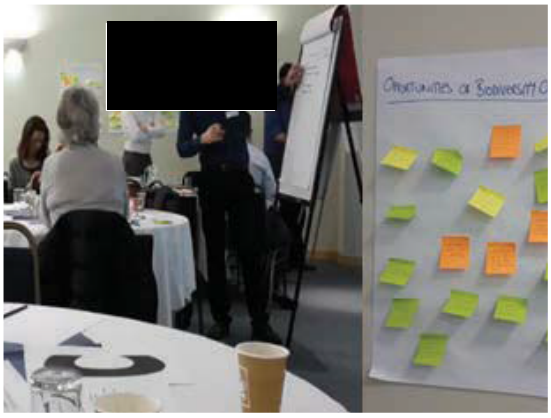

Figure 9.3 Stakeholder engagement workshop

9.5 ASSESS FEASIBILITY

An ecological scoping assessment, stakeholder consultations and PEA can inform an assessment of whether delivering BNG for the project is feasible. This can be an iterative assessment that is updated during the design stage when more information about the project becomes available. It can include the following:

- **Identifying statutory designated sites or irreplaceable habitats.** Projects negatively affecting statutory designated sites or irreplaceable habitats cannot, as a project, achieve BNG. **Technical note T3** gives advice on irreplaceable habitats.
- **Assessing risks**. **Chapter 11** lists risks to achieving BNG. Considering these at an early stage can help to plan (and demonstrate) application of the mitigation hierarchy. This is important because committing to BNG does not negate the need to first avoid and then minimise a project's loss of biodiversity. It also enables planning for a more efficient and less risky design stage.

  Highlighting risks to achieving BNG can inform a feasibility assessment of the project itself, especially when different options are being considered. For example, this could be identifying locations where a project will affect highly biodiverse features that, to address the effects, will add substantially more time and cost to the project.
- **Assessing wider benefits**. BNG can generate benefits for society, the environment and the economy, in addition to the goal of BNG. A high-level assessment of these wider benefits might be possible at an early stage, and can position BNG as part of the project's legacy. It can also identify additional benefits for the commissioning agency or landowner, for example making an estate more resilient to climate change.
- **Estimating biodiversity losses and gains**. The method for measuring a project's biodiversity losses and gains should be specified, with justification. For example, some commissioning agencies and LPAs specify a method, or if no method is specified, projects might use a commonly applied metric such as Defra's biodiversity metric (see **Technical note T9** for advice).

  Chapter 11 gives advice on measuring a project's biodiversity losses and gains. At an early stage, findings of an ecological scoping assessment or PEA might enable a calculation of estimated biodiversity losses to:

  - ☐ focus attention on measures to avoid and then minimise biodiversity loss

- highlight possibilities for on-site gains, eg estimating gains from enhancing habitats within the site footprint to compare with the time and cost implications of removing them, and the missed opportunity for achieving the gains
- produce a ballpark figure of the area and types of habitat to create or enhance to achieve BNG, which will in turn support planning for the budgets, resources and timescales (eg budgeting to create 10 ha of species-rich meadow, and maintaining this over a 25-year period).

When estimating biodiversity loss (see **Box 9.3**), milestones for updating this calculation should be set within the project programme. This aligns with the CIEEM guidelines, which describe how to analyse information gaps during a scoping assessment in order to plan and prioritise information gathering for the full EcIA.

- **Assessing resource, budget and programme requirements**

This assessment can help inform budgets for designing, implementing, maintaining and monitoring BNG. It can include:

- **data collection**, especially any new data required for a biodiversity metric during both the design and construction stages. Data on habitat condition for Defra's biodiversity metric is not typically collected for EcIA surveys, but can be collected during EcIA or other similar surveys
- **specific expertise**, eg surveyors with the right botanical skills, ecologists with experience in designing BNG, local knowledge of the ecological suitability of sites marked for habitat creation, and expertise for implementing the BNG design
- **timescales**, eg implementing a BNG design and its long-term maintenance
- **seasonal constraints**, eg affecting when data should be collected and when BNG activities can be implemented (although these could be similar to seasonal constraints affecting protected species surveys and mitigation measures, and landscaping schemes)
- **cost estimates to implement the BNG design**, eg habitat planting or enhancement (see **Section 9.5**, point 3), and management plans.

Box 9.3
Examples of options for delivering biodiversity net gain using Defra's biodiversity metric

In the worst case, the project could result in permanent loss of 38 biodiversity units of a scrub and grassland mosaic. For budgeting purposes only, this indicative calculation at the project's feasibility stage shows that the project could achieve BNG by Options A or B:

Option	Hectares	Habitat	Work required	Biodiversity net gain	Assumptions
A	6.5	Amenity grassland	Converting to scrub/grassland mosaic in moderate condition	49 biodiversity units	No spatial risk, a low difficulty risk and 10 years to reach target condition
B	7	Scrub/ grassland mosaic	Enhancing from poor to moderate condition	46 biodiversity units	No spatial risk, a low difficulty risk and 5 years to reach target condition

This indicative calculation is only to illustrate possible options for BNG. It is intended to support budgeting and programming, as part of the project's feasibility assessment. It will be updated during the design and EcIA stage, when the mitigation hierarchy will be properly applied.

9.6 SET A GOAL

Where achieving BNG is feasible, a statement on the project's BNG goal should be included in the report.

The goal can be a commitment or an aspiration if uncertainty exists, for example on resources. It can be high-level, reflecting any targets set by the commissioning agency and LPA, as well as local biodiversity priorities. It can also outline the intention to follow the good practice principles (see **Box 9.4**).

A goal shows the project team what is to be achieved, helping to get BNG budgeted and in the project programme.

Chapter 6 advises on setting BNG goals and targets that contribute towards biodiversity strategies.

(based on specific, individual features building on the project's ecological impact assessment, while refining any previous goals set for BNG, eg during a project's feasibility stage).

2 How these net gains contribute towards local and strategic priorities for biodiversity (building on the assessment of biodiversity priorities and including any targets set by the commissioning agency and LPAs).

See **Box 11.1**.

Box 11.1
Example of setting high-level biodiversity net gain outcomes during the initial design

Net gains in specific features affected by the project

The project will create new wetland habitat that provides more and better shelter and foraging resources for the wetland birds affected by the project after following the mitigation hierarchy. The project will achieve a minimum of 20% increase in biodiversity (measured in biodiversity units) through its wetland habitat creation, compared against the project's baseline.

Contributing towards biodiversity priorities

The project's wetland habitat creation will contribute towards recovery plans for wetland birds of conservation concern. The project will also create patches of marshy grassland to connect to other wetlands within the local biodiversity opportunity area, thereby increasing ecological connectivity within the locality.

For projects involving EIAs, the EIA co-ordinator can engage the engineering design team to integrate BNG outcomes throughout the design, as part of an iterative process whereby design is informed by impact assessment.

Advice for local planning authorities

Before planning proposals are submitted, working with developers on their design for BNG can secure a high quality planning application, for example by highlighting local priorities that their BNG design can contribute towards.

11.4 DESIGN FOR NET GAINS IN BIODIVERSITY

Designs for BNG are based on individual features in both qualitative and quantitative terms. Key considerations include the following:

- Should the net gains be in the same or a different type of habitat?
- Where should BNG activities be located?
- Should BNG enhance existing or create new habitat?
- How can BNG create more, bigger, better and joined-up areas for wildlife?
- How can BNG optimise wider benefits?
- Are the BNGs more than what would have happened anyway?

The following sections describe these considerations. While each is listed individually, in practice they will be complementary and influenced by practicalities such as the availability of suitable sites.

In all instances, designs should be to generate the best long-term outcomes for biodiversity taking into account all considerations in this guide.

The good practice principles call for decisions that are based on evidence, application of the mitigation hierarchy and that involve stakeholders. CIEEM (2018) says that *"evidence should be provided to support the likelihood of delivering the predicted [biodiversity] benefit"*. Accordingly, designs that adhere to the principles and these guidelines should contain justification of decisions made, with evidence where possible.

Advice for local planning authorities

The advice in this section should be used to:

- review a project's BNG design to ensure that it delivers optimal benefits as far as possible
- establish a plan-led approach to BNG that incorporates all key considerations
- produce guidance for developers on BNG that is specific to the administration area.

11.4.1 Should the net gains be in the same or a different type of habitat?

When compensating for biodiversity loss, CIEEM (2018) refers to compensating for the same type of features as those affected, and seeking to achieve at least equivalent levels of ecological functionality.

When designing BNG, good practice is achieving net gains in features of the same or higher biodiversity value as those affected by the development. It is also to achieve at least equivalent or better levels of ecological functionality and, overall, to improve the extent or condition of biodiversity affected by a project (or the biodiversity within or surrounding a project footprint if no negative impacts are incurred). See **Table 11.2**.

Table 11.2 Design aim/description

Design consideration	Biodiversity net gains
Habitats of high biodiversity value	In the same type of high-value habitat. Net gains in habitats of high biodiversity value should be in the same type of habitat. Habitats of high biodiversity value include those identified as being of principal importance for biodiversity in accordance with the Natural Environment and Rural Communities Act (2006). These are often referred to as 'priority habitats' and can be identified using data from the MAGIC website or JNCC (2011). Arable field margins specifically managed for wildlife should be considered as priority habitats. For those using Defra's biodiversity metric, habitats of 'high' distinctiveness should be considered as priority habitats.
Ecologically equivalent or better	In the same habitat as that affected by development, or a habitat of a higher biodiversity value that supports the same species affected. Generate the same or better levels of ecological functionality. **Box 11.2** describes the concept of 'ecological equivalence'. Net gains should be in the same habitat as that affected by development, or a habitat of a higher biodiversity value that supports the same species affected, for example where a project results in the loss of semi-improved grassland and achieves net gains by creating unimproved grassland. For those using Defra's biodiversity metric, net gains for losses of medium distinctiveness habitats should be achieved in habitats of medium or high distinctiveness. Whereas net gains for losses of low distinctiveness habitats should be achieved in habitats of medium or high distinctiveness. A BNG design should generate the same or better levels of ecological functionality. Ecological functionality is often not captured within biodiversity metrics but should be captured within qualitative assessments and can be essential to achieve BNG (see **Box 11.3**).
No trading down	Improve the extent or condition of biodiversity and do not result in lost or damaged features being replaced by features of lower biodiversity value A BNG design should improve the extent or condition of biodiversity affected by a project. It should not result in lost or damaged features being replaced by features of lower biodiversity value. This is regardless of whether a metric shows an increased amount of biodiversity after a project compared with the baseline. A BNG design should demonstrate the improvement in the extent or condition of specific features in qualitative terms. This should be accompanied by a quantitative assessment that shows that the numerical outcome for individual features is a net gain compared with the baseline.

Box 11.2
The principle of ecological equivalence within biodiversity offsetting

Equivalence is the principle that biodiversity offsets should provide habitat, functions, values and other attributes that are similar in type and proportionate to those affected by the project. These are referred to as 'in-kind' offsets where the offset is the same kind of biodiversity components in a similar ecosystem to that affected by the project.

There may be instances where 'out-of-kind' offsets are appropriate, ie offsets are in a different habitat from the habitat affected, but one of a higher biodiversity value. Out-of-kind offsets should demonstrably provide a greater contribution to landscape-level conservation goals (eg should better address the past disproportionate losses to specific habitat types). Maron *et al*, 2016.

Table 11.3 Examples of creating biodiversity net gain in either the same or a different type of habitat after applying the mitigation hierarchy

Example	Outcome
Creating gains in a different type of habitat so that greater benefits are achieved	A development results in losses of species-poor, semi-improved grassland that is locally common. The grassland did not support notable wildlife populations nor did it provide any key local ecological function. There is no option to achieve BNG within the development footprint.
Using Defra's biodiversity metric to achieve gains in a different type of habitat that has a higher distinctiveness than the habitat lost	The project borders a wetland reserve that is in decline, so addressing this decline and enhancing the wetland are priorities in the BAP. In agreement with the statutory conservation advisor and LPA, the project achieves BNG by enhancing the wetland and supporting ongoing management of the reserve. This contributes towards wetland targets in the BAP, and improves access to higher quality nature for neighbouring communities. Using Defra's biodiversity metric, the species-poor, semi-improved grassland scored low distinctiveness. The aquatic habitats within the wetland scored high distinctiveness.
Using Defra's biodiversity metric to achieve gains in the same type of habitat with a higher distinctiveness band	A project results in the loss of semi-improved acid grassland with a low cover of wildflowers. This habitat scored medium distinctiveness using Defra's biodiversity metric. The project achieves BNG by establishing new areas of species rich grassland with a high cover of wildflowers within the development footprint. This habitat scores high distinctiveness.
Creating gains in the same ecological function as that lost, through a different habitat type with higher biodiversity value	A transport project in an urban environment is seeking to achieve BNG. It required the removal of buddleia, which scored low distinctiveness using Defra's biodiversity metric but provided vital resources for local butterfly populations. BNG is achieved by planting linear swards of native, nectar-rich plants along the site boundaries that increase habitat for the butterflies and contribute towards targets on increasing resources for butterflies in the BAP.
Creating gains in the same ecological function as that lost from a project through the same type of habitat but of higher conservation value	A development is converting derelict land covered by species-poor grassland into housing. Common lizards occupy the site and their numbers are significant locally. Increasing cover and quality of acid grassland is a target in the BAP – for the habitat itself and to boost local populations of common lizard. The project enhances the condition of acid grassland nearby the development and creates new areas of acid grassland in locations identified in the BAP. The project commits funding to implement a 30 year management plan for all areas. This plan includes monitoring for the project to claim BNG when the newly created habitats have reached their target condition and when lizards have colonised the areas.
Designing BNG based on habitats and ecological function	A project is seeking net gains for the unavoidable loss of a hedgerow. The ecologist assesses the ecological connectivity of the hedgerow and uses the assessment to create new hedgerows that increase ecological connectivity within the landscape.

11.4.2 Where should biodiversity net gain be located?

CIEEM (2018) directs compensation of biodiversity loss to be *"as close as possible to the location where effects have occurred and benefit the same habitats and species as those affected."*

When designing BNG, keeping the net gains local to the development while contributing to local and strategic biodiversity priorities can be important. Key considerations can be:

- home ranges and/or ecological networks of species affected by the project
- areas identified of local and strategic priority for biodiversity, eg within local biodiversity plans and GI strategies.

Table 11.4 helps to decide where to locate BNG activities to generate the best outcomes for biodiversity. When conflicts exist between delivering local net gains and supporting wider priorities, the aim should be to generate the best outcomes for biodiversity that are commensurate with and proportionate to a project's effect on biodiversity.

Technical note T5
Aligning biodiversity net gain with the development consent order process

Summary

This technical note relates to the development consent order (DCO) process in place in England and Wales. The target audience for this technical note is those involved in nationally significant infrastructure projects (NSIPs) in England and Wales, who are following the DCO process. Similar large-scale projects in Scotland and Northern Ireland are dealt with by the relevant LPA.

T5.1 WHAT IS THE DCO PROCESS?

Development proposals requiring planning permission are normally dealt with at the local level by the relevant LPA. Recognising the complexity of large-scale infrastructure projects, the Planning Act 2008 put a new decision-making process in place for NSIPs in England and Wales.

A DCO for NSIPs is a legally binding permission for the project given by the relevant Secretary of State. A transport project, for example, would be determined by the Secretary of State for transport. Once given, a DCO defines the scope and extent of the scheme to be constructed, contains all powers necessary to construct the scheme and sets out requirements that have to be complied with.

The DCO process is led by a planning inspectorate and includes pre-application requirements, examination of the proposal by the planning inspectorate and a recommendation made to the Secretary of State for their final determination. As with locally determined development projects, there is a set period and process to challenge any decision made.

The types of infrastructure projects that are determined by the DCO process include waste and water infrastructure, pipelines, electricity infrastructure and large-scale road and rail projects.

T5.2 CAN BIODIVERSITY NET GAIN BE APPLIED TO NSIPS?

Yes. NSIPs typically affect large geographical areas. While potential effects on biodiversity must be addressed, NSIPs are unique opportunities for biodiversity gains over a large area. Projects of national significance should underpin and support the delivery of UK and devolved government biodiversity commitments and should focus on landscape-scale gains and a contribution to national biodiversity targets.

BNG for NSIPs should be discussed with those involved in early consultations, such as LPAs, statutory consultees and local wildlife organisations. LPAs with policies on BNG should highlight these to the developer and the planning inspectorate.

The business case for BNG (see **Chapter 5**) is amplified for NSIPs. The length of the project life cycle and large-scale nature of NSIP can result in a complex project with a considerable number of developers, contractors, consultants and landowners involved over time. By establishing BNG targets as an objective of the project as a whole, each party can promote their own contribution to the overall achievement of BNG.

T5.3 WHICH STAGE OF THE DCO PROCESS IS MOST RELEVANT FOR BIODIVERSITY NET GAIN?

The pre-application stage. This is the first stage in the DCO process. Unlike local planning applications, the applicant must undertake all the necessary consultation before submitting the DCO application. The application must demonstrate that consultee responses have been given appropriate regard. Undertaking and responding to consultations during the pre-application stage is the ideal opportunity to identify, promote and build in BNG. The six stages of a DCO application are shown in **Figure T5.1**.

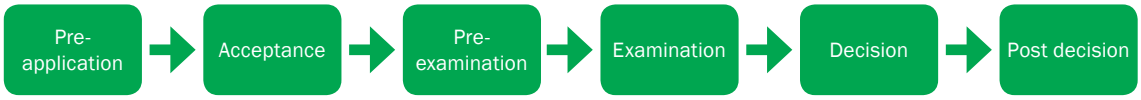

Figure T5.1 The six stages of a DCO application

T5.4 MAXIMISING OPPORTUNITIES AND BENEFITS AT THE PRE-APPLICATION STAGE

The DCO applicant must demonstrate that a comprehensive programme of consultation has been undertaken. The advice on stakeholder engagement within this guide will help ensure that the consultations are effective, in terms of exploring aspirations and options for BNG (see **Chapter 7 and Technical note T4**). Promoting the project as a BNG project and making a public commitment may help generate initial interest. Then including stakeholders in the development of BNG options can generate support for the project. A dedicated register of commitments will help to make sure that everyone understands what is being proposed for BNG.

At the pre-application stage, a DCO applicant should advertise the consultation and engage with stakeholders. BNG can be introduced as part of the project proposal at consultation events, including those focused on the local communities that may be interested in the proposal. The applicant may wish to consider using the guidance on corporate biodiversity targets and commitments within **Chapter 5**.

The applicant should consult with all relevant LPAs, statutory consultees and any people affected by the project. This gives an opportunity to engage with those who will have a specific interest in BNG. This could include wildlife organisations able to assist with locally relevant information and ideas.

During the pre-application stage, the applicant should build in the good practice for BNG as set out in this guide. **Chapter 8** on undertaking quality assurance, **Chapter 9** on feasibility and scoping, and **Chapter 11** on design will be particularly relevant.

Once a DCO application is in the pre-examination and examination phases, the benefits of early engagement will be realised, as these are the stages where consultees can make representations to the planning inspectorate. The DCO applicant can demonstrate that local biodiversity strategies have been taken into account, the mitigation hierarchy has been followed and BNG targets committed to within budgets and the project programme.

NSIPs are planned for over long time periods and there is an opportunity to build in BNG early so that time-lag between losses and gains is prevented where possible.

T5.5 HOW DOES THE LENGTH OF THE PROJECT LIFE CYCLE FOR NSIPS AFFECT BIODIVERSITY NET GAIN?

NSIPs are often in each stage of the project life cycle for several years. The construction phase alone can be extensive. The following good practice will help to keep the BNG target on track:

- Provide a dedicated resource for delivering BNG. This role should include co-ordinating, quality assurance checking and communicating (internally and externally), with full handover where there are staff changes.
- Start BNG activities early to avoid a time-lag between vegetation clearance for the project and biodiversity gains (and to minimise the penalties from time-lags when measuring the biodiversity gains).
- Apply a BNG quality assurance protocol at each life cycle stage.
- Ensure that all involved with each life cycle stage are fully aware of the BNG target and understand their roles and responsibilities.
- Set a clear BNG goal at feasibility and scoping. Given the length of time taken to establish a project design and submit a DCO proposal to the planning inspectorate, be flexible in the way that the goal is achieved. Allow the goal to benefit from any changing environmental conditions and new unforeseen opportunities that may arise during the pre-examination stages, such as creating habitat linkages as part of a newly published habitat restoration plan in the local area.
- Establish a BNG technical group to oversee the project life cycle. Include local biodiversity organisations to benefit from local expertise as well as new ideas and opportunities over time that may be relevant to any adaptive management (see **Chapter 13**).
- Given the lengthy timeframes, maximise the opportunities to create a legacy by, for example, long-term collaborations with local landowners and local wildlife organisations.

Do Bat Gantries and Underpasses Help Bats Cross Roads Safely?

Anna Berthinussen, John Altringham*

Institute of Integrative and Comparative Biology, University of Leeds, Leeds, United Kingdom

Abstract

Major roads can reduce bat abundance and diversity over considerable distances. To mitigate against these effects and comply with environmental law, many European countries install bridges, gantries or underpasses to make roads permeable and safer to cross. However, through lack of appropriate monitoring, there is little evidence to support their effectiveness. Three underpasses and four bat gantries were investigated in northern England. Echolocation call recordings and observations were used to determine the number of bats using underpasses in preference to crossing the road above, and the height at which bats crossed. At gantries, proximity to the gantry and height of crossing bats were measured. Data were compared to those from adjacent, severed commuting routes that had no crossing structure. At one underpass 96% of bats flew through it in preference to crossing the road. This underpass was located on a pre-construction commuting route that allowed bats to pass without changing flight height or direction. At two underpasses attempts to divert bats from their original commuting routes were unsuccessful and bats crossed the road at the height of passing vehicles. Underpasses have the potential to allow bats to cross roads safely if built on pre-construction commuting routes. Bat gantries were ineffective and used by a very small proportion of bats, even up to nine years after construction. Most bats near gantries crossed roads along severed, pre-construction commuting routes at heights that put them in the path of vehicles. Crossing height was strongly correlated with verge height, suggesting that elevated verges may have some value in mitigation, but increased flight height may be at the cost of reduced permeability. Green bridges should be explored as an alternative form of mitigation. Robust monitoring is essential to assess objectively the case for mitigation and to ensure effective mitigation.

Introduction

Recent research shows that major roads can have a major negative impact on bats. Bat density and diversity have been found to decline in proximity to a major road, with the scale of the impact indicating a barrier effect [1]. Studies of *Myotis bechsteinii* also provide evidence for a barrier effect with contracted foraging areas and reduced reproductive success of bats roosting close to roads [2]. Road avoidance behaviour has been observed in commuting bats [3], and street lighting [4] and traffic noise [5] reduce foraging activity and success. Numerous studies show that bats are killed on roads by collision with vehicles e.g. [6,7,8,9]. Roadkill is hard to quantify due to the difficulty of finding carcasses [10], but low reproductive rates make bats particularly vulnerable to elevated adult mortality e.g. [11].

Roads are detrimental to a wide range of animals, reviewed by [12,13]. Crossing structures, both under and over roads, have been built in an attempt to maintain connectivity across the landscape, and numerous studies report use of these structures by mammals and reptiles e.g. [14,15,16,17]. However, the use of a mitigation feature, the widely accepted criterion for success, does not make it effective. To be effective it must play a significant role in maintaining local population sizes. Evidence for a small, unspecified proportion of individuals using a structure to cross a road is not evidence for effective mitigation if a greater proportion crosses the road unsafely, is forced to reduce home range size or has to make longer journeys to find an alternative route. Reviews of mitigation techniques for a wide range of animals report that studies assessing use are typically qualitative [18,19]. In one such review, only two out of 123 studies were able to conclude a positive effect of mitigation at the population level [20].

European bats are protected by EU and national laws, see [1]. Legally required mitigation measures on road developments usually take the form of crossing structures to maintain linear elements in the landscape that bats rely on for commuting. The use of wire bat bridges or 'gantries' is becoming increasingly common: at least eight have been built in the UK in the last five years and six more are planned for the A11 in Norfolk [21,22]. However, there are no published data regarding the effectiveness of these structures. Recent reviews of case studies of bat mitigation in the UK found that most reports were at best qualitative and inconclusive [22,23]. Green bridges, underpasses and culverts have been installed across Europe with potential use as a wildlife passage frequently being an unintended or secondary function. Most of the studies reporting their use by bats are unsuited to quantitative analysis, or fail to address the important distinction between use and effectiveness e.g. [24,25,26]. Seven bat species were caught flying through motorway underpasses in Germany, but when activity levels were compared with sites in the

surrounding forest, only *Barbastella barbastellus* and *M. nattereri* were caught significantly more often in the underpasses, suggesting their effectiveness as crossing structures may be species-specific [2]. The use of underpasses by at least six bat species was also reported in Ireland, with the tendency to fly through the underpasses rather than over the road being related to the degree of clutter-adaptation of a species [27].

Our aim was to examine whether road crossing structures built for bats (or considered suitable for bats) are not only used but, moreover, are effective in guiding a significant proportion of bats safely over or under roads. The ideal study would determine the effectiveness of the structures in maintaining local bat population sizes, but this requires pre-construction data, which do not exist. We therefore studied their effectiveness in protecting crossing bats by reducing the risk of collision mortality. We studied underpasses, the most common wildlife crossing structure in Europe and North America, and wire bat gantries, bridge-like structures designed to guide echolocating bats over the road (see method for a detailed description). These are currently favoured in the UK and are also being built in other parts of Europe. They are sometimes referred to as bat bridges, but we have avoided this term to avoid confusion with other structures, such as green bridges.

Materials and Methods

Study Sites

All four study sites were located in northern England: three roads in Cumbria (A590 at 54°14′N, 2°55′W; A595 at 54°35.2′N, 3°33′W; A66 at 54° 38.3 N, 3°31.4′W), and one in Northumberland (A69 at 54°58′N, 2°15′W). All sites were located in rural lowland used primarily for agricultural grazing, with linear elements such as hedgerows, dry stone walls and tree lines providing connectivity for bats [28,29]. The importance of all sites as bat foraging and commuting routes was established during pre-construction environmental impact assessment, see Appendix A in [22], but methodological differences and inadequate data in these assessments prevented comparison with this study. All roads were built to bypass nearby settlements with traffic volumes of 12,000–17,000 vehicles per day [30,31]. All bat gantries were of similar design: two wooden or metal pylons erected at either side of the road with 2 or 3 pairs of wires spanning the road between them (approximately 20 m on two lane roads and 30 m on four lane roads), with plastic spheres at intervals of approximately 2 m, at a height of 6-9 m, and width of 2 m (see Fig. 1A for example). They are presumed to act as linear features that will guide echolocating bats across roads, above traffic height. At each gantry or underpass, we compared the number of bats using the structure with those crossing unsafely over the road. Where possible, we also compared crossing activity at the gantries and underpasses to that at adjacent or nearby severed but unmitigated commuting routes (as detailed below). The only sites we were unable to compare to nearby commuting routes were underpass B on the A590 and the A69 gantry, as explained below. Photographs are provided in Appendix S1.

The A590 High and Low Newton Bypass (Fig. 1B), opened in April 2008, is a 3.8 km dual carriageway (divided highway) in the Lake District National Park. Two underpasses, a bat gantry (Fig. 1A) and two severed but unmitigated pre-construction commuting routes (Appendix S1) were studied. Underpass A (30 m length ×6 m width ×3 m height) carries a bridleway (a wide footpath designed for horses, pedestrians and cyclists) beneath the road. It is located near to (but not on) a known commuting route, but trees and shrubs were planted along 200 m of the road in an attempt to divert bats from the unmitigated commuting route (on a severed tree-line to the north) that we also surveyed for comparison. Underpass B (30 m length ×6 m width ×5 m height, 500 m south of A) was built to carry a hedgerow-lined minor road, a known commuting route. There were no other previous commuting routes in close proximity for comparison to this underpass. The bat gantry, approximately 1000 m further south, crosses the road at a known commuting route along a severed hedgerow. We also surveyed a second unmitigated commuting route on a severed hedgerow 400 m north of the gantry, where the road now lies in a cutting (roadcut) up to 20 m deep.

The A595 Lillyhall to Parton Improvement, opened in December 2008, is a 5.1 km dual carriageway. A bat gantry was installed where the bypass bisected woodland (Appendix S1). We surveyed this gantry and an unmitigated commuting route 90 m to the north where a hedgerow was severed by the road.

The A66 Stainburn and Great Clifton Bypass, opened in December 2002, is a 4.2 km three-lane carriageway, bisecting a 30 m wide strip of mature woodland. The gantry is located at the western edge of the wood 15 m from the pre-construction commuting route, a bridleway within the wood. We surveyed both the gantry and the pre-construction commuting route. An underpass (15 m length ×5 m width ×2.5 m height) was built at the eastern edge of the wood to carry a small stream, and its use by crossing bats was also investigated.

The A69 Haydon Bridge Bypass, opened in March 2009, is a 2.9 km two-lane carriageway. A bat gantry was constructed at the site of a bat flight line where the road severed a hedgerow (Appendix S1). In pre-construction surveys, minimal bat activity was recorded on all potential commuting routes within 1 km, with the exception of Gee's Wood 800 m east, where the new road bridged a 100 m wide, 10–20 m deep wooded valley with a stream. We therefore conducted surveys at the gantry only.

Survey Methods

Surveys were conducted in June and July, on the A590 in 2010, and all other sites in 2011. Ten 90 min surveys were completed at each crossing point, five commencing at sunset and five starting 90 min before sunrise. Only the five dusk surveys were conducted on the A69 due to low activity levels at dawn. Surveys were conducted on warm, still, dry nights to avoid weather dependent variation in bat activity. At each crossing point an observer was positioned on the verge (grassed bank) either side of the road, equipped with a Pettersson D240× broadband bat detector (http://www.batsound.com, Uppsala, Sweden) and a solid state recorder (Edirol R-09HR, http://www.roland.co.uk, Swansea, UK) set up to automatically detect and record bat echolocation calls (see [1] for details). Since all events were "time-stamped", observations of crossing bats were later matched to echolocation call recordings for species identification. A Pettersson D500× (http://www.batsound.com) bat detector (suitable for automated logging) was also placed in the central reservation (median) when one was present to increase the chances of detection and aid species identification. Both detectors provide recordings that preserve all essential frequency and amplitude information of the echolocation calls, making them the most appropriate choice for species identification. Bats recorded but not observed were excluded, although this was rare. Two observers were used to maximise observations and ensure crossing bats were not missed. All equipment was time synchronised and observers conferred via two way radios. Flight height, direction, distance from the gantry and time of crossing were recorded for each bat. Records were later combined and duplicates removed. Measured points of reference were used to estimate heights and distances to the nearest metre. The bat gantry, fencing and road signs were used

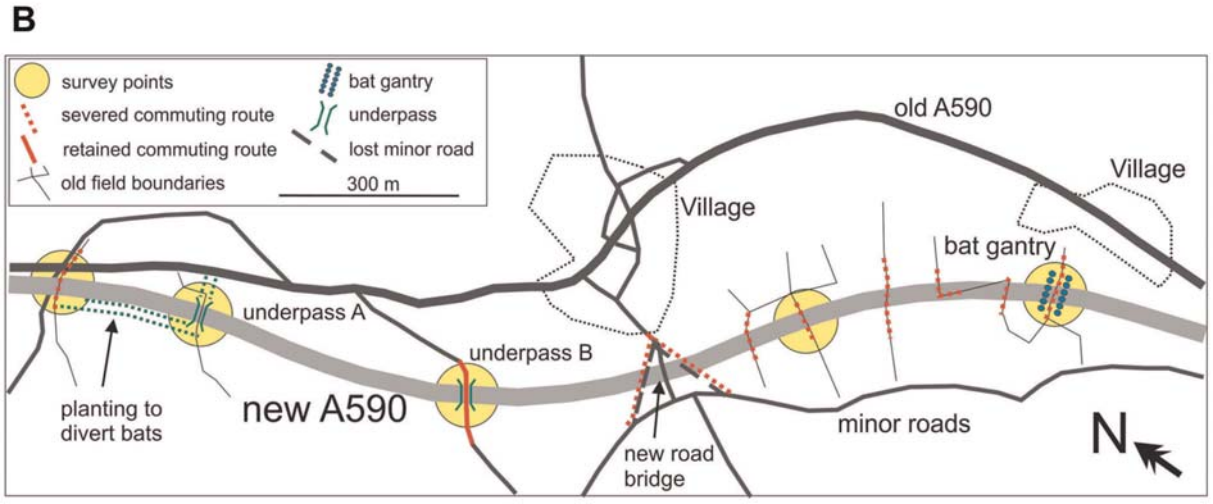

Figure 1A. Photograph of a typical bat gantry (A590). Figure 1B. Map of the study sites on the A590.
doi:10.1371/journal.pone.0038775.g001

for vertical references, and road markings and crash barrier posts provided horizontal reference points. A clear point of reference was always in view and estimations were made without difficulty. Flight height was recorded over the road, with the majority of bats (87%) crossing at constant heights. For those bats which altered their flight height during crossing (8% decreased height and 4% increased) the lowest flight height over the road was recorded. To corroborate observations night vision digital video cameras (Sony

Nightshot DCR-SR75E and DCR-SR35, http://www.sony.co.uk, Basingstoke, UK) were set up on each verge facing the gantry or commuting route over the road, alongside heterodyne bat detectors used to indicate presence on the recordings (Batbox III, www.batbox.com, Steyning, UK) and infrared lights. However, these were found to be unnecessary with visual observations providing sufficient information.

At the underpasses, these methods were repeated on the road above and an additional observer with the same equipment was positioned at one end of the underpass below. Infrared lights were used to illuminate the underpass, and a night scope (Dedal generation 2, www.nightvision.ru) was used to aid observations. A Pettersson D500× bat detector (http://www.batsound.com) was placed in the centre of the underpass to aid in species identification.

Species Identification

Batsound Pro software (http://www.batsound.com) was used to identify species from sonograms of their calls [32]. In most cases, *Myotis* and *Nyctalus* were identified only to genus because of similarity in call structure [32]. *Myotis nattereri*, *M. mystacinus*, *M. daubentonii* and *M. brandtii* are widespread in the area [33]. *Nyctalus noctula* is widespread, and *N. leisleri* is rare. However, *Nyctalus* data were not analysed as bats flew at heights greater than 15 m over the road and commuting activity was low at most sites. A small proportion (<5%) of *Pipistrellus* calls was classified only to genus level, because of the overlap of call parameters of *P. pipistrellus* and *P. pygmaeus*. *Plecotus auritus* was also present, but will have been under-recorded because of its low intensity echolocation call [32]. Species identification was not reliable for 30% of crossing bats due to noise or low intensity recordings. These records were therefore omitted for species specific analyses. All records (excluding *Nyctalus*) were used in all other analyses.

Definitions

'Safe' and 'unsafe' crossing heights were defined as being greater and less than 5 m above the road surface respectively. The maximum height for heavy goods vehicles in the UK is 4.9 m [31]. Bats crossing the road below 5 m are therefore at risk of collision.

Two estimates of 'use' of the gantry were defined: bats crossing the road within 2 m or 5 m of the gantry at a safe height. These definitions are based on observations from the literature: *Myotis mystacinus* commuting at dusk from a roost to a foraging area flew 0.3–1.7 m from a hedgerow, with the greatest distances recorded only at irregularities in the hedge structure [34]. Commuting *M. daubentonii* flew 3.2–5.8 m from a forest edge and 2.1–4.5 m from a wall [35].

Data Analysis

We have provided statistical analyses, but in some cases, whether or not a particular result was statistically significant contributed little towards assessing the effectiveness of the crossing structures. For example, even if significantly more bats cross a road safely than unsafely, the impact on population trends ultimately depends on the proportion of the population that is killed in collisions. Statistical analyses were carried out using R [36]. Wilcoxon signed ranks tests used the function *Wilcoxsign_test* from the package *coin* [37] to compare activity per survey (n = 5 for A69, n = 10 for all other sites) between underpasses and the road above and between bats crossing at gantries and at unsafe heights below. Each survey was treated as independent. Although activity was generally lower at dusk, there was no observable variation in the behaviour of crossing bats between dusk and dawn and so the data were combined. Some individuals may have been recorded several times during surveys but this was unavoidable, and each crossing event was considered to be important regardless of this. The relationship between flight height and verge height was investigated using Spearman's rank correlation (*cor.test*) and comparisons were made between species using Kruskal–Wallis tests (*kruskal.test*) and pairwise Wilcoxon rank sum W tests (*wilcox_test* function, package *coin*) with Bonferroni corrections. On the A66, observations were made across the entire 30 m section of severed woodland that included both the gantry and the severed commuting route. The heights and positions of all crossing bats were used to generate a kernel estimate of crossing intensity, using the *density* function in the *spatstat* package [38].

Results

Underpasses

At underpass A on the A590, activity was low (Table 1, Fig. 2A), but 69% bats preferred to fly over the road rather than use the underpass ($Z = -2.39$, $P = 0.03$). Of bats crossing the road, 88% did so at unsafe heights. *Pipistrellus pipistrellus* and *P. pygmaeus* were detected in the underpass. *P. pipistrellus*, *Myotis* and *Plecotus auritus* were detected flying over the road. Over the same period, more bats crossed the road at the nearby unmitigated, severed commuting route (Table 1, Fig. 2A), 58% at unsafe heights. Most were *P. pipistrellus* and *P. pygmaeus*, approximately half crossing below 5 m. Four of the five *Myotis* detected crossed below 5 m. No bats were observed flying along the planted diversion to the underpass, but observers were only able to monitor this where it left the original commuting route.

Activity levels were higher at underpass B than at A (Table 1, Fig. 2B) and many more bats (96%) used the underpass than flew over the road above at unsafe heights ($Z = 2.80$, $P = 0.002$). *P. pipistrellus*, *P. pygmaeus* and *Myotis* were all detected both in the underpass and over the road.

Activity in the underpass below the A66 was low (Table 1, Fig. 2C), with only 4% of bats crossing through it, in comparison to 60% crossing at unsafe heights over the road above ($Z = 2.80$, $P = 0.002$). *P. pipistrellus*, *P. pygmaeus* and *Myotis* were detected over the road and in the underpass.

Bat Gantries

At all sites, few bats crossed using the gantry (Fig. 3). At the A590 gantry, four times as many (41%) crossed the road at unsafe heights as crossed within 2 m of the gantry (11%; $Z = 2.61$, $P = 0.008$), and 1.4 times as many as crossed within 5 m of the gantry (30%; $Z = 1.49$, $P = 0.15$). At the A595 gantry (Fig. 3B), far more bats (84%) crossed the road at unsafe heights than flew within 2 m (<1%; $Z = 2.81$, $P = 0.002$) or 5 m (6%; $Z = 2.81$, $P = 0.002$) of the gantry. At the A69 gantry (Fig. 3C), more bats crossed the road at unsafe heights (17%) than flew within 2 m of the gantry (8%; $Z = 1.17$, $P = 0.31$), but fewer bats crossed at unsafe heights compared to those flying within 5 m of the gantry (42%; $Z = -2.14$, $P = 0.06$).

At the A66 survey area (including both the gantry and the pre-construction commuting route, Fig. 3D), far more bats (70%) crossed at unsafe heights, than flew within 2 m (2%; $Z = 2.81$, $P = 0.002$) or 5 m (9%; $Z = 2.81$, $P = 0.002$) of the gantry. The kernel density estimation for the A66 (Fig. 4) shows a high concentration of bats crossing at unsafe heights centred at the unmitigated pre-construction commuting route, and low activity around the gantry.

On the A595 the number of bats crossing at the nearby unmitigated, severed commuting route (Fig. 3) was comparable

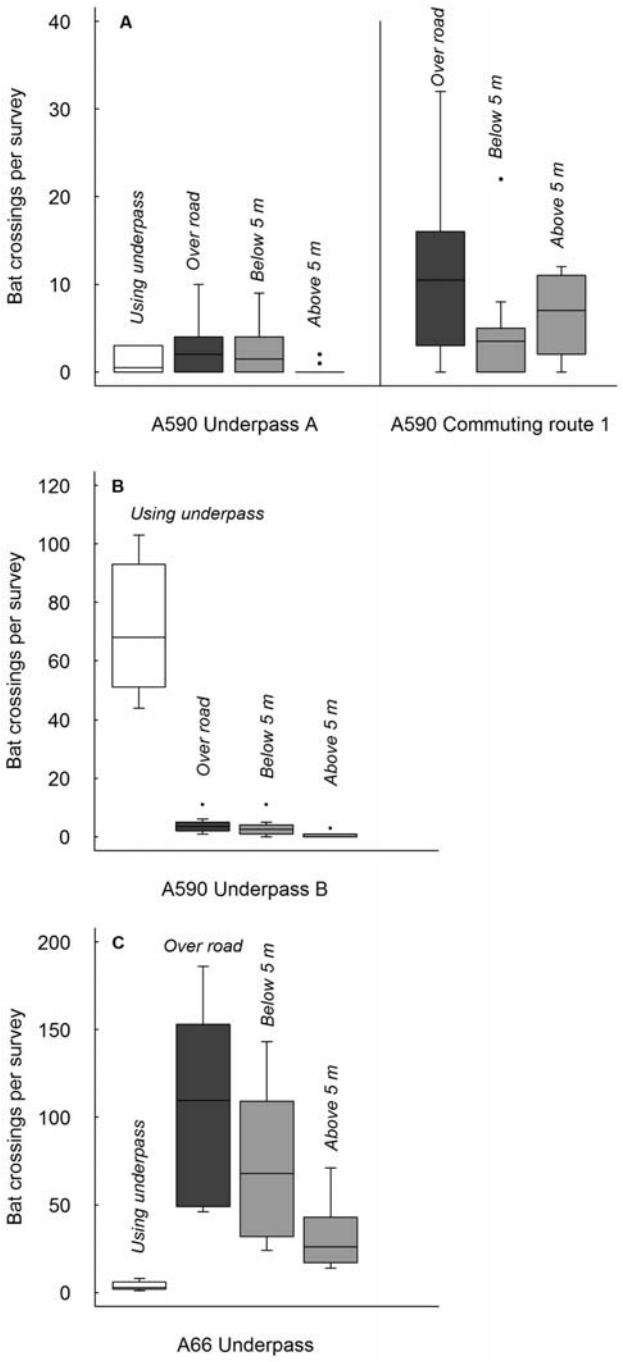

Figure 2. Boxplots of the number of bats crossing per survey at each underpass. Boxplots (median with upper and lower quartiles) for the number of bats crossing per survey (n = 10) at each underpass (numbers crossing using underpass, over the road above and at safe and unsafe heights over the road), and at the unmitigated commuting route on the A590 which was diverted to underpass A (numbers crossing over the road and at safe and unsafe heights).
doi:10.1371/journal.pone.0038775.g002

with that crossing in the vicinity of the gantry, and 94% of bats crossed at unsafe heights.

At the unmitigated, severed commuting route near the gantry on the A590 foraging activity of *P. pipistrellus* was observed during all surveys on the western side of the road, but only 19 bats crossed

Table 1. The crossing behaviour of all bats from all surveys for each study site (NB the number of bats crossing at safe heights at the gantries includes those 'using' the gantry).

Road	Site	Total crossing	'Using' gantry (within 2 m)	'Using' gantry (within 5 m)	Using underpass	Unsafe height over road	Safe height over road
A590	Underpass A	36	-	-	11	22	3
	Commuting route 1	113	-	-	-	65	48
	Underpass B	904	-	-	864	32	8
	Bat gantry	104	11	31	-	43	61
	Commuting route 2	19	-	-	-	0	19
A595	Bat gantry	96	1	6	-	81	15
	Commuting route	77	-	-	-	72	5
A66	Combined survey area	1117	24	100	39	751	327
	(Bat gantry, Commuting route & underpass)						
A69	Bat gantry	65	5	27	-	10	55

doi:10.1371/journal.pone.0038775.t001

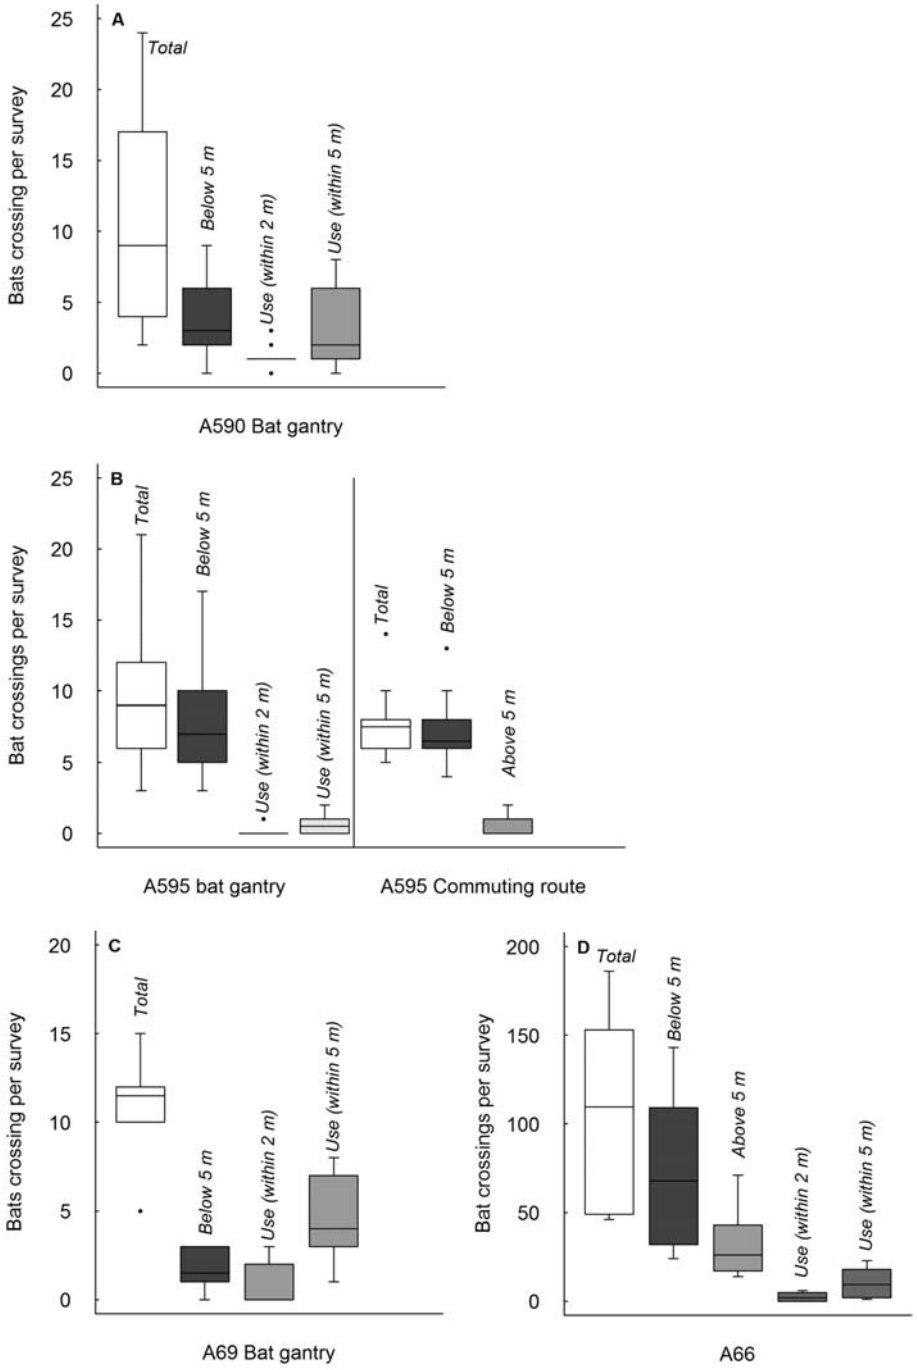

Figure 3. Boxplots of the number of bats crossing per survey at each bat gantry. Boxplots (median with upper and lower quartiles) of the number of bats crossing per survey (n = 10) at the four bat gantries, together with data on total number crossing, the numbers crossing at safe and unsafe heights, numbers 'using' the gantry according to both estimates (within 2 and 5 m), and the numbers crossing at nearby, unmitigated, severed commuting route nearby.
doi:10.1371/journal.pone.0038775.g003

over 10 surveys, all at safe heights. Although other severed commuting routes (shown in Fig. 1) were not surveyed, significant crossing activity was not observed during reconnaissance.

The Influence of Verge Height

The mean crossing height of all bats across all sites (excluding underpasses) was positively correlated with verge height (estimated to nearest 0.5 m) at the point of crossing (Spearman's rank; $r = 0.34$, $n = 1552$, $P<0.0001$). This correlation was significant at the species/genus level, with *Myotis* showing the strongest relationship (*Myotis*: $r = 0.46$, $n = 55$, $P<0.001$; *P. pipistrellus*: $r = 0.40$, $n = 284$, $P<0.0001$; *P. pygmaeus*: $r = 0.34$, $n = 343$, $P<0.0001$). Crossing height above the height of the verge was found to vary between genera (Fig. 5). No difference was found between the two

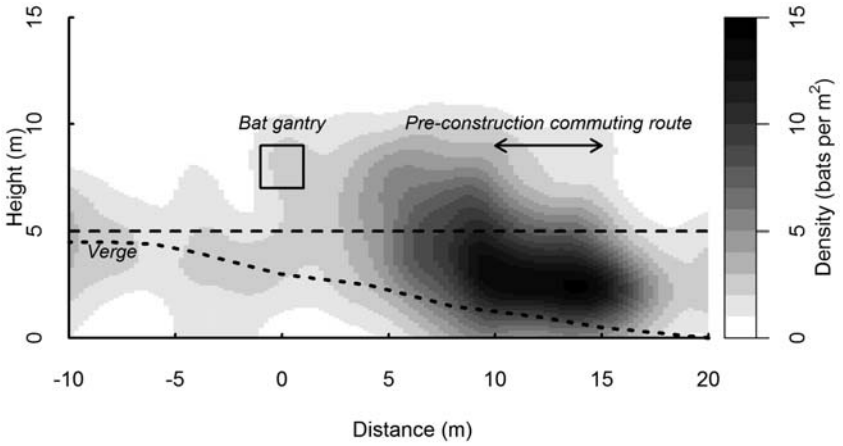

Figure 4. Kernel intensity estimation of the density of crossing bats across the A66 site. Gaussian kernel and bandwidth of 1 m used (n = 1078). The section of severed woodland at the A66 site is shown. The gantry is located at distance 0 m (height marked by square), and the pre-construction commuting route at 10–15 m. 'Unsafe' crossing heights are located below the dashed line. The dotted line marked verge shows the decrease in verge height above the road from left to right.
doi:10.1371/journal.pone.0038775.g004

Pipistrellus species (Wilcoxon rank sum; W = 47193.5, $P>0.05$ after correction), but *Myotis* flew significantly lower than both *P. pipstrellus* (Wilcoxon rank sum; W = 5306.5, $P<0.0005$ after correction) and *P. pygmaeus* (Wilcoxon rank sum; W = 5935, $P<0.0001$ after correction). Only three *P. auritus* were detected, and all crossed below the height of the verge at <3 m over the road.

Discussion

This is the first study to assess the effectiveness of road crossing structures for bats, by measuring the proportion of individuals that used these structures to cross safely. Although a limited study of such diverse structures cannot be definitive, we believe it demonstrates that some current practices are failing. We found no evidence that bats used gantries in preference to nearby, severed but unmitigated commuting routes. At all but one site (A69, where activity was low), the majority of bats crossed at unsafe heights, even in proximity to gantries. Of seven mitigation structures studied, only one underpass was effective in carrying the majority of bats safely across the road.

Underpasses

Underpass A on the A590, and the A66 underpass, are not effective mitigation measures: very few bats flew through them relative to the number crossing at unsafe heights over the road above, and in the case of underpass A, at an original commuting route nearby. Underpass B on the A590 showed high levels of use by commuting bats, with just 4% crossing at risk of collision mortality on the road above. This underpass is effective in allowing bats to cross the road safely. However, the lack of robust pre-construction population data makes it difficult to assess how effectively this underpass can protect bat populations. Even though a high proportion of bats use the underpass, if bat populations have declined since construction and the road acts as a barrier, then the underpass becomes ineffective. Nevertheless, underpass B preserved a pre-construction commuting route, with no necessity for commuting bats to alter their flight course or height. Although replication is needed, this shows that underpasses can be effective when built over existing commuting routes. This makes sense in the context of the high fidelity that bats show to their commuting routes [39,40,41]. Underpass A and the A66 underpass were unsuccessful probably because they require commuting bats to alter their course and flight height. Both underpasses are also lower than underpass B, but several studies report bats flying through even smaller structures e.g. [24].

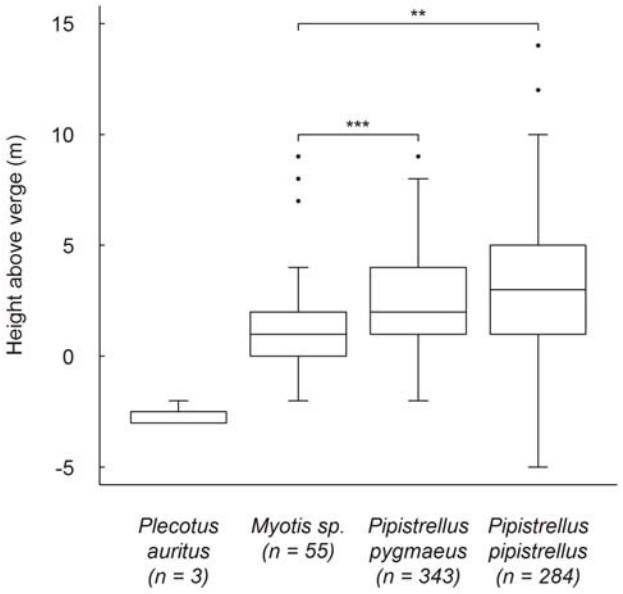

Figure 5. Boxplot of flight height above verge height of identified crossing bats at all sites. Median with upper and lower quartiles. Significant differences shown for *Myotis* and *Pipistrellus* species ** $P<0.0005$, *** $P<0.0001$. Excludes underpass sites. Verges are elevated on either side of the road and are above road height, therefore negative values indicate bats flying across the road below the height of the verge.
doi:10.1371/journal.pone.0038775.g005

Bat Gantries

Bats did not cross at gantries more than at unmitigated road crossings, and gantries did not effectively increase the height at

which bats flew above the road. There was no evidence that bats were 'using' gantries by flying in close proximity to them, as they do along hedges [34,35].

These bat gantries are failing to perform the function for which they were built, even at well-established sites such as the A66, where the gantry has been in place for nine years and is only 10–15 m from the original commuting route. Although road kill counts were not performed, it is well documented that bats are killed on roads in high numbers [6,7,8,9] and mortality may be high enough to be unsustainable [23].

Verge Height

The strong correlation between verge height and the average crossing height of bats suggests that increased verge height may have some potential in raising flight height above traffic. This effect was found to vary between species: *Myotis* species were most sensitive to changes in verge height and flew closer to the verge than *Pipistrellus* species, as did the few *P. auritus* observed. However, increased verge height generally widens the open terrain that must be crossed (since they are inclined away from the road, higher verges are usually wider, see photographs in Appendix S1), which could deter some species from crossing, increasing the barrier effect. Very few bats crossed the road at the second unmitigated commuting route on the A590, where verges are 20 m high, and the width of the open space is 80 m. Similarly, in Germany, *M. bechsteinii* were observed to frequently fly over a two lane road with a connecting tree canopy, but not over a four lane motorway with a gap in the forest [2].

Habitat Continuity

It has been suggested that crossing structures will be more effective if continuous with the vegetation on either side of the road [8]. However, even though the A66 gantry is connected to mature woodland on either side and is only 10–15 m from the commuting route, it is still ineffective. Commuting bats use linear habitat elements not just for navigation, but also to obtain protection from predation and wind and as foraging microhabitats [29,42]. More substantial structures that provide shelter and perhaps bear a closer resemblance to natural features are likely to be more successful, for example a planted green bridge that provides a continuation of hedgerow, or tree lines over the road. Green bridges, although built for other wildlife, are only just being considered as mitigation measures for bats, and evidence is still needed for their effectiveness. Ten species of bat were found to use green bridges in Germany, with higher use than conventional road bridges, but results focussed on bats using the structures and did not look at those crossing the road below [25]. A simpler (but as yet untested) alternative that may be practical and effective on narrower roads is the 'hop-over': mature trees that overhang the road so that their crowns bridge the gap above the road [43].

Species – Specific Effects

Nyctalus species do not appear to be adversely affected by roads. High foraging activity was observed over traffic at one site (A69), and small numbers of commuting *Nyctalus* were observed over the A590 at heights of over 15 m above the road. In other studies *Nyctalus* species have been observed flying high over roads with no recordings in underpasses [1,2,24], and low incidences of collision mortality [6,7]. Roads have also been found to have less of an impact on habitat use by species that also forage in more open habitat, such as *Barbastella barbastellus* [2].

All other species detected in this study crossed at unsafe heights over the road. Differences in crossing heights were found between species, with *Myotis* species (and the three detected *P. auritus*) flying lower over the road than *Pipistrellus* species, increasing their vulnerability to collision mortality.

The Effectiveness of the Survey and Monitoring Process

The bat gantries and one of the underpasses were installed because they were believed to be on significant commuting routes. However, we found activity was low at all gantry sites with the exception of the A66. Either activity has greatly diminished post-construction, adding to the conclusion of mitigation failure, or the assessment of these sites as major commuting routes was perhaps flawed. The absence of robust pre-construction monitoring means that we cannot say which explanation is correct. This raises serious questions about the effectiveness of the survey, assessment, mitigation and monitoring process. Several of the structures we have shown to be ineffective were said to be working in the commissioned reports [22], using the criterion that bats were seen to use them. Are other aspects of the reports equally flawed? Limited resources are available for conservation and it is vital that they are used effectively. Failure to do so makes no contribution to conservation and alienates further those outside conservation who question the use of public funds on conservation, e.g. the recent spending of £0.5 M on bat gantries [44,45].

Conclusions and recommendations

We assessed only a small number of mitigation structures, but the results are sufficiently striking that wider appraisal is essential if mitigation against road construction is to be effective. Wire bat gantries, of the type studied, should not be used, and attempts to divert original commuting routes should, if possible, be avoided. Underpasses built on existing commuting routes can be effective crossing structures, if commuting bats can maintain their original course and flight height. Further investigation into more substantial, natural crossing structures over roads, such as green bridges, and simpler options such as tree 'hop-overs', is needed. Unique aspects of individual sites, such as tree cover, hedges and topography must be exploited to make mitigation solutions as natural as possible and appropriate to the bat species present. Robust and comparable pre- and post-construction monitoring must be carried out that assesses more objectively the need for mitigation and its effectiveness.

WC1060 DEVELOPMENT OF A COST-EFFECTIVE METHOD FOR MONITORING THE EFFECTIVENESS OF MITIGATION FOR BATS CROSSING LINEAR TRANSPORT INFRASTRUCTURE

Final report 2015

Anna Berthinussen & John Altringham
School of Biology, University of Leeds, Leeds LS2 9JT

Executive Summary

Background

Recent research has shown that roads can have negative impacts on bats with landscape scale reductions in bat activity and diversity (Berthinussen & Altringham 2012b), reduced reproductive success (Kerth & Melber 2009), and mortality through collisions with traffic (Lesinski 2007, Lesinski et al. 2010, Russell et al. 2009). As all UK bat species are protected by European law via the Habitats Directive, they must be considered in the Environmental Impact Assessment (EIA) of developments such as roads, and any unavoidable adverse impacts must be mitigated.

EIA is an important aspect in the planning application process for large scale developments. Developers must prepare and submit Environmental Statements detailing the impact of the proposed development on the environment, including protected species such as bats. Environmental Statements should be prepared in an objective and systematic way and provide sufficient information for decision-making and to inform the mitigation process. They should also provide baseline activity data for the species in question which can be compared against data collected post-construction to draw conclusions about the effect of the development and the effectiveness of mitigation. However, in practice the quality and quantity of data are often insufficient, with poor experimental design and a clear lack of objectives, making it difficult to draw conclusions.

Little evidence exists for the effectiveness of currently used mitigation structures for bats on roads, such as underpasses, bridges and wire gantries. Recent reviews of case studies of bat mitigation in the UK found that most reports were qualitative and inconclusive (Altringham 2008, O'Connor et al. 2011, Berthinussen & Altringham 2012a), and failed to make the important distinction between the use of structures by individuals and the effectiveness of structures in maintaining local population sizes. Without this information it is impossible to know whether mitigation measures are effectively protecting local bat populations from adverse effects, as required by law. Reliable methods that can be used in EIA and proven robust in identifying effective bat mitigation are needed to ensure a more efficient development process and more positive outcomes for bats.

Aims

The aims of the project were to develop standardised cost-effective survey methods to assess the effect of linear transport infrastructure on bats (on a landscape scale) and the effectiveness of mitigation measures such as crossing structures (on a local scale). The focus is on road construction but rail has also been considered as another form of linear infrastructure. The methods were to be quantitative, robust, replicable, appropriate for statistical analysis and the comparison of pre, during and post-construction data, and suitable for providing baseline data for Environmental Statements. Clear protocols were to be created for use by conservation practitioners and the consultancy industry. The effectiveness of some currently used mitigation measures were to be assessed while testing the methods, and protocols were to be produced to inform best practice, management and appropriate mitigation solutions for future road (and rail) developments.

Survey methods

We developed protocols that we believe provide an acceptable compromise between providing robust data from which to draw conclusions and cost-effectiveness. We determined the minimum number of surveys that can be conducted per site to provide sufficient data for analysis and we tested the effect on statistical power of reducing survey duration for cost-effectiveness.

Two survey protocols were developed to address the two different aspects specified in the aims:

1. A landscape scale survey method using transects to assess the effect of linear infrastructure on bats at a population level

2. A local scale observational survey method to assess the effectiveness of mitigation measures such as crossing structures over or under linear infrastructure

We stress that these methods should be used in conjunction with existing practices: desk studies and fieldwork to identify known roosts, foraging areas and commuting routes, particularly of rare and vulnerable species. The identification of points where bats cross the proposed road is vitally important, since it is in these areas that mitigation efforts must be concentrated.

The landscape scale transect protocol measures bat activity and species diversity over a large area surrounding the linear infrastructure, and uses statistical modelling to detect changes in bat activity and diversity related to its presence. A reduction in bat activity and/or diversity in proximity to the infrastructure indicates the strong likelihood of a negative impact on nearby bat populations. Pre-construction surveys provide baseline data, and can be compared with data collected during and post-construction to detect overall changes. The transect protocol will also deliver data suitable for habitat suitability modelling.

The local scale observational protocols are more straightforward, and provide a simple and effective method for objective assessment of mitigation structures. Set definitions and criteria are used, and the effectiveness of crossing structures are assessed by comparing the number of bats using the structure to cross, with those using the original pre-construction commuting route, and those crossing at risk of being killed by traffic.

We tested the landscape scale transect protocol successfully at seven road sites (three established single carriageway A roads, an established dual carriageway A road, an established motorway, a motorway during construction and a motorway immediately post-construction) and two rail sites (both established). We found that motorways (established, pre- and during construction) had a consistent negative effect on bat abundance and diversity. The effects of A roads were inconsistent with effects noted on two of the three single carriageways studied but not on the dual carriageway, and further research is needed to explain these differences. These findings corroborate previous research (Berthinussen & Altringham 2012b), showing that roads can have large scale negative impacts on bat activity, although more research and population modelling is necessary to determine how these effects influence population sizes and viability. One of the two railway sites was found to have a negative effect on bat activity and diversity, suggesting that railways can have similar impacts on bats as roads, but further research is needed.

We also assessed the effectiveness of nine existing mitigation features for bats on roads (three underpasses, three bat wire bridges, an overpass, an environmental bridge and a green bridge). We found one of the underpasses and the green bridge to be effective in guiding a large majority of bats under or over the roads. We concluded that underpasses were more likely to be used successfully by commuting bats than overpasses and bat gantries/wire bridges, both of which were consistently ineffective. It is worth noting that a bat gantry erected close to a known commuting route was not being used by bats nine years after construction (Berthinussen & Altringham 2012b). Green bridges appear to have considerable potential as mitigation structures, but more research is needed. Although the sample sizes are small, and further research is needed to draw firmer conclusions, the results suggest that the effectiveness of crossing structures increases with their size, connectivity and similarity to natural linear features.

In addition, a radar feasibility study was also conducted by the Animal and Plant Health Agency (APHA) to test, for the first time, the use of horizontally scanning X-band radar to track bat movements across large areas of the landscape, with the aim of studying their responses to road, rail and other linear infrastructure. Initial results are promising, suggesting that the technique can track small bats close to linear infrastructure, but that use as an effective survey tool will require further development and it will not be suitable in all situations.

Reporting

We have provided and discussed the results from all sites at which we tested our survey methods. We have provided full survey protocols for both methods with a rationale, technical advice on data format, organisation and storage, and full instructions for data analysis. Example datasheets and spreadsheets are provided as well as step-by-step instructions for use with the suggested software. We also provide and explain criteria for drawing conclusions about the effects of linear infrastructure and the effectiveness of mitigation measures. Based on our findings and those of previous studies we provide advice for improving on current mitigation techniques.

1. Background and rationale

Habitat fragmentation is widely accepted to be one of the most important factors in the loss of biodiversity. Roads and railways, by their very nature as extensive linear networks, have the potential to fragment the landscape and prevent the free movement of species. The detrimental effects of roads on biodiversity are becoming increasingly well-recognised (e.g. Forman *et al.* 2003) and it has been known for some time, from work on birds, that flying animals are not immune to these effects (e.g. Reijnen & Foppen 1994; Reijnen *et al.* 1996). It was therefore assumed that bats would also be affected, particularly given the reliance of many species on linear landscape features such as treelines and hedgerows for commuting (Frey-Ehrenbold *et al.* 2013), since these are often severed by road and rail. It has been shown that bats are indeed reluctant to cross roads (Kerth & Melber 2009; Russell *et al.* 2009; Bennett & Zurcher 2013), that the presence of a motorway can reduce reproductive success by reducing habitat quality (Kerth & Melber 2009), that roads kill bats in significant numbers (Lesiński 2007; Russell *et al.* 2009; Lesiński *et al.* 2010, Medinas *et al.* 2013) and that mortality rates are in many cases likely to be unsustainable (Russell *et al.* 2009). Hotspots for mortality are found where flyways intersect with roads (Lesiński 2007; Russell *et al.* 2009). There has been little research into the effects of railways on both bats and other wildlife, and given the extensive network of rail systems in many countries it is important that rail effects are also assessed objectively. A literature review on "Bats, roads and railways" can be found in Appendix A.

All bats are strictly protected across the European Union (EU), including the United Kingdom, via the Habitats Directive. The Conservation of Habitats and Species Regulations 2010 (known as the Habitats Regulations) transpose the EU Habitats Directive into domestic law. If a development affects bats, it may be possible to avoid harm or minimise impacts via agreed method statements or by imposing restrictions on how, when or where the works are carried out. In such circumstances the specified works should be controlled by the local planning authority through the imposition of appropriate planning conditions. In most cases, a mitigation and compensation strategy would need to be put in place to ensure that favourable conservation status is not adversely affected by the development (including for example, creation of new habitats to offset any damage). A licence may be required if the works would otherwise result in offences under the Regulations (usually for damage or destruction of roost sites). Licences will only be issued if the licensing authority is satisfied that the proposed development meets the three tests set out in the Habitats Directive which are: that it fulfils one of the purposes set out in the Directive; that there is no satisfactory alternative; and that it will not be detrimental to the maintenance of the population of the species concerned at a favourable conservation status in their natural range.

A number of mitigation strategies have been developed to reduce the influence of roads on bats. These are designed to make roads easier and safer for bats to cross by maintaining commuting routes severed by the roads. Continuity of these flightlines is maintained by retaining hedges and trees as close to the road as possible, and by building underpasses, overpasses or wire bridges (or gantries). Road lighting schemes are also designed to keep commuting routes as dark as possible, since it is known that many species avoid light (Stone *et al.* 2009; Stone *et al.* 2012). Light may also be used to try to deter bats from crossing at particularly dangerous locations. More general mitigation and compensation may be carried out, through tree planting and pond digging, to replace habitat lost to development. However, little evidence exists for the effectiveness of these mitigation strategies in protecting bat populations.

Several studies have shown that a wide range of bat species use underpasses to cross beneath roads (e.g. Bach *et al.* 2004; Kerth & Melber 2009; Boonman 2011; Abbott *et al.* 2012a; Berthinussen & Altringham 2012a). However, occasional use by an unknown proportion of bats does not guarantee either habitat accessibility or safe crossing routes for the bat population as a whole. For example, despite the existence of three underpasses along 5 km of motorway that bisected a forest, Bechstein's bats, *Myotis bechsteinii,* rarely used them and lost access to important roosting and feeding habitat (Kerth & Melber 2009). Abbott et al. (2012) found that almost a third of road-crossings by lesser horseshoe bats, *Rhinolophus hipposideros,* were directly over a motorway, despite their regular use of three underpasses along a 1 km stretch. It cannot be

assumed that the reluctance of forest-adapted bats to fly in the open means that they will take detours to use underpasses: many bat species appear reluctant to deviate from their original flight paths after road severance (Kerth & Melber 2009; Abbott 2012; Berthinussen & Altringham 2012a). Conventional overpasses carrying minor roads or footpaths do not appear to be effective crossing points for bats, relative to routes under roads (Bach *et al.* 2004; Abbott *et al.* 2012a) and wire gantries or bridges tested to date (up to nine years after construction) are ineffective (Berthinussen & Altringham 2012a). Land or green bridges (wide, vegetation-covered bridges) are likely to be more effective given their similarity to natural bat commuting features, but are potentially more expensive than other structures and have yet to be tested.

The success and cost-effectiveness of such mitigation is the subject of media interest and recent parliamentary questions have queried the cost-effectiveness of structures designed to help bats cross roads. In principle, the success and cost-effectiveness of mitigation are assessed by monitoring against clearly formulated goals. In practice however, data quality and quantity have rarely been sufficient to make an objective assessment of either, in part due to poor experimental design and a lack of clear objectives. The lack of proven methods can hamper development and can result in additional costs, e.g. when expensive retrofitting of new structures is deemed necessary. Recent work has brought a more rigorous and analytical approach to the subject, demonstrating directly, for the first time, that roads can have a major, negative impact on bat activity and diversity (Berthinussen & Altringham 2012b) and that the most widely adopted mitigation measures are not effective and therefore not cost-effective (Berthinussen & Altringham 2012a). A reliable method that can be used in environmental impact assessment and proven robust in identifying effective bat mitigation would ensure a more efficient development process and more positive outcomes for bats.

The aims of the project were to develop and validate bat survey techniques for pre-, during and post-construction of linear infrastructure, and to set out clear protocols for a standardised survey in sufficient enough detail to allow it to be applied consistently by conservation practitioners and the consultancy industry. The methods were to be quantitative and appropriate for statistical analysis. The project also required the methodology(s) to be applied at a sufficient number of sites to allow a robust assessment of the success and cost effectiveness of different mitigation measures for bats on roads. The project was to focus on road construction, but also to consider the implications of rail.

The project contributes to the fulfillment of three important commitments of government and transport agencies in relation to the natural environment:

- the need for the creation of coherent and resilient ecological networks (identified by the Natural Environment White Paper in England)
- the need to improve evidence-based decision making in conservation and other areas of policy and practice
- the maintenance and restoration of European Protected Species to favourable conservation status

The project was carried out by a team from the University of Leeds, in collaboration with APHA (Animal and Plant Health Agency) for the radar work.

6. Discussion

We have developed methods that are capable of detecting changes in bat activity and diversity in proximity to linear transport infrastructure on a landscape scale, and that allow for the objective assessment of the effectiveness of mitigation structures for crossing bats on a local scale. As specified in the original aims, the methods are quantifiable, robust, replicable, appropriate for statistical analysis, and can be used to compare pre, during and post-construction bat activity as well as provide baseline data. We have tested the landscape scale method at seven road and two rail sites and the local scale method at nine road mitigation sites. The methods have been refined by reducing survey number and duration, to reach an acceptable compromise between gathering robust data from which to draw conclusions and cost-effectiveness. The statistical analysis methods have also been refined and tested to ensure that they are as accurate and robust as possible. Analysis is necessarily quite complex, but we have made it as simple as possible and provided detailed instructions and code for use in R (R Development Core Team, 2006).

The only significant practical issues we encountered were difficulty in obtaining access to some sites (such as road verges along dual carriageways, roads under construction or transect routes through private land) within the timescale of the project. However, these issues should be overcome by planning well in advance, incorporating bat surveys into the scheme from the outset and liaising with landowners, road agencies and construction companies from an early stage.

In addition to our survey methods, a radar feasibility study was also conducted by the Animal and Plant Health Agency (APHA) to test, for the first time, the use of horizontally scanning X-band radar to track bat movements across large areas of the landscape, with the aim of studying their responses to road, rail and other linear infrastructure. Initial results are promising, suggesting that the technique can track small bats close to linear infrastructure, but that use as an effective survey tool will require further development and it will not be suitable in all situations. See Appendix J for a full discussion of the results.

6.1 Interpreting the results

It is important not only to have robust and standardised survey protocols, but also for the interpretation of results to be objective. We have suggested standardised criteria from which to draw conclusions from the results for each survey method in our protocols (see Appendices D and F). Although statistical significance is useful for identifying and confirming the reliability of differences or relationships, it is not always of critical importance. For example, even if significantly more bats cross a road safely than unsafely, the impact on population trends ultimately depends on the proportion of the population that is killed in collisions. At present, the demographic information is not available to calculate the magnitude at which a negative effect becomes detrimental to a bat population, or what mortality rate is sustainable. Further studies, with appropriate modelling could provide some answers. In the absence of this information, we have based our precautionary advice on the fact that bats are long lived, have low reproductive rates and high infant mortality, and are therefore slow to recover from population crashes. Even small increases in annual mortality or a reduction in reproductive output will have profound effects on local colony size and overall population size (Sendor & Simon 2003; Papadatou *et al.* 2011).

For the assessment of mitigation structures, we suggest that up to 10% of bats may cross the road at risk of collision with traffic, but once this is exceeded, mortality rates are considered to be potentially detrimental to local bat populations. As explained above this is a precautionary figure. Although not all bats crossing at risk of collision will be killed, there is the potential for mortality rates to increase by 10% within a population. Schorcht et al. (2008) modelled the effect of a highway in Germany on a *R. hipposideros* nursery colony and results indicated that an additional mortality of 5 - 7% of this female population caused by the road would lead to colony extinction. We also suggest that for a crossing structure to be effective, at least 90% of crossing bats must use it to fly safely over or under the road. We suggest using the more conservative definition of 'use' (bats flying at a safe height within 5 m of the crossing structure rather than 2 m) which

encompasses bats flying over a relatively wide area. If bats *are* using the structure to navigate across the road then 90% should be an achievable target.

If a majority of bats are 'using' the structure but the suggested threshold is not met, then this suggests that the structure *could* be effective with some improvements. A concerted effort to improve structures should be made in these situations and the effects carefully documented to inform future mitigation. However, until the structure has been improved and the thresholds met, the structure cannot be considered to be effective and may lead to local population decline.

For landscape scale effects, we suggest that if the decline in activity in proximity to the road/railway becomes statistically significant or greater than 20%, then detrimental effects are assumed. As above, this is based on a precautionary principle and related to the ability to detect change in intrinsically highly variable foraging activity patterns in bats. If populations are to be maintained, any statistically significant decline related to the presence of a road has the potential to affect populations. Because of the highly variable nature of bat activity (due, for example, to behavioural changes), even large changes may be hard to detect statistically. We therefore suggest, as a precautionary measure, that a decline of 20%, irrespective of statistical significance, is a cause for concern. Landscape scale changes in activity do not translate directly into increased mortality, but will reflect more complex indirect effects on local bat colonies, such as reduced reproductive success, increased competition following displacement or moves to sub-optimal roosts and foraging areas.

NB. Although we give guideline figures every case should be considered carefully in relation to the local and national scarcity of the species at risk, proximity of the site to major roosts, the proportion of bats using particular flight lines and other considerations.

6.2 Landscape scale effects

Road effects

We detected changes in total bat activity that were correlated with proximity to roads at five of our seven road sites. A negative effect on bat activity was found along single carriageway roads (A487 and A134), an established motorway (M5) and motorways both immediately after construction (A1 Dishforth to Leeming) and during construction (A1 Leeming to Barton). All five of these sites showed substantial changes in bat activity and diversity with distance from the road (with statistical significance at all but one site, the A134). This corroborates our published work on the M6 (Berthinussen & Altringham 2012b), showing that roads can have large scale negative impacts on bat activity that are likely to reflect change in population size. An effect of this scale is likely to be due to a combination of a barrier effect and increased mortality due to roadkill causing a decline in local bat populations (as discussed in Berthinussen & Altringham 2012b). With an effect found on single carriageway A roads, it is possible that minor roads (such as B roads) may also have a negative impact on bats. However, at present there is no evidence for this and further research is needed.

Our results highlight the importance of carrying out species-specific analyses. Road effects on more abundant species, such as *P. pipistrellus,* may mask the effects on less abundant species when total bat activity is modelled, and species with opposing effects, such as *Nyctalus*/*Eptesicus* species may confuse interpretation of the model even further.

We advise that species-specific models are created for all species (with sufficient abundance) and *Nyctalus*/*Eptesicus* species should be removed from the data for the analysis of total bat activity. Our results and previous research show that these species are unlikely to be negatively affected by linear transport infrastructure such as roads, and may even be positively affected in some cases. *Nyctalus* species are known to fly high and forage in open spaces (e.g. Kronwitter 1988). We frequently observed them foraging high over the road surface suggesting they may be attracted to the open spaces above roads to feed. Removing these species from our data had dramatic effects on the road effects detected at two of our sites. On the A40, although model estimates remained non-significant, the road effect changed from positive to negative, and on the A134 the negative road effect was predicted to increase almost five-fold with the exclusion of

these species. At all other sites, the abundance of *Nyctalus*/*Eptesicus* species was low and removing them from the data had no impact on the road effects found. However, it is still important to carry out species-specific analyses for *Nyctalus/Eptesicus* as road effects may not always be neutral or positive. Unexpectedly high numbers of *Nyctalus noctula* were found in counts of road kill along a forested road in Poland (Lesiński *et al.* 2010).

When activity was high enough for individual analyses, we found that *P. pipistrellus*, *P.pygmaeus* and *Myotis* species all had reduced activity in proximity to the road at those sites where total bat activity was affected (with the exception of the A40). Although the magnitude of the road effect varied between species, we cannot make direct comparisons between them since model estimates and predictions may not be exact for those with a low occurrence. However, it is likely that gleaning woodland specialist species such as *Myotis* and *Plecotus* will be more affected than generalist species such as *P. pipistrellus*. Our methods are able to detect a road effect for all species, but for an accurate assessment of the magnitude of this effect on species that are less common, more data may need to be collected by increasing the number of transects at each site.

This is the first study in which road effects have been measured both during and immediately post-construction. Both stages showed significant and substantially lower bat activity and diversity in proximity to the road, with consistently large effects for all species analysed individually (*P. pipistrellus, P. pygmaeus* and *M. brandtii*/*M. mystacinus*). This suggests that the construction stage is a particularly disruptive time and that road effects occur rapidly after the commencement of construction. At our study sites large areas of land were being or had been cleared for road widening resulting in habitat loss and large, open spaces separating habitat on the two sides of the road. This highlights the need for greater consideration of the effects of the construction phase of linear transport infrastructure, and the importance of mitigating these effects prior to construction. Installing mitigation after construction has already commenced or once the road is almost complete is likely to be too late to protect local bat populations.

Changes in total bat activity were not found in proximity to one of the single carriageway roads studied (A1065). It is unlikely that this result is due to a failure of the method, given that the results on the two other single carriageway roads (A487 and A134) used the same methods and recorded a much lower number of bat passes. Abundance of *Nyctalus*/*Eptesicus* species, which may not be negatively affected by roads, was low (<1%) and therefore unlikely to have influenced the results. Individual analyses for *P. pipistrellus* and *P. pygmaeus* also did not reveal any significant or substantial changes in activity in proximity to the road. There may have been an effect on more sensitive, woodland adapted species such as *Myotis* and *Plecotus*, but more data are required to test this. Without pre-construction data and longer term monitoring we do not know whether the road has affected bats since construction, but there is no evidence to suggest that current bat populations are influenced by the road. Without further research, it is not possible to explain differences in the observed effects between roads.

Rail effects

Total bat activity, bat diversity and the activity of *P. pipistrellus, P. pygmaeus* and *M. brandtii*/*M. mystacinus* were all substantially and statistically significantly lower in proximity to the mainline in North Yorkshire. Railways can therefore have an impact on bats on a landscape scale that is comparable to that of roads. It is likely that similar mechanisms are causing these effects. Both road and rail construction result in habitat loss and degradation, and create open gaps that fragment habitat. Mortality due to collisions with trains has not been investigated. As we found with roads, not all railways appear to have a negative impact and further research is needed to understand these effects. We found no changes in bat activity or diversity in proximity to the railway in Kent, despite similarities to the rail site in North Yorkshire (e.g. size, design, train frequency), and similarly large numbers of bat passes being recorded. We cannot compare pre- and post-construction populations, but there is no measurable landscape scale effect at present. Bats may have adapted to the presence of the railway or other factors may be important. For example, the higher quality habitat surrounding the railway in Kent may be a critical factor, since high habitat quality may reduce the negative impact of roads (and therefore rail) on bats (Berthinussen & Altringham 2012b). Although habitat types along transects was very similar according to our grading system, the landscape surrounding the

railway in North Yorkshire is mainly open agricultural land, whereas in Kent there are richer bat habitats with large areas of woodland.

Time and habitat effects

Time after sunset and the habitat type at spot checks were found to have significant effects on bat activity at most sites. The habitat types found at each site are shown in Appendix H. Bat activity generally increased with habitat grade, and therefore with the height and continuity of tree and hedgerow cover along transects, a finding supported by many other studies (Russ & Montgomery 2003; Berthinussen & Altringham 2012b; Frey-Ehrenbold *et al.* 2013). Bat activity generally peaked at 90 – 100 min after sunset, with *Pipistrellus* species peaking earlier than *Myotis* species. This can be explained by the later emergence time of *Myotis* species, and may also reflect greater mobility following emergence, before bats settle to forage at their regular feeding sites. It is important that these effects follow expected patterns and are modelled alongside road and rail effects so that accurate models are produced from the data. These effects will not, however, bias the predicted road or rail effects as the GEE model takes into account the independent effects of each variable.

6.3 The effectiveness of mitigation structures

We surveyed nine mitigation structures and all yielded sufficient data for an informative assessment. We compared the proportion of bats using a structure to cross the road safely with the proportion crossing at risk of collision. Although this allows us to draw some conclusions about the current effectiveness of the mitigation, it does not tell us whether the activity of commuting bats has changed since road construction, or whether the mitigation structure has increased road permeability. In the future surveys should be conducted along bat commuting routes and potential mitigation sites before construction as well as during and for some years after. This will allow a more informative assessment of mitigation effectiveness to be made.

Setting aside the question of pre- and post-construction differences in bat activity, an important question is what proportion of bats need to be crossing the road safely for the mitigation structure to be deemed effective. This is difficult to answer because there are two important unknowns: what proportion of those at risk is killed at some point during their frequent crossings and what level of mortality is sustainable? As discussed earlier, we suggest that mitigation structures should guide at least 90% of crossing bats safely over roads to be considered effective, but local circumstance and species must be taken into account.

Over the road structures

We surveyed six over the road structures, varying from relatively simple wire bat bridges to a wide, substantial vegetated 'green' bridge (see Appendix F for details of each site). Although the sample is small, and further research is needed to draw reliable conclusions, the results suggest that the effectiveness of crossing structures increases with their size, connectivity and similarity to natural linear features.

Bat activity was very low (or absent) at all three bat wire bridges on the A11 in Norfolk. Given the number of bat mitigation structures that have been installed on this scheme we assume pre-construction activity was high to justify their construction. This suggests that there have been significant declines in bat activity since road construction began, and that mitigation is failing at maintaining local bat populations. However, without comparable pre-construction data this is unproven. Regardless of this, we can conclude that neither of the installed bat wire bridges is effective in guiding bats safely over the road. At the bridge with the highest activity, 80% of bats crossed the road at risk of collisions with traffic and only one bat of the 35 that crossed could be considered to be 'using' the gantry. None of the five bats observed at the other bat wire bridge used the wires to cross the road, and nearly all crossed at unsafe heights. These results corroborate previous research (Berthinussen & Altringham 2012a), which showed that four wire bat bridges in northern England were ineffective and used by a very small proportion of bats, with the majority crossing roads unsafely. One of the wire bridges studied by Berthinussen & Altringham (2012a) had been in situ for nine years, less than 15 m from the known commuting route. Almost all bats still used this old commuting route, suggesting that bats do not necessarily adapt to new structures with time. Note that the crossing wires on the A11 bridges form a relatively dense, v-shaped mesh, quite different to the single-wires-with-balls

previously studied (see Appendix F for photos of both). We now have evidence from six different wire bat bridges, of two designs, to show that these structures do not provide effective mitigation for bats.

Bat activity was also very low on the overbridge over the A11, which as discussed above, suggests that bat activity is likely to have declined significantly since construction, assuming this site was chosen for an overbridge based on significant pre-construction bat activity. The overbridge was also ineffective in guiding bats safely over the road. Only three bats were observed crossing near the overbridge, and none used it to cross the road. The overbridge carries a minor road over the dual carriageway below, and at the time of study had no vegetation across it and was unconnected with surrounding habitats or bat flight paths. It is unclear whether work to improve connectivity or enhance the bridge itself was planned. If such work was planned, the delay in implementing it may have had long-term effects on the suitability of the site as a bat crossing point. Previous studies have also found overbridges, built to carry minor roads or footpaths with no adaptations for bats, to be ineffective (Bach *et al.* 2004; Abbott *et al.* 2012a).

The environmental overbridge on the A487 in Wales is a unique structure, purpose built for wildlife. It differs from a conventional overbridge in that it has solid raised sides and a row of trees/shrubs in planters running across it. It does not carry traffic and is intended for use only by wildlife, but is narrower and less vegetated than a typical 'green' bridge. More bats flew over the environmental overbridge than over the road below, but 20% still crossed at risk of collision with traffic. According to our criteria this crossing structure cannot be considered to be effective at present. However, given that the majority of bats commuted across it, it has the potential to be made effective, perhaps by increasing the density and height of the vegetation. The position of the bridge maintains a pre-construction commuting route, so that bats are not required to alter their flight height or direction to fly over it, which is likely to contribute to its success as a guiding structure. Further study may help to understand why 20% of bats cross the road and how the proportion using the overbridge can be increased. It was used by most species, all showing similar patterns of use. However, use by the primary target species, *R. hipposideros*, was low. In the absence of pre-construction data we do not know if the number of bats crossing the road has remained unchanged by road construction. Additional surveys and more data would be required at this structure to determine its effectiveness for the specific target species.

Scotney Castle landscape bridge is a typical 'green' bridge. It is a relatively wide, substantial structure and although it carries a paved minor road, it is well vegetated with dense and continuous mature trees and shrubs along each side that are well connected with treelines and surrounding woodland. Although we do not know if bat activity has changed at this site since the road was originally built, we can conclude that this structure is effective in guiding bats safely over roads with 97% of bats using it to cross. At least five bat species were recorded, and foraging activity was also high over the bridge. There has been little quantitative research into the use of green bridges by bats. Ten species of bat were found to use green bridges in Germany, with higher use than conventional overbridges, but the study did not look at pre-construction data or the number of bats crossing over the road below (Bach & Muller-Steiss 2005).

Although we have only studied one green bridge the results are encouraging, and there are several factors that are likely to contribute to the effectiveness of this structure: it is well connected, providing a continuous link with bat habitat on either side of the road, the bridge follows the natural topography of the land with the road in a cutting below so that bats flying across it are not required to alter their flight height or direction, the vegetation over the bridge is mature and dense, screening noise, light and the visibility of the road below, and the minor road across the bridge carries little traffic and is closed to the public at night. Artificial lighting below the bridge may also have contributed to its success by deterring bats from crossing the road below, but further research is needed to confirm this as the effects of lighting are species-specific and can be complex.

Although green bridges have the potential to be effective crossing structures for bats over infrastructure, there are other issues that also need to be considered such as the cost, the land take required for construction of the bridge and the detrimental effects there may be on bats while it is being constructed. However, one expensive yet effective structure will always make more sense than cheaper structures that

do not work: mitigation structures must be cost effective *and* functional. Green bridges may also provide mitigation for other wildlife. Eight mammal species have been found to use Scotney Castle landscape bridge, including deer, badger and breeding dormice (National Trust, 2012), and similar structures are commonly built throughout Europe and North America for large mammals. Combining mitigation for a range of wildlife may be a cost effective solution, but would require careful planning, project management and monitoring.

A simpler over-the-road structure that may be effective on narrower roads is the 'hop-over': mature trees that overhang the road so that their crowns bridge the gap above the road (Limpens *et al.* 2005). However, this solution at present is untested and unlikely to be suitable for species that fly below the tree canopy. There may also be safety issues with trees in close proximity to and overhanging road carriageways although this is not an uncommon sight on UK roads.

Underpasses

The majority of bats at all three sites flew through the underpasses rather than over the road above. However, at both the A487 underpass and the Hopyard Farm underpass on the A465, a third of bats still crossed over the road above at risk of collision with traffic. We know that bats can be killed on roads in high numbers (Lesiński 2007; Russell *et al.* 2009; Lesiński *et al.* 2010, Medinas *et al.* 2013), and it is possible that with this proportion of bats crossing unsafely, mortality may be too high to be sustainable.

The Evesham nurseries underpass on the A465 showed high levels of use by commuting bats with just 5% crossing at risk of collision mortality on the road above. We can therefore conclude that it is effective in allowing bats to cross the road safely. This underpass is larger in both height and width than the other two underpasses studied, and also bridges a pre-existing commuting route along a tree-lined public footpath, so that commuting bats are not required to alter their flight height or direction. It has also been subject to less disturbance than Hopyard Farm underpass which was lengthened considerably during road widening, and the A487 underpass, which was constructed below a new bypass. Both Hopyard Farm underpass and the A487 underpass are also narrower and lower and do not appear to preserve original commuting routes in their entirety (even if positioned on the same alignment as original commuting routes, they may still require bats to alter their flight height to fly through them). Although these two underpasses are providing safe passage for some commuting bats (and the A487 underpass was used by all detected *R. hipposideros*, the primary target species at this site), it seems that their size and position may result in them being used less frequently by crossing bats. Similar results were found by Berthinussen & Altringham (2012a): a high underpass preserving an existing commuting route carried 96% of crossing bats below a road, but two lower underpasses not built on original commuting routes were ineffective despite attempts to divert bats to them. Underpass height was also found to be a critical factor determining the use of underpasses by bats in Ireland (Abbott *et al.* 2012a; Abbott *et al.* 2012b).

It is important to note that the Evesham nurseries underpass contained motion-activated lighting for pedestrians. This was not operational at the time of our surveys and has been permanently deactivated (because of the effects on bats, after consultation with those in charge of the footpath: Len Wyatt, pers. comm. Jan 2014), but such lighting could deter commuting bats and reduce the effectiveness of underpasses as a mitigation features.

We found up to seven species using underpasses to commute beneath roads. At all three underpasses, *Myotis* species and *R. hipposideros* flew through the underpasses in preference to crossing over the road above. *Pipistrellus* species, however, used the two smaller and narrower underpasses less frequently. At the A487 underpass, only a quarter of *P. pygmaeus* crossed through the underpass with the majority flying over the road, and *P. pipistrellus* were not recorded in the underpass at all. At Hopyard farm underpass, although we do not have species records over the road, few *Pipistrellus* flew through the underpass, which was used predominantly by *R. hipposideros*. At the larger Evesham nurseries underpass high numbers of *Pipistrellus* bats flew through the underpass with 96% of *P. pygmaeus* and 93% of *P. pipistrellus* preferring to do so rather than fly over the road above. Similar results were found in a previous study in Ireland: clutter-adapted bat species such as *R. hipposideros* and *M. nattereri* were the only species to be detected in narrow drainage pipes beneath a road, whereas all detected species flew through a larger underpass, including high numbers

of *Pipistrellus* (Abbott *et al.* 2012b). This has important implications for underpass design in relation to the species present.

7. Conclusions and best practice principles

This project confirms that roads and railways can have a negative impact on bat activity and diversity at the landscape and probably therefore the population scale. Further research is needed into the effects of rail, but bats should be given the same consideration in new railway developments as they are for roads. The methods we have developed can be applied to both, as well as other linear infrastructure.

Negative effects were found along established roads of all sizes studied (single and dual carriageway, and motorways), and also both during and immediately after road construction highlighting the importance of considering bats from the outset of such schemes and installing mitigation prior to commencing any construction work. Further research is needed into the effects of minor roads, the specific mechanisms involved in the impacts of road and rail on bats, and how these impacts affect the sustainability of local bat populations.

We conclude that the two most widespread forms of wire bat bridge do not provide effective mitigation and should not be built, particularly since there is evidence that bats do not adapt to them with time. Our results suggest that green bridges and underpasses have the greatest potential but they must be designed correctly and many factors are important such as size, position, connectivity, topography, and the density and maturity of vegetation. Such factors will be site and species-specific, and further research on specific designs is needed.

Bats need to be considered from the early planning stage of infrastructure developments, and surveys should be undertaken well in advance of decisions involving route planning, avoidance and mitigation. It is also essential that clear objectives for survey work are set, comparable pre and post-construction data are collected, and that long term monitoring of mitigation schemes is carried out to provide the evidence needed to inform future mitigation and improve on current standards. Long term monitoring is important regardless of whether an effect is found initially, as effects may be cumulative and delayed.

Standardised and objective protocols, such as those we have developed, should be used routinely and results should be documented and reported centrally. Future mitigation should be based on solutions that are proven to work, and best practice methods should be regularly reviewed and updated with the best evidence available.

We provide good practice principles for surveying bats along linear transport infrastructure based on the methods we have developed, and for mitigation based on the evidence currently available.

7.1 Best practice principles for surveying bats along linear transport infrastructure

Our survey methods are designed to provide comparable pre and post-construction data, and will provide baseline activity for the Environmental Statements that are used to assess the potential impacts of a development. They should be conducted in addition to other pre-construction surveys (using acoustic, radio-tracking and other methods) that are used in the early stages of road planning to identify bat roosts and important foraging habitats that may be destroyed or disturbed by the scheme.

We advise using a combination of landscape scale surveys to measure spatial changes in bat activity and diversity in relation to the road/railway *and* local scale surveys of specific bat flight paths to assess the effectiveness of mitigation features designed to guide bats safely under or over roads/railways. Key points for each are given below. Full, detailed instructions for survey and analysis are given in Appendices D and F.

Landscape scale effects

- Conduct the transect survey protocol (given in Appendix E) prior to construction to provide baseline data. This should be done over at least two seasons where possible.

- Repeat the transect survey protocol during and after construction. We advise surveying for a minimum of three years post-construction. Frequency of survey will depend upon the project goals but the effects of linear infrastructure on bats may persist for many years, and long term monitoring is important.

- A minimum of ten transects of 1 km length (with 10 min spot checks at 100 m intervals) must be completed per site, at the same time each year (ideally June-August). More transects may be needed if specific bat species are of interest, particularly those that are less common.

- *Nyctalus* and *Eptesicus* species should be excluded from the data for the following analyses of total bat activity, as positive impacts on these species may affect the results.

- Compare pre-construction data with during and/or post-construction data using appropriate statistical tests (such as t-tests or one way anova) to look for changes in bat activity over time. If bat activity (either total and/or for individual species) has significantly declined, the infrastructure has had a negative effect since construction.

- Analyse post-construction data using the GEE modelling method to look for changes in total bat activity in proximity to the infrastructure, and repeat the analyses for all species with sufficient data. The analysis may also be repeated for bat diversity.

- If the effect of distance from the infrastructure is positive (with a significance level of $P < 0.05$) or bat activity (either total and/or for individual species) is predicted to increase by at least 20% (regardless of statistical significance) between 0 and 1 km from the infrastructure, the effect is considered to be detrimental to local bat populations. Rare or vulnerable populations may need special consideration.

- Results of statistical tests and models should be presented in reports in text and table format, and data should be displayed visually using boxplots.

Local scale & mitigation

- Identify bat commuting routes that will be severed by the scheme prior to construction (as detailed in Appendix G) to inform the placement of mitigation structures.

- Before construction, complete a minimum of six 60 min dusk or dawn surveys at each location where mitigation is to be installed (following the local scale survey protocol in Appendix G). Longer surveys, running later into the night, may be necessary if vulnerable, woodland-adapted species are involved.

- Repeat the local scale survey protocol at each location where mitigation is installed at the same time each year during construction and post-construction. We advise surveying for a minimum of three years post-construction (frequency of survey will depend upon the project goals but the effects of linear infrastructure on bats may persist for many years, and long term monitoring is important).

- For schemes that have already been completed, surveys may be carried out post-construction only to provide a basic assessment of the mitigation. However, this will not give a complete picture of effectiveness or the impact of the scheme and is insufficient for future schemes.

- Compare the total number of bats crossing at each site before, during and after construction, and the number of bats considered to be using the mitigation structure in question (according to set definition of 'use'), and the number crossing the scheme at risk of collision with traffic.

- Mitigation structures are considered effective when the number of bats using the commuting route has not declined substantially (by a statistically significant decline of 10% or more) since construction, *and* at least 90% of crossing bats are using the structure to cross safely. Special consideration will need to be given to rare and vulnerable populations. Not all species may be affected in the same way.

- Results should be presented in reports in text and table format, and data should be displayed visually using boxplots. An optional kernel density estimation plot may also be produced to show the position and density of crossing bats at a site.

The results from both methods above should be considered, to give an overall picture of the impact of the infrastructure scheme on a landscape and local scale, and the effectiveness of any mitigation structures over the scheme.

The aim is for linear transport infrastructure schemes not to have a detrimental impact on local bat populations, and for effective mitigation of any negative impacts. This means that bat abundance in the landscape surrounding the scheme should not drop significantly during or after construction, the number of bats using a commuting route should not decline substantially during or post-construction, and at least 90% of bats crossing the scheme should do so safely without risk of traffic collision. It is also important to look at individual species, particularly those at risk due to rarity, ecology or proximity to the development.

7.2 Best practice principles for bat mitigation along linear transport infrastructure

Sample sizes for most mitigation structures are currently small, and further research is needed to make specific recommendations, especially on structure design. Based on the evidence available at present, we suggest that the best solution is a combination of underpasses and green bridges along the length of linear infrastructure to maintain bat commuting routes and increase the permeability of the infrastructure. The design and placement of mitigation structures will be site and species-specific. However, the following general principles are likely to contribute significantly to the success of these crossing structures:

- ***Mitigation should be integrated into the scheme from the earliest opportunity***
  Mitigation should be considered during the planning and design stage of the infrastructure so that it can be incorporated effectively.

- ***Crossing structures should be placed on the exact location of existing bat commuting routes***
  Attempts should not be made to divert bats from their existing commuting routes.

- ***Crossing structures should not require bats to alter flight height or direction***
  This will depend on the topography of the site. If the road is to be elevated above ground level an underpass may be used to preserve the commuting route below it, or if the road is in a cutting a green bridge may be used to carry the commuting route over the road.

- ***Crossing structures should maintain connectivity with existing bat commuting routes*** Connectivity must be maintained with undisturbed bat flight paths (e.g. treelines, hedgerows, woodland rides and streams), and bat habitat (e.g. woodland) within the surrounding landscape. Crossing structures should not be exposed or sited within open ground.

- ***Over-the-road structures such as green bridges should be planted with vegetation***
  Vegetation should be continuous and connected (see above) and sufficiently mature before road construction (e.g. by planting either relatively mature trees or fast growing tree species in advance of construction commencing).

- ***Underpasses should be of sufficient height***
  Underpasses should be as spacious as possible with height being the critical factor. The minimum requirements for underpass height will be species-specific. Required heights will generally be lower for woodland-adapted species (~3 m) compared to generalist edge-adapted species (~6 m), but larger underpasses will accommodate more species

- ***Green bridges should be of sufficient width***
  In addition to being vegetated, green bridges should be as wide as possible, to provide a large area for bats to commute across. Further research is needed to determine exact dimensions. We found a 30 m wide green bridge to be effective in this study.

- ***Crossing structures should be unlit***
  The effects of light on bats are species-specific and lighting should be avoided.

- ***Access and connectivity must be maintained***
  It is important that access to crossing structures is maintained (e.g. grilles should not be installed on underpasses) and that connecting vegetation is retained indefinitely or for as long as the mitigation structure is required.

- ***Disturbance should be minimised during installation of mitigation structures***
  For example, by limiting noise and light pollution along the bat flight path, minimising vegetation clearance, installing suitable temporary crossing structures (which should also be subject to

monitoring and evaluation), completing the installation as quickly as possible and ideally avoiding the summer months when bats are most active.

This advice is based on the evidence currently available. The aim is that with further research and appropriate monitoring and documenting of results from future mitigation schemes, the evidence base can be improved. This advice should be reviewed and updated regularly to improve on current standards.

TIMINGS AND LONGEVITY PREDICTIONS FOR MINSMERE NON-TECHNICAL SUMMARY

1. INTRODUCTION

Black & Veatch (B&V) were appointed in 2001 by the Environment Agency to address concerns over the long-term viability of the sea defence system at Minsmere on the Suffolk Coast. The section of coastline under study extends from Dunwich Cliffs in the north to the flood defence embankments protecting Sizewell power station to the south.

The current front line flood defence along this frontage consists of a dune embankment. Seaward of the embankment lies a relatively narrow sand & shingle beach that slopes to the waterline. A tidal sluice inland of the dune embankment approximately mid-way along the frontage drains the 82km^{2}catchment. The area of land drained by the sluice includes the Minsmere Nature Reserve of the Royal Society for the Protection of Birds (RSPB).

This report aims to provide a non-technical summary of the Timings and Longevity Predictions for Minsmere Report (Black & Veatch, 2006) to promote understanding of the way forward. This report summarises the current standard of protection and residual life of the existing defences along the Minsmere frontage in order to determine whether works are required and if so, when they should be undertaken. In addition, in order to design and cost any works required to provide specific standards of defence, it is necessary to determine what crest levels are required to achieve a specified standard of defence. For further information regarding the issues raised in this report, the reader is referred to the report that this is a summary of and any reports referenced therein.

2. STANDARD OF DEFENCE AND RESIDUAL LIFE

2.1 Standard of defence assessment methodology

The primary defence along the Minsmere frontage consists of a mixed shingle and sand sloped beach backed by a relic dune system. There is evidence that the upper section of the landward side of this front dune system has been built up by man with made ground consisting of slightly clayey sandy gravel. At the northern end of the frontage the dune system is low and fronted by a narrow stretch of beach. Further south the dunes widen and the fronting beach becomes considerably wider.

A secondary defence exists along the Minsmere frontage from just south of Minsmere cliffs to about 100m north of the sluice.

An examination of the current standard of defence for four defence scenarios was undertaken:

- Scenario 1 - The primary defence along the entire frontage in isolation;
- Scenario 2 - The secondary defence along the northern frontage assuming that the primary defence has been removed;
- Scenario 3 - The secondary defence assuming a small breach in the primary defence;
- Scenario 4 - The secondary defence along the northern frontage assuming that the existing front crest (primary defence) has moved back under storm events building the beach up against the secondary defence to create a berm and thereby providing additional protection.

Three different overtopping methodologies were employed to estimate the standard of defence for the existing Minsmere primary defence and secondary defence banks at each topographic survey (1 to 20) and EA beach survey (S1B2 to S1B4) location along the Minsmere frontage. The location of each of these survey point is shown in Figure 1.

As yet, English Nature have not defined a necessary standard of protection for maintenance of the site features. A range of standards from 1 in 10 to 1 in 50 is being examined for costing purposes.

2.2 Residual life assessment methodology

Study of coastal processes at Minsmere (reported in Coastal Processes Report, Black & Veatch, 2005) showed evidence of recent erosion along sections of the frontage. If current erosion rates continue there will be a time when the current dune embankment which forms the primary defence will become threatened and failure of the defence is likely to occur resulting in flooding of the hinterland.

The time of failure was assumed to be when the most landward extent of the bank/dune providing a 4mAOD crest level (approximately a 1 in 10 standard of defence) became threatened by erosion. An examination of the residual life based on erosion rates was undertaken for three of the defence scenarios above as follows:

- Scenario 1 - The primary defence along the entire frontage in isolation;
- Scenario 2 - The secondary defence along the northern frontage assuming that the primary defence has been removed; and
- Scenario 4 - The secondary defence along the northern frontage assuming that the existing front crest (primary defence) has moved back under storm events building the beach up against the secondary defence to create a berm and thereby providing additional protection.

For each beach survey point, a worst case, best case and most likely rate of change of beach level were determined based on assessments undertaken in the Coastal Process Report (Black & Veatch, 2005). This information is based on EA survey data (1992 to 2005) and Admiralty Charts (1976 to 2005). The additional increase in the rate of erosion due to sea level rise was also included. An estimate of the time before the defence is likely to be compromised by erosion processes was undertaken for the three scenarios for each erosion case.

Due to the methodology adopted, scenarios two and four yield the same result as the additional material in place under scenario four is not given special consideration. Therefore only one residual life estimate was made for each of the primary and secondary banks.

2.3 Results

Table 1 shows the predicted standards of defence and residual life estimates for the primary and secondary defence for each profile along the Minsmere frontage. The predicted standards of defence in relation to the position on the Minsmere frontage are shown in Figure 2. Figure 3 shows the predicted residual life along the Minsmere frontage. The standard of defence (SOD) results for scenario 2 are not shown as this was felt to be too much of a pessimistic approach.

In terms of standards of defence, from Table 1 the following conclusions can be drawn:

- The primary defence from profile 8 southwards require no works at the current time as the existing standard of defence is 1 in 50 or above and this is felt to be sufficient.
- North of the profile 8 the standard of defence of the primary defence drops to as low as 1 in 2 to 1 in 10 in some places. This defence line has been overtopped in recent years confirming the low crest level at this point.
- For the secondary defence, under the current scenario (scenario three), as long as the current primary defence is still in place, then if water gets to the secondary defence it still provides protection to a minimum 1 in 20 standard.
- For the secondary defence, if the current dune ridge rolls back to protect the current secondary defence line, as is thought most likely (scenario four), then without work the secondary defence would provide a standard of protection of between 1 in 2 and 1 in 100. The southern extent of the secondary bank (profiles 7 to 10) has considerably lower crest levels, resulting in a standard of defence as low as 1 in 2.

In terms of residual life, from Table 1 the following conclusions can be drawn:

- The primary defence bank on the northern frontage may breach within the next five years, the most vulnerable area being at the location of profiles 3 and 4. This is where the beach seaward of the bank is currently at its narrowest and there have been actual incidences of overtopping at this location.
- The entire most northern section of the primary defence (profiles 1 to 5) will be lost within 30 years – flood protection will have to rely on the secondary bank alone.
- The entire northern half of the secondary bank (profiles 1 to 5) may be lost within 50 years (with breaching commencing within about 20 years time), indicating that realignment may be required at this location in about 20 years time.
- On the southern section of the frontage (i.e. south of the sluice), the analysis highlights the vulnerability of the primary defence at the location of profiles S1B4 and 18 as the defence embankment mat be breached within 20 years. A localised blister bank could be constructed behind these defences in the medium term to ensure defences are maintained.

Table 1. Summary of standard of defence and residual life for Minsmere frontage

2.4 Loss of SAC habitat

Loss of SAC vegetated shingle habitat has notably occurred along the north of the Minsmere (profiles 1 to 10). Table 2 shows the current width of beach between the MHWS line and the secondary defence, and an estimate of the predicted beach width after 20 and 40 years. The reduction as a percentage is also shown.

The results in Table 2 show that the SAC habitat will be dramatically reduced over the northern section (profiles 1 to 5) as a result of coastal squeeze. However, any realignment of the frontage will cause loss of the SPA habitat behind. English Nature have advised that the SPA habitat should be maintained for 29 years to allow compensation habitat to be established for any planned realignments

in the future. In 20 years time, the defence line over profiles 1 to 5 should be realigned to provide a minimum 45m width of beach seaward of the defence throughout the design life of the realigned defence in order to allow SAC habitat to migrate landward as sea levels rise.

3. IDENTIFIED WORKS

From the assessment of standard of defence and residual life, it has been possible to identify sections of the current embankment defence system that require works in the short and medium term, and to estimate the timings of these works.

It should be noted that the timings are based on erosion rates which are highly variable. These timings are suggested only based on the current available information. Monitoring of the frontage should continue and these timings adjusted as erosion rates change.

Works required to the sluice to resolve deterioration issues have also been summarised here.

3.1 Short term works

The following works have been identified to be required to be undertaken in the short term (0 to 20 years):

- Undertake strengthening and raising works to the secondary defence from Dunwich Cliffs to profile 5 to an agreed standard of defence. Any works should be designed to last 20 years, at which point the embankment will require realignment (see medium term works). The delay in realigning will enable compensatory SPA habitat to be established prior to it being lost.
- Undertake strengthening and raising works to the secondary defence from profile 5 to the sluice to an agreed standard of protection. Any works should be designed to last 50 years, at which point the embankment will require realignment (see long term works).
- Identify and secure compensatory habitat for short and medium term realignment works to allow time to establish.
- Replacement of the concrete pipes at the toe of the outfall to avoid undermining or collapse of the outfall in a severe storm.
- Construction of a blister bank behind the existing defence over profiles 17 to 19 in 15 to 20 years time. Although the results indicate that this work will be required earlier, an assessment has shown that the crest level of the eroded bank will be sufficient to provide a 1 in 10 standard of protection in 20 years time. Works may be required earlier if a higher standard of protection is required.

3.2 Medium term works

The following works have been identified to be required to be undertaken in the medium term (20 - 50 years):

- Realign the defence line at profiles 1 to 5 in 20 years time by constructing a new earth embankment from Minsmere Cliffs to the existing cross bank. The existing cross bank will also require strengthening and raising to the agreed standard of protection.
- Identify and secure compensatory habitat for long term realignment works to allow time to establish.
- The condition survey of the sluice identified that the outfall pipes will require replacement in 30 – 50 years time. However, this work should be undertaken in consideration with the future location of any new sluice constructed in the longer term.

3.3 Long term works

In the long term it is recognised that a more substantial and sustainable realignment of the coastal frontage will be required. At present it is estimated that this will be required in 50 years time. In the meantime, monitoring of the coastline will continue. Realignment of the defences will require the relocation of Minsmere sluice.

4. REQUIRED CREST LEVELS

The overtopping methodology used previously was used to estimate the required crest level height for a 1 in 10, 20 and 50 standard of defence earth embankment, assuming that the rate of overtopping discharge should be maintained at less than 5 l/s/m run. Sea level rise was included for the life time of the defence. Additions were also made to allow for uncertainty and settlement. The required crest levels for the defence embankments are shown in Table 3.

	Standard of Defence Provided		
	1 in 10	1 in 20	1 in 50
Secondary bank profiles 1 - 5	3.9	4.2	4.4
Secondary bank profiles 6 - 10	4.5	4.9	5.3
Realigned bank profiles 1- 5	3.5 – 4.5	3.7 – 4.9	3.9 – 5.3
Blister bank profiles 17 - 19	3.5	3.7	3.9

Table 3 – Required crest levels for identified works

Required crest levels for the southern section of the secondary bank (profiles 6 – 10) are greater than that for the northern section (profiles 1 – 5), as the southern section will last 50 years (and hence includes for sea level rise of 50 years), whereas the northern section will be replaced by the realigned bank in year 20.

For this assessment it has been assumed that the realigned bank will be located just seaward of the current drainage line that crosses Coney Hill, thereby allowing the drain to be converted to a soak dyke, reducing cost. This realigned defence will join the existing cross bank, where it will tie into the existing secondary bank. A range is given for the required crest levels as if it is assumed that no wave attack will impact this defence, the crest level may be estimated by considering the surge water level only (plus the additions for sea level rise, uncertainty and settlement).

The blister bank behind the existing dune system over profiles 17 to 19 will not be exposed to wave attack. Therefore the crest levels only take into account surge water level only (plus additions for sea level rise, uncertainly and settlement).

Abstract - The diet of Little Tern chicks was studied in order to analyze the prey choice of a species that carries single, unbroken prey to its nest. Chicks less than 5 days old were fed with thinner fish than chicks older than 10 days. The average prey size was smaller for younger chicks. Prey left uneaten by chicks included larger, bulkier fish, shrimps and potentially poisonous fish. The parents select prey according to the chicks' ability to swallow, and a further selection is accomplished by the chicks themselves.

Introduction

Most studies on diet and prey choice of central place foragers deal mainly with multiple prey loaders and, to a lesser extent, with single prey loaders which are able to break-up large prey items in order to feed themselves or their chicks (Houston and McNamara 1985). Other species are single prey loaders which do not break the prey; their chicks swallow the prey whole. This constraint is particularly important, because the ability of the chicks to swallow items of increasing size continues throughout their growth, and the adults' optimal prey choice changes accordingly.
In this paper we analyze the feeding behaviour of the Little Tern *Sterna albifrons*, as a model for studying diet and prey choice of single prey loaders that do not break food items. Previous studies described the diet of the Little Tern (Glutz Von Blotzheim and Bauer 1982, Cramp 1985, Bogliani *et al.* 1992, Dementev *et al.* 1966), its foraging niche (Isenmann 1979, Dubois 1982, Fasola *et al.* 1989), and chick behaviour (Davies 1981). However no attention has been paid to optimal prey selection performed by the adults in relation to the age of chicks.

Methods

Data were collected in the Comacchio lagoon (North Adriatic coast), a very old 100 km² lagoon, presently banked up at the edges and managed as fish pond. The Little Terns breed on islets in the middle of the lagoon and search for food mainly within 4 km of the colony (Fasola and Bogliani 1990). Nests are placed mainly on bare ground and beaches covered by empty *Cardium* shells and with patches of halophytic vegetation.
Observations were made from a hide close to 40 nests from 22 June to 5 July 1983. Prey items carried by adults were identified to the lowest possible taxon, and the total length was estimated using bill length as a reference. No adjustment was made for possible systematic bias in the length estimate (Goss-Custard *et al.* 1987). One set of observations was limited to two age classes: chicks younger than five days (179 prey items) and chicks older than 10 days (107 items). Both age groups were observed simultaneously within the same colony, therefore any effect due to the uneven availability of the different prey can be excluded. It was impossible to know the sample size of chicks, because they were usually hidden among vegetation and were observed only when adults arrived with food. For the same reason it was difficult to have an accurate measurement of the handling time; only in few instances it was possible to observe chicks while disgorging food items.
In order to compare abandoned with offered prey,on 2 July 1983 we removed all prey items abandoned near the nests; from 2 July-5 July we carefully searched for recently abandoned prey items twice a day.

Results

Around the nests, 164 abandoned prey were collected; over the same four days, 784 feedings were observed.

Accepted 18 October 1993

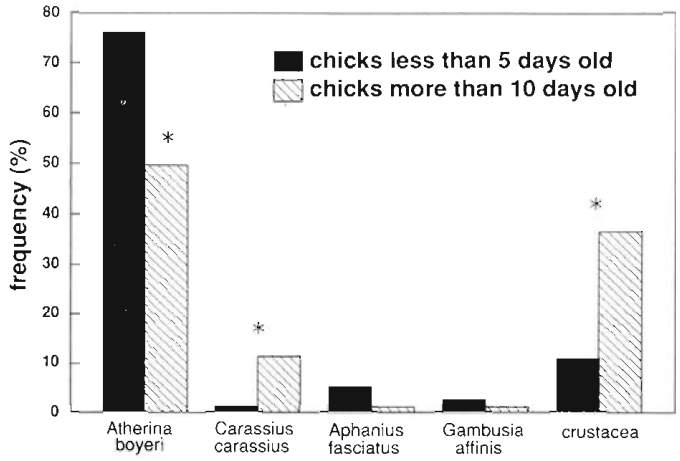

Figure 1 - Relative frequency of different prey fed to chicks aged less than 5 days (n=179) and more than 10 days (n=107). The asterisks indicate a significant difference (X^2 test, d.f.=1, p<0,01).

Table 1 - Length of the main prey delivered to chicks of differrent ages (mm).

	age of chicks							
	less than 5 days			more than 10 days			t	p
	mean	sd	n	mean	sd	n		
Atherina boyeri	34.6	6.9	136	47.7	9.5	53	9.3	<0.001
crustacea	40.1	5.7	19	51.4	2.7	39	10.3	<0.001

The frequency of occurrence of different prey items varied with the age of chicks (Figure 1). Young chicks received more Sand Smelts *Atherina boyeri* than older ones (X^2=19.7, d.f.=1, P<0.01), while the opposite occurred for the Crucian Carp *Carassius carassius* (X^2 =12.6, d.f.=1, P<0.01). Chicks over 10 days were fed with more crustaceans than were chicks less than five days old (X^2=26.1, d.f.=1, P<0.01). Young chicks received 27% smaller Sand Smelts and 22% smaller Crustacea on average (Table 1).

Overall, chicks less than 5 days old received prey items which being short and narrow were easy to swallow.

Crustaceans are probably difficult for small chicks to swallow as a consequence of the numerous appendages protruding from their bodies.

Abandoned prey was not a random sample of the offered prey. Relatively few thin fish such as Sand Smelt and Mosquito fish *Gambusia affinis* were abandoned; more bulky fish such as the Crucian Carp and Gobiidae and crustacea were overrepresented (Figure 2). Abandoned fish items were larger, on average, than offered ones (Table 2). Very few attempts at prey disgorging were observed, since chicks often took shelter immediately after receiving prey from the adult and went out of view.

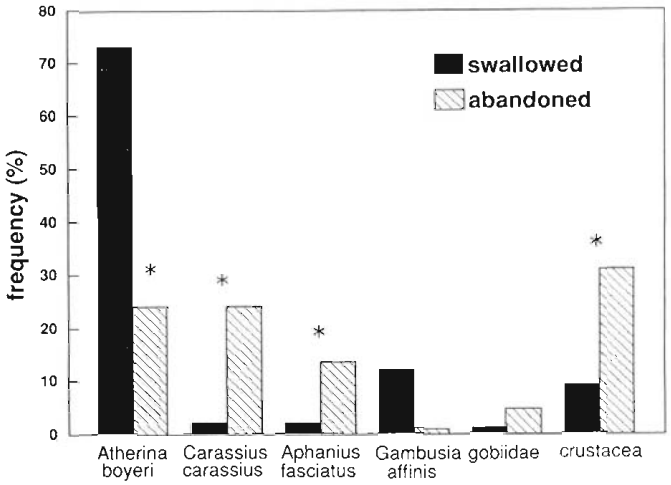

Figure 2 - Relative frequency of different prey swallowed by chicks (n=784) and abandoned uneaten near the nest (n=164). The asterisks indicate a significant difference (X^2 test, d.f.=1, p<0,001).

Table 2 - Length of the main prey observed and abandoned near the nests (mm).

	offered items			abandoned items				
	mean	sd	n	mean	sd	n	t	p
Atherina boyeri	34.7	20	574	39.9	10.4	40	3.1	<0.01
C.carassius	32.1	4.0	21	43.8	10.4	40	10.3	<0.001
Aphanius fasciatus	26.6	8.5	16	39.5	7.5	21	4.8	<0.001

Discussion

Adults selected prey of various length in relation to their chick's ability to swallow them, older chicks receiving larger prey. Obviously, a large chick is able to swallow a small prey, but this prey would not be an optimal choice for the parents. They may be qualitative differences between the pairs with young and old chicks at the same time, the latter being early layers and probably therefore older, more experienced birds. A change in the length of prey delivered to chicks of varying age has been observed in some

other species, such as the Kingfisher *Alcedo atthis* (Bogliani and Massara 1990), the Sandwich Tern *Sterna sandvicensis* (Veen 1977) and the male Common Tern *Sterna hirundo* (Wiggins and Morris 1987). In the latter species the female did not increase the length of prey as chicks got older. In the Grey Heron *Ardea cinerea*, the maximum size of fish swallowed by chicks increases with chick age (Moser 1986). Furthermore, heron chicks less than 20 days old were fed more frequently with small prey and less frequently with bulky fish than were older chicks, as was also observed with the Little Tern of varying ages in the Comacchio Lagoon. However it is not clear if the Little Tern selects for prey size and prey type according to the age of chicks, or if it simply selects for prey size; the difference in prey species could be due to the fact that small prey include species which are different from larger prey. Few items were not eaten by chicks and these tended to be those which were either more difficult to swallow than average ones, because of their shape. (e.g. fat fish), sometimes with numerous appendages causing handling problems, (e.g. shrimps), or possibly because of their bitter taste, (e.g. *Aphanius fasciatus*), which is poisonous to small mammals (Cavicchioli 1962).

There is no evidence that selection against bulky prey was due to factors other than bulk, but in the crustaceans the proportion of indigestible material they contain may reduce their palatability. This non-optimal foraging by adults would probably warrant investigation. However it seems that the amount of abandoned prey is a small fraction of prey loads brought to the nest by parents.

The difference between abandoned and swallowed prey cautions against the analysis of abandoned prey to estimate the diet of terns, as attempted by some authors (Boldreghini *et al.* 1988, Atwood and Kelly 1984). Abandoned prey are likely to be unwanted by chicks.

Acknowledgements - Thanks are due to SIVALCO, which allowed access to the Valli di Comacchio, to Alberto Meriggi for his criticisms of a draft of this paper and to Robert Coates for checking the English.

Riassunto - I pulcini di Fraticello delle Valli di Comacchio vengono imbeccati dai genitori con pesci piccoli e di forma affusolata quando hanno meno di 5 giorni; in seguito ricevono in maggior misura prede piu grandi, piu tozze o con appendici. Una parte delle prede portate dagli adulti resta abbandonata a terra. Questa frazione comprende pesci più grandi e di forma più tozza della media, crostacei con lunghe appendici e pesci potenzialmente velenosi. Gli adulti selezionano le prede in relazione all'abilita dei pulcini di ingoiarle; una ulteriore selezione viene operata probabilmente dai pulcini stessi, che scartano quelle meno idonee.

Abstract. Three Marsh Harrier's (*Circus aeruginosus*) nests were monitored during the breeding season at two lakes in the Mazurian Lakeland of NE Poland. Female Harriers visited the nests more often than males and stayed with their nestlings much longer than males. At all nesting sites, the main prey delivered to young Marsh Harriers were *Microtus* voles (56% of all prey items) and other rodents (12.5%). However, the composition of the Marsh Harrier's diet differed significantly among the three nests. Waterfowl and the domestic chicken (*Gallus domesticus*) constituted 71% of the biomass consumed. No significant differences were recorded between prey items delivered to the nests by males and females. However, some prey, such as the Crested Grebe (*Podiceps cristatus*), Coot (*Fulica atra*) and young brown hares (*Lepus europaeus*), were brought to the nests only by females. The overall prey biomass delivered to nestlings by females was approximately five times larger than that delivered by males. The diet composition determined from carcass analysis and via observations differed significantly from the data obtained from pellet analysis.
Key words: diet variation, pellets, provisioning behaviour, Marsh Harrier, Poland

Introduction

In recent decades, numerous studies of the Harriers' (*Circus* sp.) biology have been undertaken in Europe and North America. Most of them concern breeding behaviour (Simmons *et al*. 1986; Barnard *et al*. 1987; Millon *et al*. 2002; Wiącek 2006a), mating systems (Amar *et al*. 2005), territorial protection (Temeles 1989a; Wiącek 2006b), hunting activity (Schipper *et al*. 1975; Schipper 1977; Temeles 1989b; Kitowski 2007), food niches (Underhill-Day 1989; Clarke *et al*. 1993; Redpath *et al*. 2002; Garcia & Arroyo 2005) and the impact on prey populations (Underhill-Day 1989). In Poland, studies by Witkowski (1989) and Buczek and Keller (1995) have considerably extended knowledge of the Marsh Harrier's (*Circus aeruginosus*) breeding ecology. This paper presents data on the Marsh Harrier's diet composition and provisioning behaviour observed at three nesting sites within lake habitats during the breeding season. Moreover, we compared different methods used for the investigation of the Marsh Harrier's diet. This topic was dealt with in several studies which revealed the necessity for the combined use of direct (observations, images) and indirect (analysis of prey remains, pellets) investigation methods (Simmons *et al*. 1991; Redpath *et al*. 2001; Selås *et al*. 2007; Tornberg & Reif 2007). This study compared data pooled from the analysis of collected prey remains and visual observations to those obtained from pellet analysis, and estimated differences between them, e.g. related to the load-size effect (Sonerud 1992).

Material and methods

Three Marsh Harrier's nests with nestlings were observed from the beginning of June until mid-July 1997. Two nests were located at Lake Inulec and one at Lake Śniardwy in the Mazurian Lakeland, in north-eastern Poland (53°40'N, 21°30'E). The nests were built in reeds (*Phragmites australis*), within the lake's littoral zone. The nesting site at Lake Śniardwy was surrounded by broad reed beds, and located at a distance of about 50 m from the shore. At Lake Inulec, the nests were located on narrow reed strips, at about 5 m and 8 m from the shore, respectively. At all the sites, the terrestrial habitats were similar, consisting of belts of alder-woods overgrowing lake banks adjacent to vast pastures and meadows. The important difference between the nesting sites was the presence of a small village in the neighbourhood of two nests at Lake Inulec. At the Lake Śniardwy site, the nearest settlements were located over 1 km away. Another important difference concerning the aquatic habitat was the presence of a large waterfowl colony

(dominated by the Crested Grebe (*Podiceps cristatus*) and the Coot (*Fulica atra*)) at Lake Śniardwy, located about 300 m from the Marsh Harriers' nest. At Lake Inulec, waterfowl nests were also present but scattered along the shore.

The Marsh Harrier's nests were monitored from shelters set at a distance of about 10 m from each nest. The behaviour of birds outside the nests was not observed. Monitoring of the nests was carried out at all possible hours of the day and its overall duration was 208 hours. The duration of a particular observation session was 2–4 hours. Binoculars 10 × 50 were used for observations. The nest at Lake Śniardwy (Nest 1) was observed for 94 hours and the nests at Lake Inulec for 59.5 hours (Nest 2) and 54.5 hours (Nest 3) respectively. In all the nests, chicks clutched within the last ten days of May. Observations of the nests were started 7–10 days after the clutching of chicks. There were 4 nestlings both in Nest 1 and in Nest 3, and 2 nestlings in Nest 2. Observations were not noticed to exert any negative impact on the Harriers' behaviour and nesting success and all chicks fledged successfully. During the observation, all arrivals made by parents, as well as the time spent by males and females at the nests, were recorded. Prey items delivered by adults were identified, if identification was possible. During observations it was not possible to record aerial food transfers between mates, so it is hard to estimate what proportion of total food transfers from males to nestlings was mediated through females. At the end of each observation session, food remains and pellets were collected from the nest, including prey remains delivered beyond observation sessions. Remains found in the nest, if different from the observed prey delivered by parents, were treated together with food items whose delivery was monitored. Pellets were oven-dried at 50°C. All undigested remains were identified according to the key provided by Pucek (1981) and assessed in relation to the comparative content of bones, scales and feathers. Altogether, 183 prey remains and instances of prey delivered by parents were recorded; 174 prey items were found in 113 pellets. The number of prey items in pellets was calculated according to standard methods (Raczyński & Ruprecht 1974). Diet composition was presented as the percentage of individuals consumed as prey and the percentage of consumed biomass. To calculate the biomass for each prey category, the number of prey specimens of each kind was multiplied by the mean body mass for the given prey category. The mean body mass for the prey types was as follows: rodents – 25 g, insectivores (the mole *Talpa europaea*) – 80 g, mustelids (the weasel *Mustela nivalis*) – 70 g, juvenile brown hares (*Lepus europaeus*) – 300 g, passerines – 20 g, waterfowl – 1,000 g, juvenile domestic chicken (*Gallus domesticus*) – 500 g, juvenile Hooded Crow (*Corvus corone*) – 250 g, frogs – 20 g, fish – 200 g.

Nonparametric tests were used to analyse results obtained from the comparison of: the Marsh Harrier's diet among the three nests, types of food delivered by males and females, methods of 'remains analysis' and 'pellet analysis' employed in this study. For the purpose of statistical analysis, the Marsh Harrier's diet was divided into nine food categories.

Results

In all the three nests, the Marsh Harrier's chicks were fed mainly on *Microtus* voles, which constituted about 56% of all prey items (Table 1). Common vole individuals (*Microtus arvalis*) constituted 80% of all recognised voles, while the root vole (*Microtus oeconomus*) and the short-tailed vole (*Microtus agrestis*) were hunted much less frequently. Other types of mammalian prey delivered to nestlings by adults were striped field mice (*Apodemus agrarius*), moles, weasels and juvenile brown hares. Marsh Harriers also hunted birds, small passerines and waterfowl being the most common prey. Frogs and fish constituted supplementary food items and their share in chicks' diet did not exceed 5%.

The percentage of a particular type of prey in the diet of nestlings does not reflect the actual food consumption due to the fact that it does not take into account the prey biomass. Due to their large body mass, waterfowl, although not very frequently hunted, constituted the staple food for the Marsh Harrier's chicks. At Lake Inulec, juvenile domestic chickens were sort of equivalent to waterfowl and, together with juvenile hares, constituted an important component in the diet of young Harriers. Rodents, hunted in large numbers, constituted 16.7% of the consumed prey biomass.

Despite the fact that voles were the staple food of nestlings at all the sites, the composition of the food delivered to the three nests varied significantly. Both data obtained from the analysis of collected remains and from observations of prey types delivered by parents ($\chi^2 = 49.85$, df = 16, $p < 0.001$; Fig. 1) as well as data derived from pellet analysis ($\chi^2 = 32.58$; df = 16; $p < 0.01$) confirmed that these differences were significant. Moles were preyed upon only by Harriers from Nest 2, and juvenile hares only by two pairs of Harriers at Lake Inulec (Nest 2 and 3). Passerines were hunted at all sites. Waterfowl occurred regularly in the diet of nestlings at Lake Śniardwy, but were recorded only once in Nest 2. In contrast, juvenile domestic chickens were not hunted at Lake Śniardwy, but were abundant in the diet of the Marsh Harrier's nestlings at Lake Inulec.

Table 1. Diet composition of the Marsh Harrier in the Mazurian Lakeland, NE Poland. Data pooled from the analyses of food remains and pellets from the three nests. % N – percentage of prey individuals; % B – percentage of biomass consumed.

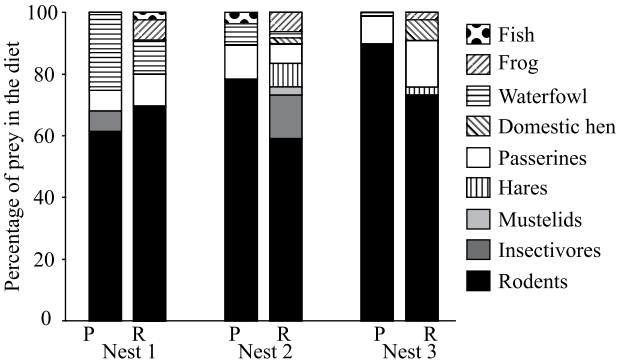

Figure 1. Diet of the Marsh Harrier's chicks depending on the investigation method: the percentage of prey in the diet obtained from pellet analysis (P) compared with the percentage of prey in the diet obtained from the analysis of food remains and visual observations of prey delivery by parents (R).

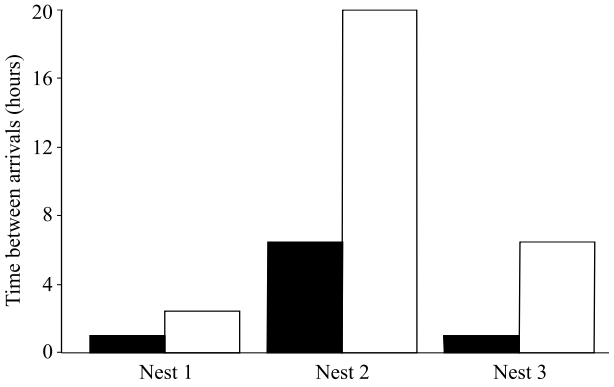

Figure 2. The average number of male (open bars) and female (filled bars) arrivals with food to each Marsh Harrier's nest per hour of observation.

At each of the three nesting sites observed, the frequency and length of parental visits varied depending on the parent's sex (Fig. 2) (Females $\chi^2 = 22.76$; df = 2; $p < 0.001$, males $\chi^2 = 14.10$; df = 2; $p < 0.001$). The frequency of female arrivals varied from one arrival per 6.7 hours to one arrival per 1.1 hours. Males visited their nests with a frequency of one arrival per 20.0 hours to one arrival per 2.3 hours.

During all observation sessions at the three nests of Marsh Harriers, a total of 281 arrivals of adult birds to the nests were recorded. Most of them (66.9%) were arrivals with food for nestlings, 21.7% were arrivals without food and in 11.4% of the cases adults arrived with plant material, which was used for fixing the nest. Females delivered food to the nests approximately three times more frequently than males ($\chi^2 = 95.5$, df = 1, $p < 0.001$).

A male, upon arrival at the nest, would usually spend just a few seconds there and after food delivery would fly away immediately. Females stayed with nestlings much longer than males ($\chi^2 = 19.4$; df = 3; $p = 0.0002$; Fig. 3).

The comparison of prey types delivered by males and by females did not reveal any significant differences ($\chi^2 = 10.3$, df = 7, $p > 0.05$). However, all domestic chickens hunted by Harriers were brought to the nests only by males while all waterfowl were delivered only by females. Females also specialised in hunting young hares.

The prey biomass given to nestlings by male and female Harriers differed in nature and amount (Fig. 4). The total biomass of rodents delivered by females was two times larger than that (the biomass composed of rodents) hunted by males. The large biomass of waterfowl hunted by females dominated the overall prey biomass. These sex-based differences in the efficacy of provisioning efforts were not so expressed in two pairs at Lake Inulec as in the Harriers' nesting site at Lake Śniardwy, where the female supplied nestlings with a large number of Coots and Grebes.

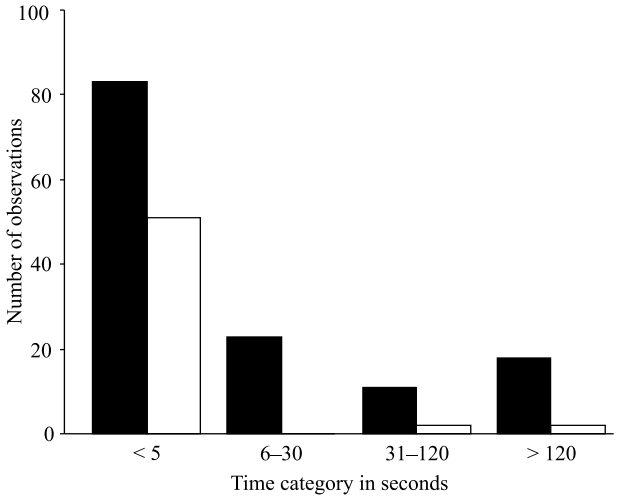

Figure 3. Time spent on nests by males (open bars) and females (filled bars).

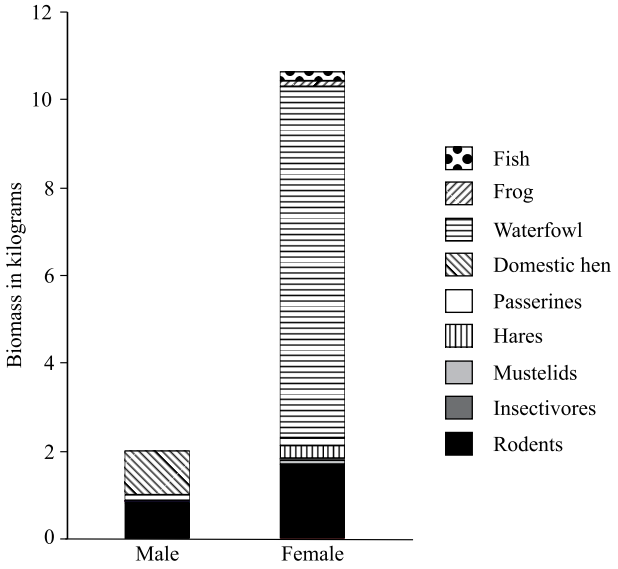

Figure 4. Biomass of prey delivered by males and females to the three Marsh Harrier's nests.

The Marsh Harrier's diet reconstructed from pellet analysis differed from that deduced from the data pooled from collected carcass analysis and observations of prey delivered by parents (Fig. 2). The differences in results obtained by the two methods were significant or nearly significant for each analysed nest (Nest 1: $\chi^2 = 14.21$; df = 5; $p = 0.014$; Nest 2: $\chi^2 = 13.58$; df = 8; $p = 0.093$ and Nest 3: $\chi^2 = 11.59$; df = 5; $p = 0.041$), as well as for the pooled data ($\chi^2 = 20.76$, df = 8, $p = 0.008$). In general, the share of rodents in the Marsh Harriers' diet reconstructed from pellet analysis was larger than in that deduced from the data pooled from carcass analysis and from observations. In contrast, remains of frogs, domestic chickens and hares were not found in pellets, although Marsh Harriers brought all these animals to the nests. In general, the diet composition based on the analysis of food remains found in the nests and from observations of prey delivery by parents is more diverse than that reconstructed from pellet analysis. Both methods showed *Microtus* voles to be the predominant prey, although the share of the four most common rodents in the diet was not the same: it varied depending on the analysis method used. The share of the common vole in the diet reconstructed from pellet analysis was significantly lower ($\chi^2 = 4.87$, df = 1; $p = 0.027$), while that of the root vole was significantly higher ($\chi^2 = 8.59$, df = 1; $p = 0.003$) when compared with the data derived from carcass analysis and observations. Percentage frequencies of *M. agrestis* and *A. agrarius* occurrence in the diet obtained by the two methods did not differ significantly.

Discussion

Results of our studies revealed the asymmetric pattern of males' and females' activity in feeding of nestlings. Prey biomass delivered by males was approximately one-fifth of that delivered by females. This is due to two factors. First, females were seen arriving with food approximately three times more frequently than males. Secondly, prey species delivered to nestlings by females were heavier than those delivered by males. However, the comparison of male and female hunting efforts and prey choices, based on observations of birds bringing food to the nest, may be biased due to the phenomenon of food transfer between the male and the female, which is common among Harriers (e.g. Wiącek 2006a). Aerial food transfer intensifies during the breeding period and, as shown by Azkona (1994), can constitute up to nearly 80% of all food transfers. In many cases, this fact makes it impossible to distinguish between prey caught by the female and prey delivered to her by the male. Thus, one must take into account that some of the prey items recorded as caught by females were in fact caught by males, whereas prey delivered by males was undoubtedly hunted on their own. The high proportion of food transferred from males to females outside the nest can explain a relatively small difference in the variety of the prey provided to chicks by both parents. Due to the difference in body size between male and female Marsh Harriers, large prey is much more accessible to females than to males. This hypothesis is partially supported by Witkowski (1989), who noted that in the Barycz River Valley, common voles constituted 63% of the prey delivered by males to incubating females. This proportion did not change significantly after the hatching of chicks, so long as prey was delivered to the nest only by the male. The number of larger prey items

delivered to young Harriers started to increase as they grew older, and the adult females joined the males in hunting efforts. Observations made by Witkowski (1989) illustrate that Marsh Harrier females and males searched for prey in different habitats and hunted different prey. In general, males specialised in hunting small terrestrial prey, mainly common voles and Skylarks, while females chiefly hunted aquatic or semi-aquatic animals such as carp, waterfowl (Coot, Grebes, Ducks) and frogs. Our study did not reveal significant differences between prey items delivered by each of the parents probably because males had previously transferred part of the hunted animals to females. On the other hand, the load size effect should also be taken into account. Small prey – below a particular energy value – is often not worth transporting to the nest over a long distance (Sonerud 1992). This rule may apply to Marsh Harrier males, who, in contrast to females, often hunt far away from the nest (Glutz *et al*. 1971; Cramp & Simmons 1980). However, during a period of particularly high food demand, one can assume that males probably deliver most of the prey they catch regardless of its size.

The number of male and female arrivals with food to the nests with four chicks was significantly higher than that to the nest with two chicks. This fact can be easily explained by higher food demands of nestlings in Nest 1 and 3. Another explanation for that could be the fact that the area inhabited by the pair with four chicks had larger food resources than that inhabited by the pair with two nestlings.

The resulting composition of the Marsh Harrier's diet, reconstructed from the analysis of food remains and from observations, differed from that deduced from pellet analysis. Similar discrepancies in results based on different methods used to study the diets of raptors were noted in the past (e.g. Redpath *et al*. 2001; Wiącek & Niedźwiedź 2005; Selås *et al*. 2007). Redpath *et al*. (2001) concluded that the share of birds that have fallen prey is under-represented and that of mammals is over-represented in the diet composition reconstructed from pellet analysis. What is more, prey remains found in the nests and the surrounding area do not fully represent the share of small species in the diet. We found amphibians to be a group of prey underestimated in pellets and this result is similar to the results reported by Selås *et al*. (2007) and Tornberg and Reif (2007) who studied food of Common Buzzards. Simmons *et al*. (1991) suggest that amphibians are always underestimated in pellets because in contrary to bones of mammals, their bones are digested and not regurgitated. Interestingly, our study illustrates that the share of very similar prey species (the common vole and the root vole) in the diet may differ depending on the analysis method used (analysis of 'pellets' *vs*. that of 'remains'). This difference was unexpected and it warrants further research.

Tornberg and Reif (2007) has concluded recently that indirect methods yield more precise results when applied for the investigation of the diet of raptors which do not specialise in a certain prey species. Meanwhile, direct methods are more reliable when studying raptors that are food specialists. However, the differentiation between specialists and generalists is not always evident and thus, it seems that to increase the reliability of results, various methods should be used for the diet analysis of raptors (Simmons *et al*. 1991; Redpath *et al*. 2001).

Nendrinės lingės (*Circus aeruginosus*) jauniklių dieta ir jų maitinimo elgesys

M. Brzeziński, M. Żmihorski

Santrauka

Trys nendrinės lingės (*Circus aeruginosus*) lizdai buvo stebimi perėjimo sezono metu prie dviejų ežerų šiaurės rytų Lenkijos Mozūrijos ežerynų rajone. Patelės atskrisdavo prie lizdų dažniau nei patinai ir praleisdavo daugiau laiko su jaunikliais. Visose lizdavietėse pagrindinę dalį laimikių, kuriuos tėvai atnešdavo savo jaunikliams, sudarė *Microtus* pelėnai (56% visų laimikių) ir kiti graužikai (12,5%). Tačiau maisto, kuriuo mito nendrinės lingės jaunikliai trijuose lizduose, sudėtis ryškiai skyrėsi. Vandens paukščiai ir naminės vištos jaunikliai sudarė 71% jauniklių suvartojamos biomasės. Tarp grobio, kurį savo jaunikliams atnešdavo nendrinės lingės patelės ir patinai, nebuvo didelio skirtumo. Tačiau kai kuriuos laimikius, kaip pavyzdžiui ausuotuosius kragus, laukius ar pilkuosius kiškius, į lizdus atnešdavo tik patelės. Patelių atnešta bendra laimikių biomasė buvo apytiksliai 5 kartus didesnė nei patinų. Mitybos sudėtis, nustatyta dvėselienos analizės bei stebėjimų pagrindu, patikimai skyrėsi nuo atrajų analizės rezultatų.

Summary

- The vegetation of the coastal grazing marshes (north of the New Cut), dunes and strandline at the RSPB's Minsmere Nature Reserve were surveyed in the summer of 1993.

- The 24 NVC communities identified on the grazing marshes included four associated with saltmarshes. One of these showed affinities with SM20 *Eleocharis uniglumis* saltmarsh, a west-coast community.

- In addition, eight aquatic communities were recognised in the grazing marsh ditches. They included *Spirodela polyrhiza - Hydrocharis morsus-ranae*, an increasingly scarce community, and two communities associated with coastal brackish ditches in south-eastern and southern England: A6 *Ceratophyllum submersum* and A21 *Ranunculus baudotii*. Seven pondweeds (*Potamogeton* and *Zannichellia*) were recorded in the ditches, including the Nationally Scarce *Potamogeton trichoides* and regionally rare *P. alpinus*. The Nationally Scarce *Sonchus palustris* is now widespread and apparently increasing along ditch banks on the Levels.

- A total of 14 salt-tolerant plant species occur on the grazing marshes and another two on the landward side of the dunes. Much of the saline influence appears to arise from the leaking sluice at the mouth of the New Cut, but some may result from seepage through the dunes and residual salt along the old course of the Minsmere River that was formerly tidal.

- The 16 NVC communities (plus 10 sub-communities) identified on the strandline and coastal dunes, included the nationally scarce SD1b *Rumex crispus - Glaucium flavum* shingle community *Lathyrus japonicus* sub-community which is a feature of the East Suffolk coast. As well as the *Glaucium* and *Lathyrus*, *Crambe maritimum* featured on the strandline, particularly towards the south (Sizewell Power Station) end of the reserve.

- The dune vegetation grades into acid fixed-dune grassland SD12a *Carex arenaria - Festuca ovina - Agrostis capillaris* and heathland (H8 *Calluna vulgaris - Ulex gallii*). The latter is largely associated with South-west England and Wales. *Sedum anglicum*, another characteristic west coast plant, also occurs on the Minsmere dunes.

- Three main conservation recommendations arise from the survey:
  - To fence off sections of dune and strandline to protect existing vegetation of conservation importance from further erosion by human trampling, and to allow it to recolonise. This particularly applies to the dunes north of the Sluice (Compartment 49).

  - To cut back trees, scrub and other tall vegetation shading the ditches around Compt. 41 at East Bridge. These ditches have some of the best freshwater aquatic communities on the reserve.

  - To retain the salt-tolerant plant communities and species on the Minsmere Levels by allowing brackish water into ditches near the Sluice and by grazing the fields with cattle.

  - To prevent scrub invasion at the southern end of the dunes (Compt. 59).

1 Introduction

The RSPB's Minsmere Nature Reserve on the East Suffolk coast has a variety of habitats, including 137 ha of grazing marsh and 33 ha of coastal dune and beach. Between June and September 1993, these last two habitats were surveyed. The grazing marsh is situated on the south-east side of the reserve, with 43 ha to the north of the New Cut Channel that flows out to the sea at the Sluice just behind the dune ridge (478662). This northern section of grazing marsh which incorporates eight fields and their associated ditches (Compts. 70-77 and 80) to the south of the old course of the Minsmere River was included in the survey (Figures 1-18). The ditches surrounding Compt. 41 at East Bridge were also covered (Figure 19). The grazing marshes to the south of the New Cut (94 ha) were surveyed in the same summer by Russell Cryer (1994). These latter marshes were acquired as an extension to the reserve in 1996. The beach within the reserve (Compartments 49, 58 and 59) extends from the Minsmere cliffs (TM477675) at the north end to the south end of the reserve (475645). The survey, however, extended a further 700m south of the reserve boundary to opposite the Sizewell Power Station (475638).

2 Aims

a) To identify the National Vegetation Classification (NVC) communities of the beach, dune, coastal grazing marsh and associated ditch habitats at the RSPB's Minsmere Reserve.

b) To identify botanical features of conservation importance associated with these habitats on the reserve.

c) To determine the effects of management, particularly grazing by cattle and geese, winter flooding and salinity on the vegetation of the coastal marshes and their ditches.

d) To assess the vulnerability of the beach and dune vegetation to human trampling.

3 Methods

The beach and dunes in Compt. 49, 58 and 59 at the RSPB's Minsmere reserve were surveyed between 14 and 24 June 1993. The coastal grazing marshes north of the New Cut (Compts. 70-77 and 80) were surveyed between 17 and 24 June, but the ditches in these compartments were examined between 11 August and 2 September.

The 1 km squares surveyed were TM4764, 4765 and 4766 (largely the coastal strip including the dunes), 4666 grazing marsh and a damp meadow in 4566 at East Bridge.

Before the NVC survey was undertaken, the strandline, dunes and grazing marshes were walked to gauge the communities to be sampled. With few exceptions, a minimum of five 2 x 2m quadrats were sampled for each community/sub-community. In a number of instances, an additional five quadrats were taken when a similar community was thought to occur in other fields or discrete areas. In each quadrat, percent cover frequency of each species and the average vegetation height were recorded. Constants were species recorded in each of five quadrats. Percent cover frequencies were converted to Domin values (1-10). NVC stands were mapped for each field. Details are given in the appendix.

The ditches were sampled either at the mid-point along them (short ditches) or at intervals 100m apart (longer ditches). Corners/junctions of ditches were avoided for sampling. The samples were each 20m long. Two sets of plant frequencies (percent cover) were recorded:

one for aquatics and emergents in the water, and second the bank vegetation up to 1m from the water. The depth and width of the water in the ditches were recorded along with height of the bank above water. Salinity of the water was measured using a conductivity meter.

NVC communities were identified using Rodwell (1991, 1992, 1995 and in prep.)

Results

4 Grazing Marshes

4.1 NVC communities

A total of 24 NVC communities plus an additional four sub-communities were identified on the grazing marshes within the Minsmere Reserve, north of the New Cut (Table 1). They included four associated with saltmarshes, six with swamps, two with mires, eight with mesotrophic grassland and four with aquatic situations.

4.2 Saltmarsh

The saltmarsh communities SM16, 20, 23 and 28 occurred in the fields nearest the sluice (Compt. 80) and those adjoining the old course of the Minsmere River that was formerly tidal.

SM16b *Festuca rubra* saltmarsh *Juncus gerardii* sub-community.
This occurred in almost all the fields except those furthest inland (Compts. 41 and 70). Such fields tended to be shallowly flooded in winter, and intensively grazed by cattle between May and October, and by geese for much of the year. *Juncus gerardii* occurred in all 25 2 x 2m quadrats sampled for this community and the average Domin frequency was 6.9. *Potentilla anserina* was the next most widespread species, occurring in 21 of the 25 quadrats (average Domin frequency 3.2). Other widespread species were *Agrostis stolonifera* and *Holcus lanatus* (each in 12 quadrats), *Festuca rubra* and *Lolium perenne* (each in 11). Other saltmarsh indicators were *Bolboschoenus maritimus* (Compts. 73 and 80e), *Eleocharis uniglumis* (Compts. 75 and 77). *Glaux maritima* (Compts. 71 and 75), *Salicornia ramossima* (Compt. 71) and *Aster tripolium* (ungrazed Compt. 80e).

SM16c *Festuca ribra* saltmarsh *Glaux maritima* sub-community.
A small area in the north-east corner of Compt. 71 was provisionally assigned to this community. In the one 2 x 2m quadrat *Glaux maritima* and *Salicornia ramossima* were each present at a Domin frequency of 7, with *Agrostis stolonifera* Domin 4. About 10% of the ground was bare.

SM20 *Eleocharis uniglumis* saltmarsh.
A saltmarsh community, featuring *E. uniglumis* as a constant and occurring at a Domin frequency of 8-9, occupied extensive areas in ungrazed Compt. 80 (sections a, b, d and f) nearest the Sluice. This community showed affinities with SM20 associated with west coast saltmarshes from North Wales northwards and apparently unrecorded on the east coast.

SM23 *Spergularia marina - Puccinellia distans* saltmarsh.
This community occurred as a lawn in a large, shallow depression in Compt. 72. The depression was flooded in winter and was heavily grazed by geese as well as cattle. Constants were *Spergularia marina* (average Domin 6.2) and *Glaux maritima* (7.0). *Juncus bufonius* was also frequent (IV 3.6), but *Puccinellia distans* was not recorded. Between 2 and 8% of the ground was bare. There were also two small areas of what was possibly a variant of this community in Compt. 71 grazed by cattle. Both *S. marina* and *Rumex maritimus* were frequent.

SM28 *Elytrigia repens* saltmarsh

This occurred on the slightly elevated margins and ridges in three fields (Compts. 72, 73 and 80). In Compt. 73 (five 2 x 2m quadrats sampled), constants were *Elytrigia repens* (average Domin 7.6), *Poa trivialis* (6.0) and *Potentilla anserina* (4.8). The average sward height was 74.0 cm. Compts. 73 and 80 were ungrazed; Compt. 72 was grazed by 15 cattle when surveyed.

4.3 Sand-dune

SD12a *Carex arenaria - Festuca ovina - Agrostis capillaris* fixed dune grassland. On a sandy rabbit-grazed ridge in Compt. 74.

4.4 Mesotrophic grassland

MG1 *Arrhenatherum elatius* coarse grassland

In the south-east corner of ungrazed Compt. 73 and narrow strips on higher ground in ungrazed Compt. 80 (a, f and g).

MG6a *Lolium perenne - Cynosurus cristatus* pasture

Apparently present as an intergrade with SM16b *Festuca rubra* saltmarsh, *Juncus gerardii* sub-community in areas of grazed Compt. 76. Possibly originating from a reseeding attempt. Constants *Juncus gerardii* (Domin 7), *Cynosures cristatus, Trifolium repens, T. pratensis* (all 5) and *Holcus lanatus* (4). No *Lolium* recorded.

MG7c *Lolium perenne - Alopecurus pratensis - Festuca pratensis* flood pasture

Present on a curved ridge of higher ground in ungrazed Compt. 70.

MG8 *Cynosurus cristatus - Caltha palustris* flood pasture

In wetter NE part of mown Compt. 41. Constants *Caltha palustris, Agrostis stolonifera, Holcus lanatus, Lotus pedunculatus* (all Domin 5), *Trifolium pratensis* and *Oenanthe fistulosa* (4).

MG10 *Holcus lanatus - Juncus effusus* rush pasture

a Typical sub-community: a lightly grazed sward that may be ascribed to this was present over a large area of Compt. 76.

b *Juncus inflexus* sub-community

A community in which *Holcus lanatus* (Domin 8), *Poa trivialis* and *Cirsium arvense* (both 5) were constants and *Juncus inflexus* occurred as scattered clumps was present in ungrazed Compt. 75 and grazed Compt. 76. Also in ungrazed Compt. 70 with *Carex hirta* (6) among clumps of *Juncus inflexus*. A community which *Holcus lanatus* (Domin 7) and *Cirsium arvense* (5) were constants but *Juncus inflexus* was absent and was also ascribed to MG10b in rabbit-grazed grassland in Compt. 74.

MG11b *Festuca rubra, Agrostis stolonifera, Potentilla anserina* inundation grassland

A community which had some characteristics of this occurred in lawns closely grazed by cattle and geese in Compts. 71, 72 and 73. Constants were *Juncus bufonius* (Domin 10) and *Potentilla anserina* (2). *Agrostis stolonifera* was frequent, but *Festuca rubra* was absent. The presence of *Glaux maritima* and *Spergularis marina* indicated brackish conditions. *Rumex maritimus* was associated with MG11b in Compts. 71 and 72. The areas would have been shallowly flooded in winter.

MG12a *Festuca arundinacea* coarse grassland, *Lolium perenne - Holcus lanatus* sub-community

This community was present on higher ground in Compts. 71 (on an east-west ridge), 77 and 80 (sections a, b, d, and g). In Compt.71 constants in the five 2 x 2m quadrats sampled were *Festuca pratensis* (average Domin frequency 7.2), *Poa pratensis* (3.2), *Potentilla anserina* (2.4) and *Cirsium arvense* (1.6). Also frequent was *Holcus lanatus* (IV 4.6) and *Juncus gerardii* (IV 3.4). This field was grazed by cattle (17 at the time of the survey). Geese grazed the short vegetation in the field, but not MG12a. Compts. 77 and 80 were ungrazed.

MG13 *Agrostis stolonifera - Alopecurus geniculatus* inundation grassland
This community featuring *Alopecurus geniculatus, Glyceria fluitans* and *Juncus gerardii* occurred in four wet depressions in Compt. 70, three in the north-east and one in the south-east. As an intergrade with S6, it was present in a wet runnel in the north-east corner of this field. In Compt. 80 section a, MG13 was present in a small damp hollow, perhaps the remains of a ditch.

4.5 Mires

M22 *Juncus subnodulosus - Cirsium palustre* fen meadow.
Two small patches in which *J. subnodulosus* was dominant occurred in Compt. 76 that was grazed by 24 cattle. A small area of what was possibly this community was present among SM16b saltmarsh in Compt. 75. In the SE half of mown Compt. 41.

M23a *Juncus effusus/acutiflorus - Galium palustre* rough pasture.
Small patches in wetter ground among MG10b *Holcus lanatus - Juncus effusus* rough pasture in ungrazed Compt. 75.

4.6 Swamps

S4a *Phragmites austriaca* reed-bed.
This community occurred along ditches bordering Compts. 72, 73, 75, 77 and 80, often as intergrades with other communities - S6 (with *Carex riparia*), S21 (with *Bolboschoenus*) and SM28 (with *Elytrigia repens*). It is transformed into other communities by grazing.

S6 *Carex riparia* swamp.
This formed prominent stands in the wettest parts of most fields (Compts. 70, 71, 72, 73, 76, 77 and 80 (sections a and b). Compts. 71, 73, 76 and 77 were grazed by cattle. *Carex riparia* was constant in 13 quadrats (average Domin frequency 7.7). *Cirsium arvense* was also frequent, occurring in 10 quadrats (average Domin 2.8).

S19 *Eleocharis palustris* swamp.
A small area occurred in a wet depression in Compt. 76. *Eleocharis* was associated with *Glyceria fluitans*. The Compartment was grazed by cattle.

S20 *Schoenoplectus tabernaemontani* swamp.
A stand along ditch 753 between Compts. 75 and 76. Also with *Juncus gerardii* and *Bolboschoenus maritimus* in a small wet depression on the south side of Compt. 72, near ditch 724. *S. tabernaemontani* is grazed by cattle. Probably a saltmarsh relict.

S21b *Bolboschoenus maritimus* swamp, *Agrostis stolonifera* sub-community.
Recorded along what was probably an 'extinct' channel in Compt. 71; over some extensive areas in both Compts. 72 and 73, and in Compt. 80 sections c, d and e. In Compt. 71 *Bolboschoenus* was a constant (average Domin frequency 8.0 for five 2 x 2m quadrats) along with *Agrostis stolonifera* (Domin 6.4). Close to ditch 724 on the north side of Compt. 73, *Bolboschoenus* occurred with *Phragmites* over a small area; Compts. 71 and 72 were grazed by cattle and geese; Compts. 73 and 80 were ungrazed. The presence of this community is further evidence of the estuarine origins of the Minsmere Levels.

5 Ditches

5.1 Aquatic plant communities

Eight aquatic NVC communities plus an additional sub-community were provisionally identified on the Minsmere Levels within the RSPB reserve (Table 1).

A2 *Lemna minor*

This floating community was widespread. *L. minor* and *L. trisulca* were present together in 20 ditch samples, *L. minor* alone in nine samples, and *L. trisulca* alone in six. Samples with abundant *L. trisulca* (703, 713, 722 a and b, 723 and 413) could be assigned to the *Lemna trisulca* sub-community.

A3 *Spirodela polyrhiza - Hydrocharis morsus-ranae.*

Ditch 411 in Compt. 41 beside the road at East Bridge was the only one in which both *Spirodela* and *Hydrocharis* were present. In addition there was much *Myriophyllum spicatus, Ceratophyllum demersum, Lemna minor* and formerly *Hottonia palustris.* It was partially shaded by roadside trees.

What was probably this community, with *Hydrocharis* constant (Domin 1-5) but no *Spirodela,* occurred in another six ditches in Compts. 70, 73 and 75. *Lemna minor, L. trisulca* and *Myriophyllum spicatum* was frequent. *Hydrocharis* was abundant in ditch 702b.

A5 *Ceratophyllum demersum.*

This community with abundant *Ceratophyllum* (90% cover) occurred in a shady ditch along the west side of Compt. 41 at East Bridge. Here the community was species-poor. It was also recorded in Ditch 724 (Compt. 72). A5 is usually associated with eutrophic fresh water.

A6 *Ceratophyllum submersum.*

Recorded in five or six ditches in Compts. 71, 72, 71/72 and possibly 75, 76/77 and 80. *C. submersum* was constant (Domin 4-7); *Lemna minor* and *L. trisulca* was frequent. The water where this community occurred was brackish (2.0% in most instances but 5.0% in Compt. 80). At three of the 10 sample sites where *C. submersum* was recorded, *C. demersum* was also present, but in general, the latter species was in fresh water. A6 is mostly confined to sites on or near the coast of south-east England (Rodwell 1995).

A11 *Potamogeton pectinatus - Myriophyllum spicatum.*

A community that could possibly be assigned to this occurred in shaded Ditch 413 in Compt. 41 at East Bridge. As well as having *Myriophyllum spicatum* in abundance (up to 95% cover), *Hydrocharis* and both *Potamogeton natans* and *P. alpinus* were present. The latter species is a rarity in East Anglia. *P. pectinatus* was not recorded, but was present with *Myriophyllum* in a species-rich ditch, 703 (Compt. 70).

A12 *Potamogeton pectinatus*

A species-poor community with *P. pectinatus* in two brackish ditches, 803 and 804 (Compt. 80), may tentatively be assigned to this. In the case of 803, there was an abundance of *Callitriche platycarpa* (A16?). The salinity in these ditches in September was 3-5‰.

A16 *Callitriche stagnalis.*

A community with abundant *C. obtusangula* in freshwater in the New Cut (near the bridge) may tentatively be assigned to this. *Callitriche platycarpa* occurred in three brackish peripheral ditches in Compt. 80: abundant in 801 and 803; frequent in 802. It was associated with *Ceratophyllum submersum* in 801 (A6?), with *Potamogeton pusillus* and *Ranunculus baudotii* in 802 (A21?) and with *Potamogeton pectinatus* in 803 (A11?).

A21 *Ranunculus baudotii.*

This community was present in all six east-west internal ditches (805-810) and possibly one peripheral ditch 802 in Compt. 80 near the Sluice. In these ditches the salinity readings ranged from 4.0-7.5‰ in September. In five internal ditches, *Ranunculus baudotii* (Domin 2-6) and *Hippuris vulgaris* (Domin 2-4) were constants. *Zannichellia palustris* was abundant in four of these ditches (Domin 6-9). *Potamogeton pectinatus* occurred in two internal ditches. Though ditch 802 was brackish (4.0‰), *Ranunculus baudotii* was only present in small quantity, while both *Potamogeton pusillus* and *Callitriche platycarpa* were frequent (A16?).

A21 occurs locally in brackish ditches around the coast of Britain and is frequent in Suffolk, Essex, the north Kent Marshes and around the Solvent. (Rodwell 1995).

5.2 Ditch flora

In the 53 ditch samples taken from ditches on the Minsmere Levels with the RSPB reserve (1993 boundaries), a total of 22 macrophytes, a moss and a charophyte was identified (Table 2). Most widespread were *Lemna minor* (58% of samples), *L. trisulca* (49%), *Callitriche platycarpa* (34%) and *Hydrocharis morsus-ranae* (32%). Eleven macrophytes and *Chara vulgaris* achieved cover frequencies of 20% or more in at least one ditch sample (Table). Among the six *Potamogeton* species were *P. alpinus* (two samples) and *P. trichoides* (one). *P. alpinus* has a largely northern distribution in Britain, and is a scarce plant in the lowlands of the south (Preston 1995). *P. trichoides* is considered a Nationally Scarce species (recorded from less than 100 10 km squares in Britain).

An interesting feature of the Minsmere Levels is the salinity gradient from 32‰ at the Sluice, where there is seepage of seawater into the New Cut and adjacent ditches, to freshwater 1.5 km inland. In Compt. 80, nearest the Sluice;, the salinity in the ditches ranged from 20 to 4.5‰ (bottom of water column) and 7.5 to 3‰ (surface). Further inland the salinity dropped from between 3.5 and 2.5‰ in Compt. 73 to 0.5‰ and freshwater in Compt. 70. In two pools on the landward side of the dunes to the north of the sluice salinities of 28 and 35‰ (seawater) were recorded in September after a dry period. Water may seep through the dunes from the sea into those pools. (Figures 14 and 17).

The ditch flora exhibited a response to this salinity gradient. *Ruppia maritima* was only recorded in the pool with a salinity of 35‰ (Compt. 49). *Ranunculus baudotii* (and Community A16) was restricted to Compt. 80 with late summer salinities ranging from 4.0-7.5‰. *Ceratophyllum submersum* (and Community A6) was only recorded from ditches in which the salinities lay between 2.0 and 5.0‰; it tended to be replaced by *C. demersum* at salinities of 2.0% and below. Species such as *Potamogeton pectinatus, P. pusillus, Zannichellia palustris* also occurred in the brackish ditches and appear to be tolerant of low salinities up to about 4.0‰.

Sixteen freshwater ditch samples had a mean of 4.9±2.3 aquatic macrophytes compared with a mean of 4.2±2.0 species in 21 slightly brackish ditch samples (2.0-3.0‰), and 3.3±1.0 species in 11 samples with a higher salinity (3.0-7.5%)(Table 4).

5.3 Aquatic plants of interest (Tables 2 and 3)

Callitriche spp.

In the absence of fruit, the species were tentatively identified by leaf shape. *C. platycarpa* was recorded in 18 ditch samples, including many which came from slightly brackish water. *C. obtusangula* was recorded from two freshwater sites on the New Cut and in a brackish ditch in Compt. 806.

Ceratophyllum submersum and *C. demersum*

C. submersum was recorded from 10 ditch samples, all of which were slightly brackish (2-5‰). It was locally abundant in three ditches: 712 (Compt. 71), 721 (between Compt. 71 and 72) and 722 (Compt. 72). It grew with *C. demersum* in two ditches: 721 and 801 (Compt. 80). *C. submersum* is distinguished by its brighter green and more flaccid foliage. *C. demersum* was recorded in 13 ditch samples and was locally abundant in the freshwater ditches in Compt. 41.

Chara vulgaris

All charophytes examined were identified as this species. (Moore 1986). It was widespread in the ditches in Compt. 75, 76 and 77, occurring in 13 samples and formed 20% or more cover in four.

Elodea canadensis
Only recorded in two of the 53 ditch samples: 413 (freshwater) in Compt. 41 and 702a (probably very slightly brackish 0.5‰ (Compt. 80).

Myriophyllum spicatum
Widespread in the ditches, recorded in 13 of the 53 samples and abundant in three. In freshwater and brackish water up to 2.5‰ salinity.

Potamogeton crispus
Only recorded in ditch 731 (Compt. 73) with a salinity of 2.5‰.

P. alpinus
Recorded in three sites along shady freshwater ditch 413 on the north border of Compt. 41 at East Bridge (Grid Ref TM451611). Identification confirmed by CD Preston (ITE, Monks Wood). Growing with *Myriophyllum spicatum* (frequent), *Lemna minor* (frequent) and *Hydrocharis marsus-ranae* (scarce). *P. alpinus* is an uncommon and decreasing plant in lowland, southern Britain (Preston 1995). It has not previously been recorded at Minsmere, but there are three post-1950 records near the East Suffolk coast (Simpson 1982).

P. natans
Only recorded in one freshwater ditch sample, 413c (Compt. 41) along with *P. alpinus.*

P. pectinatus
The most widespread pondweed on the RSPB's section of the Minsmere Levels, occurring in 11 of the 53 ditch samples. All were slightly brackish (0.5-6.0‰ salinity).

P. pusillus
Recorded in six ditch samples (Compts. 73, 75, 76 and 80). At least four of these were brackish (salinity 1.5-4.0‰).

P. trichoides (Nationally Scarce)
Only identified in small quantity in a newly cleaned ditch 772 (Compt. 77) where the salinity was 2.0‰. No other pondweeds occurred at the site and other aquatic macrophytes were very scarce. It is recorded as being rare in Suffolk (Simpson 1982). I observed it in a ditch that divides Compt. 30 from the west end of Compt. 31 at East Bridge (TM453664) in 1992.

Ranunculus baudotii
Restricted to seven brackish ditches in Compt. 80 near the Sluice. (Grid Ref TM475663). The salinity in these ditches ranged between 4.0 and 7.5‰. Associated with *Hippuris vulgaris* and *Zannichellia palustris.*

R. circinatus
Recorded in two ditch samples, 702 (Compt. 70) and 751 (Compt. 75). 702 was only very slightly brackish (0.5‰); 751 (not tested) was probably only marginally higher.

Ruppia maritima
Not recorded in the grazing marsh ditches, but abundant in a saline pool north of the Sluice (Compt. 49) - see under 6.2.

Spirodela polyrhiza
Only recorded in one freshwater ditch 411, Compt. 41 at East Bridge. Here it was locally abundant along with *Ceratophyllum demersum, Hydrocharis morsus-ranae, Lemna minor, Myriophyllum spicatum,* and formerly *Hottonia palustris.*

Zannichellia palustris
Apart from Compt. 80 (near the Sluice), where it was locally abundant in brackish (4.0-7.5‰ Cl) internal ditches, it was only recorded in ditch 773 when the salinity was 2.0‰

5.4 Emergent and bank plants of interest (Table 5)

Althaea officinalis
Fairly widespread on the Minsmere Levels where it grows on ditch banks and the edge of reedbeds. Recorded on the banks of the New Cut, Compts. 72 and 80 - nine (17.0%) of the 53 ditch samples. Tolerant of brackish conditions.

Aster tripolium
Only recorded where there was a distinct saline influence in Compt. 80c and in a saline runnel at the south end of Compt. 49 (477663), the north of the Sluice (see 6.2). Associated species were *Bolboschoenus maritimus* and *Juncus gerardii* (Compt. 80) and *J. gerardii* and *J. maritimus* (Compt. 49).

C. hirta
Locally frequent in a damp area in Compt. 70 (south) and at the foot of a sandy hill in Compt. 74 (west).

C. otrubae
Recorded in eight ditch-bank samples; widespread in Compts. 70, 75, 76, 77 and 80.

C. panicea
Only recorded in Compt. 41.

C. pseudocyperus
Only recorded on shaded bank of ditch 411 on the west side of Compt. 41 at East Bridge (452665).

Chenopodium rubrum
In a damp depression in the north-east corner of Compt. 70, along with halophytes: *Aster tripolium, Glaux maritima, Salicornia ramosissima* and *Spergularia marina*. Also on a ditch bank in Compt. 72. Frequent on ditch spoil, Compt. 78 between Compts. 71/72 and 76/77.

Glaux maritima
In short, grazed swards flooded in winter in Compts. 71, 72 and 73. Associated with saltmarsh communities SM16b and c, SM23 and with inundation grassland MG11b. Recorded from only one ditch bank sample - in Compt. 80, where there was saltmarsh vegetation.

Eleocharis uniglumis
Locally abundant in ungrazed Compt. 80, sections a, b, d and f (475662) in saltmarsh communities SM20 and SM28. Simpson (1982) states that the species is 'very rare and decreasing' in marshes near the Suffolk coast, but records it from Minsmere, Dunwich, Westleton (possible at the same site) and Leiston.

Juncus gerardii
Widespread in depressions flooded in winter in both grazed and ungrazed fields in Compts. 70 (NE cover), 71, 72, 73, 73 and particularly 80. Mainly associated with SM16b saltmarsh, but also occurring in S20, MG12a and MG13 communities. Recorded from eight (15.1%) of 53 ditch samples in Compts. 75 (three), 77 (one) and 80 (four).

Juncus subnodulosus
Recorded in Compt. 76 (two small patches), Compt. 75 (one patch in the centre where M22 intergraded with SM16b saltmarsh), and inland in Compt. 41 at East Bridge. It occurred in five ditch samples in Compts. 70/74, 76/77, 77 and 41.

Oenanthe fistulosa
Recorded in a single ditch sample - 703 in Compt. 70.

Rumex hydrolapathum
In nine (17.0%) of 53 ditch sample: New Cut (two), Compt. 70 (three), Compt. 74 (one) and Compt. 41 at East Bridge (three). The ditches in each instance contained freshwater.

R. maritimus
Occurred where water had lain in depressions during the winter in Compts. 71, 72 and 73. Associated with MG11b and SM23 communities. Abundant on ditch spoil thrown up onto a bank (Compt. 78) between Compts. 71/76 and 72/77. Recorded from three ditch samples.

Samolus valerandi
Widespread but in small quantity on bare ground on ditch banks. Recorded from seven (13.2%) of the 53 ditch samples in Compts. 70, 72, 73, 75, 76 (two) and 77 (two). Not associated with brackish ditches.

Schoenoplectus tabernaemontani
A few scattered stands in wet places: Compt. 72 and seven (13.2%) of the ditch samples, including 806, a brackish ditch, where locally abundant. Probably a salt-tolerant species.

Scutellaria galericulata
Only recorded on two ditch samples, both freshwater sites, in Compts. 70 and 77.

Sonchus palustris
Widespread and probably increasing on the Minsmere Levels. Recorded in six (11.3%) of the 53 ditch samples - Compts. 70, 71, 72 and at East Bridge, Compt. 41. Usually associated disturbed ground (ditch slubbings) on banks at the edge of reedbeds (S4a). A Nationally Scarce species.

Veronica anagallis-aquatica
Recorded in two ditch samples, in Compt. 74 (freshwater) and 80 (brackish 4.0‰.

6 Strandline and Sand-dunes

6.1 NVC Communities (Maps 1a-c)

Strandline and dune

SD1 *Rumex crispus - Glaucium flavum* shingle community.

SD1a Typical (*Crithmum - Crambetum*) sub-community.

Compt. 59 (four areas TM477657, 477655, 477653, 477650) and extending south of the Sizewell perimeter fence. On fine shingle and sand. A total of 225 *Crambe maritima* plants (including 126 seedlings), 57 *Glaucium* seedlings (no mature plants), 12 *Eryngium maritimum* plants, but no *Crithmum maritimum* within the RSPB reserve.

SD1b *Lathyrus japonicus* sub-community.

Compt. 59 (three areas 477657, 477655, 476650) and extending south of Sizewell perimeter fence. On sand and fine shingle, slightly higher up the beach than SD1a, on low dune

below eroded dune cliff. *Festuca rubra* and *Carex arenaria* constant; *Honckenya peploides* frequent.

SD2 *Honckenya peploides - Cakile maritima* strandline community.
Compt. 59 (two areas 477653, 477652) and extending south of Sizewell perimeter fence 477647 where it occurs with *Eryngium maritimum* (38 plants) and *Beta maritima.*
Compt. 49. Possibly this community with *Atriplex prostrata* (477664). On sand and fine shingle at the top of the beach.

SD6 *Ammophila arenaria* motile dune community.
SD6a *Elytrigia juncea* sub-community.
Compt. 49 (three sites) and Compt. 59 (at least two sites). On eroded edge of the dune, above the beach, with *Calystegia soldanella* and *Honckenya* in Compt. 49 (477664).
SD6b\c *Elytrigia juncea - Leymus arenarius* or *Leymus arenarius* sub-communities.
Compt. 59, (four sites - mostly in northern half of compartment on eroded edge of the dune, above the beach.
SD6d *Ammophila arenaria* sub-community.
Frequent along seaward edge of eroded dune at north end of Compt. 49 and intergrading with other communities/sub-communities. Not recorded in Compt. 59 where there is an abrupt demarcation (dune cliff) between the beach and dune.
SD6e *Festuca rubra* sub-community.
With *Calystegia soldanella* in at least one site in both Compts. 49 and 59. On seaward edge of eroded dunes.
SD6f *Poa pratensis* sub-community.
Scattered along the seaward edge of the dunes, especially at north end of Compt. 59. At one site with *Dryopteris dilatata.*
SD6g *Carex arenaria* sub-community.
Probably present intergrading with SD6e and f and SG10b in Compt. 59. With *Dryopteris dilatata* and *Rubus fruticosus* at one site.

SD7 *Ammophila arenaria - Festuca rubra* semi-fixed dune.
SD7a Typical sub-community.
Frequent in Compt. 49 and also present in Compt. 59.
SD7c *Ononis repens* sub-community.
Compt. 49 (one site 477664) and Compt. 59 (two sites - near Sluice 477661) and Compt. 59 (two sites - near sluice 477661, with *Galium verum, Trisetum flavescens* and *Achillea millefolium;* and 476656, with *Galium verum, Pilosella afficinarum* and *Dactylis glomerata*).

SD8 *Festuca rubra - Galium verum* fixed dune community.
SD8a Typical sub-community.
Compt. 59 (four sites at the north end, to the south of Sluice - 477660). With such plants as *Jasione montana, Vulpia bromoides* and *Trisetum flavescens.*

SD9 *Ammophila arenaria - Arrhenatherum elatius* dune grassland community.
SD9a Typical sub-community.
Compt. 59 - An area of tall grassland just south of the Sluice.

SD10 *Carex arenaria* dune community.
SD10a *Festuca rubra* sub-community.
Compt. 59 (in depression in dune ridge). *Anthoxanthum odoratum, Stellaria graminea, Ammophila, Agrostis capillaris* and *Arrhenatherum* constant along with *Festuca rubra.*
SD10b *Festuca ovina* sub-community.

Compts. 49 and 59 - a feature of the dune ridge over much of its length. With abundant *Dryopteris dilatata* on landward site (west-facing) slope of dune crest in Compt. 59. Integrading with SD6g.

SD11 *Carex arenaria - Cornicularia aculeata* community.

SD11a *Ammophila arenaria* sub-community.

Compt. 49 (at N. End 477670) - a small area close to the track on the landward site of the dune. With *Corynephorus canescens, Aira praecox, Festuca ovina,* and mosses *Campylopus introflexus* and *Polytrichum juniperinum.* Since the site is close to the junction with path along the bank across the Marsh, most vulnerable to trampling. Also two larger dry trampled areas (477669 and 477664) with such plants as *Rumex acetosella* and *Aira praecox.*

SD11b *Festuca ovina* sub-community.

Compt. 49 (477663) - dry gravelly area just north of the Sluice. With *Filago minima, Rumex acetosella, Plantago coronopus, Aira praecox, Cladonia portentosa.*

Compt. 59 (477662) - small area south of Sluice with *Aira praecox, Agrostis capillaris, Polytrichum juniperinum.*

SD12 *Carex arenaria - Festuca ovina - Agrostis capillaris* grassland community.

SD12a *Anthoxanthum oderatum* sub-community.

Compt. 49 - small area north of Sluice (477663) with *Sedum anglicum, Agrostis vinealis* and *Cladonia portentosa.*

Compt. 59 - a feature of the dry more level ground beside the main path on the landward side of the dunes from the Sluice to the Sizewell boundary fence. *Cladonia portentosa* abundant at 476656. With *Sedum anglicum* and *Silene uniflorum,* 476657.

SD12b *Holcus lanatus* sub-community.

Compt. 59 - replaces SD12a in some areas.

Neutral grassland

MG1 *Arrhenatherum elatius* coarse grassland community.

Compt. 49 - on a bank just north of the Sluice.

Compt. 59 - several large areas along the western edge where the dunes grade into the coastal grazing marsh.

Swamp

S26 *Phragmites australis* fen community.

Compt. 49 - small damp hollows near the track on landward side of dunes (476666). *Holcus lanatus* and *Vicia cracca* constant as well as *Phragmites. Agrostis stolonifera* and *Arrhenatherum elatuis* frequent. *Ophioglossum vulgatum* and *Oenanthe lachenalii* present. Integrading with MG1.

Compt. 59 - a large area on SW edge (475652).

Heath

H1 *Calluna vulgaris - Festuca ovina* heath?

Compt. 59 - very small areas at the extreme SW of the compartment where scrub is invading the dunes. Two clumps of *Calluna* associated with *Erica cinerea* (476650) and a third small patch (476649).

H8 *Calluna vulgaris - Ulex gallii* heath community.

H8a Typical sub-community.

Compt. 49 - some very small and scattered patches featuring *Erica cinerea* and *Ulex gallii,* but *Calluna vulgaris* absent.

Saltmarsh

SM2 *Ruppia maritima* saltmarsh community.
Compt. 49 - shallow pool north of the Sluice (477663).

SM16 *Festuca rubra* saltmarsh community.
SM16b *Juncus gerardii* sub-community.
Compt. 49 - on both (477663). With *Agrostis stolonifera, Glaux maritima, Spergularia marina* and *Atriplex prostrata*, as well as *Juncus gerardii*.

SM18 *Juncus maritimus* saltmarsh community.
Compt. 49 - Margin of saline pool and saline runnel north of the Sluice (477663). With *Aster tripolium, Juncus gerardii, Elytrigia atherica* and *Festuca rubra*, as well as *Juncus maritimus*.

6.2 Some of the more interesting plants of the strandline and dune

(*Nationally Scarce species)

Aster tripolium - saline runnel at South end of Compt. 49, near the sluice (477663).

Cakile maritima - strandline SD2, Compt. 59 (4765).

Calluna vulgaris - two clumps H1?, Compt. 59 (476650).

Calystegia soldanella - eroded edge of dunes above beach SD6a & e.
Compt. 49, (477664); Compt. 59, (476651).

Campanula rotundifolia - SD10b and SD12, Compt. 59, three sites in small quantity (4765).

**Corynephorus canescens* - dry slope on landward side of dunes
SD11 Compt. 49)477670). Very local and vulnerable to trampling. Also at N. (Dunwich) end of beach outside reserve (477675).
Introduced from Norfolk stock after the 1953 floods (Simpson 1982).

Crambe maritima - strandline SD1a. Compt. 59 (476657(A)), (476656(B)), (476653(C)) and (476650(D)). Also outside reserve, S. of Sizewell boundary fence (E).

Size of plants		Small	Medium	Large	Total
RSPB	A	44	-	18	62
	B	8	13	5	26
	C	70	19	26	115
	D	4	5	13	22
Total		126 (56%)	37 (16%)	62 (28%)	225
Sizewell E		29	10	10	49

Crithmum maritimum - strandline SH1a. Compt. 59 (476648).
(South of Sizewell boundary force, outside reserve), one plant

Cynoglossum officinale - rough grassland Compt. 59 (477660).

Deschampsia flexuosa - SD10b, Compt. 59 (477653). One small patch.

Dryopteris dilatata - locally frequent on west side of dune crest, SD6f and g, Compt. 59 (4765).

Elytrigia atherica - margin of saline pool, SM18. Compt. 49 (477663); rough grassland SD11b (477660), and landward dune SD12 (477653), Compt. 59.

Elytrigia juncea - eroded edge of dunes SD6a, b and c. Compts. 49 and 59 in a number of sites.

Erica cinerea - dry dune, H8a, three small patches with *Ulex gallii*; another two without *U. gallii*. Compt. 49 (4766); also two small clumps associated with *Calluna*, H1? at south end Compt. 59 (476650).

Eryngium maritimum - 12 plants on beach strandline, SD1a, at south end of Compt. 59 (477648). Another 38 plants, SD2, south of the Sizewell perimeter fence, outside the reserve (477647).

Filago minima - on dry gravelly E facing bank, SD11b, just north of the Sluice, Compt. 49 (477662).

Glaucium flavum - 57 seedlings on strandline, SD1a, Compt. 59 (477653). Two flowering plants and one seedling south of the Sizewell perimeter fence, outside the reserve. Also a few small plants beside track at north end of beach (Dunwich end), outside reserve (477675).

Glaux maritima - with other saltmarsh plants, saline seepage on path, SM16b, Compt. 49 (477663).

Humulus lupulus - scrub on the site of a cottage behind the dunes, near the Sluice, Compt. 59 (477660).

Jasione montana - several sites on dry dunes, SD8, SD11a and SD12, where vegetation short, Compt. 49 (one site) and Compt. 59 (4764, 4765, 4766).

Juncus gerardii - saline seepages along path and nearby runnel, with other saltmarsh plants, SM16b and SM18, Compt. 49 (477663).

Juncus maritimus - margin of saline pool and in a nearby runnel, SM18, Compt. 49 (477663).

**Lathyrus japonicus* - on sand and fine shingle at the top of the beech, SD1b, in three areas in Compt. 59 (477657, 477655 and 477650) and extending south of the Sizewell perimeter fence. Northern sites vulnerable to dune erosion. In 1970s extended into Compt. 49. The East Suffolk coast population is large and of considerable conservation importance in European terms.

Leymus arenarius - near eroded edge of the dunes, SD6b/c, at four sites in Compt. 59 (4765).

Lupinus arboreus - in some quantity, SD9, just south of the Sluice Compt. 59, mostly in 4766, but extending into 4765.

Oenanthe lachenalii - in damp hollow with *Phragmites*, S26, near path behind the dunes, Compt. 49 (477665).

Ophioglossum vulgatum - in damp hollow with *Phragmites*, S26, near path behind the dunes, Compt. 49 (477666). Has persisted at the site since at least the mid-1970s.

Orobanche minor - on dry gravelly bank, SD11b, just north of the Sluice, Compt. 49 (477661).

Plantago coronopus - frequent in trampled areas such as paths in Compts. 49 and 59.

Polypodium vulgare on west side of dune ridge, SD10b, Compt. 59 (477657).

Ruppia maritima - abundant in saline pool, SM2, north of the Sluice, Compt. 49 (477663).

Sedum anglicum - dry bare areas, SD11 and SD12, Compt. 49 (477662) and Compt. 59 (477658, 477648).

Silene uniflorum - in small quantity, SD12, Compt. 59 (477657). Also one plant just south of the Sizewell perimeter fence (477648) outside the reserve.

Smyrnium olusatrum - rough grassland just south of the Sluice, Compt. 59 (477660).

Spergularia marina - saline seepage on path, SM16b, Compt. 49 (477663).

Stellaria graminea - locally plentiful in hollows in dunes, SD10b, Compt. 59. (477653).

Trifolium arvense - dry, rather bare ground, SD11, close to the Sizewell perimeter fence at south end of Compt. 59 (477648).

Ulex gallii - four small patches on landward margin of dunes, H8a, northern half of Compt. 49 (4766).

Vulpia bromoides - on dry dune, SD8, Compt. 59 (477660).

6.3 Trees and shrubs on the Minsmere dunes

(*Probably bird 'sown'; +Planted).

Betula pendula - invading the West side of Compt. 59 from woodland to SW.

*Crataegus monogyna** - one bush, south half of Compt. 59.

Fraxinus excelsior - One small tree in thicket at NW side of Compt. 59 (site of former cottage).

*Lonicera periclymenum** - scrub north half of Compt. 49, and thicket NW side of Compt. 59.

Malus domestica+ - thicket as above, Compt. 59.

Pinus sylvestris - one bush on dunes, north half of Compt. 59, and invading SW side of that Compt.

Prunus domestica+ - thicket as above, Compt. 59.

*Quercus robur** - two small trees at south end of Compt. 59.

*Rosa canina** - one bush south half of Compt. 49; two sites south end of Compt. 59.

*Rosa tomentosa** - one bush on dunes, south half Compt. 59.

Rosa setigera+ - a bush in thicket, the site of a former cottage, NW side Compt. 59 (477660).

Rubus fruticosus agg - thickets on west side of dunes, north half Compt. 49.

Salix caprea - thicket as above, Compt. 59.

*Sambucus nigra** - scrub, north half of Compt. 49 and North end of Compt. 59.

Sarothamnus scoparius - bank north of Sluice, Compt. 49.

*Sorbus aucuparia** - one bush south half of Compt. 59.

Tamarix gallica[+] - thicket to east of path at North end of Compt. 59.

Ulex europaea - many fragmented thickets on west side of dunes in Compt. 49 and north half of Compt. 59.

7 Botanical features of conservation importance

The RSPB's Minsmere reserve is recognised as having a wide variety of habitats and hence a rich biodiversity. The survey revealed 16 NVC communities plus 10 sub-communities on the beach strandline and coastal dunes (33 ha), and 29 communities plus five sub-communities on the grazing marshes and associated ditches north of the New Cut (43 ha).

7.1 Coastal grazing marshes

An interesting feature of the vegetation of these marshes is the saline influence near the coast. There seems to be a declining salinity gradient from 30.5‰ at the mouth of the New Cut, where seawater seeps into the channel through the Sluice, to virtually freshwater in the Cut and ditches 1.5 km inland. The water in the ditches of Compt. 80, close to the Sluice had a surface salinity of between 3.0 and 7.5‰ (up to 20‰ on the bottom). It is suspected that there is some saltwater seepage under the dunes and residue salt in the soils close to the former course of the Minsmere River.

The brackish conditions in Compts. 80 and others such as 75 and 77 have enabled saltmarsh NVC communities (SM16, 20, 21b and 23) to persist. A community resembling SM20 *Eleocharis uniglumis* saltmarsh in Compt. 80 near the Sluice was unexpected since it is largely associated with saltmarshes on the north western coast of Britain. The brackish ditches in Compt. 80 have the aquatic A21 *Ranunculus baudotii* community which has a local distribution in Britain (coasts of south-eastern and southern England). Another aquatic community, A6 *Ceratophyllum submersum*, that was recorded in five or six ditches (Compts. 71, 72, 80 and possibly others), is generally associated with brackish ditches and largely occurs near the coast of south-east England.

The following 14 'halophytic' plants (tolerant of saline conditions) were recorded on the coastal grazing marshes of the Minsmere Levels north of the New Cut:

*Althaea officinalis**
Aster tripolium
*Bulboschoenus maritimus**
*Ceratophyllum submersum**
*Eleocharis uniglumis**
*Elytrigia repens**
Glaux maritima
Juncus gerardii
*Potamogeton pectinatus**
Ranunculus baudotii
Salicarnia ramosissima
Spergularia marina
*Schoenoplectus tabernaemontani**
*Zannichellia palustris**

Juncus maritimus and *Ruppia maritima* occur at a saline pool at the landwardside of the dunes, just north of the Sluice (Compt. 49).

(*Species which also grow naturally in the absence of saline conditions.)

Of the freshwater ditches, the most botanically interesting ones were those in Compt. 41 at East Bridge. In one of these ditches, the increasingly local aquatic community A3 *Spirodela polyrhiza - Hydrocharis morsus-ranae* occurred. *Hydrocharis* was a constant in the absence of *Spirodela* in six ditch samples elsewhere on the Levels north of the New Cut.

Six species of *Potamogeton* and *Zannichellia palustris* were recorded in ditches on the Levels. *P. trichoides*, a Nationally Scarce species, was recorded in one ditch in Compt. 77. In 1992, it was recorded on the reserve near East Bridge (Compt. 30/31). A new species for the reserve was *P. alpinus* in a ditch on the north border of Compt. 41, at East Bridge. It is a scarce plant in lowland, southern Britain, but not Nationally Scarce.

Sonchus palustris is Nationally Scarce; it is now widespread and apparently increasing on the Minsmere Levels, particularly associated with distributed ground along ungrazed ditch banks. Being a tall plant (over 2m) it can complete with *Phragmites*.

7.2 Strandline and dunes

Within a transect of less than 200m, across the dunes south of the Sluice (Compt. 59) it is possible to pass through up to eight sand dune communities. Towards the south end of Compt. 59 the strandline vegetation has remained reasonably intact, including some small patches of the Nationally Scarce SD1b *Rumex crispus - Glacium flavum* shingle community *Lathyrus japonicus* sub-community. In this area *Crambe maritima, Eryngium maritimum, Glaucium flavum* as well as *L. japnicus* occur. The East Suffolk coast population of *L. japonicus* is large and of conservation importance in West Europe.

The dune vegetation grades into what is virtually acid grassland (SD12a *Carex arenaria - Festuca ovina - Agrostis capillaris*) and heath (H8 *Calluna vulgaris - Ulex gallii*). *Cladonia portentosa* is locally abundant, and both *Ulex gallii* and *Sedum anglicum*, more typical of western Britain, occur.

Nationally Scarce plants that occur on Minsmere's dunes and strandline are: *Lathyrus japonicus* and *Corynephorus canescens*, though the latter was apparently introduced in the 1950s.

8 Some management recommendations arising from the survey

8.1 Strandline and dune erosion

The strandline flora which includes the Nationally Scarce SD1b community with *Lathyrus japonicus* is under considerable threat from erosion at Minsmere. It has all but disappeared from Compt. 49, to the north of the Sluice, and in Compt. 59 is now largely confined to near the southern boundary of the reserve. The *Lathyrus* was formerly more widespread (in the 1970s it was present in Compt. 49) but now only occurs in three restricted areas in Compt. 59. Much of the erosion which is cutting away the seaward face of the dune seems to be due to wave action, but in Compt. 49, to the north of the Sluice, human trampling pressure has seriously damaged the dune vegetation. Particularly at risk is the Nationally Scarce grass *Corynephorus canescens* that grows on the landward slope of the dune, almost opposite the beach exit of the footpath that cuts across the marsh from the car park and centre. Localised light to moderate trampling pressure can, however, benefit certain small plants that are out-competed by taller vegetation.

Recommendation: that sections of dunes in Compt. 49 be fenced/roped off to protect existing vegetation of conservation importance (eg *Corynephorus canescens*) from erosion by human trampling, and to allow re-establishment of strandline vegetation, particularly such species as *Crambe maritima, Glaucium flavum* and *Lathyrus japonicus*. Key areas for action are the north end (access from Dunwich cliffs) and opposite the exit of footpath across the marsh to the beach. It may be necessary to reintroduce the above plants if they do not reappear after several years of beach protection.

8.2 Ditch management

Most of the ditches on the Levels to the north of the New Cut had been recently cleaned out and were in good condition for aquatic plants. However, those around Compt. 41 at East Bridge , which were among the highest in botanical quality of the ditches surveyed, were shaded by willows and alders, and were in danger of losing their interest. This applied particularly to ditch 413 in which *Potamogeton alpinus* occurred.

Recommendation: that trees, scrub and other tall bank vegetation (eg *Carex riparia*) are cut back to allow more light to the ditches around Compt. 41. It may also be necessary to clean out sections of these ditches.

8.3 Conservation of saltmarsh and brackish ditches

An interesting feature of the Minsmere Levels is the brackish state of the ditches and fields in the vicinity of the sluice and the old course of the Minsmere River. The Sluice leaks allowing seawater to seep into the New Cut. The Minsmere River was probably tidal near its mouth in former days. There may be some seepage through the dunes. There is something of a salinity gradient as one goes inland and away from the Sluice and Minsmere River. Fifteen plant species recorded on the grazing marshes and in the ditches on the Levels were considered to be halophytes (salt tolerant). Some of the wet fields (eg 71 and 72) which are grazed by cattle are also much used by feeding geese. Conversion to a reedbed would destroy much of the botanical interest.

Recommendation: that Compts. 70-73, 75-77 and particularly 80 are retained as coastal grazing marsh which is allowed to flood in winter. This should maintain the brackish saltmarsh conditions and associated flora.

8.4 Scrub invasion of the dunes

There was evidence of birch *Betula pendula* and Scots pine *Pinus sylvestris* and even oak *Quercus robur* invading the landward side of the dunes at the south end of Compt. 59. In time this scrub could succeed the acid grassland (SD12a) and heath (H8).

Recommendation: that scrub invasion of the dunes is kept under observation and in time it may be necessary to clear it.

9 Acknowledgements

I should like to acknowledge Russell Cryer with whom I conferred while he was carrying out a NVC survey of the adjacent coastal grazing marsh to the south of the New Cut.
Geoff Welsh, Reserve Manager at Minsmere, was most helpful, supplying me with maps and advice.

Repeat Vegetation Survey of the Beach and Dunes at Minsmere RSPB Nature Reserve, Suffolk, 2004. CJ. Cadbury

Summary

The beach and dunes at Minsmere RSPB nature reserve, Suffolk have been increasingly suffering from erosion and are vulnerable to sea level rise. As a result, steps to strengthen the sea defences are being considered.

To asses the botanical conservation importance of the dune flora and the potential implications of damage to it from erosion and engineering works, a survey of the vegetation of the beach and dunes was undertaken in September 2004, repeating a similar survey in 1993.

This survey revealed encouraging recolonization by both Sea Kale *Crambe maritima* and Yellow-Horned Poppy *Glaucium flavum* of the beach north of the Sluice (Compartment 49); recolonization of the semi-fixed dune north of the Sluice by Sea Pea *Lathyrus japonicus* (NSc); strong populations of both Sea Kale and Sea Pea on an extensive fine shingle platform at the south end of the reserve (Compt 59), and two flourishing colonies of Grey Hair-grass *Corynephorus canescens* (Near Threatened) on the landward side of the dunes in Compt 49. Those sites in Compt 49 are vulnerable to both erosion and engineering works. In Compt 59, where the dunes are both wider and higher, there is erosion of the dune cliff, but strengthening of the sea defences appears less urgent.

The predominant vegetation of the fixed dune is Sand Sedge *Carex arenaria* and Marram *Ammophila arenaria* dominated (SD10) on the higher seaward ridge and Sheep's Fescue *Festuca ovina* and Sand Sedge (SD12a) on the inner landward areas. There are small fragments of a heathland type vegetation (H1 and H8), but insufficient to justify open public access. Gorse *Ulex europaeus* cover on the dune, especially to the north of the Sluice, has apparently increased since 1993. To the south of the Sluice, Sand Sedge cover has increased, particularly to the exclusion of less competitive plants. In an attempt to reduce the density and height of Sand Sedge and to control scrub invasion (mostly Pedunculate Oak *Quercus robur* and Downy Birch *Betula pubescens*) seasonal sheep grazing has been introduced at the south end of the dunes. The effect shows promise.

1 Introduction

The beach and dunes that extend along the shore of Minsmere Haven, East Suffolk, are one of the important habitats represented on the Minsmere RSPB nature reserve. They also provide an essential defence for the freshwater Minsmere Levels against sea incursion. Already there are abundant signs of erosion of the beach and dune cliff. In the winter of 2003/04 the sea over-topped the dunes at the Dunwich (National Trust) end. For the Minsmere marshes to survive in their present form it is clear that the sea defences will probably have to be strengthened, even if the measures may only be effective in the short term.

A survey carried out by the author in July 1993 had identified the botanical riches of these narrow dunes which extended from the southern end of the Dunwich cliffs to Sizewell. This survey aimed at gauging the subsequent changes in shore profile and how engineering works to strengthen the sea defences might effect the vegetation of the beach and dunes. It enables an assessment to be made of the botanical conservation importance of the Minsmere dunes, and suggests how damage to the flora could be mitigated.

2 Method

The present survey was undertaken over two days, 8 and 9 September 2004 in fine weather. The following were recorded:

a) Beach profile and substrate.
b) Height and condition (extent of erosion) of the dune cliff.
c) NVC communities of the beach and dunes back to the eastern margin of the grazing marsh.
d) Distribution of selected, less widespread plants.
e) Population size (counts of individual plants) of key strandline plants:
   Yellow-horned Poppy *Glaucium flavum*
   Sea Kale *Crambe maritima*
   Sea Holly *Eryngium maritimum*
   Sea Pea *Lathyrus japonicus (NSC)*
   Rock Samphire *Crithmum maritimum*
   Also Grey Hair-grass *Corynephorus canescens* (Near Threatened)
f) A small amount of data were collected on the effects of sheep grazing by comparing the height of vegetation, both within and outside fence lines of enclosures.

Global Positioning System was used extensively to record eight figure grid references. Data were recorded on 1:10,000 maps. Comparisons could be made with similar information collected 11 years earlier.

3 Results

Six habitats were represented on the Minsmere dunes:

a) Beach strand line and eroded dune cliff.
b) Mobile and semi-fixed dune
c) Fixed dune
d) Heathland
e) Saltmarsh

f) Scrub and woodland
The last three were only minor components.

3.1 NVC Communities (see Rodwell 2000) – Maps 1 and 3

3.1.1 Beach Strandline

In view of the changes in beach profile and erosion the strandline vegetation is likely to be particularly dynamic.

SD1 *Rumex crispus – Glaucium flavum* shingle
Yellow-horned Poppy *Glaucium flavum* was locally frequent with Sea Kale *Crambe maritima* and Sea Purslane *Honckenya peploides* on the fine shingle of the upper beach in the southern half of Compt 49. Elsewhere, however, on the shingle platform at the south end of Compt 59, where *Crambe, Honckenya* and Curled Dock *Rumex crispus* were a feature, *Glaucium* was sparse. Since Sea Pea *Lathyrus japonicus* was frequent, the community there may be assigned to the *Lathyrus japonicus* sub-community (SD1b).

(SD2 *Honckenya peploides – Cakile maritima* strandline)
With Sea Rocket *Cakile maritima* absent this community was probably not represented on the Minsmere shoreline.

3.1.2 Mobile, semi-fixed and fixed dune

SD6 *Ammophila arenaria* mobile dune community.
This Marram Grass community occurred on the seaward margin of the dunes and on the dune cliff, often where there was erosion. It was widespread, but in most places was present as a narrow band. SD6 was a feature of the upper beach north of the Sluice in Compt 49 and just south of the Sluice in Compt 59. Associates included Sea Bindweed *Calystegia soldanella* , Sand Couch *Elytrigia juncea,* Rush-leaved Fescue *Festuca arenaria* and Lyme Grass *Leymus arenarius*. None of them was present in quantity justifying SD4 *Elytrigia (Elymus) juncea* foredune or SD5 *Leymus arenarius* mobile dune communities. Tree lupin *Lupinus arboreus* was naturalized along the dune cliff just S of the Sluice in Compt 54.

SD7 *Ammophila arenaria – Festuca rubra* semi-fixed dune community.
This community formed the vegetation along the seaward fringe of the dune ridge above and on the sand cliff. Red Fescue *Festuca rubra* was frequent. In several places the Common Rest Harrow *Ononis repens* sub-community SD7c was associated with *Lathyrus japonicus* as at 4771 6555 in Compt 59.

SD10 *Carex arenaria* dune community.
This was one of the most frequent communities in Compt 59 where it extended over much of the length of the dunes on the landward (west) side of the main dune ridge. It featured a dense sward of Sand Sedge *Carex arenaria*. Associates were *Ammophila arenaria,* Spreading Meadow-grass *Poa humilis* and somewhat surprisingly Sea Couch *Elytrigia atherica*. Broad Buckler Fern *Dryopteris dilatata* was frequent in the landward side of the dune crest where there may be a more humid microclimate. *Carex arenaria* appears to have increased since 1993 and may be reducing the floral diversity of the dunes.

SD11 *Carex arenaria – Cornicularia aculeata* dune community.
This community was associated with the desiccated landward slope of the fixed dunes and was apparently restricted to a few sites in Compt 49 and the National Trust land at the north end of the dunes. Associates included Grey Hair-grass *Corynephorus canescens* (Near Threatened) in two areas (4779 6744 and 47778 6700), Sheep's Sorrel *Rumex acetosella*, Buck's-horn Pantain *Plantago coronopus*, Biting Stonecrop *Sedum acre*, English Stonecrop *S anglicum*, Sheep's-bit *Jasione montana*, Small Cudweed *Filago minima*, Cat's-ear *Hypochaeris radicata*, Early Hair-grass *Aira praecox*, Sheep's Fescue *Festuca ovina*, the mosses *Campylopus introflexus* and *Polytrichum juniperum*, and *Cladonia* lichens. The sites with *Corynephorus* were asigned to the SD11c *Ammophila* sub-community.

SD12 *Carex arenaria – Festuca ovina – Agrostis capillaris* dune grassland.
A community of the lower, drier areas on the landward side of the dunes, extending over much of the length of Compt 59. It forms a zone inland of AD10 and is considerably more open than that community *Festuca ovina* was dominant and both *Carex arenaria* and Common Bent *Agrostis capillaris* were frequent. There were areas (such as 4766 6563 and 4765 6465) where *Cladonia portentosa* was a feature. Mouse-ear Hawkweed *Pilosella officinarum*, Field Woodrush *Luzula campestris* and the moss *Dicranum scoparium* were associates. At one site (4766 6565) there was a small (relict?) patch Sea Campion *Silene uniflora* . In view of the scarcity of Yorkshire Fog, *Holcus lanatus*, the sub-community was probably SD12a.

3.1.3 Neutral grassland

MG1 *Arrhenatherum elatius* coarse grassland community
This tall grass community occurred in several places around the Sluice (Compt 59) on the landward side of the dunes. It features False oat *Arrhenatherum elatius*, Sea Couch *Elytrigia atherica* and Cock's foot *Dactylis glomerata*.

3.1.4 Heathland

Only fragments of heath occurred on the dunes among SD10 and SD12a.

H1 *Calluna vulgaris – Festuca ovina* heath
A fairly large patch of Heather *Calluna vulgaris* at the north end of the oak/birch woodland (4571 6489) probably represented this community. It was associated with an adjacent stand of Wavy Hair-grass *Deschampsia flexuosa*. Close by was SD12a dune grassland. A small patch of what could be described as H1 occurred among SD10 at 4758 6502.

H8a *Calluna vulgaris – Ulex gallii* heath
Very small and scattered fragments of what was probably this community featuring Bell Heather *Erica cinerea* and Western Gorse *Ulex gallii* occurred in Compt 49 (478 666 and 478 668). *Calluna* was in most instances absent. The community had a similar distribution in 1993.

The dunes have been proposed as an open access area on account of the presence of heathland with Heather. As shown above this is unjustified and the status should be reviewed.

3.1.5 Swamp

S26 *Phragmites australis* fen community

This occurred as a few small stands on the landward side of the dunes in Compt 49 (4776 6647) and a more extensive one on the western margin of Compt 59 abutting the grazing marsh (4772 6590). At 4776 6647 an associate was Parsley Water-dropwort *Oenanthe lachenalii*, but Adder's-tongue *Ophioglossum vulgatum*, observed there in 1993, was not refound. (This site was drier and had become invaded by *Rubus fruticosus*).

3.1.6 Saltmarsh

Saline seepage just north of the Sluice, Compt 49 has resulted in a local development of saltmarsh vegetation around two brackish pools and along the adjacent path.

SM2 *Ruppia maritima* saltmarsh

A brackish pool with abundant *Ruppia* just north of the Sluice, Compt 42. 47756631

SM16b *Festuca rubra* salt-marsh *Juncus gerardii* sub-community

This community with Saltmarsh Rush *Juncus gerardii*, Sea milkwort *Glaux maritima* and Creeping Bent *Agrostis stolonifera* predominant was a feature of runnels in the trampled path to the north of the Sluice (4775 6647 – 4775 6639). Red Fescue *Festuca rubra* was apparently absent. Silver Weed *Potentilla anserina* occurred in one section of the path.

SM18 *Juncus maritimus* saltmarsh community

This was restricted to the margins of two brackish pools and a hollow (former pit?) just north of the Sluice, Compt 49 (4775 6631 and 4775 6635). Sea Rush *Juncas maritimus* was predominant, with Sea Aster *Aster tripoleum* (ray-flowered form), Sea Couch *Elytrigia atherica* and *Agrostis stolonifera* as associates.

SM24 *Elytrigia atherica* salt-marsh community

This too, with Sea Couch *E atherica* predominant, formed stands along side SM18 around the two brackish pools just north of the Sluice. Compt 49. There were also isolated stands elsewhere, as at 4772 6604, Compt 59, where there were no obvious brackish incursions

3.1.7 Woodland and scrub

W16a *Quercus* spp – *Betula* spp – *Deschampsia flexuosa* woodland.

At the southern end of Compt 59, Pedunculate Oak *Quercus robur* and Downy Birch *Betula pubescens* had invaded SM12a dune grassland and become dense on the western margin. Wavy Hair-grass *Deschampsia flexuosa* was however decidedly scarce (see above under H1). Grazing by four or five rams in an enclosure to the north of the dense woodland had effectively killed much of the oak and young birch, but the larger birch had survived. The grazed area has reverted to SM10 with much *Carex arenaria*.

A few small stands of W16a who occur on the inner dune ridge further north.

W23 *Ulex europaeus – Rubus fruticosus* scrub

This community was widespread on the landward side of the dunes in both Compt 49 and 59. Common Gorse *Ulex europaeus* and Bramble *Rubus fruticosus* agg. were predominant, but associates were Honeysuckle *Lonicera periclymenm*, Broom *Cytisus scoparius* (scarce) and Elder *Sambucus nigra*. At 4768 6522, where the high dune cliff had been eroded, blocks of

dune with both *Lonicera* and *Rubus fruticosus* had fallen onto the beach below. The stands of *Ulex europaeus* appear to have become more extensive, particularly in Compt 49.

4 Distribution and populations of selected plants

4.1 Strand line and mobile/semi-fixed dune (see Maps 2 and 4)

Armeria maritima Thrift
A small patch on the landward slope of the eroded dune at the N (Dunwich) end TM 4778 6746. National Trust. Not recorded 1993.

Beta maritima Sea Beet
A single plant on eroded shingle and sand at N end of dunes 4779 6734. National Trust. Seven plants on a shingle platform at extreme S end, 4764 6452, Compt 59. SD1. Not recorded 1993.

(*Cakile maritima* Sea Rocket)
Recorded at 4765, Compt 59, 1993. Not observed in 2004.

Calystegia soldanella Sea Bindweed
Scattered along seaward edge of dunes, often on eroded cliff above beach. SD1, SD6, SD7.
Compt 49 4781 6716, 4781 6660, 4780 6640, 4780 6636, 4780 6633, 4780 6628.
Compt 59 4779 6614, 4774 6570, 4766 6486, 4764 6452 (shingle platform)
Probably little change from 1993, though habitat subject to erosion.

Crambe maritima Sea Kale (not scarce)
Has spread considerably since 1993 with many plants on the shingle and sand beach in Compt 49. Frequent on shingle platform at S end of Compt 59. Many young plants. SD1

Compt 49 (134 plants)		Compt 59 (267 plants)	
4779 6756	1 (small)	4779 6614	2
4782 6700	4	4777 6592	1
4781 6682	25	4777 6590	1
4782 6678	20	4776 6586	1
4782 6674	9	4772 6573	2
4781 6660	32	4772 6553	1 low cliff
4782 6659	12	4771 6550	2 shelf
4782 6654	6	4771 6545	5 step
4781 6646	7	4770 6543	2 step
4781 6638	3	4770 6541	1
4781 6633	4	4767 6495	14
4780 6628	2	4766 6488	1
4780 6626	3	4766 6476	27 sand with little shingle at base of cliff
4779 6615	5	4766 6479	20 inc one on bank
		4766 6477	1 top of cliff

4766 6475 – 7464 6452	186 fine shingle platform 292m long, 4m wide a N end, 11m at S end.

This population extends further S along the Sizewell beach. Has benefited from the change to more gentle beach profile in Compt 49 to N of the Sluice. Absent from the beach where there is a high sand cliff (2 – 5m) 4776 6536 – 4767 6501 in Compt 59. The many young non-flowering plants indicates an expanding population. The large fruits are buoyant in water and appear suitable for dispersed by sea. The dried dead plants may also be blown along the beach in winter.

Crithmum maritimum Rock samphire
Still a scarce plant in the reserve. Only three plants at 4778 6606, Compt 59. SD1. Not observed on the shingle platform at the S end of the reserve.

Elytrigia juncea Sea couch
Apparently thinly scattered on sandy foredune/strand line, but probably overlooked at this time of year. SD6 (SD1)

Compt 49	4780 6666
Compt 59	4779 6614 Eroded cliff near Sluice
	4764 6452 Fine shingle platform at S end.

Eryngium maritimum Sea Holly
Has spread and increased within the reserve benefiting from the deposition of fine shingle and sand along the beach. SD1. Only a single plant in Compt 49 N of the Sluice (4781 6633). 59 plants in Compt 59.
Compt 59:

4778 6606	1
4778 6604	5 non-flowering
4779 6600	2
4778 6597	1 nf
4777 6594	8
4777 6590	2
4776 6588	1
4776 6583	3 (1 nf)
4776 6475 – 4764 6457	26 (some nf) fine shingle platform

The latter area had 12 plants in 1993.
The population extends S towards Sizewell, but was not surveyed.

Festuca arenaria Rush-leaved Fescue
What is probably this taxon was scattered on sand at the base of beach cliff. Robust with long rhizomes and large spikelets. SD6
Compt 49: 4779 6740, 4779 6734, 4781 6716 (extending over 6m)
Compt 59: 4778 6604, 4778 6597, 4776 594, 4766 6486
Not recorded (overlooked) in 1993.

Glaucium flavum Yellow Horned Poppy

As with *Crambe maritima*, *Glaucium* has spread and become locally frequent in Compt 49 where the beach had a more gentle profile than in 1993. Many young plants indicated recent colonization. Scarce in Compt 59 but still present on the fine shingle platform at the south end where recorded in 1993. A larger population on the Sizewell Power Station beach not surveyed. SD1.

Compt 49 (684 plants)

4777 6761 – 4778 6755	113 (many young plants)
4777 6753	5
4779 6743	7

4765 6464	87	
4765 6460 – 4764 6457	100s	

Has increased in Compt 59 and spread back into Compt 49 since 1993.

Leymus arenarius Lyme Grass
Scattered along the eroded edge of the dunes, mostly in Compt 59 where recorded at four sites in 1993. Only one fairly large patch. SD6 mobile dune. Vulnerable to erosion.

Compt 49 (one site)

4871 6727

Compt 59 (seven sites)

4779 6600	1 shoot
4775 6575	c. 40 shoots
4771 6555	2 shoots
4772 6553	Many shoots
4770 6543	Extending over 29m on low cliff
4767 6501	On three eroded tussocks fallen from the dune cliff onto the beach
4765 6464	A few shoots on fine shingle platform

Salsola kali Prickly Saltwort
A single plant on sand at base of eroded cliff, Compt 59, 4766 6478. Not recorded on reserve in 1993.

Senecio squalidus Oxford ragwort
Not typically a strandline plant, but a number of plants growing on the fine shingle platform at the southern end of Compt 59, 4764 6457 and 4764 6452, SD1.

Senecio viscosus Sticky groundsel
Growing with *Honckenya peploides* on fine shingle platform at the extreme southern end of Compt 59, 4764 6452, SD1.

4.2 Fixed dune

Campanula rotundifolia Hair-bell
Only recorded in SD10 a short way S of the Sluice, 4772 6590, Compt 59. In 1993 observed in small quantity at three sites in this Compt.

Cladonia portentosa A lichen
Characteristic of dry rather open fixed dune grassland in Compt 59. SD11 and SD12a.

4766 6563	SD12a with *Silene uniflora*
4764 6551	SD12a
4768 6482	SD12a
4762 5465	SD11
4765 6465	SD12a

Corynephorus canescens Grey Hair-grass (Near Threatened)
Restricted to a site at the north end of the beach (National Trust land) and another in Compt 49. Well established but introduced from Norfolk stock after the 1953 floods (Simpson 1982). Both populations occur on desiccated fixed dune on the landward side (SD11a).

National Trust:

4776 67744	c. 330 tussocks immediately S of large Tamarisk *Tamarix gallica* bushes and steps on the landward (west) slope if the eroded shingle bank.

Compt 49:

4778 6704 – 4778 6697	1070 tussocks extending over 76m on landward slope of dry trampled dune just S of gate from path that leads across North Marsh to the dunes from the Minsmere Centre.
4780 6700	Another 50 tussocks beside and on the wide much trampled track on the dune crest close to the previous site.

Vulnerable to trampling and dune erosion. Indeed , a selection of the northern population apparently lost when the sea broke over the shingle ridge in the 2003/04 winter.

Dryopteris dilatata Broad Buckler-fern
Compt 59: Frequent along the outer dune crest, just on the landward (west) side. Also on the inner dune ridge, SD10.
Eg TM 4774 6599
47726585 – 4777 6588
4770 6584
4769 6574
4769 6567
4765 6533 abundant
4765 6528 abundant
4766 6533
4766 6515
4766 6504
4551 6595

Filago minima Small Cudweed
On dry gravely banks with vegetation sparse. With such species as *Aira praecox, Plantago coronopus, Rumex acetosella* and *Sedum anglicum*. SD11b.
Compt 49:
Eg 4776 6631, just N of the Sluice,
Also elsewhere

Jasione montana Sheep's-bit
Scattered along the seaward edge of the dune ridge and mown margins of paths further inland. In dry situations, mostly SD11b but also SD7c

Compt 49:	Compt 59:
4776 6647	4783 6513
4780 6643	4755 6475
4780 6640	
4779 6619	

Polypodium vulgare Polypody
Only recorded at one site near the northern end of the dunes. Compt 49, 4779 6719, but probably on the dune ridge in Compt 59 (see 1993 survey).

Sedum anglicum English Stonecrop
Recorded on a dry gravely bank on the landward slope of the dunes north of the Sluice, Compt 49, 4776 6631 SD11b. Probably in similar situations elsewhere but September not a good time to survey this species.

Silene uniflora Sea Campion
The small patch (1 x 1.5m) refound among *Festuca ovina – Clodania potentosa* between two tracks on the landward side of the main dune ridge, Compt 59, 4766 6565. A more extensive patch was there in 1993. It was not recorded on shingle at the S end of Compt 59 where observed in 1993.

4.3 Heathland

Calluna vulgaris Heather
Very thinly scattered on the inner side of the dunes. In no way can any part of the dunes be identified as more than isolated fragments of Heather-dominated heathland and this negates their proposed open access status.

Compt 49:

4779 6657	SD12a

Compt 59:

4763 6537	SD12a
4758 6502	Small patch of H1 in SD10
4749 6491	SD12a (ram-grazed)
4571 6489	A fairly large patch just N of dense oak/birch woodland and to W of track. Extending in small quantity to E of track.

Deschampsia flexuosa Wavy Hairgrass
Not a typical plant of the East Suffolk heathland. A single small patch adjacent to a large patch of *Calluna* just N of oak.birch woodland at the S end of Compt 59, 4571 6489. H1?

Erica cinerea Bell Heather
Thinly scattered on the dunes and more widespread than *Calluna*. In a few places where associated with *Ulex gallii*, the vegetation could be ascribed to relict H8 *Calluna vulgaris – Ulex gallii* heath but the patches are very limited. Mostly growing in SD12a.

Compt 49	Compt 59
4778 6676	4768 6597
4779 6674	4758 6502 (with *Calluna*)
4776 6656	4755 6475
4775 6653	4752 6470

Ulex gallii Western Gorse
Thinly scatted in Compt 49; one site in Compt 59. flowering, but so was some *U europaeus*.

National Trust:

4779 6739	Shingle ridge

Compt 49:

4779 6731*	With *Ulex europaeus* and *Elytrigia atherica*
4778 6700*	With *Glaux maritima*
4780 6700	With *Ulex europaeus* on dune ridge
4778 6678	Among *U europaeus* and *Rubus fruticosus*
4776 6650	With *Erica cinerea* (H8?)

Compt 59:

4751 6495	SD12a. Ram-grazed area that was oak/birch scrub. One bush.

Four small patches on landward margin of dunes in the northern half of Compt 49 (all 4766) in 1993. described as H8 *Calluna vulgaris – Ulex gallii* heath. At two of the 2004 sites halophytic plants were present, probably as a result of recent sea incursions.

4.4 Halophytes (saltmarsh)

This element of dune vegetation occurred where there was a brackish seepage just north of the Sluice, Compt 49.

Elytrigia atherica Sea Couch

Frequent around two brackish pools just north of the Sluice Compt 49 4775 6635 and 4776 6631 where associated with other halophytes (see below). SM18. Also stands among dry fixed dune grassland SD10 and SD12a.

eg Compt 49: 4779 6740, 4779 6731, 4779 6709, 4777 6624
Compt 59: 4772 6604, 4774 6596, 4772 6567, 6765 6562, 4559 6478, 4795 6466, 4765 6485

Glaux maritima

Frequent with other halophytes around a brackish seepage along the path just north of the Sluice, Compt 49 4775 6639, SM16b. Also on landward side of dune just S of gate onto dunes from the North Marsh path 4780 6607.

Juncus gerardii Saltmarsh Rush

Locally frequent in damp ruts on path just north of the Sluice and in a small area of brackish fen nearby, Compt 49, 4775 6647, 4775 6645 with *Potentilla anserina*, 4775 6639. There is a saline seepage at this point. SM16b and SM18.

Juncus maritimus Sea Rush

Locally frequent around two brackish pools just north of the Sluice, Compt 49 4775 6635, 4776 6631. SM18.

Lotus glaber Narrow-leaved Bird's-foot Trefoil

Along margin of path near brackish pools just north of the Sluice, Compt 49. 4775 6639. SM16b.

Oenanthe lachenalii Parsley Water-dropwort

A few plants with *Phragmites australis* in a small brackish fen north of the Sluice, Compt 49. 4776 6647. S26.

Plantago maritima Sea Plantain
A small quantity with *Agrostis stolonifera, Glaux maritima* and *Juncus gerardii* in a damp rut on path just north of the Sluice. Compt 49 4775 6639. Not recorded in 1993.

Ruppia maritima Beaked Tasselweed
Plentiful in the southern of the two brackish ponds north of the Sluice, Compt 49. 4775 6631. SM2.

Scrub

Cytisus scoparius Broom
Only a few bushes on dunes to N of the Sluice.
National Trust: 4779 6744. Compt 49: 4775 6641

Humulus lupulus
Scrambling over scrub just S of the Sluice. Compt 59. 4772 6606.

Ilex aquifolium Holly
One compact bush on dune ridge, Compt 59 47774 6599.
Not recorded in 1993.

Lonicera periclymenum Honeysuckle
Fairly frequent on the dune ridge, Compt 59 and extending onto the beach where the cliff has been eroded 4768 6522.

Lupinus arboreus
Naturalized on the dunes to the S of the Sluice, Compt 59. Mostly on mobile and semi-fixed dune SD6 and SD7.
4774 6612
4778 6603 (2 bushes)
4772 6604 – landward side near path
4778 6604 (2)
4778 6597 (15)
4777 6594 (2)
4776 6583 (1)

Autumn Ox-eye *Leucanthemella serotina*
A substantial strand in rough vegetation between the Sluice and the bushes to the south 477 660. The South-east European native is clearly introduced and the site is the garden of a former cottage. In full flower (large white daisies) in early October 2004. Determined by Peter Sell, Cambridge University Herbarium.

5 Grazing by sheep

Several fenced plots towards the south end of Compt 59 have been grazed by sheep in recent years. This includes a fairly large plot on the western side of the dunes north of the block of

woodland. Here the grassland had been invaded by Pedunculate Oak *Quercus robur* and Downy Birch *Betula pubescens* scrub. Up to four rams were grazed there for much of two years. They had succeeded in killing off most of the young birch and oak, but the taller birch (over 3m) had largely survived. The vegetation of the area had reverted to SD10. Measurement of vegetation taken on either side the fence line of two enclosures demonstrated a marked effect in its height but little in the species composition (Table 1)

Height (cm)	4759 6474		4769 6422	
	Grazed	Ungrazed	Grazed	Ungrazed
Cladonia portentosa	4,5	13,13	4,4	48,50
Carex arenaria	20,23	55,57	6,9	51,60
Festuca ovina	24,25	45,46	15,16	50,55

	5034 3634	
	Grazed by rams	Ungrazed
Height of ground vegetation (SD10 with *Carex arenaria*)	34, 34, 36, 43, 50	67, 73, 80, 80, 85

6 Changes since 1993

Beach profile

At the north (Dunwich) end of the beach there has been considerable erosion and the narrow dune ridge was over-topped by a surge in the 2003/04 winter which resulted in the deposition of much fine shingle and sand on the ridge.

Over a 500m stretch to the north of Sluice in Compt 49 shingle and sand has built up to give the beach a more gentle graded profile and the dune cliff has disappeared from this sector.

To the south of the Sluice in Compt 59 the dune cliff (up to 5m high) has been cut back by erosion over about a one km stretch.

At the upper part of the beach at the south end of Compt 59 there is platform of fine shingle that extends for 292m along the shore within the reserve. The shingle beach was present in 1993 but the platform had become more defined.

Strandline vegetation

As in 1993, SD1 was best respresented on the fine shingle platform near the southern boundary of the reserve, Compt 59. However, both Sea Kale *Crambe maritima* and Yellow-Horned Poppy *Glucium flavum* are now flourishing on the gentle graded beach to the north of the Sluice Compt 49, from which they were absent in 1993. Sea Holly *Eryngium maritimum* has also spread northwards to just south of the Sluice, in Compt 59. Sea Pea *Lathyrus japonicus* has several strong colonies on the semi-fixed dune (SD7) as well as on the fine shingle platform in Compt 59 and has recolonized Compt 49, where it occurred in the 1970s. Thrift *Armeria maritima*, Prickly Saltwort *Salsola kali* and Rush-leaved fescue *Festuca arenaria* were not recorded on the Minsmere dune in the 1993 survey; Sea Rocket *Cakile maritima* on the other hand appears to have disappeared since 1993.

Dune vegetation

Sand sedge *Carex arenaria* has developed a dense sward and forms the dominant fixed dune vegetation (S10) over most of the outer and higher ridge in Compt 59 to an extent that it probably excludes less competitive species. Nevertheless Broad Buckler-fern *Dryopteris dilatata* is a feature of the landward side of the dune crest.

A Sheep's Fescue *Fetuca ovina* grassland (SD12a) is still a feature of the dry landward slopes of the dunes in Compt 59. Here there are patches of the lichen *Cladonia portentosa* as in 1993. Grey Hair-grass *Corynephorus canescens* contines to be restricted to two areas on desiccated fixed dune (SD11a) on the landward slope in Compt 49. At the northern Dunwich end it is particularly vulnerable to erosion as the colony is situated close to where the 2003/04 winter sea overtopping occurred. The relict population of Sea Campoin *Silene uniflora* persists in Compt 59, but the population has diminished.

Grazing by sheep in Compt 59 had reduced the density and structure of *Carex arenaria* in enclosures to the benefit of *Cladonia portentosa* and *Festuca ovina*. A few rams had effectively checked invasive young Oaks *Quercus robur* and birches *Betula pubescens* in an enclosure, but older, taller birch had survived.

7 Risk assessment for beach and dune vegetation and mitigation of potential damage

Strengthening the sea defences at Minsmere is likely to concentrate on the sector north of the Sluice (Compt 49) and entail use of material from the beach.

Vulnerable are:

- The newly established population of Sea Kale *Crambe maritima* and Yellow-horned Poppy *Glaucum flavum* on the beach (4777 6761 – 4776 6675).

- A strong colony of Sea Pea *Lathynus japonicus* (NSc) over a 30m stretch of outer dune just north of the gate onto the dunes from the North Marsh path (4781 6716) plus at least four small colonies.

- Two populations of Grey Hair-grass *Corynephorus canescens* (Near Threatened) on the landward slope of the dunes; one at the Dunwich end (4779 6744) and the other just south of the gate onto the dunes from the North Marsh path (4778 6704 – 4778 6697 and 4780 6700).

  The Sea Kale and Yellow-Horned Poppy are short-lived plants and provided a source of seed survives in the vicinity would recolonise the beach naturally, if it is not steeply inclined and wide enough to avoid much erosion.

  The Sea Pea grows on the semi-fixed dune at the top of the beach. It too would probably re-establish naturally from a local seed source, but less readily than the previous two species. Recolonisation could be aided by sowing seed from local sources (ie to the south of the Sluice).

  The Grey Hair-grass at Minsmere was apparently introduced from Norfolk stock in 1953, but the grass occurs naturally along the Covehithe coast to the north. It is a perennial and does not spread readily. Once a colony is destroyed it would have to be

reintroduced by planting. Every effort should be made to protect the sites from damage either from erosion or engineering works. While sea defences are being raised it may be necessary to temporarily remove the dune turf where it is growing.

- South of the Sluice (Compt 59) the dunes are both higher and wider. Improving sea defences is much less urgent. Every effort should be made to protect the fine shingle platform at the upper part of the beach at the southern (Sizewell Power Station) end of the reserve (4766 6475 – 4764 6460). Here there is a good strandline flora and strong population of both Sea Kale and Sea Pea as well as Sea Holly *Eryngium maritimum*. This site provides a source of seed for recolonization on neighbouring shores.

Assessing the impact of the tidal surge of 5/6 December 2013 on the shore profile and flora of RSPB nature reserves on the Norfolk and Suffolk coast

The situation

A major surge of seawater (3.1 m AODN) in the North Sea hit the Norfolk and Suffolk coast overnight on 5/6 December 2013. Immediately prior to the surge the wind was northerly but only light and the tide was nothing exceptional (high tide at King's Lynn at 1915 hrs on 5 December was 7.1 m). A surge had been forecast and on the 5th the sea retreated alarmingly at such places as Eccles on the north-east Norfolk coast. Overnight a massive wall of water, some two metres above the normal high tide level, swept onto the shore, overtopping the dunes and sea defences in a number of places. Havergate Island on the River Ore, East Suffolk, was almost completely inundated and the surge continued up the river to Snape. Following the surge the sea retreated fairly rapidly, unlike the situation in 1953 when a strong north-east wind coupled with a high tide held up the flood water for several days, causing widespread devastation.

The cause of this tsunami-like event was high atmospheric pressure in the northern part of the North Sea that drove a huge volume of water southwards into a low pressure area off the East Anglian coast.

Project objectives

Concentrating on the RSPB's reserves on the Norfolk and Suffolk coast these were:

a) To examine the shore profile to assess what changes may have resulted from the tidal surge.
b) To record the coastal flora in areas affected by the surge and where possible make comparisons with information obtained earlier.

Methods

Much of the recording effort was along transects from about the mid-high tide level, across the beach, over the dunes to the grassland or saltmarsh inland. The different zones, whether it be substrate (shingle, sand or mud) or vegetation on pioneer, building or stable, mature dunes, dry grassland or saltmarsh were recorded and measured in paces. The transects were about 10 paces wide. All species of vascular plants were noted and their frequency recorded. Particular attention was given to those species associated with the more mobile, less stable substrates on the seaward side of the shore. At Titchwell, however, attention was given to the high saltmarsh flora of depressions landward of the main dunes since these supported communities special to north Norfolk that have affinities with those of more southerly coasts of Europe, including the Mediterranean. Previous surveys of the more notable plants enabled some comparisons of distribution and populations.

Locations

The survey covered 6 RSPB reserves.

a) **Havergate Island** (East Suffolk, vc 27) where there are no dunes, but a stable shingle ridge bordered by a steep shingle beach on the south-east side and relatively high saltmarsh to the north-west, west of the accommodation huts, and high saltmarsh beside the River Ore to the north-east, outside the seawall protecting the lagoons. At the north end of the island the seawall has been deliberately breached.

b) **North Warren** (East Suffolk) where a shingle beach extends from the car park at the north end of Aldeburgh to the south end of Thorpeness (The Haven) to the east of the coast road.

c) **Minsmere** (East Suffolk), that extends north from the northern boundary of Sizewell Power Station at the southern end of the reserve, past the New Cut Sluice to the Dunwich Heath scarp (National Trust). There is a well defined dune ridge along this stretch of coast.

d) **Dingle** (East Suffolk) extends from the car park at the north end of Dunwich to the path that leads from the beach to Dingle Great Hill. The 2014 survey only continued for one km north of the car park to a fence across the beach. There is a shingle beach that narrows northwards and is severely truncated by erosion at its northern end. A reedbed borders the inland, west side of the shore.

e) **Titchwell** (West Norfolk, vc 28). The survey covered the stretch of coast from Brancaster golf club, past the seaward end of the path from the RSPB reserve Centre to the beach, to Thornham Point. There is a sand dune all along, backed by saltmarsh and the reserve's Tidal Lagoon.

f) **Snettisham Pits** (West Norfolk). This on the east side of the Wash. There is a narrow shingle beach on the seaward side of the Pits and north of the bungalows there is another shingle beach (The Scalp) south of the Yacht Club.

More details of the transects and grid references of sites are presented in a separate hand-written report.

Havergate Island

2 visits 13 May & 18 September, 2014

One transect (13.5) from beach on SE shore (TM 40804686) to river edge of saltmarsh on NW shore, between Doveys Lagoon and the accommodation huts, 7 vegetation zones identified and recorded. SE shore from Doveys Lagoon – opposite Main Area covered. Second visit to record *Salicornia* spp., *Sarcocornia perennis* and *Spartina maritima*. Previous botanical information from 1971, including 2013.

The surge inundated most of the island, destroying the Gullery Lagoon Hide (picked up and turned 45° and Main Area Reception Centre. Main Area Hide badly damaged, having been moved several metres. Accommodation huts flooded to depth of 45 cm. Subsequently Doveys Lagoon bank lowered to allow flood water to be discharged.

SE shore of the island eroded to the effect that the shingle beach between the Huts and Doveys has become increasingly steep.

Flora

Zones along transect.

A 5 m. Shingle beach and eroded cliff (SE shore). Scattered Sea Beet *Beta maritima*, Sea Campion *Silene uniflora* and Sea Mayweed *Tripleurospermum maritimum*. 2 small patches of Sea Kale *Crambe maritima.*

B 13-23 m. Vegetated shingle ridge with a high density of nesting Herring and Lesser Black-backed Gulls. Sea Campion (abundant), Bitter Stonecrop *Sedium acre* (frequent). Early Scurvy-grass *Cochlearia danica* (F), Squirrel-tail Fescue *Vulpia bromoides* (F), Sheep's Sorrel *Rumex acetosella* and Sea Mouse-ear *Cerastium diffusum*. Ridge has become increasingly vegetated as the result of nutrient enrichment by the gulls.

C 7 m. NW slope of ridge: Red Fescue (abundant). Early Scurvy-grass (A), Sheep's Sorrel, Sea Mouse-ear and Sea Beet.

D 2-4 m. Lower slope of ridge bordering track. Sea Wormwood (abundant), Saltmarsh Couch *Elymus atherica* (A), Hoary Cress *Cardaria draba* (locally A) – probably recent coloniser.

2 m Track. Little vegetation in May but by September One-flowered Glasswort *Salicornia pusilla* (NSc) and Annual Seablite *Suaeda maritima* both abundant.

E F G 69-78 m. Saltmarsh (NW side), Sea Purslane Atriplex portulacoides (abundant), Sea Aster *Aster tripoleum* (A upper saltmarsh), Common Sea-lavender *Limonium vulgare* (F), Long-leaved Scurvy-grass *Cochlearia anglica*, Sea Arrow-grass *Triglochin maritimum*, Thrift Armeria maritima (A mid-saltmarsh), Small Cord-grass *Spartina maritima* and Perennial Glasswort *Sarcocornia perennis* (both around shallow pools, upper saltmarsh).

Detrimental effects of the surge:

Yellow Vetch *Vicia lutea* (NSc) recorded as locally frequent on stabilised shingle ridge SE of Doveys Lagoon in 9 years 1971-2013. Not refound in 2014, either in May or September. Brown Hares graze it but their population reduced after 2013. A candidate for local extinction as result of the surge.

Other species that have apparently suffered are Rock Sea Lavender *Limonium binervosum* ssp. *saxonicum* in shingle extraction pits near the Huts (decrease), and disappearance from 2 sites on shingle ridge between Huts and Doveys.

Bird's-foot Clover *Trifolium ornithopodioides* and Suffocated Clover *T. suffocatum* (NSc) – single small populations recorded in 2013 but not refound in May 2014.

Gorse *Ulex europaeus*: a large patch at N end of the Main Area Meadow all dead, but bushes on ridge E of Doveys Lagoon living. Those N of Huts showed signs of dying.

Disappeared before the surge:
Sea Pea *Lathynus japonicus* (NSc): locally abundant on shingle ridge between the Huts and Doveys Lagoon in 1971 but much reduced after 1976 drought. Not seen in 2011 and 2014. Probably still on Orefordness where it was abundant.

Slender Hare's-ear *Bupleurum tenuissimum* (NSc, Vulnerable): appeared locally in abundance following substrate disturbance in the Meadow area S of the Main Lagoon in the 1970s and 1997 but not seen subsequently. Cannot compete with coarse grasses.

Rock Samphire *Crithmium maritimum*: a large plant seen on the shingle bank SW of the Huts in 2008 but not recorded subsequently. Probably a temporary colonist where it is at its northern limit on east coast of Britain.

Species unlikely to have been affected by the surge:
Perennial Glasswort *Sarcocornia perennis* (NSc), 5 species of Annual Glassworts *Salicornia* spp. including Yellow Glasswort *S. fragilis* (NSc), though *S. pusilla* (NSc) was particularly widespread and frequent in 2014.

Small Cord-grass *Spartina maritima* (NSc, Endangered): Havergate is an important site for this species, with good populations associated with shallow pools on the upper saltmarsh.

Sea Barley *Hordeum marinum* (NSc, Vulnerable): has been abundant on Belper's Lagoon in 2001, 2011 and 2014 (local). This annual grass responds to substrate disturbance in brackish sites.

Borrer's Saltmarsh-grass *Puccinellia fasciculata*: recorded from several brackish muddy sites in 2001 and 2011 but not seen in 2014.

Curved Hard-grass *Parapholis incurva* (NSc): locally frequent on sparsely vegetated damp ground (eg tracks) in 2011 but not in 2014. The dry summer of 2014 may have affected both grasses.

Tassel-weed *Ruppia maritima*: abundant in the brackish Meadow Ditch in 2011 and 2014.

Sea Kale *Crambe maritima*: has been confined to the shingle bank on SE side of the isthmus between the Huts and Dovey's Lagoon where a small population of 7-18 plants has been recorded 2001-2014. It was considered to be a new coloniser in 2001 from Orfordness. There were 14 plants in 2014. Periodically plants are washed away and replaced by new ones (from seed) as in 2008. It probably benefited from the turn-over of shingle in the surge.

North Warren, East Suffolk (vc 25)

Shore surveyed on 23 July 2014 from between the car park at the N end of Aldeburgh to the south end of Thorpeness (The Haven). TM 46895815-47095899, a distance of c1.5 km.

A steep unstable shingle slope with little vegetation rises from the broad (20-30 m) shingle beach. The shingle beach crest is 3-12 m in width. The well vegetated landward slope is composed largely of shingle that had been swept over the crest by the surge. Inland of the main ridge is a broad expanse of grassy vegetation (78-108 m wide). At the N (Thorpeness) end the shingle had been carried landward by up to 84 m from the beach crest. Here the beach crest had been lowered and it appeared that the surge had carried material up to the fence bordering the garden of Haven House.

Sea Pea *Lathyrus japonicus* (NSc) is a feature of the beach between Aldeburgh and Thorpeness, particularly at the southern (Aldeburgh) end. In 1998 and 2000 there was a large population that extended over a strip of about 1 km x up to 16 m wide where it formed up to 50% cover on the southern part of the beach south of Sluice Cottage. It benefited from the roping off of part of the beach crest to protect a Little Tern colony and prevent trampling. In 2014, following the surge, *Lathynus* remained abundant at the south end. Its distribution extended onto the landward slope up to 27 m from the beach crest. The surge had clearly pushed the shingle over the ridge landward taking with it certain traditional beach plants including the *Lathyrus*.

Sea Kale *Crambe maritima* was locally abundant on the beach crest in 2010, particularly in the roped off area at the more southerly end. In 2014 it was abundant at both the south and north ends of the beach crest. There were many small plants on the steep shingle slope at the upper part of the beach where recent colonisation may have taken place. In one place 6 plants were growing up to 34 m inland of the ridge where the surge had carried shingle 84 m landward.

Yellow Horned-poppy *Glaucium flavum* was occasional along the beach ridge in 2014 but at one place it was growing with *Crambe* 34 m inland of the ridge. It was frequent along the fence of Haven House garden where seed appeard to have been transported by the surge and probably earlier as several plants were in flower.

Sea Holly *Eryngium maritimum* was only occasional on the landward slope of the beach crest towards the north end and up to 50 m landward from the crest in 2014.

Sea Spurge *Euphorbia paralias*: only about 15 plants on the beach crest and adjacent landward slope at the north (Thorpeness) end in 2014.

Dune Fescue *Vulpia fasciculate* (Nsc) was recorded at 3 sites on the south side of Thorpeness, including a car park, in 2010. It was not looked for in 2014.

Apart from shifting shingle onto the landward side of the beach ridge and lowering the ridge at the north end, the December surge had no major effects on the flora of Aldeburgh to Thorpeness shore.

The verge of the coast road (Thorpe Road) between Aldeburgh and Thorpeness has an interesting flora, particularly to the north of Sluice Cottage on the east side, and was not affected by the surge. Dittander *Lepidium latifolium* was well established there by 2003 and extended over 150 m south of Sluice Cottage. Both White Stonecrop *Sedum album* and Reflexed Shorecrop *S. rupestre* are naturalised. In 2003 there were hundreds of plants of Rough Dog's-tail *Cynosurus cristatus* on the east bank of the road but in 2010 there were only a few and none in 2014 by which time much of the bank had become vegetated over. In 2002 Sand Catchfly *Silene conica* (NSc, Vulnerable) was present at 3 sites on the east bank. It reappeared in 2012 but none was seen in 2014 following excavations to discourage car parking. Some scarification is, however, probably necessary for the existence of the annual. In May 2013 Bulbous Meadow-grass *Poa bulbosa* (NSc as a native) was discovered at 7 sites on sandy gravel disturbed groud in parking places and entrances to tracks on the east side of the coast road. This early flowering grass was not looked for in 2014 and may have been overlooked in previous years.

Minsmere East Suffolk (vc 25)

Fortunately the reserve survived the surge largely unscathed. There was almost no overtopping of saltwater into the freshwater habitats.

The north end of the shore from Dunwich Heath/cliffs to the New Cut Sluice (TM 477675-473661) surveyed on 2 July 2014. Eight transects from the shore-line to the bank bordering the North Marsh and East Scrape (Compt 49) carried out. A second visit was undertaken on 24 September to survey the shore from the Sluice to the concrete blocks that mark the boundary between the southern end of the reserve and the Sizewell Power Station land (473661 and 476646, Compt 59). No transects taken but the height of the dune cliff measured.

Between the sea and the dune ridge in Compt 49 there was a broad shingle beach, 32-51 m wide that was almost devoid of vegetation except in Transects 7 and 8 which had typical early phase beach colonisers. The dune ridge on its seaward side was eroded, forming a cliff, particularly south of the Sluice where it varied in height from 0.5-3.0 m. The landward slope of the dune ridge was well vegetated and to the north of the Sluice sloped down to a well-used path, though in Transects 2 and 3 the path had been obliterated by shingle that had been washed over the ridge by the surge. To the south of the Sluice the landward slope was broad and stabilised by dry grass and sand sedge.

Sea Kale *Crambe maritima*
In 1993 225 plants (56% small, 16% medium and 28% large) were counted on the beach in Compt 59, south of the Sluice. In 2004 there were 267 plants in Compt 59 and there had been a spread in Compt 49 to the north of the Sluice where there were 132 plants. In 2011 at the Dunwich (north) end of the beach where the sea had breached the ridge in the previous winter there was only a single small plant, but there were many large plants on the beach opposite the Public Hide in Compt 49.

In 2013, apart from a cluster of seedlings well up the beach among Marram, there were 11 plants in Compt 49 and hundreds to the south of the Sluice in Compt 59.

In 2014, 4 plants (2 large) at the north (Dunwich) end of Compt 49 and it was abundant on the upper beach towards the southern end of this compt. South of the Sluice in Compt 59, 310 plants were counted, mostly at the North end. There were 8 plants 10 m inland of the low cliff where the surge had carried shingle over the ridge.

Yellow Horned-Poppy *Glaucium flavum*
In 1993 there were a few small plants at the Dunwich end of Compt 49. In Compt 59 there were 57 seedlings on the strandline and 2 flowering plants at the southern boundary.

By 2004, where the beach had developed a more gentle profile in Compt 49, 684 plants were counted, including many young ones, indicating recent colonisation. In 2011 where the sea had breached the ridge at the Dunwich end of Compt 49 there were 49 flowering plants and 50 seedlings.

In 2014 there were 14 flowering and 2 young plants on the ridge at the north end of Compt 49 and 107 with only 13 flowering in Compt 59.

Babington's Orache *Atriplex globriuscula*
In 2014, frequent on the beach shingle in Compt 59. Not recorded in Compt 49. Unrecorded or overlooked in previous years.

Sea Pea *Lathyrus japonicus* (NSc)
From the 1970s to 2004 locally plentiful in Compt 49 north of the Sluice and in Compt 59 to the south where 500 plants recorded on a fine shingle platform at the south end of the reserve. An increase noted between 1993 and 2004. Not recorded in 2011 or 2012 from Compt 49, and rare there in 2013. In 2014 just 17 plants recorded in the southern part of Compt 49 and at 3 sites in Compt 59. The shingle platform where abundant in 2004 had been washed away.

Sea Holly *Eryngium maritimum*
In 1993, 12 plants recorded at the south end of Compt 59.

In 2004, there was a single plant in Compt 49 and 59 plants in Compt 59 including 26 on the fine shingle platform at the south end of the reserve.

In 2014 it was not recorded in Compt 49; there was a total of 24 plants at 2 sites in Compt 59 but the shingle platform had been washed away.

Other strand-line species that were recorded rarely and sporadically.

Prickly Saltwort *Salsola kali* (Vulnerable) was only recorded as a single plant in 2004 in Compt 59.

Sea Beet *Beta maritima*: in 2004 there was a single plant at the north end and 7 plants on the fine shingle platform in Compt 59. This latter site had been washed away by 2014.

Rock Samphire *Crithmum maritimum*: in 1993 there was one plant south of the reserve's boundary fence (Sizewell) and in 2004 3 plants appeared south of the Sluice in Compt 59 but was not seen in 2014. On the east coast of 'England' this species does not extend further north than East Suffolk.

Sea Rocket *Cakile maritima*: appeared on the strandline in Compt 59 in 1993 but has not been recorded since.

Sea Sandwort *Honckenya peploides*: a strandline plant that seems to be restricted to a few sites in Compt 59. In 1993 in 2 areas towards the southern end, NVC SD2. 2004 on the fine shingle platform at the extreme south end of the Compt, NVC SD1.

Sticky Groundsel *Senecio viscosus* and Oxford Ragwort *Senecio squalidus* were both growing on the fine shingle platform at the south end of Compt 59 in 2004.

Sea Bindweed *Calystegia soldanella*
1993 & 1994: scattered along the eroded edge of the dune above the beach in Compts 49 and 59. In 2014 frequent on shingle and sand on upper beach and low cliff at the southern end of Compt 49 and on steep banks just south of the Sluice in Compt 59.

Rush-leaved Fescue *Festuca arenaria* (*F. rubra* ssp oraria/*arenaria*)
2004: scattered on semi-mobile sand at the base of the beach cliff in Compt 49 and 59. In 2014 recorded in similar situations in Compt 59. Not recorded (overlooked?) in 1993.

Lyme-grass *Leymus arenarius*
1993, 2004 & 2014: scattered along the eroded edge of the dunes, mostly in Compt 59.

Hybrid Sea Couch *Elymus x obtusiusculus* (*E atherica* x *E farctus*)
2013: abundant on dune ridge south of gate onto the shore.
2014: not recorded in any of the 8 transects in Compt 49 north of the Sluice but a few clumps on dune ridge in Compt 59, including where shingle had been washed over the ridge by the surge.

Grey Hair-grass *Corynephorus canescens* (Rare native, Near Threatened)
Apparently introduced to Minsmere with Marram from Norfolk after the 1953 floods (Simpson 1982) but native in East Suffolk at sites south from Kessingland. Restricted at Minsmere to Compt 49 north of the New Cut Sluice.

1993, 1997, 2003 and 2004: a population of up to 330 tussocks at north end of the dunes (National Trust land). Another large colony (1070 tussocks extending over 76 m in 2004) south of gate from track onto the shore. A third colony (50 tussocks in 2004) to the south.

In 2011, following the sea breaking over the shingle ridge at the North end in November 2006 and 2007 and washing southward down the path none seen at any of the 3 sites.

2012-2014: reappeared at the site south of the gate (TM 47786604-47786697) with 92 tussocks in 2012, 90 in 2013 but only 42 in 2014. *Corynephorus* requires mobile sand. This site on a dry landward-facing bank has become increasingly overgrown with *Carex arenaria*, *Agrostis capillaris* and

Festuca rubra. *Corynephorus* also vulnerable to heavy trampling and seems to be susceptible to saline water.

Thrift *Armeria maritima*
2004: s small patch on the landward slope at the North (Dunwich) end of the dunes. 2014, 27 clumps in this area which is subject to the eroding effect of sea incursions, including the surge. Two clumps further south in Compt 49.

The following plants occur on the landward side of the dunes and are unlikely to have been affected by the 2013 surge.

Sheep's-bit *Jasione montana*
1993, 2004 and 2014: scattered along the dune ridge where the vegetation is short at the southern end of Compts 49 (2 transects in 2014) and 59 (2 sites in 2014).

Bell Heather *Erica cinerea*
1993, 2004 and 2014: thinly scattered on the dunes in both Compt 49 (one transect in 2014) and 59 (one patch 1.5 x 1.5 m in 2014).

Ling *Calluna vulgaris*
1993: 2 clumps west of the track at the south end of Compt 59.

2004: thinly scattered on the landward side of the dunes NVC SD12a, one patch in Compt 49, 4 sites in Compt 59 including a fairly large patch just north of dense woodland and west of track at the south end.

2014: not seen but main site in Compt 59 not covered.

English Stonecrop *Sedum anglicum*
This species has a largely coastal distribution in East Suffolk, the only area where it is frequent on the east coast of Britain.

1993, 1994, and 2014: locally frequent in dry, sparsely vegetated locations on the landward side of the dunes in both Compts 49 and 59.

Harebell *Campanula rotundifolia*
1993: in small quantity at 3 sites on vegetated stable dune in Compt 59. in 2004 only recorded at one site a short way south of the Sluice, Compt 59. In 2014 at 3 sites in this Compt, including on a dune cliff.

Small Cudweed *Filago minima*
1993: on a dry gravelly east facing bank just north of the Sluice, Compt 49.

Sea Campion *Silene uniflora*
1993: in small quantity among *Festuca ovina* and *Cladonia portentosa* between two tracks on the landward side of the dune's Compt 59. 2004: only one small patch (1 x 1.5 m) there NVC 12a. Not seen at this site in 2014.

Wavy Hair-grass *Deschampsia flexuosa*: 1993 and 2004, a small patch adjacent to a large patch of *Calluna* just north of oak-birch woodland at the south end of Compt 59. Site not visited in 2014. An acid, grassland plant.

Polypody *Polypodium vulgare*
1993: on west side of dune ridge, Compt 59. NVC SD10b.

2004: one site at north end of dunes, Compt 49 but probably unrecorded Compt 59.

2014: a small patch on dune, Compt 59. Not in any of the 8 transects in Compt 49.

Broad Buckler-fern *Dryopteris dilatata*
1993 & 2004: locally frequent on west (landward) side of the dune ridge in Compt 59. NVC SD6f & g. 2014: apparently much less frequent: in small quantity at 3 sites (one with 13 plants and another with 7).

Lichen *Cladonia portentosa*
1993 & 2004: on dry gravelly are just north of the Sluice (Compt 49) with *Filago minima*, *Rumex acetosella*, *Aira praecox*, *Plantago coronopus* and *Sedum anglicum*. A feature of dry more level ground beside the main path on the landward side of the dunes in Compt 59. NVC SD11 and 12a.

2014: much less frequent in Compt 59.

Shrubs and dunes:
Western Gorse *Ulex gallii*: essentially a plant of old heath in the eastern part of East Suffolk. Has a largely western distribution in Britain, and is absent from more central parts.

1993, 2004 and 2014: thinly scattered on the landward slope of the dunes in Compt 49. In 2014 some large patches which showed no signs of dying.

Common Gorse *Ulex europaeus*: 2014: 9 bushes on the dunes in Compt 59; one 15% dead, one 10% dead, 2 5% dead, 3 3% dead and 2 1% dead (24.9). 5 bushes had considerable patches in full flower on 24 September suggesting hybridisation with *U. gallii* but shoots resembled those of *U. europaeus*.

Downy Birch *Betula pubescens*: 2014: 3 compact bushes in Compt 59; one 33% dead, one 22% dead and a third 10% dead (24.9).

Holly *Ilex aquifolium*: 2004 & 2014: one compact bush on dunes at north end of Compt 59. In 2014 shoots on the seaward side dead, but healthy on north (landward) side.

Elder *Sambucus nigra*: 1993: scrub at north end of Compt 49 and north end of Compt 59. 2014: 24 bushes in Compt 59, mostly at the north end; all dead except one sprouting at the base.

Broom *Cytisus scoparius*: 2004: only a few bushes at 2 sites on dunes to the north of the Sluice, Compt 49. 2014 4 bushes on a dry bank just north of the Sluice, Compt 49.

Tree Lupin *Lupinus arboreus* (naturalised): 1993: in some quantity just south of the Sluice, Compt 59. 2004: at least 24 bushes at 7 sites, mostly on mobile or semi-fixed dune in Compt 59. 2014: 13 bushes and 9 seedlings at the north end of Compt 59 – 2 dead, 3 part dead and 5 thriving bushes as were the seedlings. Two live and 2 dead on the upper beach on the rest of the dunes in Compt 59.

Honeysuckle *Lonicera periclymenum*: 2014: Compt 59, extending onto the beach where the cliff had been eroded. Abundant and flowering on the vegetated dune. Probably has increased.

Hawthorn *Crataegus monogyna*: 1993: one live bush at the south half of Compt 59. 2014: 5 dead bushes, possibly *Crataegus*, on beach cliff and another 10 m landward of the cliff, Compt 59.

Brackish seepage influence at south end of Compt 49, just north of the Sluice.

1993, 2004, & 2014: saline runnel along path at the margin of 2 brackish pools have halophytes - *Juncus gerardii*, *J. maritimus*, *Aster tripoleum*. *Glaux maritima*, *Spergularia marina* (1993), *Plantago maritima* (2004) and *Lotus glaber* (2004). Tassel-weed *Ruppia maritima* in the brackish pools.

Parsley-leaved Water-dropwort *Oenanthe lachenalii*.
1993, 2004, 2014: a few plants among *Phragmites* in a damp hollow near the path just north of the Sluice. 8 plants flowering in 2014 but the site has become drier.

Adder's-tongue *Ophioglossum vulgatum*: in the same ready hollow, mid 1970s, 1993 & 2004. Not seen 2014.

Effects of the December 2013 surge

Sea Kale: little change in population, some change in distribution as the result of shingle being rearranged.

Yellow Horned poppy: probably temporary decline at north end of beach.

Sea Pea: minor recovery in Compt 49 but a large population on the shingle platform at the south end of Compt 59 washed away.

Babington's Orache: may have benefited on beach in Compt 59 but not recorded or overlooked in 1993 and 2004.

Sea Holly: little change in the population but one of the main populations on the shingle platform at the south end of compt 59 washed away.

Sea Beet: a small population in 2004; not recorded in 2014.

Sea Bindweed: little change.

Hybrid Sea-couch: may have suffered a considerable decrease between 2013 and 2014 as the result of erosion.

Grey Hair-grass: virtually disappeared at the 3 sites in Compt 49 following sea breaching the ridge at the north end in 2011. Reappearance at one site 2012-2014 but decline in population in successive years.

Elder: the bushes just south of the Sluice, Compt 59, all dead except one in 2014. Their condition in previous years not known. Probably not a surge effect.

Common Gorse: bushes on the dunes in Compt 59 showed signs of dying, but this may have resulted on storm exposure.

Former comprehensive surveys of the beach and dunes
1993: Cadbury, C. J. (1996) Vegetation survey of the Coastal Grazing Marshes and Dunes at Minsmere RSPB Nature Reserve, 1993. Unpubl. rept. Reserves Ecology. RSPB, Sandy.

2004: Cadbury, C. J. (2004). Repeat vegetation survey of the Beach and Dunes at Minsmere RSPB Nature Reserve, Suffolk, 2004. Unpubl. rept. Reserves Ecology, RSPB, Sandy.

Dingle, north of Dunwich, East Suffolk (vc 25)

Surveyed from the car park at the north end of Dunwich (TM 47927086) to the electric fence across an extensive spread of shingle at the north end (48237167). Total distance 1.3 km, 11 June 2014. With James McGill 4 transects from the tide line across the beach and ridge to the reedbed at the edge of the marsh.

	Transect	**2011**	**2014**
Beach crest width	3	14-18 m	11 m
	4	4 m	1 m

Zone A. A wide shingle beach, including the seaward slope of the beach ridge and much of the beach crest. 43 m wide at the southern end (Transect 1) narrowing to 18 m (Transect 4). Almost unvegetated except for a few plants of Yellow Horned-poppy *Glaucium flavum* on the beach crest.

Zone B. Vegetated landward slope of beach ridges, 11-19 m wide but beach crest only 1 m wide in Transect 4.

Vegetation largely composed of Sea Campion *Silene uniflora*, Cat's-ear *Hypochaeris radicata*, Sea Pea *Lathyrus japonicus* in Transect 1 (abundant) and 2 (frequent), Sea Beet *Beta maritima*, Rest Harrow *Ononis repens* and Yellow-Horned-poppy (occasional in 3 transects).

Zone C. Litter heaps (presumably deposited by the surge) on the landward side of the beach ridge, 15-26 m wide.

Vegetation mostly Sea Campion, Sea Mayweed *Tripleurospermum maritimum*, Spear-leaved Orache *Atriplex protrata* and Sea Beet.

Zone D. Dry grassland on shingle 13-35 m wide.

Vegetation mostly Red Fescue *Festuca rubra*, Sea Campion, Buck's-horn Plantain *Plantago coronopus* and Sea Beet.

Zone E. Untrampled, ungrazed brackish damp grassland at the edge of reedbed, 5-9 m wide.

Red Fescue (abundant), Saltmarsh Couch-grass *Elymus atherica* (frequent), Sea Rush *Juncus maritimus* (3 transects, frequent in one), Silverweed *Potentilla anserina* (abundant in 1 transect). Divided Sedge *Carex divisa* (localy frequent).

More notable species:

Sea Kale *Crambe maritima*: in 2011 23 plants (15 large, 7 medium, 1 small) at southern (Dunwich) end of beach where shingle ridge still wide. 23 plants (1 large, 5 medium and 17 small where ridge narrowed and lowered and the sea had broken over the top further north. The higher proportion of small plants indicative of recent colonisation.

In 2014: a total of 50 plants (11 large, flowering, 7 medium and 32 small, non-flowering at 8 sites). 78% of the small plants were on the seaward slope of the beach crest; 64% of the large plants were on the beach crest or landward slope.

Sea Pea *Lathyrus japonicus* (NSc). In 2011, 4 large patches (>2 m in diam), 4 medium patches (0.5-2.0 m diam) and 72 small patches (<0.5 m diam). All 4 large patches and 3 of the medium ones were on the main uneroded ridge at the Dunwich end (TM 479710-483720). In 2014, 8 large patches, 5 medium patches and 49 small patches, all on the landward side of the beach crest where shingle pushed by the surge from the beach crest inland. 12 of the 15 sites were at the southern (Dunwich) end of the beach, 480710-48712. Towards the north end, 48027124, 20 small plants were growing on shingle washed almost to the reedbed.

Yellow Horned-poppy *Glaucium flavum*.

2011: occasional on both the eroded beach with sparse vegetation and on the landward side of

the main ridge.

2014: only recorded at the Dunwich car park end of the beach crest.

Sea Fern-grass *Catapodium marinum*
2014: at two sites just on the landward side of the beach crest, at one locally frequent.

Common Gorse *Ulex europaea*
2014: 12 bushes on the landward side of the beach crest. Of these 6 were dead, 2 had dead top shoots, and one plus 3 small bushes were alive.

Species unlikely to have been affected by the surge:
Borrer's Saltmarsh-grass *Puccinellia fasciculata* (NSc, Vulnerable).
2011 and 2014: locally frequent on a damp bare path on the seaward side of the reedbed. Extended over 29 m in 2014.

Curved Hard-grass *Parapholis incurva* (NSc)
2011 and 2014: locally frequent on a damp gravelly path on the seaward side of the reedbed with *Puccinellia fasciculata*.

Divided Sedge *Carex divisa* (NSc, Vulnerable)
2014: at 3 sites in damp grassland on the seaward margin of the reedbed (Zone E). Locally frequent at one of the sites.

Marsh Sowthistle *Sonchus palustris* (NSc)
2014: scattered small plants at the edge of the reedbed, N of the Dunwich car park. With *Carex divisa* and Parsley-leaved Water-dropwort *Oenanthe lachenalii*.

Tasselweed *Ruppia maritima*/*R. cirrhosa* (NSc)
2011: abundant in channel by path from Dingle Great Hill to beach (TM 488731). Identified (on 28.6) as *R. maritima* but non-flowering.

2014: abundant in brackish pool (482717). Identified (11.6) by spirally twisted peduncles as R. cirrhosa.

Saltmarsh: TM 482717. A small area near the brackish pool (above) with *Atriplex portulacoides*, *Aster tripoleum*, *Carex distans*. *Elymus atherica*, *Glaux maritima*, *Juncus gerardii*, *J. maritimus*, Puccinellia maritima, *Spergularia media*, *Salicornia ramosissima* and *Triglochin maritimus*.

Titchwell, West Norfolk (vc 28)

This stretch of coast was subdivided into three sectors and surveyed over three days.

a) West from Brancaster golf club-house TF 770452 to the tidal creek 7605 4469, a distance of c1 km. Six transects surveyed from high tide mark across the dune to the saltmarsh on 6 August 2014. Included a dry saltmarsh depression in Transect 2.

b) East from the seaward end of the path from the RSPB's Titchwell Reserve Centre, 750451, to the first tidal creek 760448, a distance of c1 km. Four transects surveyed across the shore and dune to the Tidal Lagoon, 29 July 2014.

c) West from the seaward end of the path to Thornham Point, 742452, a distance of c1 km. Four transects surveyed from the high tide mark across the dunes to the saltmarsh, 8 July 2014. In addition 4 transects were covered across the extensive saline depression landward of the dunes.

a) Titchwell (Brancaster sector)

Zone A: a broad unvegetated sandy beach (or creek margin Transect 5), 103 m in the east (Transect 1) decreasing to 20 m at the tidal creek (Transect 5) where there was c0.5 m high mud cliff.

Zone B: a narrow embryonic dune, 4-21 m wide, where both Prickly Saltwort *Salsola kali* (Vulnerable) and Frosted Orache *Atriplex lacireata* were frequent or abundant; Sea Couch-grass *Elymus farctus* was plentiful.

Zone C: a wider sandy fare-dune, 13-24 m (absent from Transect 6) where Prickly Saltwort and Frosted Orache featured prominently along with Sea Sandwort *Honckenya peploides*, Sea Couch-grass and hybrid Couch *Elymus x obtusiuscula* (frequent in Transect 2).

Zone D: dune that varied in width from 15 m (Transect 3) – 43 m (Transect 1). In Transects 1, 4 and 5 there was an eroded cliff (0.4, 1.7 and 0.5 m high respectively) on the seaward side. The grasses Marram *Ammophila arenaria*, Lyme-grass *Leymus arenarius*, hybrid Couch and Rush-leaved Fescue *Festuca rubra* ssp. *arenaria* all featured prominently. Saltmarsh Couch *Elymus atherica*, Sea Bindweed *Calystegia soldanella* (Transect 1), and Shrubby Seablite *Suaeda vera* (Transect 3) were each abundant in one transect. Sea Spurge *Euphorbia paralias* was locally frequent (Transect 5).

Zone E: between the dune and saltmarsh there was a marginal belt 4-12 m wide where Sea Purslane *Atriplex portulacoides* and Purple Glasswort *Salicornia ramosissima* were abundant along with Saltmarsh Couch and Shrubby Seablite. Perennial Glasswort *Sarcocornia parennis* occurred in this zone.

Zone F: the dry saltmarsh in Transect 2 (31m wide) featured Matted Sea-lavender *Limonium bellidifolium*, Rock Sea-lavender *L. binervosum* and Sea Saltmarsh-grass *Puccinellia maritima*. In the wet saltmarsh Common Sea-lavender *Limonium vulgare*, Sea Saltmarsh-grass, Cord-grass *Spartina anglica*, Sea Purslane and Purple Glasswort were prominent.

More notable plants:

Sea Holly *Eryngium maritimum*: present in Transects 5 & 4 (20 and 3 plants) on the landward slope of the dune.

Sea Bindweed *Calystegia soldanella*: abundant on the dune in Transect 1 Zone D.

Sea Rocket *Cakile maritima*: rare on the landward slope of the dune, Transect 5.

Sea Spurge *Euphorbia paralias*: locally frequent on the dune, Transect 5.

Hybrid Cough-grass *Elymus x obtusiuscula*: abundant on the dunes in 5 transects.

Rock Sea-lavender *Limonium binervosum* ssp *anglicium*: frequent in dry saltmarsh depression landward of the dunes, Transect 2.

Matted Sea-lavender *Limonium bellidifolium* (Rare): abundant in dry saltmarsh depression, Transect 2.

Perennial Glasswort *Sarcocornia perennis* (NSc): occasional-rare at the margin of saltmarsh in 4 transects.

One-flowered Glasswort *Salicornia pusilla* (NSc): occasional in dry saltmarsh depression, Transect 2.

b) Titchwell (east sector)

Zone A: a broad sandy lower beach with abundant razor-clam shells, 21 m (west, boardwalk) – 67 m (east, creek) wide. No vegetation.

Zone B: a narrow band of embryonic dune 1-3 m wide. Sparsely vegetated with Sea Couch *Elymus farctus* and Frosted Orache *Atriplex lacineata*.

Zone C: a band of bare sand, 4-14 m wide with little vegetation except occasional Prickly Saltwort *Salsola kali*.

Zone D: a broad fore-dune, 22 m (west) and 45 m (east) wide. Prickly Saltwort (abundant), Frosted Orache (locally frequent), Sea Couch frequent-abundant, Marram *Ammorphila arenaria* (abundant in 2 transects), Sea Sandwort *Honckenya peploides* (frequent in one transect).

Zone E: broad dune including both seaward and landward slopes, 36-45 m wide with a 0.7 m cliff in Transect 2 and 0.5 m high in Transect 3 on seaward side. Well vegetated with Marram (frequent/abundant), Saltmarsh Couch (abundant), Rust-leaved Fescue *Festuca rubra* ssp *arenaria* (locally abundant) and Sea Spurge *Euphorbia paralias* (frequent).

Zone F: saline depression in Transects 1, 3 and 4, 20-48 m wide. Sea Milkwort *Glaux maritima* (abundant), Common Sea-lavender *Limonium vulgare*, (local/frequent). Rock Sea-lavender *L. binervosum* (frequent/abundant in drier areas), Matted Sea-lavender *L. bellidifolium* (rare Transect 3 and 4), Red Fescue *Festuca rubra* (abundant in 2 transects), Long-bracted Sedge *Carex extensa* (Transect 3 – frequent, Transect 4 – scattered).

Zone G: Tidal Lagoon margin in Transects 1 & 2, 10 and 5 m wide. Saltmarsh Couch (abundant), Shrubby Seablite *Suaeda friticosa* (frequent), Rock Sea-lavender (frequent Transect 1), Corn Sawthistle *Sonchus arvensis* (frequent one transect).

Zone H: Inner dune landward of saline depression Transect 3 24 m wide. Sea Spurge (abundant), Saltmarsh Couch (abundant), Red Fescue (frequent), Creeping Bent *Agrostis stolonifera* (locally frequent), Rock Sea-lavender (occasional).

Zone J: Creek Prickly Saltwort (frequent). Shrubby Seablite (abundant seedlings on island), Sea Couch (frequent on island), Frosted Orache (occasional), Purple Glasswort *Solicornia ramasissima* (occasional).

More notable plants:

Yellow Horned-poppy *Glaucium flavum*: 8 non-flowering plants on shingle E of the Creek TM 75514488. Only site recorded.

Sea Rocket *Cakile maritima*: rare in Transects 2 and 3.

Rock Sea-lavender *Limonium binervosum* ssp *anglicum*: saline depression in Transects 1 (scattered), 3 (abundant) and 4 (frequent). Also on margin of Tidal Lagoon and seaward end of track from Centre.

Matted Sea-lavender *Limonium bellidifolium* (Nationally Rare): Transects 3 and 4, saline depression (rare).

Sea Holly *Eryngium maritimum*: 2 plants on dune, Transect 2.

Sea Spurge *Euphorbia paralias*: all 4 transects on dune; abundant on inner dune, Transect 3 (TM 754450); frequent Transect 2 (752450); otherwise occasional.

Long-bracted Sedge *Carex extensa*: in saline depression, frequent Transect 3 (TM 754449) and scattered Transect 4.

b) Titchwell (west sector)

Zone A: bare sand on broad lower beach, 62-80 m wide.

Zone B: embryonic dune, 15-20 m wide. Sparse vegetation with Sea Couch *Elymus farctus*, Frosted Orache *Atriplex lacineata* and Prickly Saltwort *Salsola kali* (Vulnerable).

Zone C: foredune with drift line, 4-15 m. Prickly Saltwort (abundant), Frosted Orache and Sea Couch (both frequent).

Zone D: wide building dune, 22-29 m. Sea Couch and Marram *Ammophila arenaria* (both abundant), Sea Sandwort *Honckenya peploides* (locally abundant), Prickly Saltwort (frequent), Lyme-grass *Leymus arenarius* (frequent in Transect 2). Sea Holly *Eryngium maritimum* (rare in 3 transects).

Zone E: dune ridge 1-7 m wide, with eroded cliff. Cliff 2 m high Transect 3, 3.5 m high Transect 4. Marram (abundant in all 4 transects), Saltmarsh Couch *Elymus atherica* (in 3 transects, abundant Transects 1 & 4), Lyme-grass (frequent Transects 1 & 2), Sea Bindweed *Calystegia soldanella* (frequent Transects 3 & 4), Sand Sedge *Carex arenaria* (Transect 4), Sea Buckthorn *Hippophae rhamnoides* (Transect 4).

Zone F: landward slope of dune. 42-50 m. Not represented in Transect 4 Marram (abundant), Saltmarsh Couch (frequent), Sand Sedge, Shrubby Seablite *Suaeda fruticosa* (frequent saltmarsh margin).

Saline depression between dune and Thornham Point Mound. 4 transects.

Transect A (N-S) 74354510 (dune side). 120 paces across. Rock Sea-lavender *Limonium binervosum ssp anglicum* and Red Fescue *Festuca rubra* abundant on N margin and frequent S margin. Shrubby Seablite *Suaeda vera*, Saltmarsh Couch *Elymus atherica*, Common Sea-lavender *Limonium vulgare* all abundant. Thrift *Armeria maritima* frequent in the wetter centre.

Transect B (N-S) 74204514 (dune) 39 paces across. Rock Sea-lavender on N & S margin, and W limit of depression 74074511, Matted Sea-lavender *Limonium bellidifolia* (Nationally Rare) in centre and S margin, Sea Heath *Frankenia laevis* (frequent) on S margin with Sea Campion *Silene uniflora*, Shrubby Seablite and Red Fescue. Sea Buckthorn *Hippophae rhamnoides* (abundant) and Marram on Thornham Point Mound.

Transect C (N-S) 74134513 west end. 50 paces across. Rock Sea-lavender (abundant on dune margin, occasional S margin), Matted Sea-lavender (abundant in centre and S margin), Sea Heath (abundant S margin), Sea Milkwort *Glaux maritima* (abundant in centre, also S margin).

Transect D (W-E) 74074112-74564500. 783 paces. Matted Sea-lavender (abundant-frequent over 300 paces W end), Rock Sea-lavender (frequent over 100 paces on pebbly sand, W end), Sea Milkwort (frequent-abundant over 225 paces in centre), Common Sea-lavender (frequent-abundant in wetter saltmarsh over 300 paces in centre and east), Thrift (abundant over 260 paces at E end). Other species towards the wetter E end were Greater Sea-spurrey *Spergularia media*, Cord-grass *Spartina anglica* (v local), Sea Plantain *Plantago maritima*, Sea Purslane *Atriplex portulacoides*, Shrubby Seablite (scattered), Purple Glasswort ISalicornia ramosissima and Red Fescue.

Sea Wormwood *Artemesia maritima* occurred with Shrubby Seablite on the drier, sandy E margin 74574502/4.

This large saline depression is an important site for a community associated more with Mediterranean shores and is restricted to North Norfolk in Britain. It does not seem to have been affected detrimentally by the surge and may have benefited from some limited flooding.

Conclusions on Titchwell shore

The Titchwell beach is essentially sandy. The tidal surge on 5/6 December 2013 may have removed up to 30-40 m of dune on the seaward side but it is reforming as embryonic and fore dune. Dune loss most extensive on east sector. The erosion resulted in a sandy cliff forming on the seaward side of the dune, up to 1.7 m high in the Brancaster sector, up to 0.7 m in the eastern sector and up to 3.5 m in the western sector. The board-walk at the seaward end of the path from the Centre to the shore was heaved up and destroyed. The east bank suffered extensive damage and a small amount of leakage occurred at the S end, although the bank was not breached. There was a small amount of over topping along the west bank. Sea water came over the west bank at the Parrinder Hide junction, flooding the path to a depth of c30 cm.

The churning up of the sandy beach and the formation of embryonic and fore dune resulted in a proliferation of Prickly Santwort *Salsola kali* and Frosted Orache *Atriplex lacineata*, Sea Sandwort *Honckeyna peploides* and Sea Couch-grass *Elymus farctus* were also prominent plants in these zones. The dunes were dominated by Marram *Ammophila arenaria*, Saltmarsh Couch *Elymus atherica* and the hybrid Couch *Elymus x obtusiuscula*. Sea Bindweed *Calystegia soldanella*, Sea Spurge *Euphorbia paralias*, Rush-leaved Fescue *Festuca rubra* ssp *oraria/arenaria* and Lyme-grass *Leymus arenaria* were locally frequent. Sea Holly *Eryngium maritimum* was generally scarce on the dunes and in the virtual absence of shingle Yellow Horned-poppy only occurred at a single site.

Botanically the most notable habitat was the fairly dry saline depressions behind the main dune. This supported a nationally very restricted community of plants: Rock Sea-lavender *Limonium binervosum* ssp *anglicum*, Matted Sea-lavender *L bellidiflorum* and Sea Heath *Frankenia laevis* as well as Shrubby Seablite *Suaeda fruticosa*. This community was probably not affected deleteriously by the surge and may have benefited.

Snettisham Pits, West Norfolk (vc 28)

Surveyed 10 June 2014
The shore on the seaward side of the South Pit (1.5 km) plus a short stretch south of the Yacht Club (TF 648322). Five transects surveyed from the low beach to the path at the top of slope.

The 5/6 December 2013 surge flooded the South Pit, destroying the causeway across the South Pit and washing large quantities of shingle from the S end of the South Pit southwards. The Shore Hide was damaged and both The Sanctuary and Roost Hides were destroyed. The boardwalk connecting the southern hides was also destroyed. Part of the roadway allowing vehicle access to the reserve was swept away.

Transect 1 TF 647319 (from bare intertidal mud) at N end of South Pit
2 648317
3 648315 (from accreting saltmarsh just N of former jetty
4 648312 (S of former jetty)
5 647311 (S end of South Pit)

Zone A: Lower beach. Transects 1-4 pebbles, 1-2 m wide. Zone absent in Transect 5.
Accreting saltmarsh 15-20 m wide below pebble zone in Transect 3. Vegetation limited to sparse Glasswort *Salicornia* sp and Annual Seablite *Suaeda maritima* except for accreting saltmarsh where Long-spiked Glasswort *Salicornia dolichostachya* (lower) and Purple Glasswort *S ramosissima* (upper) abundant. Also 10 plants of Perennial Glasswort *Sarcocornia perennis* NSc (one plant in 2013) and Annual Seablite.

Zone B: Mid-beach. Shingle with drift-line.
13-21 m of shingle plus 1-4 m width of drift debris. Zone absent in Transect 5. Vegetation limited to drift-line in Transects 3 & 4. Sea Mayweed *Tripleurospermum maritimum* (3 of 4 transects), Sea Sandwort *Honckenya peploides* (2 transects), Yellow Horned-poppy *Glaucium flavum* (2 flowering plants, many rosettes Transect 1), Sticky Groundsel *Senecio viscosus* (frequent Transect 3), Spear-leaved Orache *Atriplex prostrata* (abundant drift line Transect 4), Prickly Saltwort *Salsola kali* (Vulnerable) and Shore Orache *Atriplex littoralis* (drift-line, Transect 3).

Zone C: Upper beach. Well vegetated shingle.
4-19 m wide. Transects 1-4, Sea Sandwort (abundant 3 transects), Sea Spurge *Euphorbia paralias* (4 transects, abundant Transect 1, sparse Transect 3 but extending over 26 m along beach), Sea Mayweed (3 transects, frequent/abundant in 2), Yellow Horned-poppy and Bitter Stonecrop *Sedum acre* (both frequent Transects 2 & 4), White Stonecrop *Sedum album* and Sea Campion *Silene uniflora* (both in Transects 1 & 2), Saltmarsh Couch *Elymus atherica* (frequent but small, Transect 4), Curled Dock *Rumex crispus* (occasional 4 transects).

Zone D: Seaward slope. Vegetated shingle.
12 m width Transect 1 (N end) increasing to 28 m Transect 4. Sea Mayweed (abundant in 2 transects), Marram *Ammophila arenaria* (abundant Transect 3, frequent Transect 4), Saltmarsh Couch (abundant Transect 4), Curled Dock (2 transects, abundant Transect 2), Common Rest-harrow *Ononis repens* (abundant Transect 3), Yellow Horned-poppy (rosettes frequent Transect 1).

Zone E: Top of slope adjoining the path.
On Transect 2, 10 m wide with drift-line. A 4 m wide dry shelf on Transect 4. In Transects 1 and 3 this zone incorporated with Zone D. White Stonecrop (abundant Transect 2, frequent Transect 4), Bramble *Rubus fruticosus* agg and Rose *Rosa* sp (each in 3 transects), Teasel *Dipsacus fullosum* (rosettes) and Rose-bay Willowherb *Chamerion angustifolium* (Transects 1 & 2). On dry shelf in Transect 4, Viper's Bugloss *Echium vulgare*, Carlina Thistle *Carlina vulgaris*, Fern-grass *Catapodium rigidum* and Bearded Fescue *Vulpia ciliata*.

Transect 5 at the S end of South Pit
Saltmarsh (14 m wide) with glasswort *Salicornia* sp (abundant), Sea Spurry *Spergularia media* (frequent), Shrubby Seablite *Suaeda vera* (frequent), Bare shingle (9 m) with little vegetation. Rather large open shingle (17 m) with Sticky Grounsel *Senecio viscosus* (abundant), Sea Campion (frequent), White Goosefoot *Chenopodium album* (frequent), Yellow Horned-poppy and several ruderal plants such as Common Fumitory *Fumaria officinalis* and Black-bindweed *Fallopia convolvulus*.

More notable plants:
Perennial Glasswort *Sarcocornia perennis* (NSc): an accreting saltmarsh N of former jetty. TF 64803154. 2013, one plant; 2014, 10 plants.

Shrubby Seablite *Suaeda vera* (NSc): 2002 & 2014, a large patch on bank at S end of South Pit. Scattered small plants in accreting saltmarsh N of former jetty. (2014). A large patch S of the Yacht Club.

Sea Spurge *Euphorbia paralias*: 2006, a few small plants on shingle beach at N end of the reserve, TF 6474399. By 2013 there were 2 extensive patches (a) extending over 82 paces, 6473193; (b) over 116 paces 64803184. In 2014, patch (a) was 73 x 18 paces in extent, 647753195 (N) – 64793189 (S); (b) was 105 paces long, 64793167 (N) – 64813161 (S). There were 3 plants on the upper beach in both 2013 and 2014.

Bearded Fescue *Vulpia ciliata* (NSc): 2014, on dry shelf at the top of the seaward slope near path TF 64803168, with Fern-grass and Sand Cat's-tail *Phleum arenarium*,

Prickly Saltwort *Salsola kali* (Vulnerable).
2009: abundant along much of the shore, close to the tide-line. TF 64783190-64793172; sparser further S to 64793163. Also 64813159-64763120, 63603280 and near Yacht Club 646334.

2013: small quantity on strandline, 64773113.

(2014): not recorded in any of the 5 transects that covered the beach.

Appears to have declined, but lack of sandy substrate perhaps the cause. No evidence that the surge had a noticeable effect.

Sea Kale *Crambe maritima*
1996: 9 plants on shingle N & S of the Yacht Club, TF 646334-647326.

(2002): None seen at the above site.

2014: 18 plants well up the shingle beach, S of the Yacht Club, 64753270. 1 large plant Snettisham Scalp, 64653272. Stiring up the shingle by the surge may have been beneficial to this species.

Frosted Orache *Atriplex lacineata*
2002: scattered along strandline on shingle beach, including S of the Yacht Club.

2014: a total of 7 plants at 6 sites on lower beach, including in Transects 3, 4 and 5.

Sea Rocket *Cakile maritima*
2014: 2 single plants on shingle at south end, including Transect 5.

Yellow Horned-poppy *Glaucium flavum*
2002: along strandline N of the N end of South Pit northwards.

2013: abundant along strandline on beach S from the gate at N end of reserve.

2014: frequent in Transects 1 (Zones B and D), Transects 2 and 4 (Zone C) including many non-flowering rosettes.

Sea Bindweed *Calystegia soldanella*
2013 & 2014: locally flowering in quantity on SE-facing bank S of gate at N end of the reserve, TF 64813193.

Hoary Cinquefoil *Potentilla argentea*
2013: 20 plants on W-facing bank near slabs of concrete on W side of South Pit, TF 64843169. New species for the reserve.

2014: 31 plants at 7 sub-sites on both E and W side of track in approximately the area of the 2013 site, 64843157-64843170. Probably not affected by the surge.

Glabrous Cat's-ear *Hypochaeris glabra* (Vulnerable).
2013: 4 plants on W facing bank near slabs of concrete on W side of South Pit TF 64843169.

2014: 3 plants at the same site.

Knotted Pearlwort *Sagina nodosa*
2002: a 7 x 7 patch in damp area on E side of the South Pit just S of the causeway, TF 64963133. Not recorded subsequently. A scarce plant on the Norfolk coast.

Upright Chickweed *Moenchia erecta*
1996: east side of South Pit, south of causeway, TF 650309 (Stuart Fisher). Not recorded subsequently.

Red Hemp-nettle *Galeopsis angustifolia* (NSc *arachaeophyte*, Critically Endangered): 3 main sites on shingle back from the beach.
a) East side of South Pit, both north & south of the causeway, TF 64943140-64953139.
b) Within fenced area south of South Pit, 64803069 (former shingle extraction pit) and 64813069 (close to a small elder bush).
c) Unfenced area south of the Sanctuary Hide, south of the South Pit 64933044.

Sites (b) and (c) monitored most years since 1996; (a) since 2009.

Number of plants				
	Site			
	a	**b**	**c**	**Total**
2009	1300	1444	262	2006
2010	1045	710	763	2518
2011	Several thousand	521	114	3660 +
2012	Thousands small plants	168	1078	5000 +
2013	2700	204	30	2934
2014	771	433	273	1477

Heavily grazed by rabbits or hares in some years as in 2003 and 2009, resulting in a major reduction of plants later in the season and flowering on secondary growth.

2003	b&c	993 plants (24.7)	603 (14.8)	116 (13.9
2009	a, b & c	3006 plants (28.7)	452 (8.8	

In 2006 there were no plants at site (c) where the shingle had become overgrown with False-oat *Arrhenatherum elatius* , Sea Campion *Silene uniflora* and Red Fescue *Festuca rubra*. In the autumn of that year a plot 2 x 2 m had vegetation removed and was scarified.

	2007	**2009**
Scarified	22	177 plants
Control	Nil	7 plants

There is no conclusive evidence that the populations at the 3 sites were detrimentally affected by the surge in December 2013, though the shingle at both sites (b) and (c) had been considerably churned up.

Hoary Mullein *Verbascum pulverulentum* (NSc).
Up to 2002/03 its distribution was largely around the chalets to the north of the reserve, particularly in 2 gardens overlooking the North Pit (TF 64743317).

1996: 2306 plants in all stages, mostly around the chalets close to Cockle Road (647332-648327).

1997: Compt 2 – 17 plants (5 flowering); Compt 3, 2 plants (1 flowering), Compt 4, 184 plants (19 flowering). Total 203 plants (23 flowering).

2003: gardens of 2 chalets (64743317), 258 plants (86 flowering). South of gate onto the reserve (647322-647324), 10 plants (8 flowering).

2009: shingle ridge, south of gate just inside the reserve (64793193), 11 dead inflorescences from 2008, hundreds of rosettes.

2010: south of gate within the reserve (same as 2009 site) 410 plants (159 flowering); by hide at south west of South Pit (64773089), 3 flowering plants.

2014: south of gate, 6463195, only 19 plants (3 flowering); near concrete blocks at north end of South Pit (64823124), 1 rosette; south west end of South Pit (64823124), 1 flowering plant. The December 2013 surge seems to have checked the spread on the reserve.

Bird's-foot Clover *Trifolium ornithopodiodes*
2014: one small plant in trampled path by corner at south end of South Pit, TF 64733094.

Prickly Sedge *Carex muricata*
2014: a single clump on dry shingle at south end, TF 64903049.

Japanese Rose *Rosa rugosa* (naturalised)
2014: a large patch 14x7 m near path at the top of the shore opposite South Pit, TM 64803168).

Rock Sea-lavender *Limonium binervosum* ssp *anglicum*
1998: c8,000 plants (80% non-flowering young) on shingle back from the beach south of the Yacht Club TF 648322-648325.

2009: locally abundant extending over 103 m, south of the Yacht Club, The Scalp, 64653272-64703266.

2013: thousands of plants over 100x10 m strip on dry sandy shingle to east of a large patch of Shrubby Seablite to south of Yacht Club.

2014: scattered over a strip 104 m long at same site as above 64663271 (north) – 64693266 (south). Some decrease in number of plants but not distribution since the December 2013 surge.

Matted Sea-lavender *Limonium bellidifolium* (Rare)
1998: 7 plants over 15 m (diam) in depression among Shrubby Seablite south of Yacht Club, TL 647327.

2000: 10 plants at the above site.

2009: 3 plants at the same site.

(2010): no plants at the site.

2013: 4 plants on dry sandy shingle to north of an extensive area of Shrubby Seablite, south of the Yacht Club 64643272. Vulnerable to drying at the depression and being outcompeted by the *Suaeda*.

(2014): no plants at the above site.

This species has been lost from other sites around the Wash.

Effects of the surge on the flora

Benefits:
Reappearance of Sea Kale in the vicinity of the Yacht Club.

Declines:
Prickly Saltwort appears to have (temporarily) disappeared, but was already decreasing, possibly as the result of sandy substrate on the beach being replaced by shingle.

Red Hemp-nettle suffered a decline in the number of plants at site a by the causeway across South Pit, but the populations at the other two sites at the south end increased from the 2013 counts.

The spread of Hoary Mullein onto the north end of the reserve seems to have been checked.

Rock Sea-lavender that was locally so abundant south of the Yacht Club was only scattered at the site in 2014.

Little change:
Sea Spunge – the two possible patches on the beach remained from 2013 to 2014.

Sea Bindweed – a patch south of the date at north end of the reserve continues to flourish.

Hoary Cinquefoil – discovered on the reserve in 2013 showed a spread in 2014, but this was unlikely to have resulted from the surge.

Can intensive agricultural landscapes favour some raptor species? The Marsh harrier in north-eastern Spain

Abstract

Agricultural intensification over the last 60 decades has been linked to decreases in biodiversity and in the breeding populations of several avian species in farmlands. However, agricultural intensification has not affected all species in the same way and transformed landscapes can still provide suitable habitats for species tolerant to some degree of anthropogenic change. Understanding habitat selection in man-made landscapes is a pre-requisite to effective management and conservation of the species that use them. However, habitat-related choices made by individuals occupying these landscapes are often difficult to explain, as the cues they use may be decoupled from the ecological context in which they evolved. Here, we investigated nesting habitat selection in a ground-nesting raptor breeding mainly in wetlands, which, unlike many other species occupying farmlands, has experienced a population increase in some agricultural regions. We used multivariate analysis to assess the extent to which habitat characteristics, human disturbance or proximity to other occupied sites influenced nesting-site occupancy. Our results indicate that Marsh harriers occupied breeding sites according to habitat cues obtained at two complementary spatial scales (i.e. the breeding site and the foraging area). This study indicates that a raptor species that uses human-made structures such as ponds for breeding while exploiting their surrounding crops for hunting can take advantage of agricultural intensification. Environmental disturbances are often viewed only in terms of their harmful impacts on the affected species. However, human activities are causing many types of alterations in natural landscapes that can be exploited by certain species with positive responses towards these transformations. The adaptation of some raptors to human-altered environments, such as the Marsh harrier in our study area, raises doubts regarding the appropriateness of using such species as indicators of natural habitat quality.

Introduction

Agricultural intensification over the last six decades has been linked to decreases in biodiversity and in breeding populations of several avian species in farmlands (Tucker & Heath, 1995; Chamberlain *et al*., 2000; Donald, Green & Heath, 2001). Contributing factors to the overall impact of intensification include pesticide use, removal of hedges and other uncultivated areas to produce larger fields, earlier harvesting dates and an increase in monocultures (Newton, 2004). Generally speaking, such agricultural practices have resulted in losses of habitat quality and heterogeneity that have negatively affected avian species directly through increments in mortality or reproductive failures or indirectly by reducing or degrading their hunting and nesting habitats (Benton, Vickery & Wilson, 2003; Newton, 2004). In this context, studies of habitat selection in farmlands have been central in conservation biology and have been described as an essential tool to assess the habitat requirements of a species and to develop effective management strategies (e.g. Blanco, Tella & Torre, 1998; Tella *et al*., 1998; Arroyo, García & Bretagnolle, 2002; O'Connell & Yallop, 2002; Carrete & Donázar, 2005; Arroyo *et al*., 2009).

Agricultural intensification has not affected all species in the same way, and transformed landscapes still provide suitable habitats for species tolerant to anthropogenic alterations. For example, in intensively managed lands, where artificial ponds and irrigated crops have replaced natural wetlands or created new ones, some bird species have benefitted through the creation of new foraging or breeding habitat (Czech & Parsons, 2002; Tourenq *et al*., 2004; Sánchez-Zapata *et al*., 2005; Moreno-Mateos, Pedrocchi & Comín, 2009; Sebastián-González, Sánchez-Zapata & Botella, 2010). The Marsh harrier *Circus aeruginosus* is a medium-size raptor that breeds mainly in wetlands and behaves as an open-habitat hunter (Cramp &

Simmons, 1994). The European Marsh harrier population underwent a dramatic population decline from 1960 to 1980 due to drainage of wetlands, contamination and direct persecution, but recovered in recent decades, when the species underwent a moderate increase, $<10\%$, (Cramp & Simmons, 1994; BirdLife International, 2004). Contrary to other species occupying farmlands, the recovery of this species has been very noticeable in some agricultural regions, even in areas dominated by intensified crops. Within some of these regions such as the Iberian Peninsula, the increase in the Marsh harrier population has been accompanied by an increase in its geographic range, with some pairs occupying artificial ponds and reservoirs related to agricultural practices. However, the extent to which these recent occupations are due to habitat characteristics, to the proximity of other occupied sites or to a combination of these factors, is unclear. Understanding the attractiveness and quality of wetlands for wildlife in human-transformed environments is vital to the success of attempts to reconcile development and biodiversity conservation (Froneman *et al*., 2001; Moreno-Mateos *et al*., 2009; Sebastián-González *et al*., 2010). Furthermore, the expanding Marsh harrier population provides an opportunity to identify some of the anthropogenic factors involved in apparently natural invasion processes that are currently favouring worldwide biotic homogenization (McKinney & Lockwood, 1999; Rice & Pfenning, 2008).

Here, we investigate the factors influencing nesting-site occupancy in an expanding population of Marsh harriers located in an agricultural area in the Iberian Peninsula, the Catalan Ebro Basin (Fig. 1a), where the species has increased from eight breeding pairs in 1997 to 53 in 2008 (Fig. 2). For this purpose, we establish the relative importance of habitat characteristics and social behaviour in the occupancy rate of breeding sites at two spatial scales. The results are discussed within the current scenario of agriculture intensification and its potential effects on biodiversity.

Materialsandmethods

Studyareaandfieldprocedures

The study area comprises 7300 km^2 within the Catalan Ebro Basin, north-eastern Spain (Fig. 1a and b). The landscape is mostly low-lying and flat, broken by discrete ranges of small hills (0–400 m a.s.l.), and has a semiarid Mediterranean climate. The annual precipitation is 300–500 mm, with most rain occurring in spring and autumn, and an annual thermal amplitude of 19–20 °C (Bosch, 2004). Traditional agriculture in this area comprises extensive cultivation of cereal crops separated by field margins, where harvested fields remain uncultivated for 1 or more years (fallow system) and are grazed extensively by livestock (Suárez, Naveso & de Juana, 1997). During the 20th century, agriculture in this area underwent several dramatic changes, including the replacement of traditionally cultivated cereals (e.g. spring-sown wheat and barley) with a variety of alternative crops (e.g. winter-sown wheat and barley, alfalfa, maize, sunflowers, deciduous fruit trees, horticultural crops and rice), the establishment of irrigation systems and the disappearance of the fallow system and field margins (Tella *et al*., 1998). Now, the study area is an agricultural mosaic composed of arable, non-irrigated cereal crops (mainly winter-sown wheat and barley), irrigated fields (mainly alfalfa, winter-sown wheat, winter-sown barley and some sweet corn), dry fruit trees (mainly olive and almond trees) and irrigated fruit trees (mainly peach, pear, apple and nectarine trees). A total of 617 wetlands have been described over the study area, of which *c*. 92% are artificial ponds and reservoirs related to agricultural irrigation (A. Varea, unpubl. data).

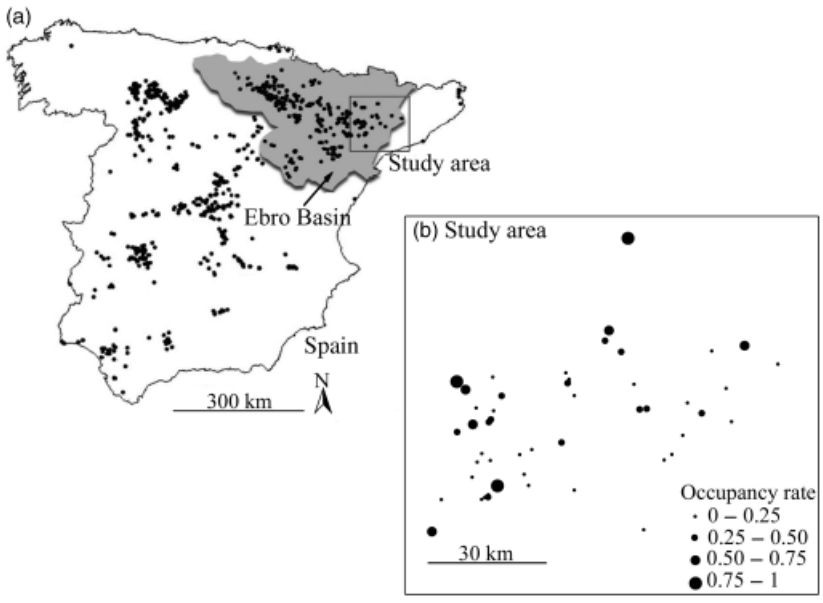

Figure1 (a) Distribution of the breeding population of the Marsh harrier *Circusaeruginosus* in Spain in 2006 (Molina & Martínez, 2008). The Ebro Basin is shown in grey; (b) occupancy rate of monitored breeding sites in the study area (Catalan Ebro Basin, Spain, 1997–2008).

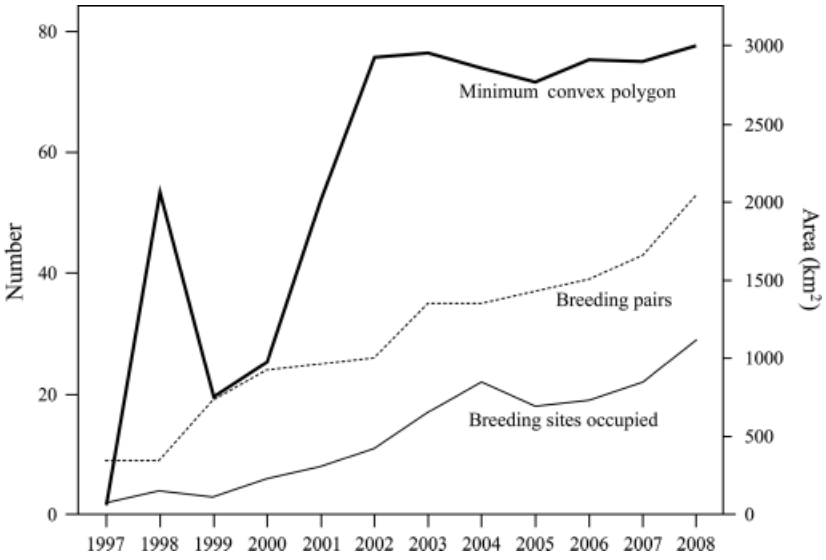

Figure 2 Population trend for the breeding population of Marsh harrier*Circusaeruginosus* in the Catalan Ebro Basin, Spain, showing the number of breeding pairs, the number of breeding sites occupied and the minimum convex polygon area including the occupied breeding sites recorded each year (Source: Departament de Medi Ambient i Habitatge de la Generalitat de Catalunya and own data).

The breeding population of Marsh harriers in the study area was systematically monitored from 1997 to 2008 (Fig. 2). Each year, known breeding sites and other areas potentially suitable for breeding were visited repeatedly to determine occupancy, looking for signs of breeding behaviour (i.e. territorial displays or deliveries of nest material or prey items to the nest). Potentially suitable breeding sites were considered to include all wetlands (defined as artificial ponds, reservoirs, marshes and parts of rivers or watercourses; see Table 1) with the presence of tall standing reeds *Phragmites australis*, reedmace *Typha angustifolia* or other dense emergent aquatic vegetation (Cramp & Simmons, 1994). Visits began in early April, when nest building started, and continued until fledging (May–July). A breeding site was considered to be occupied when at least one breeding pair laid eggs.

Characteristicsofthebreedingareas

The location of monitored breeding sites and associated habitat variables were entered into ArcView 3.2 Geographic Information System. We measured a total of 14 habitat variables within each monitored wetland and within a 3 km radius around the wetland to describe nest site and landscape characteristics, respectively (Table 1). Three kilometres is the average home-range size of breeding Marsh harriers estimated on the basis of radio-tracking data (Cardador *et al.*, 2009).

Variables measured at the wetlands were obtained from 1:5000 aerial photographs from 2005 (Institut Cartogràfic de Catalunya) ground-truthed in the field during 2006 (Table 1). The type of wetland was assessed in the field, while land uses and variables describing human disturbance such as distance from wetlands to the nearest villages, roads and paths were obtained from 1:50 000 digital land-use maps (Departament de Medi Ambient i Habitatge de la Generalitat de Catalunya; Table 1).

Proximity to other occupied sites was estimated as the linear distance from wetlands to the nearest occupied site (NND), and through an isolation index (S) describing the relative position of a given wetland within the spatial distribution of the breeding population (Carrete *et al.*, 2006). Because our Marsh harrier breeding population was the continuation of a larger breeding population located in the west of the Ebro basin (Fig. 1a), for calculations of NND and S values, we took into account Marsh harrier breeding locations both within and outside of our study area. The NND of each wetland could be calculated annually, and we used their average value as the input data. The S was taken from metapopulation theory relating to connectivity, and calculated for wetland i as $S_i = \Sigma\exp(-d_{ij}) \times A$j (with $i \neq j$), where d_{ij} is the linear distance between wetland i and j, and Aj is the number of breeding pairs in the wetland j, j representing all known occupied wetlands. Because this index is formulated to describe connectivity (Moilanen & Hanski, 1998), smaller values indicate increasing isolation. Because accurate information of the whole Marsh harrier breeding population outside the study area was only available for 2006 (data from Dirección General de Desarrollo Sostenible y Biodiversidad, Zaragoza, and SEO/BirdLife) and because the global geographic distribution of the population (and thus S) has remained unchanged during recent years (based on the comparison between distribution maps of the Marsh harrier breeding population from 1998 and 2006; Martí & Moral, 2003; Molina & Martínez, 2008), we used S from 2006 as a single estimate of isolation. This approach is justified by the fact that, for the territories in this study, estimates of S in 2006 were correlated with estimates of this parameter in all other years (Spearman's rank correlation range = 0.263–0.944; P-value range: <0.0001–0.031).

Analysis

We used logistic regressions (using the genmod procedure of SAS 8.0; SAS Institute, 2004), with a stepwise procedure, to analyse the factors affecting occupancy of wetlands by

Table 1 Variables used in models to analyse the occupancy of Marsh harriers *Circus aeruginosus* in Catalonian Ebro Basin, Spain, 1997–2008

Variables	Definition
Habitat variables	
Breeding-site level	
Type	Artificial pond (included constructions of small dimensions <13 ha to store water related to agricultural practices), reservoir (included water bodies originated by a floodgate), river (included junctions of rivers and meanders of permanent rivers), watercourse (included reedbeds in natural channels through which water flows only occasionally, during periods of maximum rain), inland natural wetland (included inland marshy terrains and salt marshes where water availability drastically decreases or even dries completely during spring and summer).
Vegetation	Area of emergent vegetation at the wetland (ha)
Shape	Length of emergent vegetation edge per surface of emergent vegetation ($m\,ha^{-1}$)
Water	Area of open water (ha)
Landscapelevel	
Intensified-herbaceous	Extent of intensified, irrigated herbaceous crops within 3 km of the wetland (%)
Intensified-tree	Extent of intensified, irrigated fruit trees within 3 km of the wetland (%)
Traditional-herbaceous	Extent of traditional, non-irrigated herbaceous crops within 3 km of the wetland (%)
Traditional-tree	Extent of traditional, non-irrigated fruit tree crops within 3 km of the wetland (%)
Vineyard	Total extent of intensified vineyards within 3 km of the wetland (%)
Other	Total extent of unsuitable habitats for the species (i.e. urban areas and forest) within 3 km of the wetland (%)
Village	Distance to the nearest village (m)
Road	Distance to the nearest road (m)
Path	Distance to the nearest path (m)
Proximity to other occupied sites	
NND	Distance to the nearest occupied wetland (km)
S	Isolation of the wetland with respect to the other occupied ones

NND, nearest neighbour distance.

Marsh harriers (binomial error distribution; logit-link function). As wetland sites comprise only emergent vegetation and open water, the inclusion of these two variables means that the size of the entire site was accounted for in the models (Table 1). We used the occupancy rate (number of years occupied/total years monitored) as the dependent variable. For each significant model ($P<0.05$), we calculated the percentage of deviance explained ($100\times(\text{deviance}_{\text{null model}}-\text{deviance}_{\text{model}})/\text{deviance}_{\text{null model}}$). As neighbouring wetlands could have similar environmental conditions due to their spatial autocorrelation, we added, in every model, a spatial term composed of the X and Y coordinates (UTM Projection), and all of their interactions terms up to the third order (Legendre & Legendre, 1998). However, to avoid artificial increases in the explained variation, we first tested the nine explanatory terms in our logistic regression models using a stepwise procedure and we only retained the significant ones (Borcard, Legendre & Drapeau, 1992).

Following Carrete *et al*. (2007), we used deviance partitioning to take account of co-linearity between spatially related variables. Deviance partitioning entails the calculation of incremental improvement in models due to the inclusion of a variable in every possible model incorporating that variable. This allows the 'pure' effect of each explanatory variable to be separated from joint effects that cannot unambiguously be attributed to one variable or another (Fig. 3a). For a more detailed description of this method, see Carrete *et al*. (2007).

Finally, we tested whether the relationship between area of emergent vegetation (vegetation) and occupancy rate could be accounted for by a null model involving only random settlement with respect to vegetation area. Following Gillings & Fuller (2001), we used a randomization procedure that produced the expected occupancy rate for locations of different sizes (for each location, this procedure was repeated 100 times). Thus, our database included a set of observed values of occupancy rates (one for each locality) and a set of expected values derived from random settlement (100 for each locality). A generalized linear model (GLM) (binomial error distribution; logit-link function) with occupancy rate as the dependent variable was used to determine whether there was a significant difference in the relationship between vegetation area and occupancy rate for the observed set and the random set of data. Specifically, we tested the potential interaction between 'vegetation' and 'type of data' (a categorical variable with two levels: observed/random).

Results

Wetlandscharacteristicsandoccupation patternofthebreedingpopulation

In total, 51 wetlands within the study area had the minimum requirements described for Marsh harrier (i.e. the presence of dense emergent aquatic vegetation) and were monitored during the study period (Fig. 1b). Wetland sizes ranged from 0.5 to 287 ha, but 88% of them were smaller than 15 ha, with an average size of 4.9 ± 4.1 ha. Only 32% of monitored wetlands were of a natural origin, while 39% were artificial ponds and 29% were reservoirs related to intensive

agriculture (for definitions of artificial ponds and reservoirs, see Table 1). Emergent vegetation was mainly composed of a mixture of reed and reedmace, with reed being the dominant species in *c*. 90% of wetlands. Thirty-five out of the 51 monitored wetlands were occupied at least once from 1997 to 2008 (Fig. 3, Table 2). During this period, we recorded 375 breeding attempts, 354 of which resulted in egg laying. For wetlands occupied at least once during the study period, the mean number of breeding pairs per year of occupation was 1.45 ± 1.79 (range 1–11.50, $n = 35$).

Occupancy models for the breeding population

Our results show that Marsh harriers occupied breeding sites using habitat cues obtained at two complementary spatial scales. Proximity to other occupied sites seemed not to strongly affect occupancy rates (NND: $\chi^2 = 0.04$, $P = 0.84$; *S*: $\chi^2 = 0.09$, $P = 0.76$).

The habitat model explained 67% of the deviance in the dataset, a value that increased to 71% when the latitude (*Y*) was also included. The deviance partitioning analysis shows that the area of emergent aquatic vegetation had the greatest effect on the occupancy rate of wetlands by Marsh harriers, its pure effect accounting for *c*. 65% of the total deviance explained (Fig. 3b). A GLM showed that the observed relationship was significantly greater than a null model would predict (interaction vegetation × type of data: $\chi^2 = 6.20$, $P = 0.013$), indicating that the observed increase in the occupancy rate with vegetation area was steeper than expected and could not arise solely by a random settlement pattern (Fig. 4). The pure effects of the type of wetland (25%) and the percentage of intensified herbaceous crops in the surroundings (17%) were also important in explaining variability in occupancy (Fig. 3b). A smaller amount of deviance (< 5%) was explained by each of the joint effects of these variables (d, e, f and g). Thus, the occupancy rate of wetlands by Marsh harriers increased with their area of emergent aquatic vegetation and the percentage of irrigated herbaceous crops in their surroundings, with a minimum at inland-natural wetlands (see Table 3).

Analysis of changes in mean productivity of locations with respect to the habitat characteristics measured in the study suggested that no significant relationships existed between this demographic parameter (i.e. mean number of young fledged per breeding pair) and habitat attributes

Table2 Characteristics of breeding sites occupied at least once during the study period, Catalan Ebro Basin, Spain, 1997–2008

Variable	Mean ± SD	Range	Units
Habitat variables			
Breeding-site level			
Vegetation	8.4 ± 19.6	0.5–103.2	ha
Shape	551 ± 290	105–1268	m ha^{-1}
Water	18.5 ± 49.8	0–224	ha
Landscape level			
Intensified-herbaceous	41.4 ± 31.5	0.0–99.5	%
Intensified-tree	18.3 ± 22.4	0.0–83.4	%
Traditional-herbaceous	20.0 ± 27.4	0.4–94.8	%

Vineyard	4.8 ± 11.4	0.0–41.4	%
Other	12.6 ± 17.3	0.0–74.8	%
Human pressure			
Village	2348 ± 1107	75–4235	m
Road	66 ± 129	0–631	m
Path	40 ± 79	0–280	m
Proximity to other occupied sites			
Distance	13.8 ± 8.6	3.8–32.2	km
Isolation	0.13 ± 0.26	0–1	

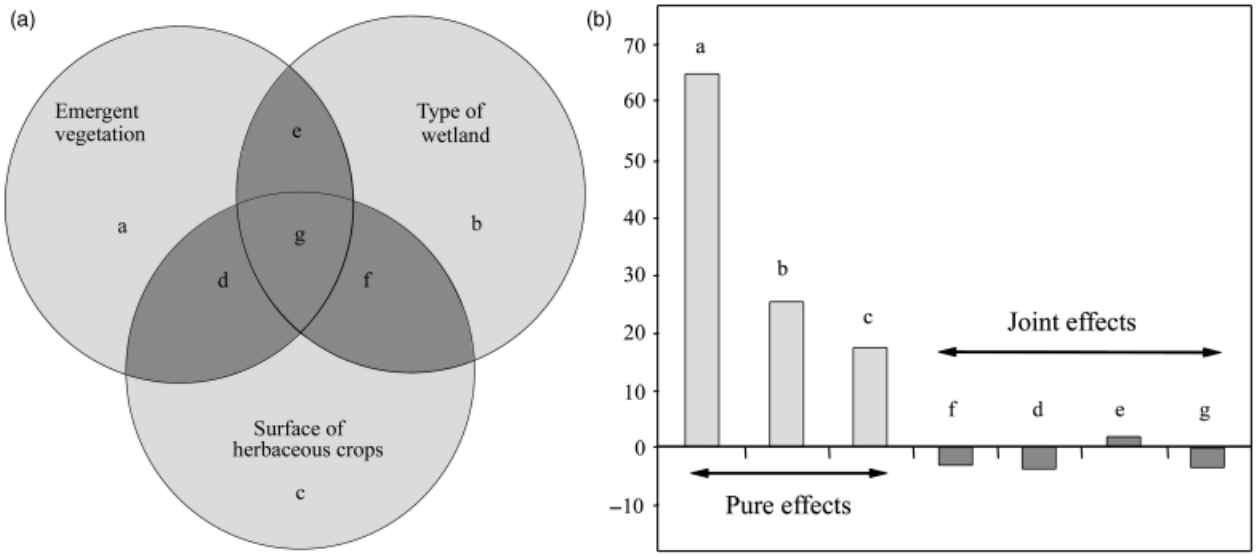

Figure3 (a) Deviance partitioning analysis for the occupancy rate of breeding sites by Marsh harriers *Circus aeruginosus*. (b) Percentage of variability in occupancy rate explained by the pure and joint effects of habitat variables.

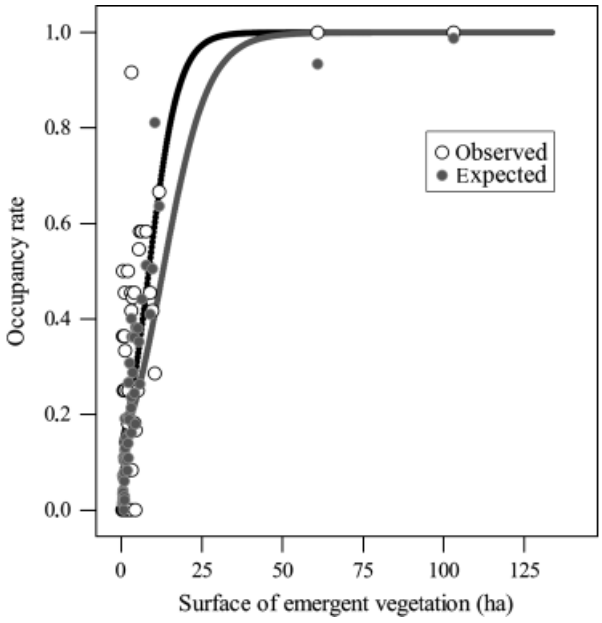

Figure4 Effect of surface of emergent vegetation on the occupancy rate, derived from fitted values from GLM estimates (binomial error distribution, logit-link function). The observed trend is shown with a black line. The grey line indicates the expected trend under a null model in which occupancy rate variation arises solely by individuals settling randomly with respect to vegetation area. Observed occupancy rates and mean expected occupancy rates from 100 replicates (see ''Materials and methods'') are also shown.

(GLMs, normal error distribution, identity link function: all $P > 0.45$).

Discussion

Factors affecting occupancy rate: can human-made landscapes provide suitable breeding habitat for Marsh harriers?

When choosing a site at which to settle, individuals need to simultaneously consider the quality of available sites in terms of their environmental conditions, resource availability and the presence of predators and/or parasites (Martin, 1993; Penteriani, Gallardo & Roche, 2002). However, this quality can be modulated by the presence of conspecifics, which may either decrease or enhance the appeal of a site (Stephens & Sutherland, 1999). In our study model, the occupancy rate of wetlands by Marsh harriers was mainly explained by the independent effect of habitat features acting at two spatial scales, that is, the breeding site (area of emergent aquatic vegetation and type of wetland) and the foraging area (percentage of intensified, irrigated herbaceous crops in the surroundings). Neither human pressure variables nor proximity to other occupied sites seemed to be important determinants of occupancy rates in this expanding population.

Table3 Generalized linear model obtained for the occupancy of breeding sites by Marsh harriers *Circus aeruginosus* in the Catalonian Ebro Basin, Spain (1997–2008)

Parameter	Estimate	SE	χ^2	P
Intercept	−148.06	48.85	9.19	0.0024
Y	0.00003	0.00001	8.89	0.0029
Type (inland-natural wetland)	−3.69	0.92	16.18	<0.0001

Nest protection and food availability are key determinants of habitat selection patterns in different avian species (Martin, 1993; Penteriani *et al*., 2002; Sergio, Pedrini & Marchesi, 2003). In our study species, both factors seem to influence occupancy. Indeed, occupancy rate increased with emergent vegetation area steeper than expected by a random settlement pattern. This relationship was particularly apparent in wetlands with small and intermediate surfaces of emergent vegetation (up to *c*. 50 ha). The occupancy rate was higher in wetlands with larger surfaces of emergent vegetation, perhaps because harrier breeding attempts in such sites experience lower rates of failure due to terrestrial predators, disturbance by humans or local flooding events (Bavoux *et al*., 1989; Fernández & Azcona, 1993; Buczek & Keller, 1994; Stanevicius, 2004; Eglington *et al*., 2009). At a landscape scale, harriers responded positively to the area of irrigated herbaceous crops, suggesting that they offer a larger abundance or accessibility to prey (Preston, 1990). This interpretation is reinforced by a previous finding showing how radio-tracked Marsh harriers occupying intensified habitats tended to have smaller home ranges than birds nesting within non-irrigated ones (Cardador *et al*., 2009). Intensified farmlands in our study area included cereals (basically irrigated wheat and barley), alfalfa and some maize crops. Some of these crops, such as intensified cereals and maize, are used infrequently by Marsh harriers, probably because the height and uniformly dense growth that characterize these crops for much of the summer result in low availability of prey to hunting harriers (Cardador & Mañosa, in press). However, Marsh harriers may be taking advantage of regularly mowed fields (intensively managed alfalfa), which offer an adequate vegetation structure for hunting during a major part of the year (Ursúa, Serrano & Tella, 2005; Kitowski, 2007). Furthermore, intensified herbaceous crops in our study area, mainly alfalfa fields, seem to hold higher densities of small mammal prey, especially Mediterranean Pine Vole, than do more extensive crops (A. Varea and A. Folch, unpubl. data). More specific studies on hunting habitat selection are necessary to determine whether and to what extent managed herbaceous crops are preferred hunting habitats of Marsh harriers.

The occupancy rate at natural wetland sites was lower than for any other habitat type, and may be a consequence of their drainage pattern. In the study area, water reserves at natural wetlands decrease drastically, or even dry out completely, during spring and summer, when harriers breed. Thus, their emergent vegetation is less developed compared with that of other wetlands (i.e. reservoirs, artificial ponds, rivers and watercourses), offering less suitable breeding sites for nesting.

Agricultural intensification and changes in bird communities: winning and losing species in a world of change

Agricultural intensification has had deleterious effects on farmland bird populations at a scale that is comparable to deforestation and global climate change, thus being a major anthropogenic threat to biodiversity (Donald *et al*., 2001). The key to explain this phenomenon seems to be the loss of ecological heterogeneity, which is important in maintaining resources for species-rich communities of organisms (Benton *et al*., 2003). Examples of steppe and pseudo-steppe bird species declining after the intensification of agricultural practices are numerous in Spain, which is the western European stronghold of many of these species (Rodríguez & de Juana, 1991; Tella, Torre & Sánchez, 1996; Suárez *et al*., 1997; Blanco *et al*., 1998; Tella *et al*., 1998). However, there are also some cases of species gaining new habitat opportunities due to the development of intensive crops and the associated agricultural infrastructure. The abundance of some waterbirds at artificial ponds, for example, seems to be larger in comparison with their populations in natural (but degraded) wetlands (Sebastián-González *et al*., 2010). Our results indicate that a raptor species using wetlands for breeding while relying on the surrounding vegetation for feeding can also take advantage of agricultural intensification, at least when food availability is not compromised. Given what is known about other European Marsh harrier populations, many of which have undergone recent expansion (BirdLife International, 2004), our results suggest that this bird could be a winning species in a world of change.

Direct anthropogenic introductions are not the only mechanism favouring the spread of species towards new environments. Human activities are causing many types of alterations in natural landscapes that can be exploited by certain species with positive responses towards these transformations (McKinney & Lockwood, 1999). However, the benefits of transformation on some widespread species (referred to as 'winning species'; McKinney & Lockwood, 1999), such as waterbirds in our study area (Estrada *et al*., 2004), and the harmful effects on others (referred to as 'losing species'; McKinney & Lockwood, 1999), such as pseudo-steppe birds in our study area (Estrada *et al*., 2004), could lead to biotic homogenization processes that can be considered an unprecedented form of global change (Ricciardi, 2007) and one of the most important forms of biological impoverishment world-wide (Olden *et al*., 2004).

Raptors have been proposed as appropriate indicators for monitoring changes at an ecosystem scale because they are at the top of food chains, occurring across a broad gradient of anthropogenic disturbance, from pristine wilderness to metropolitan areas, and because individual species are often associated with particular habitat types (e.g. Tella *et al*., 1998; Sánchez-Zapata *et al*., 2003; Carrete & Donázar, 2005; Carrete *et al*., 2009). Moreover, in some biological systems, these top predators are strongly associated with high biodiversity values (Sergio *et al*., 2008). However, the adaptation of some raptors to human-altered environments (Anderson, 2001; Panasci & Whitacre, 2002; present results) makes their widespread potential use as valuable indicators of natural habitat quality controversial (Rodríguez-Estrella, Donázar & Hiraldo, 1998; Carrete *et al*., 2009). Our results suggest that Marsh harriers respond positively to some degree of intensification, which reduces their usefulness as an indicator species of natural habitat quality. Moreover, preliminary analysis of changes in productivity with respect to the habitat characteristics measured in this study suggests that no significant relationships exist between this demographic parameter and habitat attributes, suggesting that none of the habitats occupied in this area are population sinks. However, further research is needed to determine whether finer cues such as individual survival can indicate other forms of ecosystem degradation such as water pollution or pesticide use during crop development.

FORAGING HABITAT USE AND SELECTION OF WESTERN MARSH-HARRIERS (*CIRCUS AERUGINOSUS*) IN INTENSIVE AGRICULTURAL LANDSCAPES

LAURA CARDADOR[1] AND SANTI MAÑOSA
Departament de Biologia Animal, Universitat de Barcelona, Facultat de Biologia, Avinguda Diagonal 645, 08028 Barcelona, Catalonia, Spain

ABSTRACT.—We studied foraging habitat use and selection of the Western Marsh-Harrier (*Circus aeruginosus*) in agricultural areas, by radio-tracking seven individuals in the Ebro Basin (northern Iberian Peninsula). Generalized Linear Mixed Models indicated that the probability that a certain point within the study area was used by harriers was influenced by both distance to the nesting site and habitat. Probability of occurrence decreased with the distance to the nesting site and increased in wetlands and herbaceous crops (both those with high-intensity agricultural practices and those with low-intensity agriculture). In areas dominated by high-intensity herbaceous crops (irrigated maize, cereal, and alfalfa), marsh-harriers ($n = 2$) did not use all crop types equally throughout the year; they selected different crops in relation to the crop stage (growing, fallow, and stubble) and to particular agricultural practices (irrigated, unirrigated).

KEY WORDS: *Western Marsh-Harrier*; Circus aeruginosus; *agriculture*; *habitat use*; *habitat selection*; *radiotelemetry*.

USO Y SELECCIÓN DEL HABITAT DE FORRAJEO DE *CIRCUS AERUGINOSUS* EN PAISAJES DE AGRICULTURA INTENSIVA

RESUMEN.—Estudiamos la selección y el uso del hábitat del aguilucho *Circus aeruginosus* en áreas agrícolas, mediante el uso de radio-telemetría en 7 individuos en la depresión del Ebro (en el norte de la Península Ibérica). La aplicación de Modelos Lineales Generalizados Mixtos mostró que la probabilidad de uso de un punto dentro del área de estudio dependía tanto de la distancia a la zona de cría como del hábitat. La probabilidad de ocurrencia disminuyó con la distancia al nido y aumentó en zonas húmedas y cultivos herbáceos (tanto en campos de uso poco intensivos de secano como en campos de uso muy intensivos de regadío). En zonas dominadas por cultivos herbáceos intensivos (maíz, cereal y alfalfa), los aguilucho ($n = 2$) no utilizaron todos los cultivos por igual a lo largo del año. Además seleccionaron diferentes cultivos en función de su estadio (crecimiento, sembrado, rastrojo) y de determinadas prácticas agrícolas (con y sin riego).

[Traducción del equipo editorial]

Food supply is one of the main limiting factors for raptors (Newton 1979). Breeding densities and breeding success can vary in relation to food availability (Salamolard et al. 2000, Redpath et al. 2002). Land-use change from extensive dry agriculture into intensive farmlands has been described as a major cause leading to impoverished food resources and reduction or degradation of foraging habitats for many open-habitat birds occupying farmlands (Tella et al. 1998, Newton 2004). However, agricultural intensification has not affected all species in the same way, and some species can still take advantage of such modified environments (Siriwardena et al. 1998).

The Western Marsh–Harrier (*Circus aeruginosus*) is a medium-sized raptor that occurs within a wide range of open habitats, including agricultural landscapes. During recent decades, the species has undergone a moderate increase (<10% in Europe; BirdLife International 2004). In some areas, such as the Iberian Peninsula, the increase and spread of the Western Marsh-Harrier population has been noticeable in some agricultural regions (Molina and Martínez 2008). There the species seems to be benefiting from both artificial irrigation ponds and reservoirs for nesting habitat and from the intensive herbaceous crops in their surroundings for hunting (Cardador et al. 2011). However, little is known

about foraging habitat use and selection of the Western Marsh-Harrier in agricultural areas (Kitowski 2007, Luo et al. 2010). Because male harriers provide most of the food during the nesting period (Simmons 2000), we investigated the foraging habitat use and selection of male marsh-harriers in an agricultural region within the Iberian Peninsula in relation to habitat type and distance to the breeding site.

METHODS

Study Area. The study area was located in the Catalan Ebro Basin, in the northeastern portion of the Iberian Peninsula. The landscape is mostly low-lying and flat, broken by discrete ranges of small hills (0–400 m asl), and has a semiarid Mediterranean climate. During the twentieth century, agriculture in this area underwent several changes, including the replacement of traditionally cultivated cereals (i.e., spring-sown wheat and barley) with a variety of alternative crops (e.g., winter-sown wheat and barley, alfalfa, maize, or fruit trees), the establishment of irrigation systems, the increase in the use of fertilizers and pesticides, and the reduction or disappearance of fallow systems and field margins (Tella et al. 1998). However, the degree of intensification was not homogeneous in the study area, which is now composed of a mixture of high-intensity herbaceous crops (mainly irrigated alfalfa, irrigated winter-sown wheat and barley, and some irrigated maize crops), high-intensity orchards (mainly irrigated peach, pear, and apple trees), low-intensity herbaceous crops (mainly dry winter-sown wheat and barley) and low-intensity orchards (mainly dry almond and olive trees; Aldomà 2004).

We captured harriers and tracked them at two sites, 30 km apart from each other: the ''intensive farmland'' (41°43′N, 0°23′E), which was dominated by high-intensity herbaceous crops and had scattered small ponds where one, or occasionally two, harrier nests were found (Fig. 1); and the ''mixed farmland'' (41°29′N, 0°30′E), which was a more heterogeneous area, centered on Utxesa, a 280-ha reservoir that harbors a colony of 14–16 breeding pairs (Fig. 1).

Capture and Radiotelemetry. During the breeding periods (May–June) 2000–03, we captured and tagged two male harriers in the intensive farmland and five in the mixed farmland. Marsh-harriers were captured in the breeding areas using bal-chatri traps ($n = 6$) or bow nets ($n = 1$). Each harrier was fitted with a backpack transmitter: 12-g AYAMA-Segutel (Mataró, Barcelona, Spain) transmitters or Biotrack (Wareham, Dorset, U.K.) transmitters. Tracking of the birds was conducted from a car. We began each tracking session near the breeding site (<1000 m), and we then followed the signals until the bird was located (i.e., when we knew the position of the bird to within 100 m by visual contact or radio-signal proximity). We used AYAMA or TELEVIT-900 receivers and a three-element Yagi antenna. Tracking sessions lasted on average 6 ± 2 hr ($n = 283$ tracking sessions). Birds were located at all hours between sunrise and sunset. Tagged harriers in the mixed farmland were tracked following a rotational scheme; once one harrier was located, we searched for the next one. Tagged harriers in the intensive farmland could be tracked continuously. We noted the habitat (low intensive herbaceous crops, low intensive fruit trees, high intensive herbaceous crops, high intensive fruit trees, and wetlands; classified in the field by the observer), and plotted each location on 1:25 000 aerial photographs. To avoid autocorrelation, the minimum interval between successive locations of a single bird was 2.5 hr in both the intensive and mixed farmlands and, on average, 2.31 ± 1.02 relocations per harrier per tracking day ($n = 340$ tracking days) were obtained. In cases when several locations were obtained within one 2.5-hr period, the earliest location was selected for inclusion in the dataset. In the intensive farmland (where harriers were tracked continuously), we noted the total time harriers were observed searching for food in fields with different herbaceous crops (alfalfa, cereal and maize), crop stages (growing, fallow and stubble) and agricultural practices (whether the crops were being irrigated or not) during the entire tracking session. We also recorded hunting attempts when witnessed. Harriers were monitored during periods ranging from 1 to 15 mo and were located 1.7 ± 1.4 d/wk ($n = 197$ weeks). We did not expect biases associated with differences in tracking years or periods because marsh-harriers showed high site-fidelity to foraging areas both between and within years in the study area (Cardador et al. 2009).

Habitat Selection. We used a generalized linear mixed model (GLMM; binomial error distribution; logit-link function), to describe mathematically the probability that a certain point within the study area was used by birds in relation to its habitat characteristics (included as a categorical variable with five levels: low intensive herbaceous crops, low intensive fruit trees, high intensive herbaceous crops, high

intensive fruit trees, and wetlands) and its distance to the nesting site. The dataset included radio-locations of individuals (value 1) and an equal number of randomly selected points not used (value 0) but included within the available study area (Carrete and Donázar 2005). We considered that the total study area was a circle of 15-km radius (the maximum distance from the study site recorded during the study period) focused on the nesting sites. Random points were obtained as independent *x,y* random coordinates within the uniformly sampled study area by using the Animal Movement extension of ArcView 3.2. Habitat types at those points were obtained from a 1:50 000 digital land-use map (Departament de Medi Ambient i Habitatge de la Generalitat de Catalunya, year 1997). In the construction of the model, we included ''individual'' and ''farmland'' as a nested random factor (individual within farmland) in the model to control for the potential nonindependence of data associated with repeated measures of the same individual and farmland.

In the intensive farmland, where harriers ($n = 2$) could be tracked continuously, we also analyzed habitat selection in relation to different herbaceous crops (alfalfa, cereal, and maize), crop stages (growing, fallow, and stubble) and agricultural practices (whether the crops were being irrigated or not). Following Ursúa et al. (2005), habitat selection was analyzed using the Savage selectivity index $w_i = U_i/p_i$, where U_i is the proportion of hunting attempts recorded in a given habitat and p_i is the proportion of total foraging time harriers spent searching for food in that habitat. This index varies

Table 1. Results of GLMM to analyze foraging habitat use of seven male Western Marsh-Harriers relative to habitat and distance to the nesting site (Ebro Basin, 2000–04).

PARAMETER[1]	ESTIMATE	SE	*t*-VALUE	*P*
Intercept	1.5	0.5	3.3	0.017
Distance	−0.0005	0.00003	−19.3	<0.001
Habitat				
Wetlands	2.1	0.6	3.4	<0.001
Low int. herb.	3.5	0.5	7.6	<0.001
High. int. herb.	1.5	0.4	3.4	<0.001
Low int. fruit trees	−0.25	0.9	−0.3	0.78
High int. fruit trees	–	–	–	–

[1] These results were obtained while controlling for the potential effect of individual and farmland fitted as a nested random term (individual within farmland) in the model ($P = 0.35$). Deviance explained by the model: 53.7%; df = 1259.

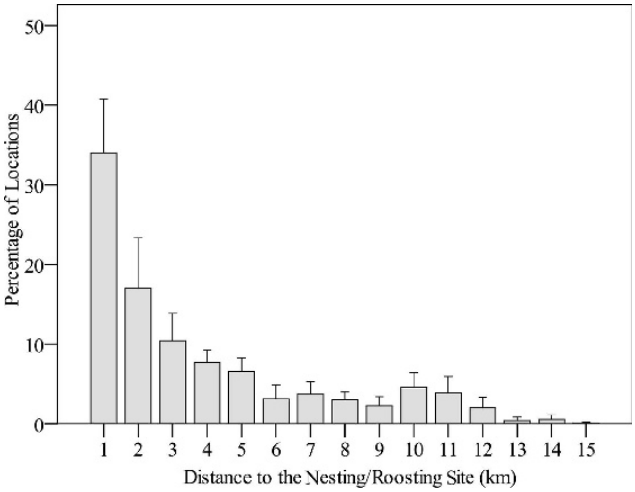

Figure 2. Distribution of distances to the nesting/roosting sites of seven radio-tagged male Western Marsh-Harriers (mean ± SE), relative to distances to the nesting/roosting sites, Catalan Ebro Basin, Spain, May 2000–April 2004.

from 0 (maximum negative selection) to ∞ (maximum positive selection), 1 indicating no selection. The statistical significance of this index was obtained by comparing the statistic $(w_i - 1)^2/\mathrm{se}(w_i)^2$ with the corresponding critical value of a χ^2 distribution with one degree of freedom. The standard error of the index $[\mathrm{se}(w_i)]$ was calculated by $[(1 - p_i)/u_+ * p_i)]^{1/2}$ where u_+ was the total number of hunting attempts sampled.

RESULTS

Seven male harriers were captured and radio-tagged during the study period: five in the mixed farmland (three in 2000 and two in 2001) and two in the intensive farmland (one in 2002 and one in 2003). In total, 678 radio-locations were obtained. The GLMM analysis indicated that the probability that a certain point within the study area was used by harriers was influenced by both distance to the nesting site ($F_{1,1259} = 373$, $P < 0.001$) and habitat ($F_{4,1259} = 22$, $P < 0.001$). Probability of occurrence decreased with the distance to the nesting site and increased in wetlands and herbaceous crops, both high intensive and low intensive (Table 1, Fig. 2).

Radio-tagged harriers in the intensive farmland ($n = 2$) were observed searching for food a total of 227 hr. They principally used alfalfa, maize, and cereal fields (94 ± 2% of total time, $n = 2$). They used alfalfa all year round. Maize use increased during autumn and winter, and cereal use increased during winter and spring (Fig. 3). In total, we observed 455 hunting attempts during this time. Hunting attempts were not distributed at random over the herbaceous crops prospected by harriers. On the contrary, harriers selected different crops relative to habitat type, crop stage, and irrigation (Fig. 4).

DISCUSSION

Raptors are highly mobile predators, which typically have large home ranges, and which often use more than one type of habitat to satisfy their ecological requirements (Newton 1979). As expected, habitat use of marsh-harriers was mainly delineated by two different habitat types: wetlands (which coincided with the breeding/roosting sites and represented <2% of total available habitat), and the herbaceous crops around wetlands (Schipper 1977, Altenburg et al. 1982, Luo et al. 2010), which may offer an adequate vegetation structure for hunting (Preston 1990). Relative to farming practices, marsh-harriers used both low intensive and high intensive herbaceous crops. Proximity to the nesting site also influenced the probability that an area was used for foraging. Although male harriers can hunt far from the nest (up to 14–15 km), most hunting locations were within 3 km of the bird's nest (62 ± 21%, $n = 7$, Fig. 2). Indeed, differences in crop distribution around breeding sites may explain why marsh-harriers in the intensive farmland mainly foraged in high intensive herbaceous crops while those in the mixed farmland mainly foraged in low intensive herbaceous crops (Fig. 1). As in other central-place foragers, the foraging-habitat selection pattern of marsh-harrier may result from a trade-off between the quality of the different patches and the distance at which they were located from the nesting/roosting sites (Carrete and Donázar 2005, Cardador et al. 2009).

Within intensive irrigated farmlands, Western Marsh-Harriers ($n = 2$) mainly foraged in alfalfa fields (81 ± 2% of total foraging time), followed by cereal (9 ± 2%) and maize fields (4 ± 2%). These percentages differed from those estimated from 1:5 000 aerial photographs (Institut Cartogràfic de Catalunya) ground-truthed in the field in 2003 over an area of approximately 90 km² (alfalfa: 50%; cereals: 25%; maize: 15%), suggesting that harriers did not prospect all crops at random. Maize fields, which are sown in April–May, were scarcely used before September, probably because their green cover is too dense and high (0.6–2 m) for hunting and were used primarily during autumn and winter when fields are either covered with stub-

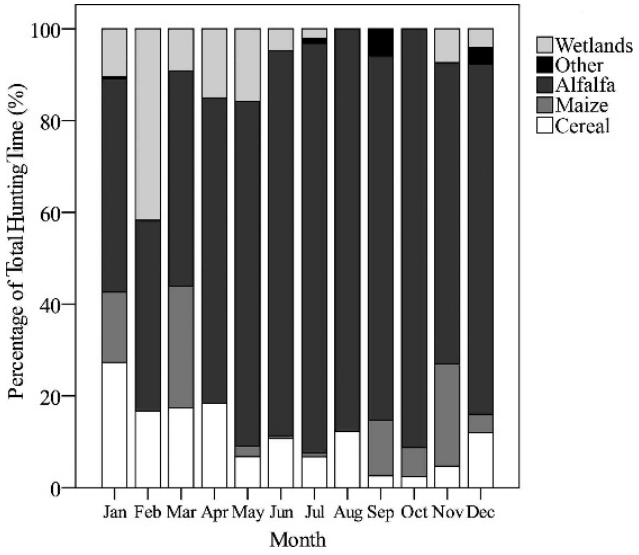

Figure 3. Proportion of hunting time in different crop types by two radio-tagged marsh-harriers in the intensive farmland throughout the year. Mean values for the two harriers are shown. Total observed time = 227 hr.

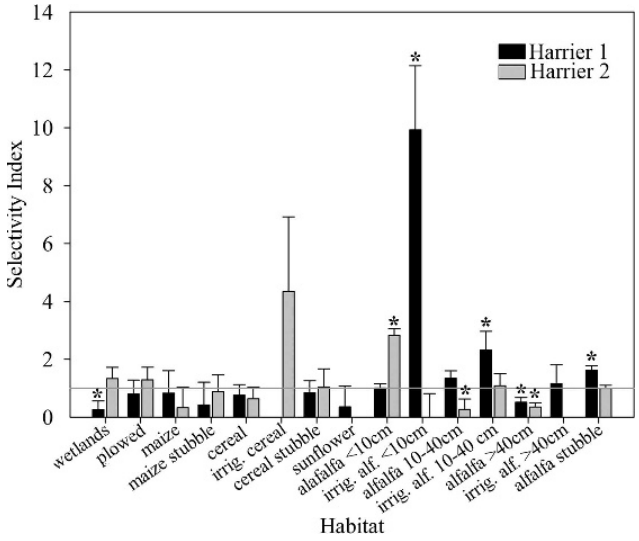

Figure 4. Savage selectivity index (±SE) for each habitat for the two radio-tagged marsh-harriers in the intensive farmland (Catalan Ebro Basin, 2002–04). The horizontal line shows the index value (=1) indicating no habitat selection. Asterisks indicate significant positive/negative selection.

ble or plowed (Ursúa et al. 2005). When harriers used them, hunting attempts were distributed as expected based on the amount of foraging time spent in such crops. Wheat and barley fields were used primarily during winter and spring, during their growing period (before reaching maximum vegetative cover) and harriers did not preferentially use them for foraging. In contrast, Western Marsh-Harriers took advantage of the presence of regularly mown fields (intensively managed alfalfa), which may offer an adequate vegetation structure for hunting during most of the year, especially when crops are <10 cm in height or when stubble is present (Ursúa et al. 2005, Kitowski 2007), and hunting attempts were more frequent than expected based on foraging time spent in these habitats. Interestingly, one of the harriers also increased the number of foraging attempts per hunting-flight time in some fields (alfalfa <10 cm and alfalfa of 10–40 cm) during irrigation. Our observations at the site suggested that the irrigation of such fields may increase the accessibility of small mammals to harriers. The small sample size in our study prevented further analysis of habitat selection and precluded extrapolation of the results outside the studied population.

Although intensification has been considered a major threat for this and other open-habitat bird species occupying farmlands (Benton et al. 2003), our results agreed with previous findings, and showed that intensive agriculture still may offer adequate foraging habitats for some species, at least when food availability is not compromised (Ursúa et al. 2005, Balbontín et al. 2008). Like other generalist predators, Western Marsh-Harriers may be able to exploit transient resources in intensive agricultural habitats, and may be less sensitive to habitat degradation than other more specialized species (Siriwardena et al. 1998).

Feeding behaviour and diet composition of Marsh Harriers *Circus aeruginosus* in agricultural landscapes

LAURA CARDADOR*, ENRIC PLANAS, ANNA VAREA and SANTI MAÑOSA
Departament de Biologia Animal, Facultat de Biologia, Universitat de Barcelona, Avinguda Diagonal 645, 08028 Barcelona, Catalonia, Spain

Capsule Diet composition and feeding behaviour of breeding birds differed between areas of high and low agricultural intensification.
Aims To analyze diet composition and feeding behaviour of Marsh Harriers *Circus aeruginosus* in agricultural landscapes with different degrees of agricultural intensification.
Methods Diet composition and feeding behaviour was assessed by focal observations at nests during breeding seasons in 2001–03 in two agricultural areas within the eastern Ebro Basin (on the northern Iberian Peninsula) which differed in their degree of agricultural intensification: a traditional non-irrigated and non-intensively managed farmland area; and an irrigated and intensively managed farmland area.
Results Marsh Harriers in the intensively managed area took higher percentages of small mammals than harriers in the traditional area managed at low-intensity, where they also had a more diverse diet. Male delivery rates increased throughout the breeding season in the intensively managed area. On the contrary, no significant trend in delivery rates was observed in the traditional area, where harriers turned to larger prey late in the season.
Conclusion Marsh Harriers probably took advantage of different prey types in intensively managed and traditional farmland according to prey availability. Differences in diet composition seem to be related to different foraging strategies adopted by harriers in traditional and intensively managed farmlands. In the traditionally managed farmlands, harriers responded to increases in the energy requirements of the brood over the course of the breeding season by taking larger prey, whereas in the intensively managed farmlands harriers increased feeding rates.

Agricultural intensification over the last six decades has been linked to decreased biodiversity and declines in breeding populations of several farmland bird species (Donald *et al.* 2001). This phenomenon is partially explained by the loss of ecological heterogeneity, which is important in maintaining resources for species-rich communities (Benton *et al.* 2003, Fahrig *et al.* 2011). Among other processes, land-use change from extensive traditional agriculture into intensively managed farmland has led to changes in food availability and reduction or degradation of foraging habitats for many bird species (Newton 2004). However, agricultural intensification has not affected all species in the same way and transformed landscapes still provide suitable habitats for species tolerant of anthropogenic alterations (Siriwardena *et al.* 1998).

Food supply is one of the main limiting factors for birds of prey. Breeding densities and breeding parameters such as laying date, clutch size or productivity can vary in relation to food availability or diet composition (Newton 1979, Redpath *et al.* 2002, Arroyo & García 2006). Food availability is mainly determined by both the abundance and accessibility of food resources (Preston 1990), which in turn can be affected by changes in the composition and structure of foraging habitats. Therefore, the effective conservation and management of birds of prey in anthropogenic landscapes such as farmland requires an understanding of their trophic ecology (Butet & Leroux 2001, Amar *et al.* 2003).

Marsh Harriers *Circus aeruginosus* occur within a wide range of habitats, including farmland. After a dramatic

© 2012 British Trust for Ornithology

population decline during 1960–80, the European population has shown a moderate increase (< 10%) in recent decades (Cramp & Simmons 1994, BirdLife International 2004). Unlike many other farmland birds, this species has made a notable recovery in some agricultural areas, including those dominated by intensively managed crops. Within some areas such as the Iberian Peninsula, the increase in the Marsh Harrier population has been accompanied by increases in both its geographic range and in the variety of habitats it occupies, with some pairs nesting in artificial irrigation ponds and reservoirs related to intensive agricultural practices (Cardador *et al.* 2011). However, diet composition and feeding behaviour of Marsh Harriers in these new habitats remain unknown.

We investigated whether diet composition and food provisioning patterns of Marsh Harriers in an expanding Spanish population differed between two localities with different degrees of agricultural intensification. We also surveyed small mammal abundances to assess whether possible variations in diet and feeding behaviour were related to food abundance.

METHODS

Study area

The study area was located within the eastern Ebro Basin on the northern Iberian Peninsula. The area is mostly low-lying and flat, broken by discrete ranges of small hills (0–400 m asl) and with a semi-arid Mediterranean climate. Almost one-third is covered by farmland, which is managed at a wide range of intensities. Diet composition and feeding behaviour of Marsh Harriers were monitored at two sites, 30 km apart. The 'intensively managed farmland' site (41°43′N, 0°23′E) was dominated by intensively managed herbaceous crops (irrigated winter-sown wheat and barley, irrigated alfalfa and some irrigated maize crops) and had scattered small ponds where one or occasionally two harrier nests were found. The 'traditional farmland' site (41°29′N, 0°30′E) was a more heterogeneous area, centred on Utxesa, a 280-ha reservoir that harboured a colony of 14–16 breeding pairs (Cardador & Mañosa 2011). This area included a large central patch of traditional herbaceous crops managed at low intensity (mostly non-irrigated winter-sown wheat and barley) surrounded by fruit trees. Previous information showed that harriers nesting in this region used the traditional herbaceous crops for hunting (Cardador *et al.* 2009, Cardador & Mañosa 2011).

Data collection

Data were recorded by means of focal observations at nests during breeding seasons (April–August) in 2001–03. We conducted 1049 hours of observation (523 in the traditional farmland site and 526 in the intensively managed farmland site) and recorded 752 prey deliveries to nests from a total of 22 nests (located at Utxesa reservoir) over the 3 years in the traditional farmland site and a total of 10 nests (located in 3 irrigation ponds) in the intensively managed farmland site. Watches were made from vantage points located 200–700 m from the nests using 10 × 42 binoculars and 20–60× telescopes. Observations were conducted between 07:00 and 21:00 hours and lasted on average 4.6 hours ± 2.4 sd ($n = 226$ sessions). For each monitored pair, number of prey deliveries to nests by males and females were recorded. Feeding rates were then calculated for three periods (incubation; nestling; and post-fledging) as the total number of prey delivered to the nest by each sex divided by the total hours of observation (prey h^{-1}), when at least one delivery was recorded. When possible, prey items were identified to class or a lower taxonomic level, and assigned to one of four size categories: very large (e.g. lagomorphs or Mallards *Anas platyrhynchos*); large (e.g., rats *Rattus* spp. or Red-legged Partridges *Alectoris rufa*); medium (e.g., rodents or passerines); and small (e.g. shrews or orthoptera).

Food abundance

An index of abundance of small mammals was recorded in June 2001. In each site, four 1 × 1-km squares located in representative habitat and separated by at least 1 km were delimited. In each square we placed 100 Sherman traps at a minimum spacing of 10 m throughout 2 successive nights (between 21:00 and 08:00 hours approximately). The index of abundance in each square was calculated as the sum of small mammals trapped during the two nights. Sherman traps were not efficient for Mediterranean Pine Voles *Microtus duodecimcostatus*, because they were placed on the ground and voles are mainly fossorial (Torre *et al.* 2010). Therefore, we estimated vole abundance by using an indirect index based on counts of occupied burrows, which we identified as those with fresh digging (Liro 1974). These counts were carried out in six sampling squares of 30 × 30 m within each study site in July 2002, located in representative habitat and separated from one another by at least 170 m.

Data analyses

Identified prey were grouped in five categories: small mammals (i.e. rodents and shrews); large mammals (i.e. lagomorphs and carnivores); birds; reptiles; and fish. For each site and sex, we calculated diet diversity using the Simpson inverse diversity index, which tends to weight in favour of abundant prey types. We used sample-based random re-sampling (50 runs) to derive estimates of prey diversity that are independent of sample size or completeness by using ESTIMATES 8.2 (Colwell 1999). Differences in dietary diversity between groups were established by visually comparing sample-based accumulation curves and their corresponding 95% CIs.

We then analyzed differences in diet composition between sites and whether those differences varied between sexes or periods of the breeding season. For these analyses, we pooled into single categories small mammals and other mammals ('mammals') and those categories of prey that were very rarely taken by Marsh Harriers ('other prey' – i.e. reptiles and fishes; see Fig. 1). Then, for each prey category considered (i.e. mammals, birds and other prey), we conducted a GLMM with site, sex, period (fitted as an ordinal variable, with incubation < nestling < post-fledging) and the interactions between site and period and between site and sex as fixed factors. We used a hierarchical backward stepwise elimination, following Crawley (1993) – all explanatory variables were fitted to the model, extracted one at a time from this maximal model (starting from higher-order interactions), and the associated change in model deviance was assessed by an *F*-test. Main effects contained in a significant interaction term were retained in models. We fitted a binomial error distribution for the dependent variables (the probability that the delivered item was or was not the category of prey considered in each model), and used a logit-link function. We included nest and year as random terms in those models to control for repeated observations of the same nests and years.

We tested for differences in feeding rates between sites and whether those differences varied among sexes or periods of the breeding cycle by using GLMMs with a hierarchical backward elimination method (see earlier). We fitted period, site, sex and the interactions between site and sex and between site and period as fixed factors in those models. We used the normal error distribution and the identity-link function for continuous data (i.e. feeding rates: prey h^{-1}) and the binomial error

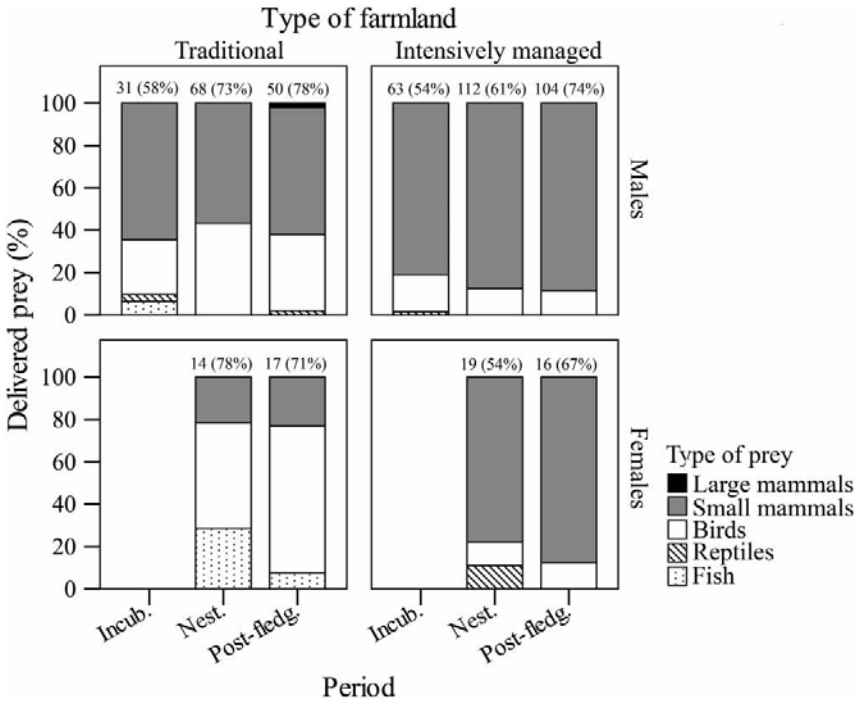

Figure 1. Comparative data on diet composition according to agricultural landscapes (traditional or intensively managed), period of the breeding cycle, and sexes of Marsh Harriers in the Catalan Ebro Basin (Spain), 2001–03.
Number of identified prey and percentage that it represents from total observed deliveries (in parentheses) are shown.

distribution and the logit-link function for presence/absence data (i.e. the probability that the delivered item was or was not the category of prey size considered – large, medium or small; very large prey were not considered for analyses because they were very rarely taken by the species, < 1% of total identify prey). We included nest and year as random terms in those models to control for non-independence of data.

Finally, we tested for differences in food abundance between sites by using GLMS with site as a categorical factor. We fitted a Poisson error distribution for the dependent variables (abundance of each category of food) and used a log-link function. All tests were performed using SAS 9.2.

RESULTS

Diet composition

Marsh Harriers occupying the traditional site had a more diverse diet than harriers occupying the intensively managed site (Fig. 2). Delivery rates of mammals and birds to the nest by monitored harriers significantly differed between the type of farmland (Table 1) and those differences seemed consistent among different periods of the breeding season (variable period not retained in models). Marsh Harriers in the traditional site delivered fewer mammals and more birds than in the intensively managed one (Fig. 1, Table 1). Males delivered more mammals to the nest than females (Fig. 1, Table 1), but differences between sexes were more pronounced in the traditional farmland site (significant interaction 'site × sex'). Mediterranean

Table 1. Results from GLMMS for differences in the consumption of different prey categories between the two studied sites (traditional versus intensively managed farmlands), periods of the breeding cycle and sexes.

Parameter	Estimate ± se	df	*F*-value	*P*-value
Mammals				
Traditional	−2.80 ± 0.63	464	26.08	< 0.001
Males	0.33 ± 0.46	464	9.01	0.003
Traditional × Males	1.40 ± 0.70	464	3.94	0.047
Birds				
Traditional	1.35 ± 0.35	466	12.97	< 0.001
Other prey				
Traditional	1.97 ± 0.83	464	5.09	0.024
Males	−3.73 ± 0.81	464	23.60	< 0.001
Period	−1.17 ± 0.51	464	5.40	0.021

Pine voles were the most commonly consumed prey within the small mammal category in the intensively managed site. Conversely, mice (*Mus* sp.) were the most commonly consumed prey in the traditional site (Fig. 3). Other prey accounted only for a small proportion of prey items in both farmland types (Fig. 1), but differences between sites, sexes and periods of the breeding season were found (Table 1). Deliveries of other prey were more frequent in the traditional farmland site, decreased late in the season, and were conducted more frequently by females than by males.

Abundance indices of small mammals differed between sites. Abundance indices of Algerian Mice *Mus spretus* ($\chi^2 = 25, P < 0.001$) and Wood Mice *Apodemus sylvaticus* ($\chi^2 = 4.16, P = 0.04$) were higher in the traditional site, while abundance indices of voles (voles' burrows: $\chi^2 = 216, P < 0.001$) and Greater White-toothed Shrews *Crocidura russula* ($\chi^2 = 4.82, P = 0.03$) were higher in the intensively managed site (Fig. 4).

Variation of feeding rates

A significant interaction between site and period and between site and sex was found (Table 2), meaning that the relationship between feeding rates and type of farmland was complex and linked to periods of the breeding cycle and sexes. Feeding rates in the intensively managed farmland site increased throughout the breeding season, while feeding rates remained nearly unchanged in the traditional farmland site (Table 2). Females only provided food to the chicks during nestling and post-fledging periods (Fig. 5) and at a lower rate than males in both traditional and intensively managed farmland, but differences between sexes were less pronounced in the traditional farmland site (significant interaction 'site × sex'; Table 2).

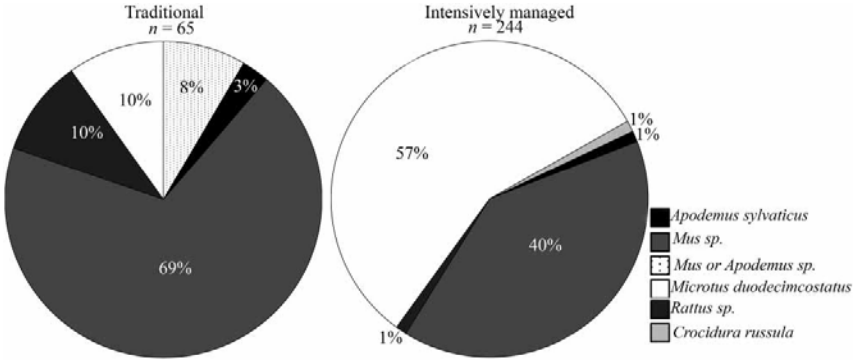

Figure 3. Occurrence of different prey species, within the 'small mammal' category, in traditional and intensively managed farmland sites. Number of total small mammals that could be identified to genus or species is shown; the total number of small mammal deliveries observed was 94 in the traditional farmland site and 264 in the intensively managed farmland site.

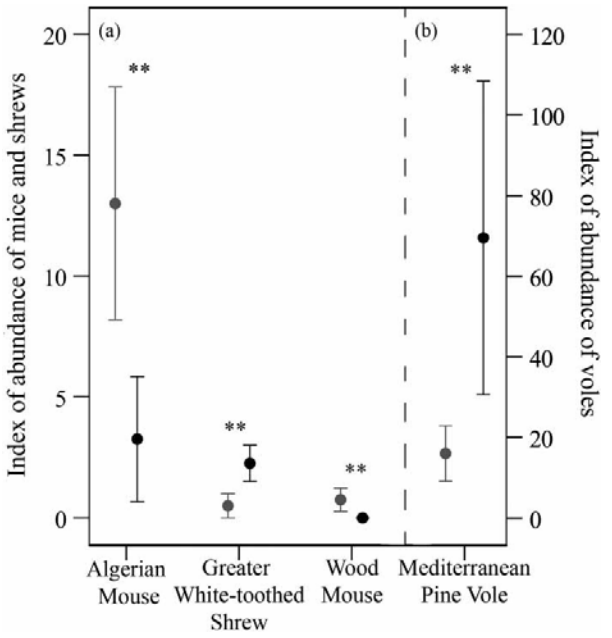

Figure 4. Variation in the abundance (mean ± se) of small mammals between traditional (•) and intensified (•) farmlands in the study area, Abundance was estimated (a) directly, as the number of individuals caught in two successive nights by trapping in 1 × 1-km squares or (b) indirectly, as the number of active burrows counted within 30 × 30-m squares.
**Significant differences ($P < 0.005$) in abundances between farmlands based on GLMS (Poisson error distribution, log-link function).

Variation in prey size

Harriers from intensively managed and traditional farmland sites did not take prey of different sizes with the same frequencies throughout the breeding season (significant interactions 'site × period' in final models for medium and large prey; Table 3). Harriers in the traditional farmland site increased the percentage of large prey throughout the breeding season, while harriers in the intensively managed farmland site took an increasing proportion of medium-sized prey as the season progressed (Fig. 6, Table 3). No significant differences were found in the percentage of different prey size categories delivered to the nest between sexes (variable 'sex' not retained in models). No temporal trend was observed in either traditional or intensively managed farmland areas for small prey (none of the variables considered were retained in models).

Table 2. Results from GLMMS for differences in the consumption of large and medium-sized prey between the two studied sites (traditional versus intensively managed farmlands), periods of the breeding cycle and sexes.

Parameter	Estimate ± se	df	*F*-value	*P*-value
Large prey				
Traditional	−1.07 ± 1.07	582	1.00	0.32
Period	−0.32 ± 0.23	582	0.06	0.81
Traditional × Period	0.72 ± 0.33	582	4.66	0.03
Medium prey				
Traditional	−1.60 ± 0.88	582	3.32	0.07
Period	0.38 ± 0.16	582	0.10	0.75
Traditional × Period	−0.68 ± 0.27	582	6.26	0.01

Table 3. Results from GLMMS for differences in feeding rates between the two studied sites (traditional versus intensively managed farmlands), periods of the breeding cycle and sexes.

Parameter	Estimate ± se	df	*F*-value	*P*-value
Traditional	0.60 ± 0.23	46	4.52	0.039
Males	0.52 ± 0.09	46	41.37	< 0.001
Period	0.18 ± 0.05	46	11.75	0.001
Traditional × Period	−0.16 ± 0.06	46	7.53	0.010
Traditional × Males	−0.37 ± 0.10	46	12.41	0.001

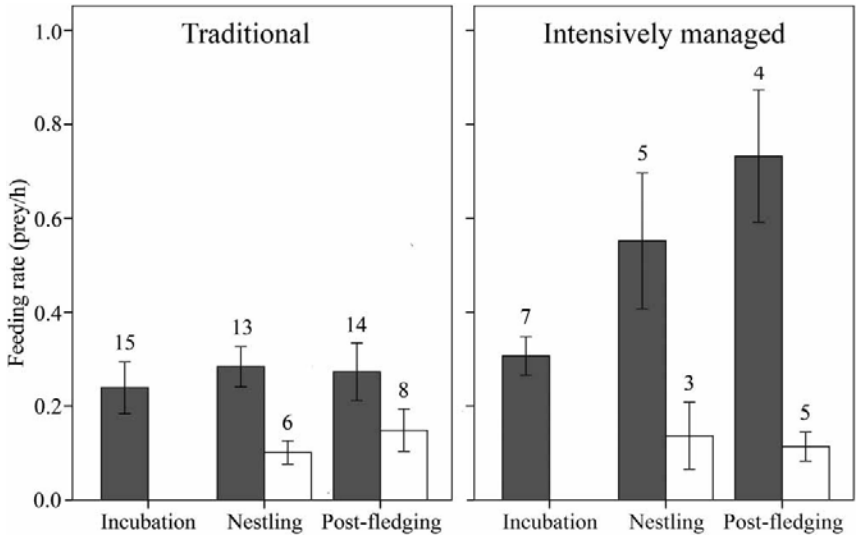

Figure 5. Mean ± se food delivery rates (prey h^{-1}) for male (grey bars) and female (open bars) Marsh Harriers throughout the breeding season in traditional and intensified farmlands, within the Catalan Ebro basin (Spain), 2001–03.
Sample sizes (number of harriers observed delivering food at least once in each period) are shown above the histogram bars.

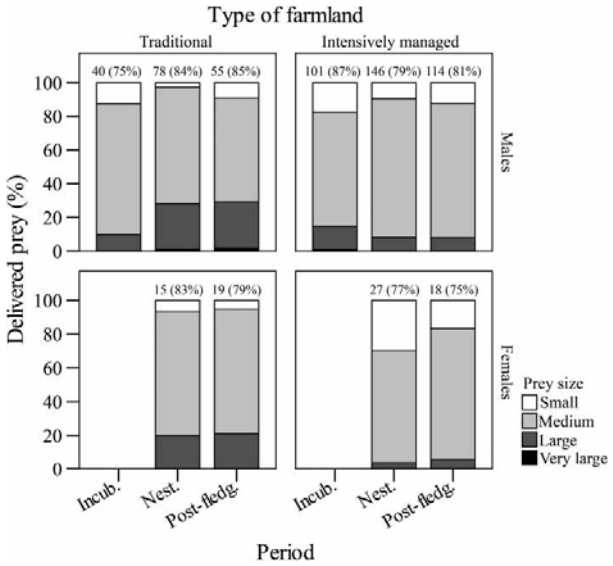

Figure 6. Seasonal variation in diet composition according to prey size delivered by male and female Marsh Harriers breeding in traditional and intensively managed farmlands.
Number of total identified prey and percentage that it represents of the total observed deliveries (in parentheses) are shown.

DISCUSSION

The diet of Marsh Harriers in our study area mainly comprised mammals and birds, with other groups, such as reptiles or fishes, accounting for a much lower proportion of prey items. These results agree with those reported for other European populations (Cramp & Simmons 1994), indicating consistency in the diet of Marsh Harriers over much of their geographic range. Within mammals, small mammals were the most commonly consumed prey, contrasting with previous studies in central Spain, where Marsh Harriers mainly preyed on lagomorphs (González 1991). Marsh Harriers in intensively managed areas took larger percentages of small mammals and had a less diverse diet than those in more traditional habitats. Additionally, Marsh Harriers in traditional and intensively managed farmlands did not prey on the same small mammals species. In intensively managed farmland, Mediterranean Pine Voles were the most frequently taken species within the 'small mammals' category (approximately 60%); but, they only comprised 10% in traditional farmland, where mouse species were the most commonly consumed prey within this category. Although limited (only one year), censuses of small mammals in the study area suggest that diet composition of Marsh Harriers reflected differences in the abundance of such prey between farmlands. This result seems consistent with previous studies, which have shown that microtine species reach higher densities than other small rodents species in more intensified agricultural systems (Millán de la Peña *et al.* 2003, Burel *et al.* 2004). However, we cannot completely discard the possibility that other local or temporal processes, not related to intensification, could be affecting our results.

Optimal foraging theory predicts that individuals will forage in such a way as to maximize their energy gain and that diet diversity will decrease as abundance of preferred prey increases (Pyke *et al.* 1977). Small mammals have been described as a preferred and high-quality prey for *Circus* species in some regions, positively affecting breeding parameters and body condition (Butet & Leroux 1993 , Dijkstra & Zijlstra 1997, Sternalski *et al.*2010). Under this perspective it seems that the diet of Marsh Harriers in intensively managed farmland (with a higher proportion of small mammals and less diverse than in traditional farmlands) could be the result of the particularly favourable foraging conditions offered by this habitat in terms of optimal prey availability, as has been suggested by previous studies on ranging behaviour and habitat use (Cardador *et al.* 2011, Cardador & Mañosa 2011). However, this is not the only possible interpretation, as a high percentage of small mammals in the diet of Marsh Harriers in intensively managed habitats could also be a by-product of there being relatively few alternative prey, such as birds (Terraube & Arroyo 2011). More specific studies on foraging efficiency and time budgets in different habitats with prey types are needed to clarify whether small mammals or birds have higher or equal value for Marsh Harriers (Terraube *et al.* 2010) and whether the higher consumption of small mammals in intensively managed farmland is the outcome of an optimal foraging strategy or the result of a reduction of alternative prey diversity and availability.

Differences in diet composition between traditional and intensively managed farmlands in our study area may explain the differences in feeding strategies followed by Marsh Harriers in these two types of landscapes throughout the breeding cycle. Among harriers, males provide most prey items for chicks and females during the breeding season (Cramp & Simmons 1994), while females only help with chick provisioning late in the season, and at lower rates than males, since they need to combine their hunting activities with nest defence (García & Arroyo 2005). In intensively managed areas, where male harriers preyed mainly on small mammals, they increased their feeding rate late in the season (during nestling and post-fledging stage), probably in response to increased energy demands (Underhill-Day 1993, García & Arroyo 2005). On the contrary, in traditional farmlands, where male harriers fed on more diverse prey, they followed a different strategy: they turned to larger prey late in the season, but did not vary their feeding rate.

Agricultural intensification has led to changes in prey composition and abundance in farmland areas (Donald *et al.* 2001, Benton *et al.* 2003). Marsh Harriers in our study area appear to adapt their feeding behaviour to prevailing feeding conditions. Preliminary analysis suggests that mean productivity of birds breeding in intensively managed farmland is similar to that experienced by birds breeding in traditional farmland habitats (Cardador *et al.* 2011). However, the effects of agricultural intensification and related dietary shifts on other demographic parameters such as inter-annual variations in productivity or survival are unknown, and more specific studies will be needed before the global and long-term effects of agricultural intensification on Marsh Harrier population can be elucidated.

ACKNOWLEDGEMENTS

We wish to thank all volunteers who assisted in fieldwork; A. Folch provided data on censuses of Mediterranean Pine Voles in intensified farmlands; J. Navarro, V. Bretagnolle, J.T. García, R. Nager, M. Wilson and J. Terraube provided valuable comments on the manuscript; Ajuntament de Torres de Segre provided logistic and financial support. This work was partially financed by Departament de Medi Ambinet i Habitatge de la Generalitat de Catalunya. We also thank the Fundació Bosch i Gimpera for administrative management of the project. L.C. was partially supported by a postgraduate grant from Ministerio de Educación of Spain.

NATURAL ENGLAND

Foreword

Natural England commission a range of reports from external contractors to provide evidence and advice to assist us in delivering our duties. The views in this report are those of the authors and do not necessarily represent those of Natural England.

Background

The implementation of a wide range of plans or projects can affect species or habitats on sites which have been designated for their nature conservation importance as European Protected Areas.

Areas of land or sea outside of the boundary of a European site may be important ecologically in supporting the populations for which the site has been designated or classified. Occasionally impacts to such habitats can have a significant effect upon the species interest of such sites, where these habitats are considered to be functionally linked to the site.

Natural England advisers need to judge whether the impacts on habitats that are functionally linked to a site, may adversely affect its integrity and whether the effects are significant in light of the conservation objectives for the site.

This report aims to provide an analysis of authoritative decisions that have considered functional linkages in cases assessed under the Habitats Directive and Regulations. It will be used as a referencing tool for Natural England and other decision makers, in particular Natural England advisers involved in casework.

Summary

Introduction

This report aims to provide an analysis of authoritative decisions which considered effects from projects being considered for authorisation on areas of land or sea that were considered to be functionally linked to a European site, but which lay outside the boundaries of the site. It is intended to serve as a referencing tool for use by Natural England to inform a review of its approach to casework in light of interpretations of the Habitats Directive and Regulations.

In the context of this report, the term 'functional linkage' refers to the role or 'function' that land or sea beyond the boundary of a European site might fulfil in terms of ecologically supporting the populations for which the site was designated or classified. Such land is therefore 'linked' to the European site in question because it provides an important role in maintaining or restoring the population of qualifying species at favourable conservation status. This report only looks at areas which are functionally linked for species rather than qualifying habitats.

An 'authoritative decision' is a decision which has been subject to sufficient scrutiny, at an appropriate level, to impart a degree of *authority*. In this report, 'authoritative decisions' used are those relating to domestic court judgments, and Secretary of State and certain Planning Inspector decisions in respect of a proposed plan or project.

It may be necessary to consider the date of a decision or the extent to which a particular case is consistent with previous judgments or practice before relying upon it in a decision-making process. It is the responsibility of the reader to interpret and apply the findings in this report appropriately. The findings and conclusions of the report should be considered fairly, as a whole, and not quoted, used or applied selectively, in order to support a pre-determined or preferred conclusion.

In Habitats Regulations Assessment the concept of functional linkage is relevant to both the stage 1 'screening decision' and the stage 2 'integrity test'. If effects on functionally linked land or sea are likely to have a significant effect on the population of species for which a European site was designated or classified, those effects must be considered fully in a Habitats Regulations Assessment.

Methodology

The researchers compiled a list of potentially relevant cases drawn from:

i. their own library of decisions, and their empirical knowledge of case work;
ii. a further web-based search of European Court judgments and opinions;
iii. a web-based search for decisions relating to nationally significant infrastructure projects and projects consented under the Electricity and Pipeline Acts in England and Wales and their territorial and UK offshore waters; and

iv. suggestions made by officers in Natural England following an e-mail enquiry of case officers by the research project manager.

Over 180 cases were originally identified as being relevant to the assessment of plans and projects affecting European sites. Following an initial screening exercise, twenty five of these decisions were subject to detailed examination in this review as being relevant to the consideration of functional linkage.

One Court of Appeal case is included only to contribute to the discussion on evidence requirements. Of the twenty four cases subject to further analysis, 19 referred to effects on birds, 4 were related to effects on bats, and two referred to effects on Atlantic salmon. One of the 19 SPA cases also identified potential effects in respect of marine mammals.

Discussion and conclusions

Bats

The issues in the four cases relating to bats examined the potential loss, interruption, or diminution of the ecological value of the routes (flyways) used by the bats from the SAC to reach their foraging grounds, which were spread around the countryside beyond the SAC boundary. Hence the bats would be indirectly affected by way of loss of habitat, or by the interruption or severance of the flyways or by the introduction of deterrent effects in the flyways and/or in the foraging areas. Reduction in ecological value of the foraging areas and/or impediments to the bats reaching their foraging areas could undermine achievement of the conservation objectives of the SACs and therefore affect the conservation status of the bats in the SACs. The failure of the developer in one case to carry out the surveys reasonably required to establish the importance of an area reasonably likely to be part of a critical flyway, led to the refusal of the application and dismissal of the appeal. This was because an appropriate assessment could not be properly completed without it. In all cases the risk to the population of bats, for which the SAC had been designated, arising out of effects which could occur beyond the boundary of the SAC was accepted by the decision maker.

Birds

Twelve SPA cases related to terrestrial or coastal habitats involving a range of waterfowl. Seven related to the marine environment and sea birds. In all cases the decision maker recognised the potential importance of functionally linked land or sea and that it should be treated as part of the Habitats Regulations Assessment.

In the terrestrial or coastal environments, three points became clear from the research:

a) the scope for SPA bird species to use land, whether in close proximity or further away from the SPA, is often limited by urban development, land use patterns, noisy or other disturbing activities or operations, barriers and of course suitability of the habitat, even where there is open land or water;
b) there are often good quality, pre-existing records, such as Wetland Bird Census data, to indicate the use of specifically defined areas outside the SPA by birds;

c) surveys of use, or potential use, of land or water bodies by relevant SPA species is usually reasonably obtainable even if surveys are required over a period of time.

In the terrestrial or coastal environments, the functionally linked land was identified by surveys of actual or probable use, rather than mere assumption that birds from the local SPA might use the area because it might be suitable.

Consequently, in the terrestrial and coastal environments, the possibility of the presence of functionally linked land is more readily identifiable, and the land areas more easily defined as relatively discrete areas, than in the marine environment discussed below. Where pre-existing records were not available, but an area affected by a development appeared likely to be used as functionally linked land, new survey work was undertaken to establish the level of use in order to inform a Habitats Regulations Assessment, screening or appropriate assessment, as the case may have been. Even where good data about levels of use were available, survey effort was continued in some cases to improve understanding.

By contrast, the seven sea bird SPA cases, relating to offshore wind farms, had to approach the potential of functionally linked sea areas differently. All new proposals involved surveys to establish the use of the proposed wind farm areas by all species of birds. It was then necessary to consider whether the birds that were recorded in these offshore areas may reasonably be assumed to be individuals associated with an SPA. This depended in part on the proportion of that species which bred in SPAs, and the distance that the area lay from SPAs for the relevant species. The critical distance was usually the species-specific, maximum recorded foraging distance, or in some cases the known flight paths, which varied considerably from one species to another. No standard cut off distance from an SPA could be used as a surrogate for the risk of a significant effect. All of this was relevant before the ornithological analyses attempted to calculate collision risk or displacement for the birds that were recorded as using the development area.

On the scientific evidence in the Habitats Regulations Assessments accompanying the decision in each of these cases, the calculations of displacement and collision risk modelling related to bird populations which could reasonably be assumed to be those relating to an SPA; in all cases the SPAs potentially affected were specifically identified.

Atlantic salmon

One case concerned effects on individuals of Atlantic salmon, when they would be upstream of the SAC boundary. With the project being located upstream of the designated SAC, the functional linkage between the population for which the SAC had been designated and the individuals potentially affected by the proposed development was clear, because they would all have had to migrate through the SAC to reach the upstream stretches. These risks had not been adequately assessed when the original permission had been granted. In the other case it was the risk to migrating smolt caused by the deterrent effect of noise from piling operations that had the potential to prevent Atlantic salmon from making their seaward migration from the SAC out into the Irish Sea. The risk was avoided by a seasonal restriction on the driving of the piles.

Harbour porpoise and seals

In this case the functional linkage of a wind farm site to 26 pSCIs around the North Sea (most in the territorial seas of other member states), which had been designated for harbour porpoise and two for grey seals and harbour (common) seals was necessarily based on certain assumptions. For each species, the long distances from the European sites and the extensive range over which the species were known to forage led to the conclusion that displacement was not considered to represent a threat to the integrity of any of the sites potentially affected.

Evidence requirements

The 'Boggis' case helps to establish some principles about the requirement for at least credible evidence that there is a functional link between an area that may be affected by development and a European site. In 15 of the 24 other cases examined in detail the researchers considered that there was a good level of survey or other evidence demonstrating a relatively clear (or even obvious) link to the SAC/SPA and its species.

Other cases, in the marine environment, had to be based on reasonable scientific assumptions. But these cases should not be regarded as having a weak evidence base for the links. In the precautionary approach of the Habitats Regulations sufficient evidence pointed to a possibility or a risk of an effect on SPA or SAC populations.

In respect of two cases, the evidence base was considered to be 'poor' with links not well established. In one of these cases a legal challenge to a plan consequently failed. In the other case, referred to under bats above, the developer declined to carry out surveys that could have demonstrated how important the functional link was and how effective mitigation measures might have been, so the application of the precautionary principle led to the refusal of the application and dismissal of the appeal.

In essence, the research shows, amongst other things, that:

a) The identification of an area as functionally linked land in the terrestrial or coastal environment is generally relatively straightforward and readily recognised, but may sometimes not be apparent and may require some initial survey and analysis or collation of pre-existing data, to establish the link;
b) The identification of an area as functionally linked sea is more challenging and has to be approached differently for marine developments; nevertheless an approach in respect of sea birds and marine mammals appears to be developing and although necessarily relying to a greater extent on assumptions, it provides a robust approach which is suitably precautionary without being onerous;
c) Once identified as functionally linked land or sea, the evidence required by decision makers in stages 1 and 2 of the Habitats Regulations Assessment process are no different to those that might reasonably be expected in relation to direct or on-site effects on the European site. The precautionary principle applies equally to functionally linked land and sea. Where effects might be significant and there is insufficient information to ascertain that there would not be an adverse effect on the integrity of a site, in terms of the population of the species for which the site has been

classified or designated, authorisation has been denied; consistently with the provisions of the Regulations. However, in the majority of cases sufficient evidence was available for the decision-maker to conclude that there would be no significant effect, or no adverse effect on site integrity, if the project was authorised.

A Background to this research

A.1 Status of this report

This report sits within a series reviewing the findings of 'authoritative decisions'. It is concerned with how areas of land or sea that are functionally linked to a European site have been considered by authoritative decision makers when projects may affect them. At the time of writing, two other reports are available regarding 'small scale effects' and 'longevity of effects'.

A.2 Who the report is for

The research was commissioned by Natural England "*for the production of a report which can act as a referencing tool for use by Natural England to inform a review of its approach to casework in light of recent interpretations of the Habitats Directive and Regulations"*. Whilst the report has primarily been drafted for Natural England, it will be of interest to all practitioners and advisers working in the assessment of plans and projects under the 'Habitats Regulations'[1].

A.3 Aims of this report

Natural England advisers in casework frequently issue advice on the potential effects that proposed plans or projects might have on European sites. For the purpose of this report the term 'European site' includes:

- Special Protection Areas (SPAs) classified under the EU Birds Directive[2];
- Special Areas of Conservation (SACs) designated under the EU Habitats Directive[3];
- Ramsar Sites listed under the Ramsar Convention[4].

Cases involving proposed SPAs or SACs could also be relevant because of European Court rulings as to how member states should secure the protection of such sites before they are fully designated or classified. Later in this report there are references to 'Sites of Community Importance' or 'SCI', because this is a term widely used in respect of European sites by the European Court and the European Commission.

Advice is given by Natural England based on the best available information in light of the characteristics and specific environmental conditions at the site concerned[5]. However, it can be difficult to ascertain what is acceptable under the specific tests set out in the assessment provisions of the Habitats Regulations (regulation 61), commonly referred to as a 'Habitats Regulations Assessment' or 'HRA'.

[1] The Conservation of Habitats and Species Regulations 2010 SI 490
[2] Council Directive of 30th November 2009 on the conservation of wild birds (2009/147/EC)
[3] Council Directive of 21/5/92 on the conservation of natural habitats and of wild fauna and flora (92/43/EEC)
[4] Convention on wetlands of international importance especially as waterfowl habitat, Ramsar, Iran 2/2/71 as amended by the Paris protocol 3/12/92 and the Regina amendments 3/6/87.
[5] Refer paragraph 48 Case C-127/02 *Waddenzee*

This report aims to provide an analysis of authoritative decisions which considered potential effects on land or sea outside a European site, but which provided supporting habitat, or other ecological function, linked to the designated area or its qualifying features, which can serve as a source of reference for advisers and decision makers.

A.4 The importance of case law to the decision making process

Case law is a vital source of information regarding how legislation should be correctly interpreted and applied. The Habitats Regulations transpose the requirements of the EU Wild Birds Directive and the EU Habitats Directive into domestic legislation. They set out a suite of legal obligations and responsibilities for a broad range of statutory agencies and decision making bodies (known as 'competent authorities'). As with all statutory instruments of this nature, there is scope for inconsistency in how the statutory provisions are interpreted and applied.

Too strict an interpretation might lead to plans or projects being delayed, subject to unnecessary restrictions, or ultimately refused under circumstances which were not intended to be incompatible with the underlying Directives. This can result in increased costs to, and frustration for, project proposers, which might have been avoidable, or unnecessary impediments to economic growth and development.

Too lenient an interpretation carries different risks. Plans or projects might go ahead without sufficient consideration of the potential harm to the sensitive habitats and species for which the sites have been designated. This in turn might lead to the deterioration of protected habitats and species, or a legal challenge through either the domestic or the European Courts regarding a failure to comply with the Regulations or the Directives.

Case law is therefore important in establishing a common understanding of how the tests involved in the assessment of plans and projects under the Habitats Regulations should be applied. There are credibility risks for decision makers, and those advising them, if a decision taken in respect of one proposed plan or project is not taken on the same basis as another plan or project, whether by the same or different competent authorities. Decision makers should strive to be consistent to ensure that the effects on the habitats and species protected under the Habitats Regulations are weighed appropriately and consistently in comparison with the benefits of proposals for change.

A.5 The meaning of 'authoritative decision'

Applying a 'plain English' interpretation, an 'authoritative decision' is a decision which has been subject to sufficient scrutiny, at an appropriate level, to impart a degree of *authority*.

In the context of this series of reports, 'authoritative decisions' are limited to those of the European and domestic (UK wide) court judgments and rulings (see A.6 and A.7 below), Secretary of State, or the Scottish or Welsh Ministers and certain Planning Inspector (in Scotland Reporter) decisions in respect of a proposed plan or project (see A.8 and A.9 respectively), and certain legally enforceable management measures such as a bye-law or statutory order (included in Secretary of State decisions in A.8). Article 6(4) 'opinions' from

the European Commission are also regarded as sufficiently authoritative to be included (A.10).

However, in this report all of the decisions referred to were made by the UK domestic courts, a Secretary of State, or an Inspector so, whilst the authority of decisions of the European Courts and 'Opinions' of the European Commission are introduced in A.6 and A.10 respectively, to provide relevant context, they are not considered further.
All these authoritative decisions are explained in the following sub sections so that they can be better understood in respect of:

a) how they should be read in relation to each other (some authoritative decisions carry greater weight than, or may supersede, other decisions); and
b) how they should be read in relation to a case which might currently be under consideration (where the reader is seeking guidance from this report as to a decision to be made).

A.6 Decisions of the European Courts

The relevant European court was the European Court of Justice until 1st December 2009, when the provisions of the Lisbon Treaty came into force and the court became known as the Court of Justice of the European Union. For the purpose of this report, all cases are referred to simply as those of the 'European Court'.

The European Court has two principal functions. Firstly, deciding cases of dispute between, on the one hand, the European Commission (EC), seeking to enforce the terms of the Directives; and, on the other hand, member states, who may be accused by the EC of failure to comply with the Directives. In these cases the European Court issues 'judgments' following consideration of written material and oral hearings. A judgment issued in the case of such a dispute is referred to in the documentation in terms of an 'action' of the court, because the decision reached by the court carries direct consequences for the parties involved.

The European Court also provides 'preliminary rulings'. These are not intended to resolve a dispute in the European court itself, but to answer questions submitted to the European Court by a court of a member state. Questions will almost invariably relate to how the domestic court of the member state should properly interpret the Directives when making a judgment in their own court. These decisions are also included in the term 'judgments'. The documentation relates to the 'reference' or 'request' made to the court rather than an 'action' related judgment in the case of a dispute.

This report uses the generic term 'judgment' in respect of European Court decisions, unless it is important to distinguish that a particular case was a 'ruling'. All judgments of the European Court carry the greatest weight because they are binding on member states in terms of both decision making and domestic court proceedings.

Importantly, all judgments of the European Court are accompanied by an 'opinion' from an Advocate General of the Court. The Advocate General's opinion is published in order to inform the Court's judgment. The relevant opinion exerts considerable influence over the

respective judgment. Opinions are also helpful because they often include more information concerning the details of the case concerned. The Advocate General's opinion carries less weight than the final judgment and the opinions are not binding on member states. However, they are so influential and carry such weight in European Court judgments and rulings that they are regarded as 'authoritative decisions' in the context of this research.

European Court decisions are binding on member states. They must therefore be given due weight by competent authorities and the courts of member states. They provide the definitive interpretation of how the Directives should be interpreted. However, not all areas of potential uncertainty have been the subject of a case in the European Court. In the absence of a judgment from the European Courts, the UK Courts may need to make decisions based upon their own interpretation.

A.7 Decisions of the UK Courts

Decisions taken in the UK Courts, which are of relevance to the application of the Habitats Regulations arise from judgments in the "High Court", the "Court of Appeal", and the "Supreme Court".

Relevant legal proceedings will start in the High Court, and if the High Court judgment is not referred to the Court of Appeal it will stand. However, if a High Court judgment is referred to the Court of Appeal the latter judgment will prevail and the legal principles established are binding on subsequent High Court judgments. Similarly, if a Court of Appeal judgment is referred to the Supreme Court the latter judgment will prevail and the legal principles established are binding on all lower courts including the Court of Appeal.

In Scotland, the Outer House of the Court of Session is equivalent to the High Court and the Inner House of the Court of Session is equivalent to the Court of Appeal.

A.8 Decisions of the Secretary of State / Scottish or Welsh Ministers

A decision taken by a Secretary of State, or an equivalent decision made by the Scottish or Welsh Ministers (the Ministers) is regarded as authoritative because it has been considered by a Government Department and signed off at a Ministerial level. It will usually (for example in the case of orders for development consent) be accompanied by or contain a detailed record of the related Habitats Regulations Assessment. Relevant decisions made by a Secretary of State or the Ministers relate to one of the following:

- an application for an 'Order for Development Consent' under the provisions of *The Planning Ac*t 2008 for a 'Nationally Significant Infrastructure Project'; or
- a consent required by a Secretary of State under primary legislation, for example, under the Electricity or Pipeline Acts; or
- in respect of a 'call-in' application, or a 'recovered' appeal under the provisions of the *Town and Country Planning Act* 1990 and related legislation (see further below), or
- the confirmation of a bye-law or other kind of statutory Order.

A decision made by a Secretary of State or the Ministers stands unless revoked or modified by them, or it is quashed by a Court because it has been challenged and found by the Court

to be unlawful. The grounds for such a challenge are limited and do not relate simply to the planning merits of the decision.

The Secretary of State and the Ministers also have powers to require a local planning authority to refer an application to them for their own determination, referred to as a 'call in' of a planning application. An Inspector (in Scotland a Reporter) will be appointed to conduct a local public inquiry and to report and make recommendations to the Secretary of State or the Ministers as the case may be. The Secretary of State and the Ministers follow established policies as to when they consider it to be appropriate to 'call-in' a planning application, but they are likely to do so if, for example, a local planning authority was minded to grant a planning permission that could have a significant adverse effect on a European site, against the advice of the statutory nature conservation body and in the face of national policy.

Where an applicant is aggrieved by a decision of a local planning authority to refuse permission for a development, or to grant it only subject to conditions that the applicant finds unacceptable, they have the right to appeal against the decision. The appeals are normally determined by a Planning Inspector or Reporter, (see A.9 below) but certain types of appeal can be 'recovered' for decision by the Secretary of State or the Ministers. Again the Inspector or Reporter will normally proceed to conduct a local public inquiry and report with recommendations to the Secretary of State or the Ministers. In both 'call-in' and 'recovered' cases the Secretary of State and the Ministers are not bound to accept the Inspector's or Reporter's recommendations.

A.9 Decisions of Planning Inspectors and Reporters

Planning Inspectors (and in Scotland planning Reporters) are the decision maker (the competent authority in the terms of the Habitats Regulations) in their own right in respect of all delegated appeals against the decisions of local planning authorities, which are not 'recovered' by the Secretary of State. Appeals are considered by way of an exchange of written representations (the majority of cases); or by way of an exchange of written material followed by a public 'hearing', or in a small proportion of cases, considered by a prior exchange of written material followed by the calling and examination of evidence at a local public inquiry, conducted by the Inspector making the decision. In the context of this report, the most authoritative decisions of Planning Inspectors / Reporters are regarded to be those which have followed a public inquiry, because in these cases the evidence has been subject to particularly intense scrutiny and the parties will have had the opportunity to make legal and other submissions to the Inspector or Reporter, however 'hearing' cases may also be regarded as sufficiently authoritative where evidence has been subject to particular scrutiny.

Planning Inspectors also conduct the 'examination' of local development plan documents submitted to the Secretary of State, in order to test them for 'soundness' before they can be adopted. The Inspector's report to the local planning authority is binding, but it is the authority who adopts the plan, having made any changes required by the Inspector's report.

A.10 Article 6(4) Opinions of the European Commission

Under the provisions of Article 6(4) of the Habitats Directive, it is open to a member state to seek an opinion from the European Commission (EC) as to whether the justification for authorising a particular plan or project would amount to 'imperative reasons of overriding public interest'. These are cases where the competent national authority cannot ascertain that there would not be an adverse effect on a European site, because a priority habitat or species may be adversely affected. This would normally rule out the consideration of economic or social reasons to authorise the project, but the option is available to seek an opinion as to the merits of the case from the EC. If the EC agree that the plan or project can proceed, they will examine compensatory measures and advise the member state accordingly. These are regarded as 'authoritative decisions' in the context of this research, because they have been scrutinised by the EC and the Commission's opinion is published. These opinions are also helpful because in making the case as fully as possible, the member state must set out the details of the effects of the project on the qualifying features and must explain in detail its proposed compensatory measures.

A.11 A note of caution

Given the large number of cases investigated, and the large volume of documents in relation to each case that had to be read, it was beyond the capacity of the researchers to undertake any investigations as to the accuracy of data, or to test the outputs of predictive models, or to undertake any other corroborative or verification work, as part of this research. All figures and factual information in this report are drawn directly from the documents which were read during the research. They are taken at face value. No assurance can therefore be given as to the accuracy or otherwise of information that was presented in the reports and decisions in the cases examined. For the purposes of this research it was sufficient to assume that all data recorded in the case reports and decisions were accurate and correct.

Having set out the basis on which this research considers a decision to be sufficiently 'authoritative' to be given weight in considering other decisions, it is worth bearing in mind that judgments stand unless superseded by a judgment in a higher court. Decisions made by the Secretary of State or an Inspector stand unless quashed by a Court, after having been challenged and found to be unlawful. Some decisions, and indeed, occasionally some domestic judgments, may not appear to be entirely consistent with established legal principles (for example those set by the European Court), or established approaches to decision making in terms of policy or scientific practice, but they nevertheless stand unless challenged or superseded. A judgment or a decision can only be made on the facts of the case as known at the time. If the evidence or arguments presented are incomplete or misleading the outcome may be affected. The application of case law evolves over time. Some judgments (or decisions taken in light of judgments at the time) may have been made before an important legal principle was established by a subsequent judgment.

For example, the Briels ruling in 2014 required a modification to the approach previously taken in respect of distinguishing mitigation and compensatory measures. Decisions made prior to this ruling did not have the benefit of that interpretation by the European court but were lawful and compliant at the time they were made.

Furthermore, no two cases are the same. What may initially appear to be inconsistency might, on closer examination, be a proper response to differences between the particulars of two cases which otherwise appear, at face value, to be equivalent.

It may be necessary, therefore, to consider the date of a decision or the extent to which a particular case is consistent with previous judgments or practice before relying upon it in a decision-making process.

It is the responsibility of the reader therefore to interpret and apply the findings in this report appropriately. The findings and conclusions of the report should be considered fairly, as a whole, and not quoted, used or applied selectively, in order to support a pre-determined or preferred conclusion.

B Why ‘functional links’ to European sites are important to decision making

B.1 What is meant by ‘functional linkage’

In the context of this report, the term ‘functional linkage’ refers to the role or ‘function’ that land or sea **beyond the boundary** of a European site might fulfil in terms of supporting the populations for which the site was designated or classified. Such an area of land or sea is therefore ‘linked’ to the site in question because it provides a (potentially important) role in maintaining or restoring a protected population at favourable conservation status. Whilst areas beyond a site boundary might serve a function in respect of a designated habitat type, for example by being linked hydrologically to the qualifying habitat, in the context of this report ‘functional linkage’ refers only to land or sea which is linked to a qualifying species (whether an Annex II species for which a SAC has been designated, or a bird species for which a SPA has been classified).

Whilst the boundary of a European site will usually be drawn to include key supporting habitat for a qualifying species, this cannot always be the case where the population for which a site is designated or classified is particularly mobile. Individuals of the population will not necessarily remain in the site all the time. Sometimes, the mobility of qualifying species is considerable and may extend so far from the key habitat that forms the SAC or SPA that it would be entirely impractical to attempt to designate or classify all of the land or sea that may conceivably be used by the species. Thus, for some sea birds the SPA may be confined to the cliffs where the sea birds breed, and will not extend to their feeding areas, which may be many kilometres away, or to the routes used by the birds either to reach their feeding grounds, or on migration, or during the winter. In respect of bats, for example, the SAC may need to be confined to the key roost sites used for hibernation, resting or breeding. The majority and, in many cases, the whole of the foraging areas of the bats in that roost, and the ‘commuting’ routes (flyways) between the foraging areas and the roosts, cannot practically be included in the SAC.

This approach to the definition of boundaries for SACs, where a qualifying species is mobile, is reflected in Article 4(1) of the Habitats Directive which states:

“...For animal species ranging over wide areas these sites shall correspond to the places within the natural range of such species which present the physical or biological factors essential to their life and reproduction. For aquatic species which range over wide areas, such sites will be proposed only where there is a clearly identifiable area representing the physical and biological factors essential for their life and reproduction...”

In practical terms, if the boundaries of a designated site were drawn to include *all* land or sea which might serve some function, at some point in time, in terms of the population for which the site had been designated or classified, the strict protection afforded by Article 6 would be applied more extensively than would be necessary to meet the objectives of the Directives. This could potentially place unnecessary restrictions on plans and projects which might not otherwise be required. By way of example, sites designated for harbour porpoise would need to potentially include vast areas of sea, if the boundaries were drawn to include all the areas

which might possibly provide some degree of support, at some point in time, for a given population. Regulatory procedures would be imposed on plans and projects simply on the basis that a harbour porpoise *might* occasionally feed or travel through the area affected by them.

The concept of 'functional linkage' is best explained in the context of the protection afforded to species under the Directives. EC guidance[6] on the strict protection of animal species of community interest refers to the Habitats Directive laying down two main 'pillars' which aim to meet the Directive's broad objectives. The first is linked to the protection afforded through designation of SACs (Articles 4-6 of the Directive) and the second is the protection of individuals of the 'European protected species' throughout a Member State's territory under Article 12. In summary:

"In order to achieve its objectives, the Habitats Directive provides for two main instruments: the Natura 2000 network of protected sites and the species protection provisions. The provisions for species protection apply to the whole of a Member State's territory and concern the physical protection of specimens as well as their breeding sites and resting places. Both regimes allow for exceptions under certain conditions. Both instruments are complementary and jointly aim to ensure a favourable conservation status for all species of Community interest."

The favourable conservation status of a given species is not therefore limited to how the species fares within the defined boundary of designated SACs. The guidance states at paragraph 17 that:

"Assessing and evaluating the conservation status of habitats and species within the Natura 2000 network is therefore not always enough, especially when the occurrences of habitats or species are only partly covered by the network, maybe even in some cases only to a relatively small extent."

Likewise, the Birds Directive refers not only to the protection of species within special protection areas, with reference to the network of SPAs, Article 4(4) provides:

"...Outside these protection areas, Member States shall also strive to avoid pollution or deterioration of habitats".

In practice, therefore, in respect of protected species, three potential situations arise as set out below. This report is relevant to the second of these three situations:

1. Land or sea within the boundary of a SAC or SPA which supports a qualifying species is strictly protected by the assessment approach set out in Article 6 (commonly referred to in the UK as a 'Habitats Regulations Assessment');
2. Supporting habitat in areas beyond the boundary of a SAC or SPA which are connected with or 'functionally linked' to the life and reproduction of a population for which a site has been designated or classified should be taken into account in a

[6] Guidance document on the strict protection of animal species of Community interest under the Habitats Directive 92/43/EEC, February 2007.

Habitats Regulations Assessment. However, that assessment will need to determine how critical the area may be to the population of the qualifying species and whether the area is necessary to maintain or restore the favourable conservation status of the species. Effects which would not be acceptable within the boundary of a European site may or may not be acceptable if they occur on functionally linked land or sea;

3. Individuals of a protected species, whether or not they are part of a population for which a European site has been designated or classified, are in any event afforded protection under the Directives, including in most cases their breeding and resting places, wherever they may be, inside or outside of the designated area. Species listed under Annex IV of the Habitats Directive are protected under the provisions of Article 12 as a 'European protected species'. Wild birds are similarly protected under the provisions of the Birds Directive.

The provisions of Article 6(3) and 6(4) of the Habitats Directive, as applied through a Habitats Regulations Assessment, do not apply to individuals of European protected species or individuals of species of birds which are not part of a population for which a European site has been designated or classified.

B.2 How functional linkage relates to the Habitats Regulations Assessment process

The concept of functional linkage is therefore an important consideration in decision making under the Habitats Regulations because the tests arising from Article 6(3) and 6(4) will need to be applied in respect of plans or projects which may significantly affect such supporting habitat and its contribution to the favourable conservation status of the relevant species.

Figure B.1 on the next page, provides an outline of the four stage process of Habitats Regulations Assessment. **The key question which this report is looking to address is how decision-makers have applied the Habitats Regulations Assessment (HRA) process where effects on species relate to functionally linked land or sea (situation 2 above) rather than the area within the boundaries of the relevant European site (situation 1 above)**. Few plans or projects will progress to stages 3 and 4 so the majority of the authoritative decisions referred to in this report concern the stage 1 'screening' test and the stage 2 'appropriate assessment' and 'integrity test'. These initial stages are briefly introduced below, but the relevance of functionally linked land (FLL) to the Habitats Regulations Assessment process is encapsulated in the following quote from paragraph 27 of the High Court judgment in RSPB and others v Secretary of State and London Ashford Airport Ltd [2014 EWHC 1523 Admin]:-

"There is no authority on the significance of the non-statutory status of the FLL. However, the fact that the FLL was not within a protected site does not mean that the effect which a deterioration in its quality or function could have on a protected site is to be ignored. The indirect effect was still protected. Although the question of its legal status was mooted, I am satisfied …. that while no particular legal status attaches to FLL, the fact that land is functionally linked to protected land means that the indirectly adverse effects on a protected site, produced by effects on FLL, are scrutinised in the same legal framework just as are the direct effects of acts carried out on the protected site itself. That is the only sensible and purposive approach where a species or effect is not confined by a line on a map or boundary

fence. This is particularly important where the boundaries of designated sites are drawn tightly as may be the UK practice".

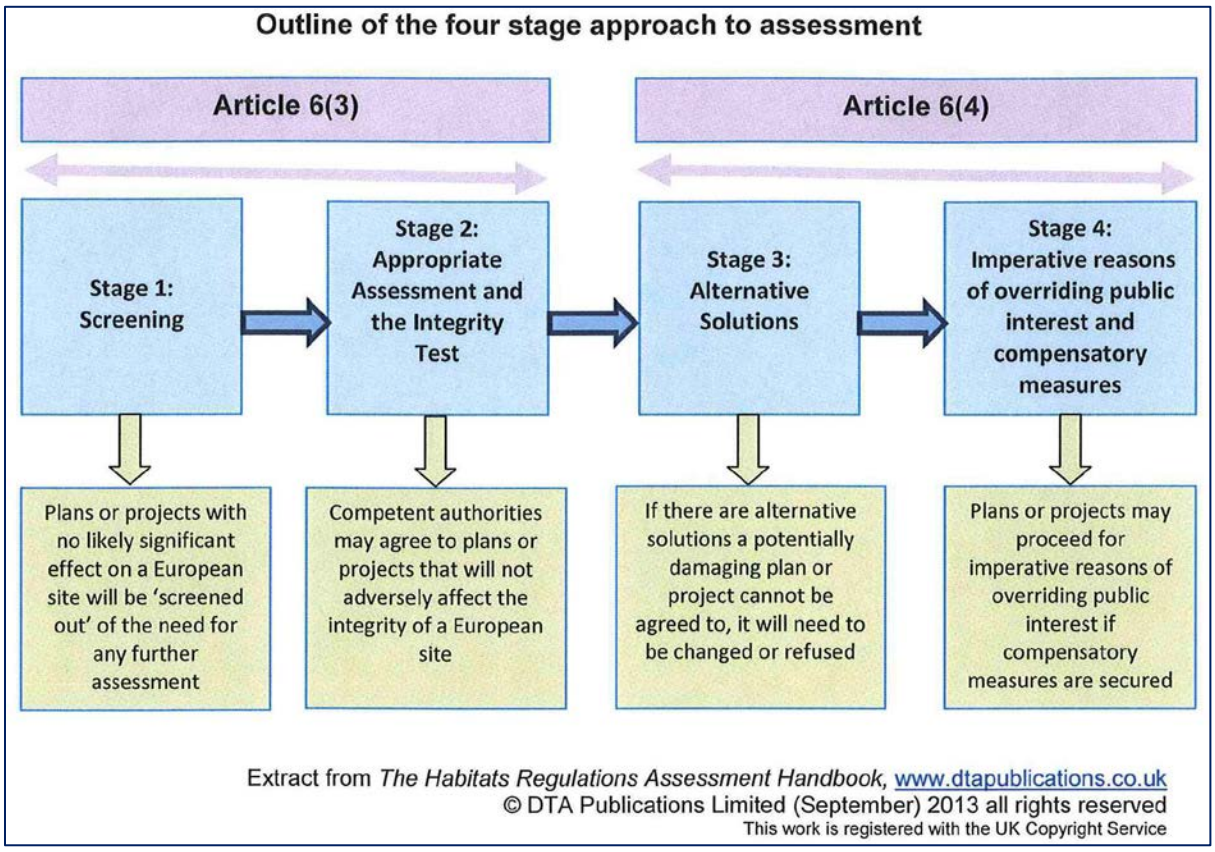

Figure B.1: Outline of the four stage approach to a Habitats Regulations Assessment

Stage 1: the 'screening' test

If it is not directly connected with or necessary to site management the decision-maker must determine whether a proposed plan or project is likely to have a significant effect[7] on the site. The decision on whether an appropriate assessment is necessary should be made on a precautionary basis. This is in line with the European Court's ruling in Case C-127/02 hereafter referred to as the Waddenzee judgment[8], which states that:

"*any plan or project not directly connected with or necessary to the management of the site is to be subject to an appropriate assessment of its implications for the site in view of the site's conservation objectives if it cannot be excluded, on the basis of objective information, that it will have a significant effect on that site, either individually or in combination with other plans or projects*."

Taking account of advice from the statutory nature conservation body, they should consider whether the effect of the proposal on the site, either individually or in combination with other

[7] Regulation 61(1)(a)
[8] *Landelijke Verenigning tot Behoud Van de Waddenzee, Nederlandse v Vereniging tot Bescherming von Vogels v Straatssecretaris Van Landbouw, Natuurbeheer en Visserij* (C-127/02: [2005] Env. LR14 [ECJ])

proposals[9], is likely to be significant in terms of the ecological objectives for which the site was designated, classified or listed. The statutory nature conservation body in England and its territorial waters out to 12 nautical miles (nm) is Natural England. Beyond that, in offshore waters, it is usually the Joint Nature Conservation Committee (JNCC), but arrangements have been made in some cases for Natural England to be the single consultee for both jurisdictions for projects, such as offshore wind farms, which may straddle the 12nm limit.

If a plan or project would not be likely to have a significant effect on the site alone, it should nevertheless be considered in combination with other plans and projects to establish whether there may be a significant effect arising from their combined impacts.

Stage 2: The 'appropriate assessment' and 'integrity test'

If the decision-maker concludes that a proposed plan or project not directly connected with or necessary for site management is likely to significantly affect a European site, they must make an 'appropriate assessment' of the implications of the proposal for the site in view of the site's conservation objectives[10]. These relate to each of the qualifying features for which the site was designated, classified or listed and will be provided by the statutory nature conservation body. The scope and content of an appropriate assessment will depend on the nature, location, duration, frequency, timing and scale of the proposed project and its effects, and the qualifying features of the relevant site. It is important that an appropriate assessment is made in respect of each qualifying feature for which a likely significant effect has been identified, and for each designation where a site is designated, classified or listed under more than one international obligation.

In the Waddenzee judgment, the European Court ruled that an appropriate assessment implies that all the aspects of a plan or project which can, by themselves or in combination with other plans or projects, affect the site's conservation objectives must be identified in the light of the best scientific knowledge in the field.

In the light of the conclusions of the appropriate assessment, the decision-maker must determine whether it can ascertain that the proposal will not adversely affect the integrity of the site(s)[11]. This test incorporates the precautionary principle. It is not for the decision-maker to show that the proposal would harm the site, in order to refuse the proposal. It is for the decision-maker to consider the likely and reasonably foreseeable effects and to ascertain that the proposal will not have an adverse effect on the integrity of the site before it may grant permission. If the proposal would adversely affect integrity, or the effects on integrity are uncertain but could be significant[12], the decision-maker should not grant permission, subject to the provisions of regulations 62 and 66, which relate to alternative solutions, imperative reasons of overriding public interest and compensatory measures. These are not discussed further in this report because they are not relevant to the research.

[9] Regulation 61(1)(a)
[10] Regulation 61(1)
[11] Regulation 61(5)
[12] See *ADT Auctions Ltd v Secretary of State Environment, Transport and the Regions and Hart District Council* (2000) JPL 1155 at p. 1171 where it was held to be implicit in the wording of reg 61(5) that the adverse effect on the integrity of the site had to be a significant adverse effect.

In the Waddenzee judgment, the European Court also ruled that a plan or project may be authorised only if a decision maker has made "*certain*" that the plan or project will not adversely affect the integrity of the site. "*That is the case where no reasonable scientific doubt remains as to the absence of such effects*." Decision-makers must be "*convinced*" that there will not be an adverse effect and where doubt remains as to the absence of adverse effects, the plan or project must not be authorised, subject to the derogation procedure outlined in Article 6(4) of the Habitats Directive[13].

The integrity of a site is the coherence of its ecological structure and function, across its whole area, which enables it to sustain the habitat, complex of habitats and/or the levels of populations of the species for which it was classified, designated or listed[14].

In determining the effect on site integrity, the advice of the statutory nature conservation body, the conservation objectives and any additional representations will need to be carefully considered. The UK courts have held that considerable weight should be given to the representations of the statutory nature conservation body and their advice should be adopted unless there are cogent and compelling reasons not to do so[15].

As part of the judgement on integrity, the decision-maker must consider the way in which it is proposed to carry out the project and whether conditions or other restrictions would enable it to ascertain that site integrity will not be adversely affected[16]. The decision-maker should consider whether a consent could be issued in accordance with regulation 61 subject to conditions. In practice, this means that it should identify the potential risks so far as they may be reasonably foreseeable in light of such information as can reasonably be obtained, and put in place a legally enforceable framework with a view to preventing the risks from materialising[17].

B.3 How functional linkage might influence the stage 1 and 2 conclusions

The concept of functional linkage is relevant to both the stage 1 screening decision and the stage 2 integrity test. In terms of the screening decision the extent to which an effect might 'undermine the conservation objectives' where it occurs beyond the boundary of the European site will be influenced by the role or function that the area serves and its importance to the maintenance of the population for which the site has been designated, classified or listed. An effect over a very small area of functionally linked land or sea, which is rarely used, might not undermine the conservation objectives, whilst the same effect over an area which provides prime feeding ground would be of more concern. A point will be reached where, in spite of an effect occurring while the species is beyond the boundary of a

[13] Regulation 62

[15] *R (Akester and Anor) v DEFRA and Wightlink Ferries* [2010] EWHC 232 (Admin)
[16] Regulation 61(6)
[17] See *WWF-UK Ltd and RSPB – v – Secretary of State for Scotland et al* [1999]1 C.M.L.R. 1021 [1999] Env. L.R. 632 opinion of Lord Nimmo-Smith

European site, the nature of the effect would be considered to undermine the conservation objectives for the qualifying species and an appropriate assessment would be required.

Turning to the stage 2 integrity test, in light of the accepted definition of integrity quoted in B.2 above, a site's integrity is inextricably linked to the concept of sustaining the population of a species for which the site has been designated, classified or listed. Where functionally linked land is necessary for that population to be so sustained then it must be *linked* to the site's integrity.

C The Case Studies

C.1 Selection

The researchers compiled a list of potentially relevant cases drawn from:

i. their own library of decisions, and their empirical knowledge of case work;
ii. a further web-based search of European Court judgments and opinions;
iii. a web-based search for decisions relating to nationally significant infrastructure projects and projects consented under the Electricity and Pipeline Acts in England and Wales and their territorial and UK offshore waters; and
iv. suggestions made by officers in Natural England following an e-mail enquiry of case officers by the research project manager.

The researchers were aware of many cases in the terrestrial environment across the UK, where decision-makers considering onshore wind farm proposals had taken account of land that may be functionally linked to SPAs or SACs, for example as a flight path or as a feeding area for birds or bats. Cases have been determined in all administrative jurisdictions, including decisions by Secretaries of State, Scottish Ministers, planning Inspectors and Reporters, under the provisions of the Town and Country Planning and Electricity Acts. The cases go back over 15 years, when the first examples arose, in Islay and the Mull of Kintyre, where wind farm proposals were refused by the then Secretary of State for Scotland, because of the potential collision risk of geese as they flew between their roost in an SPA and their feeding grounds in the countryside beyond. It was clearly impractical to attempt to identify, summarise and analyse all such onshore wind farm cases which involved consideration of functionally linked land.

Consequently, this report selects one of the most recent Electricity Act cases (E.22 Frodsham), a planning Inspector decision under the planning acts (E.25 Parkhead Farm) and a High Court case (E.7 Hargreaves) as representative of these many cases. These three adequately illustrate the issues and, along with the other cases in the report, help to answer the brief's particular emphasis in respect of the level of evidence required. These cases therefore represent many others in terms of a well-established principle that offsite habitat loss, or offsite displacement, disturbance or collision risk of SPA birds, triggers the application of the Habitats Regulations Assessment process. This is the case irrespective of the location of the project.

On the other hand, the recent range of issues arising in case work relating to the offsite effects of offshore wind farms, bear more detailed consideration. So all of the offshore wind farms which were nationally significant infrastructure projects, determined between 2013 and when the research was undertaken in January / February 2015, are considered in detail because they raise different issues and require different approaches to those now established in the onshore wind farm case work.

In light of the above, in the research for all three reports in January and February 2015, over 180 cases were identified as being relevant to the assessment of plans and projects affecting European sites. Following an initial screening exercise, twenty five of these

decisions were selected for detailed examination in this review, being relevant to the consideration of how decision-makers have taken account of functionally linked areas. One Court of Appeal case ***Boggis*** (E.9) is not directly relevant to functional linkage, as defined in section B.1, because the effects under consideration related to coastal processes and how they may affect an SPA, rather than effects on qualifying species whilst they were beyond the boundary of the SPA. It is included to illustrate the principles underlying evidence requirements so, except in respect of the discussion on evidence requirements, this case is excluded from further analysis in section D below.

Of the twenty four cases subject to further analysis, 19 referred to effects on bird species, 4 were related to effects on bats, and two referred to effects on Atlantic salmon. One of the 19 SPA cases also identified potential effects in respect of harbour porpoise and seals (E.10 Hornsea).

C.2 The summary table

Table C.1 below lists, in date order, the cases which were identified as relevant to this report, in that effects on functionally linked land or sea were material to the decision taken. Individual summaries of these cases are available in the Appendix to this report (Part E), with further analysis provided in part D 'Discussion and conclusions'.

Table C.1:

a) identifies the case by reference, title or familiar short title;
b) provides the date of the decision (or principal decision) and the decision-maker;
c) refers to the quality of the supporting evidence (see further discussion after the table);and
d) states the nature of the functional linkage.

The abbreviation 'SoS' in the table stands for Secretary of State.

Table C.1: Summary table of the 25 Cases reviewed in this report

Case	Date	Supporting Evidence	Nature of functional linkage
E.1: Abbotskerswell PC v Teignbridge DC	16/12/14 High Court	Good	Strategic flyways and sustenance zones for bats from South Hams SAC located in the plan area
E.2: Lydd Airport	16/05/14 High Court	Good	Supporting habitat for several SPA species adjacent to airport site.
E.3: Forest of Dean FoE v Forest of Dean DC (1)	01/05/14 High Court	Good	Strategic flyways and sustenance zones for bats
E.4: Buckinghamshire CC v SoS and HS2 Ltd	15/03/13 High Court	Good	Supporting habitat for over-wintering SPA wildfowl species
E.5: Forest of Dean FoE v Forest of Dean DC (2)	20/06/13 High Court	Good	Strategic flyways and sustenance zones for bats
E.6: Shadwell Estates	11/01/13 High Court	Poor beyond 1,500m buffer	The 1,500m buffer zone from the SPA and areas where at least five nesting attempts had occurred for stone curlew outside the SPA was sufficient, no evidence of a deterrent effect beyond it

Table C.1: Summary table of the 25 Cases reviewed in this report			
Case	**Date**	**Supporting Evidence**	**Nature of functional linkage**
E.7: Hargreaves v SoS	02/08/11 High Court	Good	Supporting habitat for over-wintering pink-footed geese
E.8: Sandale Developments	31/03/10 High Court	Good	Supporting in-river habitat for Atlantic salmon
E.9: Boggis	20/10/09 Court of Appeal	Poor	Asserted that sea defence scheme would affect coastal processes within SAC/SPA along coastline.
E.10: Hornsea Project One offshore wind farm	10/12/14 SoS	Based on assumptions about flight distances	Collision risk assessed for two SPAs (each more than 100km away). Also potential effects on harbour porpoise individuals which might be part of populations for which 26 pSCIs/SCIs designated (closest 44km, furthest 512km). Also on grey seal and harbour seal from two pSCIs at 44km and 64km respectively
E.11: Walney Extension offshore wind farm	07/11/14 SoS	As above	Collision risk assessed for 6 SPAs ranging from 20 - 287km from windfarm
E.12: Burbo Bank Extension offshore wind farm	26/09/14 SoS	As above	Collision risk assessed for 5 SPAs ranging from 6 - 55km from windfarm
E.13: North Killingholme power station project	11/09/14 SoS	Good	Supporting habitat for SPA species close to the SPA
E.14: Rampion offshore wind farm	16/07/14 SoS	Based on assumptions about flight distances	Collision risk assessed for SPA up to 490km distance
E.15: East Anglia 1 offshore wind farm	17/06/14 SoS	As above	Collision risk assessed for 3 SPAs; one at 54km, the other two at 259km
E.16: Able Marine energy park	28/08/13 SoS	Good	Function of important black-tailed godwit roost would be lost with loss of intertidal feeding areas
E.17: Triton Knoll offshore wind farm	11/07/13 SoS	Based on assumptions about flight distances	Collision risk assessed for SPA 83km away
E.18: Galloper offshore wind farm	24/05/13 SoS	As above	Collision risk assessed for SPA population from site 26.9km away.
E.19: Preesall Saltfield under-ground gas storage	09/04/13 SoS	Good	Supporting habitat used by pink-footed geese
E.20: Heysham to M6 Link Road	19/03/13 SoS	Good	Some birds known to feed and nest in affected fields but NE considered intensity of use was low and no particular fields favoured, with alternative sites nearby
E.21: Hinkley Point C nuclear power station	19/03/13 SoS	Good	Six large fields used for roosting by SPA populations
E.22: Frodsham onshore wind farm	19/10/12 SoS	Good	Site was a dredging disposal ground which hosted notably high numbers of over-wintering and passage waders from SPA immediately adjacent
E.23: Portsmouth Stadium	15/06/95 SoS	Good	Prime winter feeding ground for Brent geese from nearby SPA
E.24: Lemonford Caravan Park	06/03/14 Inspector	Poor	Strategic flyway for greater horseshoe bats

Table C.1: Summary table of the 25 Cases reviewed in this report			
Case	**Date**	**Supporting Evidence**	**Nature of functional linkage**
E.25: Parkhead Farm	11/05/09 Inspector	Good	Collision risk to geese from SPA located 5km away

The assessment of the quality of the supporting evidence is a professional judgment by the researchers based on the evidence available. It relates to how well it was demonstrated that there was, or probably was, a functional linkage between the area of land or sea affected and the population of the species for which a site had been classified or designated. Where this is assigned as 'good' it indicates actual survey or other evidence and relatively clear (or even obvious) links to the SAC/SPA.

As described in section D below, other cases, in the marine environment, had to be based on reasonable scientific assumptions. This is because assumptions had to be made about where the birds in the development area might breed and about recorded foraging distances. Nevertheless, these cases should not be regarded as having a weak evidence base for the links. In the precautionary approach of the Habitats Regulations sufficient evidence pointed to a possibility or a risk of an effect on SPA populations.

In the case of E.20, there was good evidence that SPA bird species used the affected area for nesting and feeding, but there was agreement that the use of the area was so low that the proposed link road would not have a significant effect. There was a functional link, but not an important one, emphasising that the two decisions are different: Is there a functional link? Is there a significant effect on the European site?

In respect of three cases, the evidence base was considered to be 'poor' with links not well established. The first of these was Boggis, already discussed above. The second was in Breckland (E.6) where the court found there was no convincing evidence that birds would be deterred from breeding by housing located beyond the 1,500m buffer zone agreed in the adopted local plan. In the other case (E.24) the developer declined to carry out surveys that could have demonstrated the functional link that the Inspector and the planning authority clearly considered to be likely.

D Discussion and conclusions

D.1 Cases concerning effects on bats

Four cases reviewed (E.1, E.3, E.5 and E.24) concerned effects on bat SACs. An analysis of the cases confirms the following points.

The qualifying features of the bat SACs were the population of the bats using the SAC as a roost. Each individual of the relevant species is protected in its own right as a European protected species, so too are its breeding and resting places, whether it or the places are in the SAC or anywhere outside it. However, there is additional protection for the animals through designation of their key roost areas as SACs. Furthermore, if the bats in the SAC rely on habitat outside the SAC, the loss or reduction (in area or ecological value) of which could have a significant effect on the population of the SAC bats, then that supporting habitat should be treated in a Habitats Regulations Assessment in the same way as the habitat in the SAC. In short, whilst the European protected species legislation protects the bats and their breeding and resting places, it is the effect of the designation of the SAC that protects, through the Habitats Regulations Assessment process, the habitat of the bats outside the SAC.

The issues in the four cases examined related to the potential loss, interruption, or diminution of the ecological value of the routes (flyways) used by the bats from the SAC to reach their foraging grounds, which were widely spread around the countryside beyond the SAC boundary. Hence the bats would be indirectly affected by way of loss of habitat, or by the interruption or severance of the flyways or by the introduction of deterrent effects in the flyways and/or in the foraging areas. Reduction in ecological value of the foraging areas and/or impediments to the bats reaching their foraging areas could undermine achievement of the conservation objectives of the SACs and therefore affect the conservation status of the bats in the SACs.

In all cases the risk to the population of bats, for which the SAC had been designated, arising out of effects which could occur beyond the boundary of the SAC was accepted. In the case of Forest of Dean FoE v Forest of Dean DC (2) (E.5) the judgment stated: *"Although the Northern United compound has not been designated a SAC, the designation of an area as a SAC protects the population of the species using the site and not just the site itself".*

In the Lemonford case (E.24) the Inspector noted:

"the South Hams SAC is self-evidently an important area in biodiversity terms and its functionality in terms of the strategic flyways is clearly fundamental to its integrity as habitat"

In three of the four cases the approach to functional linkage was underpinned by substantive survey work showing a reasonable likelihood that the area that would be affected was functionally linked to the relevant SAC bat population. But in the case of the Lemonford appeal (E.24), it was the uncertainty that arose from the inadequacy of the survey work that led to the dismissal of the appeal. The appellant had been reluctant to undertake the survey work recommended by the planning authority's ecological adviser and Natural England. If

carried out, this survey could have established the relative importance of the area of offsite habitat that would have been affected and the likely efficacy of mitigation measures.

The Inspector recognised that regulation 61 of the Habitats Regulations must be applied in respect of the potential changes that the development would make to the ecological function of the flyway for the bats from the SAC. The information requested by the planning authority in this case was not regarded as onerous. The applicant / appellant had declined to submit it so the Inspector concluded: "*Appropriate assessment cannot, in my view, be adequately undertaken on the basis of the information to hand".* On the precautionary basis of the regulations he dismissed the appeal for this and other reasons.

D.2 Cases concerning effects on bird species

Twelve of the 19 cases involving SPAs related to terrestrial or coastal habitats involving a range of waterfowl species, mainly geese, ducks and waders. Seven related to the marine environment and sea birds.

Terrestrial and coastal SPAs

In all twelve cases involving terrestrial or coastal SPAs the decision maker recognised the potential importance of functionally linked land and that it should be treated as part of the Habitats Regulations Assessment. Table D.1 below summarises the 12 cases. It indicates the case reference number in section E, the type of development proposed, the distance of the development from the SPA, the key issue and whether the decision concluded no likely significant effect (LSE) or an adverse effect on integrity (AEOI) of the SPA.

Table D.1: Cases involving effects on birds associated with terrestrial or coastal SPAs

Development	Distance	Issue	LSE / AEOI
E.2 Airport expansion	<1km	Disturbance and displacement of several species of feeding and roosting birds on fields located varying distances from the SPA by aircraft noise and operational activity	No LSE
E.4 High speed rail	8km	Disturbance and displacement by construction and operational noise of railway c.400m from a water body used by wildfowl from an SPA 8km away. Subject to further research LSE unlikely	No LSE
E.6 Residential	1.5km buffer	Disturbance and displacement of breeding stone curlew as a result of residential development near to nesting sites. Plan included a buffer ensuring no new residential development within 1.5km of the SPA boundary or areas outside SPA of suitable habitat and where at least 5 nesting attempts had been recorded since 1995	No LSE beyond buffer
E.7 Wind turbines (2)	5km	Pink-footed geese roosted in the SPA and fed on fields adjacent to the development 5km from the SPA. Without mitigation collision mortality risk was up to 50 geese per year. Mitigation measures accepted as sufficient to avoid a significant effect	No LSE

Table D.1: Cases involving effects on birds associated with terrestrial or coastal SPAs			
Development	**Distance**	**Issue**	**LSE / AEOI**
E.13 Gas power station	Adjacent	Large numbers of golden plover, curlew, lapwing and other species used fields close to the development site. Construction noise could disturb them and wildfowl on a nearby wetland if birds were in the zone of influence of 500m. Noise mitigation measures accepted as sufficient to avoid a significant effect	No LSE Beyond buffer zone
E.16 Marine energy industry	Adjacent	Large numbers of black-tailed godwit could be displaced because of loss and reduced functionality of intertidal areas in the SPA, compounded because they relied on adjacent wetland pits outside the SPA for roosting so would be displaced from both areas	AEOI
E.19 Underground gas storage	Adjacent	Loss of small area of land used by feeding pink-footed geese from SPA owing to construction of access road. Displacement effect likely to be within 500m of construction activity, on edge of large area used by geese	No LSE
E.20 Road link	3km	Proposed road would pass through fields used for breeding and feeding by birds from SPA. NE advised intensity of use was light, species did not favour any particular field and alternative areas also outside the SPA were available to them	No LSE
E.21 Nuclear power station	Adjacent	Fields to be used during construction supported significant numbers of waterfowl from 2 adjacent SPAs requiring substantial mitigation measures during construction and operation of a lay-down area	LSE but no AEOI due to conditions
E.22 On shore wind farm	Adjacent	Site was a dredging disposal ground which hosted notably high numbers of over-wintering and passage waders, redesign and additional mitigation measures secured	No LSE
E.23 Football stadium	<1km	Development site considered to be prime winter feeding grounds for dark-bellied brent geese from nearby SPA, refused permission, effectively concluding AEOI could not be ruled out	AEOI
E.25 Wind turbines	5km	Potential for feeding habitat loss and significant collision risk for pink-footed geese flying to other feeding grounds from SPA roost. Mitigation package agreed with NE and RSPB	No LSE

In each of the above twelve cases there was some degree of evidence that birds from the relevant specific SPA (or reasonably assumed to be birds from that SPA) were actually using, or were highly likely to use, the area affected by the development. In the case of the stone curlews in Breckland, the issue was securing a buffer zone that was large enough to ensure that breeding birds would not be disturbed by proposed development, the calculation of the buffer zone being based on scientific survey and analysis including historical records of breeding attempts.

In the terrestrial or coastal environments, three points became clear from the research:

a) the scope for SPA bird species to use land, whether in close proximity or further away from the SPA, is often limited by urban development, land use patterns, noisy or other disturbing activities or operations, barriers and of course suitability of the habitat, even where there is open land or water;
b) there are often good quality, pre-existing records, such as Wetland Bird Census data, to indicate the use of specifically defined areas outside the SPA by birds;

c) surveys of use, or potential use, of land or water bodies by relevant SPA species is usually reasonably obtainable even if surveys are required over a period of time.

Consequently, in the terrestrial and coastal environments, the possibility of the presence of functionally linked land is more readily identifiable, and the land areas more easily defined as relatively discrete areas, than in the marine environment discussed below. Where pre-existing records were not available, but an area affected by a development appeared likely to be used as functionally linked land, new survey work was undertaken to establish the level of use in order to inform a Habitats Regulations Assessment, screening or appropriate assessment, as the case may have been. Even where good data about levels of use were available, survey effort was continued to improve understanding, case E.22 Frodsham onshore wind farm, being a case in point.

Sea bird SPAs

In contrast, the seven sea bird SPA cases relating to offshore wind farms had to approach the potential of functionally linked areas of sea differently. Pre-existing survey information that was location specific to the development sites was scarce. All new proposals involved surveys to establish the use of the proposed wind farm areas by all species of birds. It was then necessary to consider whether the birds that were recorded in these offshore areas may reasonably be assumed to be individuals associated with an SPA.

In some cases individual breeding birds such as gulls, were tagged in the SPA and tracked to see if they ventured into the development area. In other cases, however, such tracking studies would have been impractical. So the likelihood of an area being functionally linked to an SPA was established by considering the likelihood of the birds having come from an SPA. This depended in part on the proportion of that species which bred in SPAs, and the distance that the area lay from SPAs for the relevant species, compared to the known recorded foraging distance or migratory behaviour of the species. For example, if all pairs of a species which was recorded feeding in, or otherwise using, a wind farm area, bred in an SPA, and one or more SPA for that species was located within the known maximum recorded foraging distance from the wind farm site, it could reasonably be assumed that the birds that could be affected in the breeding season were linked to one or more such SPA; and the wind farm area was functionally linked.

Whilst in respect of kittiwakes some assessments considered their seasonal migration routes, the critical distance was usually the known maximum breeding season recorded foraging distance, or in some cases the known breeding season flight paths, which varied considerably from one species to another. No standard cut off distance from an SPA could be used as a surrogate for the risk of a significant effect. All of this was relevant before the ornithological analyses attempted to calculate collision risk or displacement for the birds that were recorded as using the development area. In Habitats Regulations Assessment terms it was first necessary to establish the likelihood of the birds potentially affected being qualifying features of an SPA somewhere. Inevitably this involved some assumptions.

Some of the distances involved, between a particular wind farm and an SPA potentially significantly affected, may appear to be considerable, and were sometimes considered by applicants to be over-precautionary. However, on the scientific evidence in the Habitats

Regulations Assessments accompanying the Secretary of State's decision in each of these cases, the calculations of displacement and collision risk modelling relate to bird populations which can reasonably be assumed to be those relating to an SPA. In all cases the SPA(s) potentially affected was specifically identified.

Relevant to this discussion, Table D.2 below indicates the proportion of the British population of the relevant species of sea bird which breed in a UK SPA.

Table D.2: Relative percentage of GB breeding population of seabird species which are associated with the UK SPA network	
Seabird species	**% of GB population breeding in UK SPA suite**
Gannet *Morus bassanus*	98%
Kittiwake *Rissa tridactyla*	78%
Manx Shearwater *Puffinus puffinus*	100%
Lesser black-backed gull *Larus fuscus*	100%
Sandwich tern *Sterna sandvicensis*	72%

In the case of effects upon gannet, manx shearwater and lesser black-backed gull therefore, where site surveys identify individuals within the project area, it is reasonable to assume that they are from a population for which an SPA has been classified. The uncertainty may sometimes relate to which SPA they were associated with. In the case of sandwich tern, where 72% of the breeding population are within the SPA network, it might be considered reasonable (on a precautionary basis) to assume that at least a proportion of individuals within a project area would be likely to be associated with an SPA. However, in the case of the Triton Knoll offshore wind farm (E.17) the development was thought to be located at the upper limit of the tern's foraging range and, although sandwich terns were recorded in the area, the prospect of the SPA terns reaching the area was considered to be low.

Table D.3 attempts to encapsulate the evidence about sea areas considered to be functionally linked in these seven cases. It indicates, for each of the main sea bird species, their maximum recorded foraging distance, and then the case reference number in section E, the name of the development and the distance of the development from the SPA, with an indication as to whether the decision-maker concluded a likely significant effect (LSE) or an adverse effect on integrity (AEOI) of the SPA.

Table D.3 Maximum foraging distances of sea birds and location of offshore wind farm case studies		
Species	**Maximum foraging**	**Cases / distance from SPA(s)**
Gannet *Morus bassanus*	c.590km	E.14 Rampion 490km LSE in combination no AEOI
		E.15 East Anglia One 259km LSE in combination no AEOI
		E.17 Triton Knoll 83km LSE in combination no AEOI
Kittiwake* *Rissa tridactyla*	c.60km / c.120km	E.14 Rampion 490km no LSE alone or in combination
		E.15 East Anglia One 259km no LSE alone or in combination
		E.17 Triton Knoll 83km no LSE alone or in combination
Manx Shearwater *Puffinus puffinus*	330km	E.11 Walney Extension 120km, 147km, 287km LSE in combination no AEOI

Table D.3 Maximum foraging distances of sea birds and location of offshore wind farm case studies		
Species	**Maximum foraging**	**Cases / distance from SPA(s)**
Lesser black-backed gull *Larus fuscus*	c.140km	E.12 Burbo Bank 6km, 6km, 42km, 55km LSE no AEOI
		E.15 East Anglia One 54km LSE no AEOI
		E.18 Galloper 27km (surveys tracked one bird 159km from the SPA)
Sandwich tern *Sterna sandvicensis*	Uncertain	E.17 Triton Knoll 47km thought to be upper limit of likely range, species recorded in the area no LSE

*as mentioned in the text, possible effects on kittiwakes during seasonal migration were considered but also concluded not to be a likely significant effect.

D.3 Cases concerning effects on Atlantic salmon

The Sandale case (E.8) concerned effects on individuals of Atlantic salmon, when they would be upstream of the SAC boundary. With the project being located upstream of the designated SAC, the functional linkage between the population for which the SAC had been designated and the individuals potentially affected by the proposed development is clear, because all salmon in the upper reaches must be salmon who had migrated through the SAC.

In the case of Sandale, the *risk* to the SAC from effects on individuals while they were within the Camowen River was considered to be sufficient to require further investigation. These risks had not been adequately assessed when the original permission had been granted. The evidence regarding the presence of Atlantic salmon was from a desktop study supported by 'reports' of individuals being observed.

In the case of Burbo Bank the location of the project site meant that the noise from piling activity had the potential to prevent Atlantic salmon from making their seaward migration from the SAC out into the Irish Sea. The risk to the smolt migration could, however, be avoided through a proposed timing restriction on the driving of the piles. This enabled a conclusion of no adverse effect on the integrity of the site. Whilst the SAC was located 32km away from the project area, the mouth of the estuary through which the individuals had to migrate to reach the Irish Sea was only 8km from the project area.

D.4 Cases concerning harbour porpoise and seals

Only one case subject to review, Hornsea (E.10), considered functional linkage in the context of marine mammals. The effects considered related only to displacement, rather than displacement and mortality as in the case of the sea birds. Hornsea identified potential effects on the populations of harbour porpoise for which 26 pSCIs/SCIs mostly in the territorial waters of other member states, had been proposed or designated and the populations of grey seals and harbour (common) seals from which two pSCIs had been proposed by the Netherlands.

Whilst on-site surveys revealed that individuals of the species were present within the project area, the links to populations for which a SAC had been designated were necessarily based on assumptions. The distance from the European sites, and the range over which the

species were known to forage for food being so extensive, particularly in the case of harbour porpoise, meant that risks from displacement were not considered to represent a threat to the integrity of any of the sites affected, for any of the species for the reasons indicated in the following quotations (emphasis added).

"it is unlikely that harbour porpoise from these European sites are solely using the Hornsea area to feed in. This is particularly unlikely given the highly mobile and wide foraging nature of harbour porpoises and their ability to feed on a range of prey sources.

"Given the relatively small maximum displacement rate (1.7 km from piling work) predicted for harbour seals relative to their typical foraging range (40-50 km), it is unlikely that even if all the offshore wind farms in the North Sea are undertaking concurrent or sequential piling activity that harbour seals from Doggersbank pSCI, and the Klaverbank pSCI will be without sufficient foraging habitat given their diverse diet preferences and foraging range.

D.5 Evidence requirements

Extending the discussion on evidence requirements in D.1 and D.2, as to the initial identification of an area that may be functionally linked, this section examines the evidence requirements for the assessment of the effects on the species.

The case of Boggis (E.9) established some important principles with regard to the evidence in respect of a perceived *risk* to a European site (emphasis added).

"a claimant who alleges that there was a risk which should have been considered by the authorising authority so that it could decide whether that risk could be "excluded on the basis of objective information", must produce credible evidence that there was a real, rather than a hypothetical, risk which should have been considered".

The level of supporting evidence relating to risks concerning functional linkage varies across the cases reviewed. In the cases of terrestrial plans and projects affecting SPA bird species, survey information was available and the use of affected areas by the populations for which the SPA had been classified was plainly established. Of relevance to the outcome of the decisions was the level of use of the functionally linked land affected and its importance to the maintenance of the populations for which the site had been classified.

In the case of the North Killingholme Power Project (E.13), whilst the applicant's Environmental Statement found that the area adjacent to the project was important for SPA bird species, with findings of up to 10,000 golden plover on land to the north of the development representing 2.5% of the British wintering population (and exceeding the threshold for SPA classification in its own right), the maximum area over which the birds were likely to be affected by the proposed visual and noise disturbance effects was small (within 500m). With reference to this 'zone of influence' *"The SoS is satisfied that there would be no adverse effect on SPA/ Ramsar birds outside the designated site boundary from construction disturbance as only a small population of birds are recorded in close proximity and disturbance effects will be mitigated by using hoarding and barriers to screen operations."*

Likewise, in the case of the Heysham to the M6 link road (E.20), although birds from the SPA were known to utilise the fields alongside the proposed route, Natural England did not consider functional linkage effects merited appropriate assessment on the basis that "*the intensity of use by these species was light and species do not favour any particular field with suitable alternatives available nearby*".

In contrast, in the case of Hinkley power station (E.21), surveys revealed that more than 1% of the Severn Estuary SPA populations and approximately 25% of the Somerset Levels and Moors SPA population of golden plover were affected while on functionally linked land. The land was clearly important to the maintenance of the SPA populations and (emphasis added):

"The Secretary of State has considered the potential disturbance and displacement effects on birds that are features of the Severn Estuary SPA and Ramsar. In view of the numbers of birds close to the foreshore and the sensitivity of those species, most notably Shelduck, he considers it necessary to impose a range of mitigation measures during construction and operation to reduce disturbance due to noise, artificial light, vessel movements and the presence of personnel and machinery on site.

" ...The Secretary of State has considered the potential impacts on bird species and the assemblage of birds that are the feature of the Somerset Levels and Moors SPA/Ramsar. For the same reasons that apply to the Severn Estuary SPA/Ramsar (covered in chapter 7 of this document), he concludes that, with the relevant DCO and EA Environmental Permit requirements in place, the impacts from HPC alone and in combination would not have an adverse effect on site integrity."

Case E.22, Frodsham onshore wind farm, is also a notable example of the high level of confidence in the data obtained about the use of functionally linked land. Although the immediate proximity of the site to the SPA and the locally well-known ornithological value of the application site would always have indicated a high probability of a functional link, this case is characterised by a considerable survey effort and extensive analysis in order to fully understand the use of the site by birds and its links to the SPA. Furthermore, the proposal was redesigned and resubmitted in a variation to the application, as a result of this detailed work assessing the ecological functionality of the site. As a result of this effort and redesign, together with the mitigation package, Natural England withdrew its objection and the Secretary of State concluded that, despite the high levels of use of the site by SPA populations and the immediate proximity to the SPA, there would be no likely significant effect on the SPA or the Ramsar site either alone or in combination with other plans or projects.

The adequacy of the assessment undertaken in respect of functional linkage is also influential. A perceived threat or risk from effects occurring beyond the boundary of the site was identified in the cases of Shadwell (E.6), Sandale developments (E.8) and Lemonford caravan park (E.23). The first case concerned birds, the second Atlantic salmon and the third bats. But all cases considered a 'risk' related to functional linkage and the extent to which that risk had been adequately addressed.

In the case of Shadwell, the approach adopted by the Council had been to create a buffer zone of 1,500m from the SPA boundary and likely offsite breeding areas for the stone curlew. In court it was argued that an allocation beyond 1,500m and in an area where the birds had been observed to breed in the past ought not to have been included in the plan. But the court gave considerable weight to the extensive survey work, analysis and expert opinions expressed by Natural England and the RSPB. The challenge centred on how the underlying reports had been interpreted and applied and further risk (beyond that already addressed in the agreed approach) based on anecdotal reports. With reference to the risk identified in this challenge, the court ruled that "*The evidence... is nowhere near providing the 'cogent and compelling' reasons that are needed in order to depart from the views of a statutory consultee.... No new evidence has been produced which undermines the validity of the 1,500 metre distance".* And then making a reference to Boggis (E.9) "*In order to succeed on ground 3, Shadwell has to produce credible evidence of a real risk to the integrity of the SPA".* In other words the court was satisfied that the competent authority, in consultation with the statutory nature conservation body, had correctly identified the risks from effects on functionally linked land and had undertaken the necessary assessment work and developed an agreed approach based on the evidence obtained. The risk raised by the claimants lacked evidence of equivalent credibility.

In both Sandale Developments and Lemonford Caravan Park a credible risk was identified to the qualifying features of the European site from effects on functionally linked areas but, in both cases, there was insufficient evidence that these risks had been adequately assessed. A precautionary approach was thereby taken. In the absence of evidence upon which the credible risks could be excluded by obtaining relevant information and making an assessment of the significance of the effects on the qualifying features (salmon and bats), the Sandale decision was found not to satisfy the requirements of the Regulations and the Lemonford appeal was dismissed for want of adequate information to make an appropriate assessment.

"the underlying lack of specific information about the manner in which the site is actually used by the Greater Horseshoe Bat militates against the robustness of conclusion that is in this instance required."

"Appropriate assessment cannot, in my view, be adequately undertaken on the basis of the information to hand." (Lemonford (emphasis added))

"In light of the applicant's evidence about protected salmon above the watercourse in the Camowen River the potential impact is clear and must be excluded"

"More particularly, the information that has now emerged does indicate that the risk exists that the proposed development will have significant effects on the SAC, in that the salmon may be affected by discharges into the watercourse. The precautionary principle dictates that the risk exists because it cannot be excluded on the present state of knowledge" (Sandale (emphasis added)).

In essence, the analyses in D.1 to D.5 show that, amongst other things:

a) The identification of an area as functionally linked land in the terrestrial or coastal environment is generally relatively straightforward and readily recognised, but may sometimes not be apparent and may require some initial survey and analysis or collation of pre-existing data, to establish the link;
b) The identification of an area as functionally linked sea is more challenging and has to be approached differently for marine developments; nevertheless an approach in respect of sea birds and marine mammals appears to be developing and although necessarily relying to a greater extent on assumptions, it provides a robust approach which is suitably precautionary without being onerous;
c) Once identified as functionally linked land or sea, the evidence required by decision makers in stages 1 and 2 of the Habitats Regulations Assessment process are no different to those that might reasonably be expected in relation to direct or on-site effects on the European site. The precautionary principle applies equally to functionally linked land and sea. Where effects might be significant and there is insufficient information to ascertain that there would not be an adverse effect on the integrity of a site, in terms of the population of the species for which the site has been classified or designated, authorisation has been denied; consistently with the provisions of the Regulations. However in the majority of cases sufficient evidence was available for the decision-maker to conclude that there would be no significant effect, or no adverse effect on site integrity, if the project was authorised.

Technical Guidance Series

Competencies for Species Survey: Natterjack Toad

www.cieem.net

1. Introduction

The purpose of this document is to set out the knowledge, skills and experience required to survey, disturb or to carry out research works (hereinafter referred to generically as 'survey') for the natterjack toad, *Epidalea calamita*, in a professional capacity. To be undertaking such work, CIEEM would consider attainment of the criteria outlined in this guidance to be a minimum for an individual to competently survey for natterjack toads. The Institute aims to drive up standards in the ecological profession for the benefit not only of ecologists but also of the public.

This document does not provide guidance on the techniques to be employed in carrying out survey activities: references to published sources of guidance on survey methods are listed in Section 5.

2. Status

The natterjack toad has a localised distribution in the UK, and has undergone substantial historical declines due to habitat loss and fragmentation. The remaining strongholds are dune systems and upper saltmarshes along the coasts of Merseyside, Cumbria and Dumfriesshire; with smaller and more isolated coastal populations in Lincolnshire, Norfolk, Suffolk, Kent, Dorset, Denbighshire, Flintshire, Cheshire and Lancashire. There are a few lowland heathland populations in Hampshire and Surrey. There are also coastal populations in County Kerry, southwest Ireland. Natterjacks are absent from Northern Ireland. The few inland populations in southeast England represent a great reduction from their historical range, largely due to loss of heathland. In coastal areas, their range has shrunk due to urbanisation and loss of habitat due to other land-use changes.

The natterjack toad is a 'pioneer-opportunist' which relies upon sparsely-vegetated habitats with shallow, ephemeral ponds. There are around sixty populations in the UK, with only about 3,000 breeding females in total (ARC 2009). The natterjack toad is a UK BAP Priority Species, with a long-standing reintroduction programme, and intensive conservation efforts. Inbreeding depression has contributed to the decline of some isolated populations, and chytrid fungus has been cited as another possible cause of declines. Although declining in the north of its European range, the natterjack toad is listed as a species of least concern on the IUCN Red List because it is locally abundant across much of its range.

3. Legislation and Licensing

Legislation

Natterjack toads are protected under the following legislation. This outline of legislation is not comprehensive and the appropriate legislation should always be consulted for a definitive list of offences.

COUNTRY	LEGISLATION GIVING PROTECTION	SCHEDULE OR ANNEX LISTING
England	Conservation of Habitats and Species Regulations 2010 Wildlife and Countryside Act 1981 (as amended)	Schedule 2 Schedules 5
Wales	Conservation of Habitats and Species Regulations 2010 Wildlife and Countryside Act 1981 (as amended)	Schedule 2 Schedules 5
Scotland	Conservation (Natural Habitats, &c.) Regulations 1994 (as amended)	Schedule 2
Republic of Ireland	European Communities (Natural Habitats) Regulations 1997 (as amended) Wildlife Act 1976 (as amended)	First schedule Schedule 5

Licensing

The following Statutory Nature Conservation Organisations (SNCOs) are responsible for issuing licences to permit actions that would otherwise be illegal under the relevant legislation:

COUNTRY	SNCO
England	Natural England
Wales	Natural Resources Wales
Scotland	Scottish Natural Heritage
Republic of Ireland	National Parks & Wildlife Service

A *survey licence is required:* for any survey work using techniques likely to disturb natterjack toads at any site where there is a reasonable likelihood that they are present. *e.g.* terrestrial searches or netting.

A *survey licence is not required*: for non-intrusive surveying such as listening for the natterjack toad's distinctive call, or for spawn string counts.

In the event that a natterjack toad is encountered *e.g.* when conducting a spawn string count, an unlicensed surveyor must cease survey work, unless they are in the presence of a surveyor with an appropriate licence.

It is the role of the appropriate licensing authority to define the criteria for issuing such licences as may be required for survey work, therefore, attainment of the skills set out is no guarantee that a licence will be obtained; other criteria will need to be considered.

4. Knowledge, Skills and Experience

To independently and competently undertake survey of natterjack toads an individual would be expected to possess all of the following knowledge, skills and experience.

A surveyor needs to recognise their level of attainment along a continuum. Those without the breadth and depth of the knowledge, skills and experience that CIEEM consider a minimum, should always work with, or seek advice from, an adequately experienced individual.

Knowledge

Individuals should have a knowledge and understanding of:

a. conservation status;
b. distribution;
c. threats to populations, species range and species survival;
d. natterjack toad ecology, breeding biology and behaviour;
e. known ecological requirements (*e.g.* ponds and terrestrial habitats);
f. legal protection;
g. licensing and permissions;
h. appropriate survey seasons;
i. current relevant guidance on survey methods and standards;
j. survey methods used to survey for natterjack toads (*e.g.* catching and handling and indirect methods such as spawn counts, tadpole and metamorph estimation, terrestrial searches, call identification and torchlight survey) and the strengths, weaknesses and limitations of these methods;
k. range of factors that might lead to bias in the survey results, and false negatives;
l. factors affecting surveying (*e.g.* temperature/weather conditions);
m. biosecurity procedures and disease transmission risks, in particular chytrid fungus;
n. sources of information on known occurrence and distribution of natterjack toads (including NBN Gateway, local biological/environmental records, county atlases and local contacts/Amphibian and Reptile Group(s));
o. metadata standards / data sharing; and
p. health and safety issues associated with surveying for natterjack toads.

Skills

Individuals should have skills and experience enabling them to:

a. confidently identify natterjack toads in all life stages, including adult males' breeding calls;
b. confidently distinguish natterjack toads from other native and non-native amphibian species that may be present;
c. assess habitat suitability of a site for natterjack toads;
d. scope fieldwork appropriately;
e. plan and implement sound scientific surveys;
f. select suitable temperature and weather conditions for survey;
g. carry out visual surveys;
h. make spawn or animal counts and classify population size classes;
i. interpret and analyse survey data (recognising any constraints on survey results);
j. take appropriate biosecurity precautions; and
k. take appropriate health and safety precautions.

If surveys involve netting or using refugia, individuals should also be able to:

a. survey ponds for natterjack toads (all appropriate life stages) using a net;
b. survey terrestrial habitat for natterjack toads using refugia;
b. legally and humanely handle natterjack toads; and
c. effectively record biometric data from live toads.

Practical Experience

Whilst some of the knowledge and skills set out in this guidance can effectively be gained from personal study, vocational training and structured education, applicants for natterjack toad survey licences would be expected to have gained practical experience (over a number of survey seasons) under the direct supervision of an experienced and licensed natterjack toad surveyor. Individuals planning to apply for their own natterjack survey licence should have the following specific experience:

a. performing surveys of natterjack toads across all life stages (spawn to adult), including capture and biometric measurement, in compliance with the *Natterjack Toad Conservation Handbook* (Beebee & Denton 1996); and

b. survey of at least 10 different breeding ponds, ideally at several different sites, under supervision of a natterjack toad licence-holder; and survey over at least five different occasions, spanning the breeding season April to July.

This experience should be fully recorded and documented in a portfolio which can be presented to the statutory authorities when a licence is applied for.

5. Reading

The following references are essential reading for those wishing to gain the necessary knowledge, skills and experience to survey for natterjack toads.

SUMMARY

The Chartered Institute of Ecology and Environmental Management (CIEEM) has developed these Guidelines to promote good practice in Ecological Impact Assessment (EcIA) relating to terrestrial, freshwater, coastal and marine environments in the UK and Ireland.

EcIA is a process of identifying, quantifying and evaluating potential effects of development-related or other proposed actions on habitats, species and ecosystems[2]. The findings of an assessment can help competent authorities understand ecological issues when determining applications for consent. EcIA can be used for the appraisal of projects of any scale including the ecological component of Environmental Impact Assessment (EIA). When undertaken as part of an EIA, EcIA is subject to the relevant EIA Regulations. Unlike EIA, EcIA on its own is not a statutory requirement. It is an evaluation process undertaken to support a range of assessments.

EcIA is a process that is most effective if all contributing ecologists and other specialists work in collaboration. An EcIA report (or the ecological chapter of an EIA Environmental Statement) should clearly and simply describe the significant effects of any project so that all interested parties understand the implications of what is proposed. These Guidelines explain the key elements of the EcIA process:

Chapter 1 – Introduction. Overview of the EcIA process and underpinning principles.

Chapter 2 – Scoping. Determining the matters to be addressed in the EcIA, including consultation to ensure the most effective input to defining the scope. Scoping is an ongoing process – the scope of the EcIA may be modified following further ecological survey/research and during impact assessment.

Chapter 3 – Establishing the baseline. Collecting information and describing the ecological conditions in the absence of the proposed project, to inform the assessment of impacts.

Chapter 4 – Important ecological features. Identifying important ecological features (habitats, species and ecosystems, including ecosystem function and processes) that may be affected, with reference to a geographical context in which they are considered important.

Chapter 5 – Impact assessment. An assessment of whether important ecological features will be subject to impacts and characterisation of these impacts and their effects[3]. Assessment of the significance of the residual ecological effects of the project (those remaining after mitigation), including cumulative effects.

Chapter 6 – Mitigation, compensation and enhancement. Incorporating measures to avoid, reduce and compensate negative ecological impacts and their effects, and the provision of ecological enhancements. Monitoring impacts and their effects. Evaluation of the success of proposed mitigation, compensation and enhancement measures.

Chapter 7 – Implications for decision making. Consideration of the legal and policy framework throughout the EcIA process.

1 INTRODUCTION

1.1 The purpose of these Guidelines is to promote good practice in Ecological Impact Assessment (EcIA) relating to terrestrial, freshwater, coastal and marine environments in the UK and Ireland.

1.2 The context of EcIA is well established. The EU Biodiversity Strategy[4] and national biodiversity strategies[5] reflect the need to conserve biodiversity[6] in the face of pressure from development, other land use change and climate change. These strategies reflect the aspirations of the Convention on Biological Diversity. International work on the benefits of nature to society (natural capital and ecosystem services), the UK National Ecosystem Assessment[7] and *The Economic and Social Aspects of Biodiversity in Ireland*[8], have increased understanding of the importance of conserving biodiversity for human wellbeing and the economy. This is reflected in national policy objectives for biodiversity and nature conservation, such as the Natural Environment White Paper[9] in England, the White Paper on Natural Resources[10] in Wales, the *Land Use Strategy for Scotland*[11], and the *National Biodiversity Action Plan 2017-2021*[12] in Ireland. EcIA supports implementation of national biodiversity strategies and national planning policies for safeguarding biodiversity and supporting the delivery of sustainable development. In the marine environment this is reflected through UK adoption of the Marine Strategy Framework Directive, a programme of measures designed to achieve or maintain Good Environmental Status in UK seas by 2020[13], the UK Marine Policy Statement[14] and the Integrated Marine Plan for Ireland (2012)[15].

1.3 *EcIA is a process of identifying, quantifying and evaluating the potential effects of development-related or other proposed actions on habitats, species and ecosystems.* EcIA can be used for the appraisal of projects of any scale: it is a systematic and repeatable process applicable to a wide range of projects.

1.4 Two particular uses of EcIA are:

- providing the ecological component of Environmental Impact Assessment (EIA) required under EIA Regulations
- demonstrating how a project accords with relevant planning policy and legislation where an EIA is not required.

1.5 The EcIA process can be fitted seamlessly into the EIA process or it can stand alone. Summary information on EIA is provided in Box 1. It is recommended that the EcIA process is used to present an assessment of the ecological effects of any project which could affect biodiversity.

Box 1: Environmental Impact Assessment

EIAs are carried out to meet the requirements of Council Directive 85/337/EEC on the assessment of the effects of certain public and private projects on the environment, as amended by Council Directives 97/11/EC, 2003/35/EC and 2009/31/EC and redrafted in a codified version Directive 2011/92/EU. The amended Environmental Impact Assessment (EIA) Directive 2014/52/EU entered into force in 2014 to simplify the rules for assessing the potential effects of projects on the environment and Member States had to apply these rules from May 2017[16].

The Directive requires EIA to be carried out before development consent is granted for projects that are likely to have significant environmental effects. EIA is a mandatory requirement for projects listed in Annex I of the Directive. It is also required for projects that meet the criteria for Annex II development and are likely to have significant environmental effects (as defined in Annex III of the Directive). EIAs should provide a comprehensive understanding of the implications of a project proposal, including consideration of impacts on biodiversity, and interactions with soil, water and air.

The main statutory instruments that implement the Directive in the UK (updated in 2017) are available on the website for UK legislation[17]. In the Republic of Ireland, the EIA Directive was transposed in planning legislation in 2000 and given further effect in 2013[18].

1.6 Work undertaken for EcIA can inform Habitats Regulations Assessments (HRA), the Appropriate Assessment process in Ireland and Water Framework Directive Assessments. These Guidelines do not cover these Assessments, but a summary is provided in Box 2.

Box 2: Habitats Regulations Assessment, Appropriate Assessment in Ireland and Water Framework Directive Assessment

Projects affecting designated sites protected by the Habitats Directive[19] (transposed into national Regulations[20]) will require specific assessments in accordance with the Directive. Similarly, projects affecting water bodies may require assessment under the Water Framework Directive[21]. These Guidelines do not explain the specific assessment processes to be applied or the criteria governing decisions. Guidance on implementing the Habitats Directive is provided by the European Commission in *Managing Natura 2000 sites the provisions of Article 6 of the 'Habitats' Directive 92/43/EEC*[22] and in more detail in The Habitats Regulations Assessment Handbook[23] and in Appropriate Assessment of Plans and *Projects in Ireland: Guidance for Planning Authoritie*[24]. Information on the Water Framework Directive is available on the Joint Nature Conservation Committee website[25] and on the Irish Water Framework Directive website[26].

Information assembled for an EcIA that is relevant to subsequent Habitats Regulations Assessment (HRA) and/or Water Framework Directive assessments should be presented in a format that can be readily extracted for these other assessments.

Use of the Guidelines

1.7 These Guidelines should be followed by ecologists undertaking EcIA. The Guidelines also provide regulators, decision-makers and those submitting projects with an indication of the information needed to adequately consider projects in the light of biodiversity legislation and policy.

1.8 These Guidelines are applicable to ecologists acting for:

- a project proposer such as a developer submitting a planning application
- a competent authority making the decision about consent for a proposed project
- public bodies with biodiversity and landscape duties and/or Water Framework Directive duties / Marine Strategy Framework Directive duties
- consultees such as those who advise the competent authority in a statutory or voluntary capacity.

Differing Scales of EcIA and a Proportionate Approach

1.9 EcIA can be applied to projects of widely varying scales. The EcIA principles and process outlined in this guidance are relevant to all developments that may impact on ecological features – this term is used throughout to cover habitats, species and ecosystems. However, the level of detail required in an EcIA will inevitably be proportionate to the scale of the development and complexity of its potential impacts. These Guidelines do not prescribe exactly how to undertake an EcIA, but provide guidance to practitioners for refining their own methodologies.

1.10 Scoping (Chapter 2) should be proportionate to potential effects on ecological features. Professional ecologists need to use their knowledge and experience to judge the resources required to complete an adequate and effective EcIA.

1.11 Emphasis in EcIA is on 'significant effects' (see Box 3) rather than all ecological effects. Relevant legislation, regulations, plans and policies should be considered at an early stage, as these will have a bearing on the scope of investigations, how potential effects are interpreted, and the criteria needed for determining significance.

Box 3: Significant effects

Significance is a concept related to the weight that should be attached to effects when decisions are made. For the purpose of EcIA, 'significant effect' is an effect that either supports or undermines biodiversity conservation objectives for 'important ecological features' (explained in Chapter 4) or for biodiversity in general. Conservation objectives may be specific (e.g. for a designated site) or broad (e.g. national/local nature conservation policy) or more wide-ranging (enhancement of biodiversity). Effects can be considered significant at a wide range of scales from international to local.

A significant effect is an effect that is sufficiently important to require assessment and reporting so that the decision maker is adequately informed of the environmental consequences of permitting a project.

In broad terms, significant effects encompass impacts on structure and function of defined sites, habitats or ecosystems and the conservation status of habitats and species (including extent, abundance and distribution).

See paragraphs 5.24 – 5.40 for further explanation of significant effects.

A Rigorous and Transparent Approach

1.12 A scientifically rigorous and transparent approach to EcIA is essential. EcIA should be undertaken by qualified professionals with an appropriate level of experience in ecological survey and impact assessment who are recognised by a relevant professional body such as CIEEM.

1.13 All interested parties should understand the assessment process and who is responsible for implementing and monitoring the actions needed to deliver biodiversity objectives. The EcIA must provide reliable and defensible information about, and interpretation of, the likely significant ecological effects from inception to operation, maintenance and, where appropriate, closure and decommissioning.

1.14 Account needs to be taken of existing information and understanding, in conjunction with the results of EcIAs undertaken elsewhere. CIEEM encourages all practitioners to share data and results, for example through Local Record Centres (LRCs) in Britain[27], the Centre for Environmental Data and Recording (CEDaR) in Northern Ireland[28], the National Biodiversity Data Centre in Ireland[29] and the National Biodiversity Network Atlas Scotland[30]. Consideration should also be given to the publication of findings to allow review and learning by others, for example the Marine Data Exchange.[31] Guidelines for accessing and using biodiversity data, including the submission of data, have been produced by CIEEM (2016)[32].

1.15 The EcIA should consider the significant ecological effects of a project in the light of relevant planning policies and legislation. Legislation relating to terrestrial, freshwater, coastal and marine environments is evolving and practitioners should always check for changes and revisions. These Guidelines are based on requirements at the time of publication and changes in legislation and policy may necessitate periodic review. The Guidelines do not attempt to explain legislative detail, and users should refer to relevant legislation and case law or seek specialist legal advice.

1.16 EcIA benefits from early consultation with the relevant competent authority, Statutory Nature Conservation Bodies (SNCBs), Environment(al) Protection Agencies (EPA) and Non-Governmental Organisations (NGOs). Through EcIA the developer/project proposer can be made fully aware of matters such as site designations, protected habitats and protected species, and their implications, before pursuing a project. Engagement with consultees on a regular basis will help refinement of the proposal, smooth progression through the planning process and minimise misunderstanding and controversy.

1.17 There will be examples on the coast where a project will be subject to both marine and terrestrial consent processes. Early consultation provides an opportunity to agree the scope of the assessment and approach for the assessment process in these circumstances. In England a Coastal Concordat has been published which promotes co-ordination between regulatory authorities responsible for the range of consents, permissions and licences, and the provision of a single point of entry into the regulatory system for applicants[33].

1.18 Good communication is essential between ecologists and other professionals engaged in the assessment process (e.g. geomorphologists, hydrologists, social practitioners, EIA coordinators), together with proponents, to help inform judgements and refine proposals. It may also require engagement with comparable international bodies where trans-boundary effects are predicted e.g. in the marine environment.

Key Principles

1.19 The following principles[34] underpin EcIA:

Avoidance	Seek options that avoid harm to ecological features (for example, by locating on an alternative site).
Mitigation	Negative effects should be avoided or minimised through mitigation measures, either through the design of the project or subsequent measures that can be guaranteed – for example, through a condition or planning obligation.
Compensation	Where there are significant residual negative ecological effects despite the mitigation proposed, these should be offset by appropriate compensatory measures.
Enhancement	Seek to provide net benefits for biodiversity over and above requirements for avoidance, mitigation or compensation.

The EcIA Process

1.20 The EcIA process is summarised in Box 4. EcIA is an iterative process; for example, scoping is an ongoing process - the initial proposed scope of the EcIA may be modified following further ecological survey/research and during impact assessment.

Box 4: Summary of the EcIA process

Initial project design

At the outset of the project, the proponent's ecologist(s) should:

- obtain information on the project, any alternatives that have been studied and existing ecological information
- undertake a gap analysis of known and needed information and plan and prioritise gap filling
- review ecological implications of alternatives
- discuss key ecological considerations about the project design (and alternatives) with the project proposer and the design team (e.g. engineers, architects)
- recommend modifications to the design to avoid negative ecological impacts or, where this is not possible, to reduce them
- explore opportunities for ecological enhancements and net gain of biodiversity as early as possible

Screening (EIA only)

The project proposer may seek a formal screening opinion from the competent authority to determine the need for EIA under the EIA Regulations.

Scoping EcIA

Scoping determines the issues to be covered by the EcIA. Where an EIA is required, the competent authority must provide a 'scoping opinion' if requested by the developer. In all other cases, it is advisable to seek the views of competent authorities and key consultees on the proposed scope of the EcIA.
In all cases, scoping will need to:

- identify any potential licensing requirements for survey and/or development regarding legally protected species
- identify all proposed construction, operating, maintenance, closure and decommissioning activities that may generate significant ecological effects
- identify significant other developments that may give rise to cumulative effects
- collect initial baseline information, such as through a Preliminary Ecological Appraisal (PEA), to enable identification of potentially important ecological features within the zone of influence of the project
- identify for assessment those important ecological features that could sustain significant positive or negative impacts, as far as possible given the information available (and employing the precautionary principle)
- identify relationships with other environmental aspects e.g. water, landscapes
- identify data gaps
- propose suitable spatial and temporal scopes for the assessment and identify the main ecological issues to be addressed
- undertake preliminary assessment of potential ecological impacts on identified features, incorporating existing data/information
- reconsider spatial and temporal scope and amend the extent of preliminary investigations if necessary
- list those features that do not need further assessment, with appropriate justification
- identify suitable survey/research methodologies that (ideally) have been agreed with consultees
- confirm potential opportunities for avoidance of impacts, mitigation, ecological enhancement and biodiversity net gain
- ensure biodiversity data collected is suitable for potential use in biodiversity metrics for assessment of 'net gain' of biodiversity
- ensure compliance with standards and consistency with formal methods of evaluation.

For EIA projects, and as good practice for non-EIA projects, scoping should also:

- involve appropriate consultation with the competent authorities, statutory agencies, other regulatory bodies, and possibly relevant NGOs and other non-statutory consultees, regarding the project and the proposed scope of the assessment
- produce a scoping report that can be circulated for comment and modified accordingly.

Impact assessment

The EcIA team will be involved in the following assessment process, which should cover all phases of any project:

- determine the importance of ecological features affected, through survey and/or research and with reference to available contextual information
- assess impacts potentially affecting important features
- characterise the impacts, e.g. extent, magnitude, duration, reversibility, timing and frequency
- identify cumulative impacts
- identify significant effects of impacts in the absence of any mitigation.

The surveys and research that are undertaken may indicate that the scope of the assessment should be adjusted and further studies carried out.

Evolution of project design and mitigation

- consider alternative location(s) or layouts for the proposed development
- identify mitigation measures and explain their likely success
- identify opportunities for ecological enhancement and net gain of biodiversity

- design and agree monitoring strategy and monitoring of mitigation performance with the competent authority (and, in some cases, consultees)
- provide sufficient information for mitigation measures to be implemented effectively, e.g. through an Environmental Management Plan (EMP).

Identify significant residual effects and their legal, policy and development management consequences

- produce a clear summary of the residual impacts and the significance of their effects following incorporation of avoidance and mitigation measures
- consider the implications of significant effects on the important ecological features in accordance with planning policies and legislation
- where significant negative effects cannot be avoided or mitigated, identify compensation measures to be implemented
- include mitigation, compensation and enhancement measures in the EMP or similar
- make an assessment of the significance of any cumulative effects.

Reporting

The final EcIA report (or for EIAs, the Environmental (Impact) Statement) should clearly set out all the ecological information necessary for a robust decision to be made. Key aspects include a description of the following:

- ecological baseline and trends if the project were not to go ahead, including the survey data used to inform the baseline
- criteria used to evaluate ecological features
- criteria used to assess the significance of effects arising from the impacts of the project
- justification of methods used
- the identification of likely impacts (positive and negative) on ecological features together with an explanation of the significance of the overall effects for each important ecological feature
- mitigation, compensation and enhancement measures
- legal and policy consequences
- identification of any limitations to the assessment, or the surveys which underpin it, and an explanation of the implications
- a presentation of any analytical techniques used and the analysis itself.

The report should also set out the ecological monitoring required to:

- confirm the implementation of conditions/planning agreements
- audit predicted impacts against the actual situation
- take measures to rectify unexpected negative impacts and ineffective mitigation, compensation and enhancement measures.

EcIA reports

1.21 EcIA reports should be tailored to suit individual circumstances and different formats are acceptable. However, CIEEM considers it important that the structure and content of EcIA reports are standardised. A logical structure for a report is provided in *CIEEM Guidelines for Ecological Report Writing*[35] and is reproduced in Appendix 3. Where an EIA is required, the Ecological Impact Assessment will be presented in a way that fits the overall style and structure of the Environmental (Impact) Statement. However, the content of Appendix 3 remains relevant. Where elements of this content lie outside the presentation of the main Ecological Impact Assessment (usually an ecological chapter of the EIA), cross-reference should be included.

Note: The following definitions are used for the terms 'impact' and 'effect':

Impact – Actions resulting in changes to an ecological feature. For example, the construction activities of a development removing a hedgerow.

Effect – Outcome to an ecological feature from an impact. For example, the effects on a dormouse population from loss of a hedgerow.

6 AVOIDANCE, MITIGATION, COMPENSATION AND ENHANCEMENT

Introduction

6.1 A sequential process should be adopted to avoid, mitigate and compensate negative ecological impacts and effects. This is often referred to as the 'mitigation hierarchy' (see 1.19 and 5.1). For most projects, avoidance, mitigation, compensation and enhancement measures should be identified as part of the EcIA process.

Avoidance and Mitigation

6.2 Negative impacts should always be avoided where possible, for example by deciding not to locate a project in a particular area or making a change to scheme layout to ensure no negative impacts. Avoidance can also be part of mitigation. Mitigation includes measures to avoid or reduce the negative impacts of a project, for example careful timing of an activity to prevent an impact occurring.

6.3 Avoiding and/or minimising negative impacts is best achieved through consideration of potential impacts of a project from the earliest stages of scheme design and throughout its development. Many impacts can be avoided or reduced by consideration of alternatives.

6.4 Mitigation measures incorporated into the scheme design are often described as 'embedded mitigation' or 'mitigation by design'. This can include the re-design of the layout of the scheme, or adjusting the location of certain activities. Mitigation by design is particularly beneficial as there is greater certainty that it will be delivered. Wherever possible mitigation should be by design rather than left to a request by the competent authority. In Ireland, NPWS has produced guidance for developers in the construction and extractive sectors[112]. The efficacy and any potential knock-on effects of both embedded and non-embedded mitigation should always be assessed.

Compensation

6.5 Compensation describes measures taken to offset residual effects resulting in the loss of, or permanent damage to, ecological features despite mitigation. For example, it may take the form of replacement habitat or improvements to existing habitats. Compensation can be provided either within or outside the project site (defined by the red line of a planning application). Compensation should always be seen as a last resort, when all other mitigation options have been exhausted. Compensation is particularly difficult to achieve in the marine environment (see paragraph 5.36).

6.6 As a general rule, compensation should be focused on the same type of ecological features as those affected and equivalent levels of ecological 'functionality' sought. There will be cases when it is not possible to achieve ecological equivalence through compensation. Any replacement area should be similar in terms of ecological features and ecological functions that have been lost or damaged, or with appropriate management have the ability to reproduce the functions and conditions of those ecological features. Compensation should be provided as close as possible to the location where effects have occurred and benefit the same habitats and species as those affected.

6.7 Replacement ratios of compensatory habitat greater than one-to-one are frequently appropriate because of the uncertainty inherent in compensation, particularly in cases which require ecological restoration, habitat creation or translocation of species or habitats. The scientific basis for deriving appropriate ratios is not exact and will vary depending on the habitat or species concerned. Increased replacement ratios can also help take account of the time lag in delivering compensation and regaining the same maturity, complexity and diversity of habitats and the full complement of associated species.

6.8 Biodiversity offsets is a concept that provides a measurable approach to compensation with the aim of achieving 'no net loss'[113]. Box 19 summarises biodiversity offsets.

Box 19: No net loss and biodiversity offsets

Biodiversity offsets are a form of compensation which may be considered when a development is expected to have significant residual impacts on biodiversity despite planned mitigation measures. Biodiversity offsets have a formal requirement for measurable outcomes. The main requirement is to quantify losses (through effects, after avoidance and mitigation) and gains (through offsets) using the same 'metric', for example hectares of habitat of a particular quality[114]. Using an offset metric in this way provides for transparency of outcome and enables explicit demonstration of 'no net loss'. Such metrics can also be used to support the achievement of net gains (see paragraphs 6.11 to 6.13).

6.9 The delivery of compensation measures, including biodiversity offsets, is likely to involve access to land, or land purchase, outside a scheme footprint and a commitment to long-term management through legal agreements. They therefore require early consideration in project design. The principles of offsetting should be agreed with the competent authority at an early stage, particularly where this is not clearly set out in a policy or biodiversity offsetting strategy.

6.10 The distinction between mitigation and compensation can be difficult to determine. Where ecological equivalence can be delivered within the project site this is sometimes incorrectly considered mitigation rather than compensation. However, the correct distinction between mitigation and compensation is that mitigation avoids or reduces the occurrence of negative impacts and effects and compensation addresses effects which are residual, after avoidance and mitigation have been considered. Measures to address impacts and effects that will occur should therefore be referred to as compensation whether the compensation is located within or outside of the project site.

Enhancement

6.11 It is important that development is sustainable and, where possible, projects produce a net gain for biodiversity and nature conservation. National policies promote the inclusion of measures to enhance biodiversity within development proposals. Enhancement of biodiversity should be an objective of all projects. Principles for achieving net gain within development have been published by CIEEM, CIRIA and IEMA (2016)[115].

6.12 Enhancement is improved management of ecological features or provision of new ecological features, resulting in a net benefit to biodiversity, which is unrelated to a negative impact or is 'over and above' that required to mitigate/compensate for an impact. For example, mitigation for bats may involve erecting bat boxes in a woodland to replace suitable bat *roosting* features that have been removed, and the woodland habitat itself may be enhanced for *foraging* bats by increased woodland planting and the creation of glades. Enhancement could be linked to the delivery of wider socio-economic benefits such as wetland restoration and flood risk management. Enhancement measures should be described in the EcIA.

6.13 Enhancement measures should be designed to deliver biodiversity objectives that are specified in relevant policy documents, and evidence should be provided to support the likelihood of delivering the predicted benefit. They should be incorporated into scheme design and assessed within the EcIA. To ensure that enhancements are enduring, their delivery and management should normally be guaranteed through a legal obligation, such as, in England and Wales, a planning obligation under section 106 of the Town and Country Planning Act 1990[116], or its equivalent provision elsewhere.

Designing Mitigation and Compensation

6.14 The design of mitigation and compensation measures is an iterative process. It needs to consider what is realistically achievable and the likely extent to which success can be guaranteed, based on good practice guidance and evidence. Measures need to be agreed and a commitment made by the developer before a planning application is submitted to the competent authority. Such commitments must then also be agreed with the competent authority and secured through appropriate planning conditions, consents, permits and/or legal agreements. The aim should be to provide the competent authority with as much certainty as possible over the likely effectiveness and deliverability of the proposed measures (see BS 42020 clauses 6.6 and 8.1[117]).

6.15 Mitigation and compensation measures should address specific effects. For example, where a development will result in an effect on the conservation status of a population of great crested newts (or, for example, common frog and smooth newts in Ireland) through the loss of terrestrial foraging habitat, compensation should involve the provision of new foraging habitat rather than new breeding ponds. Mitigation and compensation measures should achieve long-term results. Their duration should match the duration of the impact.

6.16 Mitigation, compensation and enhancement measures should have defined criteria for success, which allows success or failure to be measured by monitoring. It is not appropriate to propose measures that cannot be delivered within a reasonable time frame, or simply present a wish-list of measures.

6.17 However, mitigation measures can include 'contingency measures' where there is uncertainty as to whether or not an effect will occur. For example, this may be relevant to effects that only occur if activities take place at particular times of year (such as site clearance during the bird nesting season), or as a result of unpredictable changes (such as where a badger sett, absent at the time of the EcIA, has been established prior to construction). In such cases the contingency measures should identify how such issues will be resolved and consider the possible effects on the project programme.

6.18 For many species, particularly those with legal protection, there is published guidance that describes appropriate approaches to mitigation. In some cases, it will be necessary to design new approaches to mitigate an effect, and the advice of relevant experts and statutory and non-statutory consultees should be sought. If standard methods are not being used, this will need to be explained and justified.

6.19 In some cases compensation measures will need to be in place and 'functioning' before the significant harm occurs. This is particularly likely where the effect is on designated sites or legally protected species. Lead-in times to deliver the measures will need to be carefully considered and explicitly stated in the EcIA.

6.20 The design of mitigation and compensation measures should be revisited with other members of the design team as there may be constraining factors or knock-on effects that need to be considered by other specialists: an integrated approach will increase successful delivery of the design. Should mitigation for one habitat or species have a negative effect on another, it may still be appropriate to implement the mitigation, although the negative effects will need to be considered in the assessment.

Delivery

6.21 Mitigation and compensation measures often carry a degree of uncertainty. Uncertainty associated with a design will vary according to a number of factors, and where necessary these should be discussed in the relevant section of the EcIA. Factors to be considered include:

- technical feasibility of what is proposed – using experience from projects where a similar measure has been carried out
- overall quantity of what is proposed – is it large enough to be viable? Is it of equivalent function to any habitat lost?
- overall quality of what is proposed – does it compare favourably with features lost or damaged?
- level of commitment – is there a realistic understanding of the resources and effort required to achieve predicted outcomes?
- provision of long-term management
- timescale for predicted benefits.

Reporting Mitigation, Compensation and Enhancement

6.22 The description of mitigation, compensation and enhancement measures within the EcIA must be sufficient to allow the competent authority and relevant stakeholders to see clearly how effects will be addressed. The level of detail needed will vary between schemes, between different measures within a scheme and should include quantity, location, timing, techniques and resources.

6.23 It is helpful to set out how a project has evolved in response to ecological considerations and to indicate how mitigation that has been incorporated into the scheme design has avoided or minimised negative impacts. Presenting the results of the assessment 'with' and 'without' mitigation allows the need

for mitigation and/or compensation to be clearly identified. Where mitigation is fully integrated into the scheme and there is high confidence that it will be implemented, it may be appropriate simply to assess the significance of effects of the mitigated project, with this assessment reflecting the likelihood of the incorporated measures being successful. Where there is any uncertainty, then the with/without mitigation approach to assessment described above should be used to ensure transparency.

6.24 Ideally, details of mitigation, compensation and enhancement measures will be incorporated into an Ecological Design Strategy (EDS) or Environmental Management Plan (EMP) which sets out methods and responsibilities for delivery. The plan should detail timescales for delivery and key criteria for judging success.

Monitoring

6.25 The EcIA should set out the ecological monitoring required to audit predicted impacts and effects against the actual situation. This will enable any necessary remedial action to be taken, including adjustment to the activity generating the impacts and adjustment to the mitigation or compensation measures.

6.26 The EcIA should identify where monitoring is required for mitigation, compensation and enhancement measures. It should set out the methods to be used, the criteria for determining success/failure, appropriate timing, mechanisms for implementation, frequency and duration of monitoring, and frequency of reporting.

6.27 Monitoring should be secured through a planning condition or obligation built into legal agreements, which the proponent must implement fully (Chapter 7). Monitoring may be used to determine:

- whether the measures have been implemented as agreed
- the success/effectiveness of the measures
- early warning of proposed measures which are not proving effective
- how to remedy the situation should any of the implemented measures fail e.g. due to lack of management.

6.28 Where measures are routinely applied and can be relied upon to deliver well tried and tested mitigation, monitoring is unlikely to be necessary, so long as the competent authority is able to enforce the measures. However, where there are uncertainties in predicting the effectiveness of measures, or mitigation packages are novel, monitoring will be required to determine whether the predicted efficacy of the mitigation meets expectations. In the case of major projects, good practice established in the marine and coastal environment has seen the development of legally binding Mitigation, Compensation and Monitoring Agreements (MCMA). These documents clearly define the measures that need to be taken if the project is to be consented.

6.29 It is vital that monitoring has clear indicators of success or failure, set against a suitable baseline. Monitoring needs to have clear aims and objectives to specifically determine the success of the measures, both in the short-term and longer-term. Longer-term monitoring is appropriate where:

- the success or failure of the measures will take longer to assess – such as for some habitat creation/ management measures
- the mitigation is relevant to a feature upon which the effects may vary during the life of the project.

6.30 It is important that there is an agreed robust feedback mechanism to ensure that where objectives have not been met, provision is made for remedial measures and these are implemented.

6.31 Ideally the results of monitoring should be widely shared, to inform the design of mitigation, compensation and enhancement measures of other projects.

7 CONSEQUENCES FOR DECISION-MAKING

Introduction

7.1 The competent authority determines whether the mitigated project:

- complies with legal requirements e.g. for protected species
- meets national and local policy goals and objectives
- requires conditions and legal obligations attached to the consent concerning detailed design, implementation and monitoring of the project.

7.2 The scoping stage presents the first opportunity to make explicit the legal and policy context. Everyone engaged in the process should be fully aware of, and constantly referring back to, the legal and policy context that applies to the area and issues being studied, and the context of the case. Failure to take account of the legal and policy context, and to provide sufficient information to comply with this, may lead to delay and can result in an application being refused or a decision challenged.

7.3 The consequences, in terms of development control/management, will depend on the importance of the ecological features and the significance of effects upon them and the relevant legislation, policy, and guidance.

Legal Implications

7.4 The legal implications arising out of an EcIA should be made explicit and legal advice sought as necessary. Where an EcIA is undertaken to inform an EIA, it is subject to the relevant EIA Regulations.

7.5 The findings of an EcIA are a material consideration in the planning process and other consent regimes. The competent authority must be provided with all the information needed to assess and evaluate the likely significant environmental effects of a project. The competent authority has the duty to consider the environmental information before it reaches a decision regarding the granting of consent. Key aspects of the EcIA report that the competent authority should take into account when determining an application include[118]:

- the soundness of technical content of ecological information including
    - adequate and up-to-date data
    - ecological methods in accordance with good practice
    - departures from good practice made clear
- whether ecological features are likely to be affected and all potential impacts are described adequately
- whether effects are significant and, if so, are capable of being mitigated
- whether the mitigation hierarchy has been applied
- whether it is adequately demonstrated that the proposal will deliver stated outcomes, with regard to likely effectiveness and certainty over deliverability
- whether the measures are capable of being secured through appropriate planning conditions and/or obligations, and/or are likely to be permitted through other consent regimes e.g. licences for Protected Species
- whether the proposals are compliant with statutory obligations and policy
- whether there is clear indication of likely significant losses and gains for biodiversity
- whether any material considerations have been identified that might require changes to the application.

7.6 When determining a planning application, the competent authority should not adopt a 'wait and see' approach. It should not impose a condition requiring further work to identify the likely environmental effects after permission has been granted. It is a well-established principle that the planning authority should ensure it takes account of all material considerations before making its decision (and does not take account of immaterial considerations not relevant to planning). It is therefore crucial that all information about the potentially significant ecological effects of the proposal is available to the planning authority before it grants permission.

7.7 Where the competent authority considers that the information is insufficient it can request further information or evidence to verify the information already provided. Working closely with the decision-maker, statutory bodies and other consultees during the assessment process should help reduce the likelihood of the competent authority needing to do this.

7.8 In the event that uncertainty cannot be resolved, a compelling case may remain for taking forward a project. In these circumstances, a decision has to be taken in the knowledge that there is uncertainty. In such cases, adaptive management, linked to a bespoke monitoring programme, is recommended as a way of ensuring that any negative impacts or effects are addressed in the course of the development and during the subsequent operational phase. This process depends upon ongoing engagement by the statutory bodies and upon regular reporting by the developer and their consultants.

Policy Implications

7.9 All parties engaged in EcIA should be familiar with the national and local policies that are relevant to a project. Key national policy documents that should be considered during EcIA can be found on government websites and local policy documents are usually available on local authority websites.

7.10 If the project being assessed has emerged from the process of preparing a development plan for which a Sustainability Appraisal (SA) or Strategic Environmental assessment (SEA) has been undertaken, the results of the SA/SEA may be relevant to the EcIA. SA/SEA requires the explicit consideration of alternatives to the project, biodiversity objectives and outcomes. These results should be taken into account along with any mitigation measures, recommendations and monitoring.

Implications for Detailed Design and Implementation

7.11 Conditions, planning obligations and legal agreements are often needed to secure and enforce the implementation of mitigation, compensation and enhancement measures outlined in an EcIA. These obligations can be enforced by the competent authority. This can be particularly challenging when the obligations were developed with one organisation but a different organisation implements the consent.

7.12 All parties should understand the actions they need to take during the implementation stages of a project. This will mean identifying and designing in detail the measures necessary to avoid, mitigate and compensate negative effects, and any measures necessary to achieve enhancements. Details of these measures will be set out in the EcIA and may be presented in an Environmental Management Plan (EMP) or similar document.

7.13 The project proposer should demonstrate commitment to the package of mitigation, compensation and enhancement measures. This is most effectively done by proposing to enter into a legally enforceable agreement, such as, in England and Wales, a planning obligation under section 106 of the Town and Country Planning Act 1990, consent /permit conditions in Ireland and/or its equivalent provision elsewhere. It would normally be between the proposer / developer / landowner and the planning authority, with input from the professional ecologist working on the project. The relevant instrument can include specific obligations which may be set out in detail in a schedule, and may take the form of a Mitigation, Compensation and Monitoring Agreement (MCMA) in the UK or a Monitoring Programme/Plan in Ireland. This should include a detailed explanation of what is to be done, how it will be achieved, where and when it is to be carried out, and who is responsible for ensuring that works are undertaken as proposed. The information provided should include:

- summary of the impacts to be addressed, with clear description of whether they will be dealt with by mitigation measures or compensation measures, and explicit reference to supporting data to ensure an audit trail
- details of how the proposed measures will be funded
- location and extent of the proposed measures on scale plans
- a timetable for implementation of design options and integration with phases of development e.g. construction, operation, habitation, decommissioning, restoration

- expertise of persons responsible for implementing design options
- availability and security of land to implement the design options
- a description of all other resources required to implement the design options
- a statement of how design options will be secured within the planning process or consent process
- details of proposed liaison with local experts and how local people can contribute ideas
- supervision during works by an Ecological Clerk of Works or Project Ecologist
- a monitoring scheme to evaluate the success of mitigation measures and/or compensation measures
- remedial measures in the event that mitigation measures and/or compensation measures are unsuccessful or there are unforeseen effects
- proposed auditing/reporting and publication procedures.

7.14 Good practice in major or novel development projects (e.g. port developments) has seen the development of 'Regulators Groups / Committees' that meet at intervals to discuss progress and the outcomes of monitoring that has been undertaken. This sort of arrangement is best suited to major projects that take place over several years. It could be adapted to smaller projects to ensure that there is a formal completion to the project and to the delivery of compensation, mitigation and monitoring associated with the project. Regulator groups are particularly useful for overseeing adaptive management (see 7.8).

7.15 A clear audit trail should be maintained by both the project proposer and the competent authority in relation to the rationale and timescale for mitigation, compensation and enhancement measures and their delivery and monitoring. This is particularly important where the final project is completed by a successor body inheriting these responsibilities.

APPENDIX 1

Example Assessment of the Significance of Effects: Impacts of road widening on a population of Cetti's warblers

Note: The worked example provided below, whilst intended to be as realistic as possible, is fictitious and for illustrative purposes only. Its aim is to show the general principles of how the approach to EcIA recommended in these Guidelines might be applied in practice. The actual values of various parameters and the conclusions reached could differ in a real situation; other parameters could be relevant and other research findings brought to bear.

The scheme proposals and key biophysical changes

The hypothetical road scheme involves widening a 3 km stretch of two-lane road (c. 9.3 m wide) into a dual carriageway with hard strips (final hard surface increase to c. 19.1 m). This scheme is being implemented largely to take traffic out of the centre of a country town. The widening will require the removal of improved grassland in this location. The scheme is located within the county of Cymrent in the west of Britain and is aligned north-south. Once commissioned, the scheme would permit an almost three-fold increase in traffic volume from 9,500 to an estimated 28,000 vehicles per day and an increase in average speed from 80 kph to 100 kph (c. 50 mph to 60 mph). Site clearance would occur over a six week period, and it is intended to complete the construction works within eight months.

Description of ecological features

- The feature being assessed is a local population of five breeding pairs of *Cetti's warblers Cettia cetti.*
- Approximately 50 m to the east of the A road is a 25.5 ha County Wildlife Site (CWS) called 'The Cuts', which runs parallel to the A road for some 400 m and some 640 m away from it to the east. 'The Cuts' supports five pairs of Cetti's warblers (as well as a diverse range of other species including whitethroat, willow warbler in notable numbers and occasional uncommon migrants, which are not considered further here but which might experience similar impacts to the Cetti's warblers). 'The Cuts' comprises six marshy grassland fields, demarcated by ditches and hedgerows on low bunds. These hedges consist of dense stands of blackthorn, bramble, common alder and grey and goat willow. Common nettle and great hairy willow-herb occur densely adjacent to the bunds. There is a 0.5 ha area of open water and a 1.5 ha reedbed at the centre of one field, but due to natural succession this zone is rapidly being invaded by scrub. The territories of the Cetti's warblers are localised along the bunds, extending typically for lengths of up to 400 – 500 m (in four of the five cases along two or three sides of a field) the birds defending areas of hedgerow, ditch and tall marshland up to c. 20 m either side of the mid-point of the bunds. This average territory size is in keeping with that found in other sites in Britain, though there is high variability (see Snow and Perrins 2000). According to the local Wildlife Trust, territories extend neither into the easternmost c. 150 m of 'The Cuts', where the ditches are dry due to the over-abstraction from local watercourses and boreholes for agriculture, nor into the westernmost 100 m or so (nearest the existing road).
- The Cetti's warbler was unknown in the Britain until 1961. Breeding was first recorded in Kent in the early 1970s. This is a species on the northern edge of its European range that is expanding fairly rapidly in population size and geographical extent (northwards) in response to the recent series of relatively mild winters. It is thought susceptible to very cold winter weather and its population in the mid-eastern counties of England was eradicated by some of the cold winters in the 1980s. The current population size is estimated at over 850 breeding pairs (based on numbers of singing males in 2002), two thirds of this population being in the south-eastern counties of England. Wales was colonised from 1980. The population in Cymrent has been estimated at 50 pairs (singing males).
- Male Cetti's warblers advertise territory with loud song sung from deep cover. Recent research has shown that these songs are highly individual and that recognition of specific neighbours occurs.
- 'The Cuts' is accessed by a footpath usable by the landowner and permit-holding members of the local Wildlife Trust and there is a bird watching hide near the reedbed.

Raising the profile of professional ecological and environmental management and promoting the highest standards of practice for the benefit of nature and society.

In the rare instances when tree-nesting does occur, the nest is usually built on a bushy canopy.

Foraging

Marsh Harriers prefer a diversely structured environment, with variation in vegetation height and features such as ditches which offer them the most chances for surprise as they fly over these and suddenly appear at close quarters to prey hidden in them. They therefore tend to avoid large, uniform areas without tall vegetation. The hunting-niche separation of sympatric harriers has been extensively studied in Holland by Schipper *et al.* (1975) in winter and by Schipper (1977) in the breeding season. A clear difference was shown in the height of vegetation preferred for hunting both between species of harrier and between sexes of the individual species. Female Marsh Harriers preferred hunting over wet reedbeds, and males hunted there, too, but they exploited adjoining habitats with shorter vegetation more than the females did.

The habitats surrounding reedbed nest sites are all-important, with farmland species featuring heavily in the diet in some studies. In Flevoland, the dry reedbeds could provide few marshland bird prey, so a preference was shown for hunting in crops (Schipper 1977). Shifts in hunting-habitat preference from reedswamp to arable farmland can take place once there are young in the nest if the arable habitat provides a higher return. Mixed cropping gives even more options. In Norfolk, Sills (1984) found that the pea crop preferred as hunting habitat was far richer in insects than other crops and attracted the juvenile Starlings featuring heavily in the harriers' diet.

Roosting habitats

Marsh Harriers roost predominantly in reedbeds, but, in breeding areas where these are small, autumn communal roosts form in crops. Barley appears to be preferred, but other cereals are used, as are beans, potatoes, sugar beet and other crops. On the coast, alternative roosting habitat is on saltmarsh.

In winter, the presence of other species of harrier in good numbers often seems to draw Marsh Harriers into dry habitats such as grassland for roosting purposes, and even onto bare ground. I regularly saw several Marsh Harriers at a roost predominantly of Montagu's and Pallid Harriers in dry grassland in Gujarat, north-west India. The roost peaked at 2000 birds, the largest harrier roost recorded in the world in recent times (Clarke in press b).

Meinertzhagen (1956) reported a group of 66 migrant male Marsh Harriers roosting together for one night on ploughed land in Afghanistan. In eastern India, Donald (1905) witnessed a roost of 'crowds' of Marsh, Pallid and Pied Harriers on bare ground. He concluded that they were not passing migrants, as they scattered in all directions in the morning.

On 22 January 1993, I was taken to a communal harrier roost in the Little Rann of Kutch, a desert in Gujarat, north-west India. The roost site was 1–2 km inside the desert, where the ground is flooded by the sea in the monsoon, but dries out from about September into a flat surface of cakes of salty mud. Arriving at the roost six minutes after sunset, we counted 11 harriers already standing on the desert; 20 minutes after sunset there were at least 20, but our position was rather too distant from the main concentration to make a satisfactory final count. The following evening we positioned ourselves more centrally and our final count was 30 harriers: about 20 roosted in one main group spread over about 500 m of desert, with several outliers, mostly in a small, loose sub-roost a further 500 m away. Those close enough to be identified by telescope were as follows: Montagu's Harriers – 3 adult females, 7 adult males; Pallid Harrier – 3 juveniles, 1 adult male; Marsh Harrier – 7 adult females or juveniles. This roost was not just a temporary phenomenon, since our guide, Anil Mulchandani, had found similar roosts in the area both the previous winter and earlier that same winter. In the absence of vegetation in which to hide, the harriers clearly must rely on their hearing to protect themselves at night. The dried mud had in many places formed a crust of small 'tiles' with raised edges and separated by cracks;a human foot spanned two or three and produced a crackling sound as weight was put onto it. Mammalian predators must also find it difficult to walk silently on this

6

BREEDING BIOLOGY

Age of first breeding

Some immature Marsh Harriers remain on the wintering-grounds in Africa or India in summer. Others colonize unoccupied or newly developed breeding habitats and some fill vacancies in the adult breeding population. In many raptor species, females are recruited into the breeding population earlier in life than males. Reliable information on the ages of breeding female Marsh Harriers is difficult to obtain by observation alone, since their plumage can be difficult to age. With males the position is clearer: full adult plumage is reached in their third or fourth calendar-year, and the age of younger birds can be gauged by their plumage (*see* Chapter 2). Although many sub-adult males are predominantly brown above, their light underwings are soon obvious, and it is uncommon to find a male Marsh Harrier beginning to breed in true juvenile plumage with mainly brown underwings. However, this does occasionally happen, probably mostly at new sites where there is no competition from established males. For example, the male of the first pair to breed in Cambridgeshire in the twentieth century was in brown plumage and gradually moulted into dingy male plumage during breeding. Several young males have been noted breeding in the initial stages of the new semi-colony on the Isle of Sheppey in Kent (P. Hadrill, pers. comm.). As a general rule, older males return earlier to the breeding-grounds, begin the breeding cycle earlier in the year than immature birds, and have greater success (Altenburg *et al.* 1987).

The age structure of the Marsh Harrier summering population seems to vary between the north and the south of Europe. In the Camargue, Thiollay (1970) recorded that, of a sample of 330 observations in spring, only about 28.5 per cent were of adult birds. He estimated that about 30 immatures were present in the area containing up to seven or eight breeding pairs, a predominance which may be more typical of marshes in southern Europe. Altenburg *et al.* (1987), who studied the evolution of a population which began to colonize Lauwersmeer polder in the Netherlands in 1969, found that when habitat first became suitable for breeding younger males predominated, but not in later years. They assessed that up to 20 non-breeding Marsh Harriers in immature plumage were present throughout the breeding season with up to 72 pairs which were breeding, indicating that about 12 per cent of birds present were non-breeding immatures. In Poland, Witkowski (1989) noted only 1–3 unmated territorial males in subadult plumage and up to five unpaired juvenile females among 30–50 breeding pairs. Observations in one well-recorded area in east England in 1988 suggested that about 34 per cent of the summering population were non-breeders

there (Rare Breeding Birds Panel). For Britain, over the period 1947–80, Underhill-Day (1984) found a highly significant correlation between non-breeding summering birds and the number of breeding attempts in the following year. This may be expected in a recovering population.

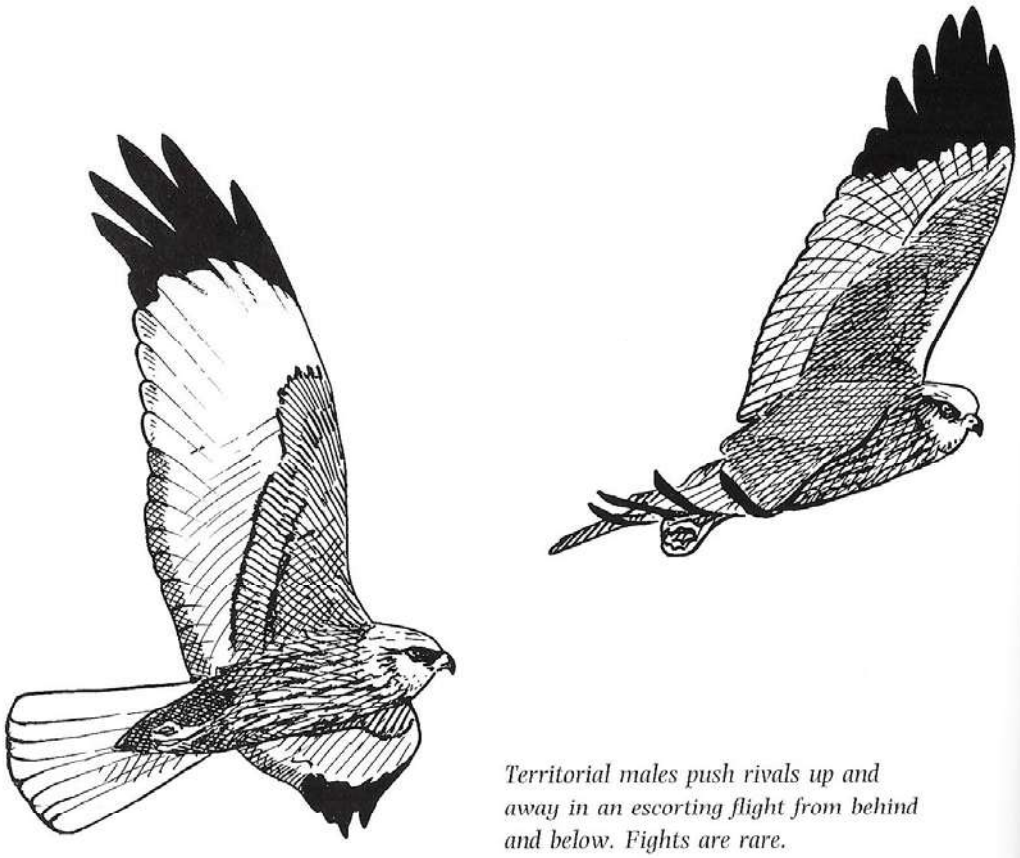
Timing of the breeding cycle

The Marsh Harrier begins to nest earlier in the year than other harriers. This follows the general rule among raptors that larger species begin their longer breeding cycles earlier.

They return to breeding areas north of the wintering range from mid March to early May, depending on latitude (Glutz von Blotzheim *et al.* 1971). On the east coast of England individuals take up territory from March. The passage of migrants brings new birds into sites until mid May and stimulates territorial behaviour. In western Poland, Witkowski found that the return of males peaked at the end of March, but that of females in mid April. Bengtson (1967) in Sweden found that males usually return ten days before females. Spring migration statistics from the Mediterranean show that males migrate significantly earlier on average.

Courtship commences immediately the birds return, and the nest is normally built in about 2–3 weeks. Incubation begins with the first egg and lasts about 33 days. The young hatch asynchronously and stay in the nest for about 28 days. They are brooded continuously by the female for the first few days but gradually become more mobile and venture into the surrounding vegetation, returning to the nest to be fed. From about 28 days, the young can fly, but mostly sit about in the vicinity, typically on bushes; from about 45 days they fly around more but are still fed; from about 73 days they are more independent.

A clear relationship can be shown between latitude and the mean date of commencement of the clutch. In Spain and the south of France, many pairs begin laying in early or mid April. In England, the Netherlands and Poland, all at about the same latitude, the second half of April is the normal time, and farther north, in Scandinavia, clutches are begun in the second week of May. There also appears to be a differential between coastal and inland sites. I have suspected this from casual observation at the few inland nests in England, and Hildén and Kalinainen (1966) measured this in Finland, where the mean first laying date was 9 May on the coast, but 14 May inland. Schipper (1979), Witkowski (1989) and González (1991) all established that laying date was influenced by temperature. Laying began a few days after a rise in temperature, but only at the right time of year and if there was not a subseqent sharp cold spell. The rule put forward by Schipper (1979) for the Netherlands was as follows: 'The first date after 9 April with a temperature of over 4 °C followed by at least two days of temperature rise, whereas on the third or fourth day the temperature should not fall more than 28 per cent.' Apart from the obvious benefits of laying eggs in warmer, more settled temperatures, the key to this rule probably lies in the sychronization of breeding with the peak availability of young of waterfowl and other prey.



8

TERRITORIAL BEHAVIOUR

The numerical strength of the Marsh Harrier breeding population pivots on the capacity of available marshland, a scarce resource. Spatial strategy is therefore highly important for this species. Harriers in general tend to nest in clumps or 'semi-colonies' but hunt individually, ranging out extensively over surrounding land. This arrangement effectively maximizes the capacity of scarce nesting habitat. The Hen Harrier and Montagu's Harrier also breed in marshes, but not nearly as exclusively so as the Marsh Harrier, and the tendency of Hen Harriers, for example, to nest in semi-colonies in one area of a wide tract of seemingly uniform moorland habitat indicates that there may be some additional factor to clumping. The basing of non-breeding activities on a communal roost site is a similar spatial arrangement used by most harriers, but winter communal roosts are also known in solitarily nesting species of raptor.

Breeding density seems to be less in the Marsh Harrier than in the smaller Hen and Montagu's, perhaps as a result of its larger size and more restricted habitat preferences which limit numbers and require greater spacing of nesting pairs, especially in the early stages when the birds spend more time in the breeding marsh. Breeding density, however, can be as high as a mean inter-nest distance of 100 m (Berg and Stiefel 1968), in effect a loose colony. Witkowski (1989) recorded a mean annual density of down to 26.5 ha per pair within the area used by Marsh Harriers for nesting, with a mean distance of 210 m between nests in the wider reedbeds along the shore. In the Czech Republic and Slovakia, Danko et al (1994) found that marsh habitat was used very intensively in dry years, with nests often only a few tens of metres apart.

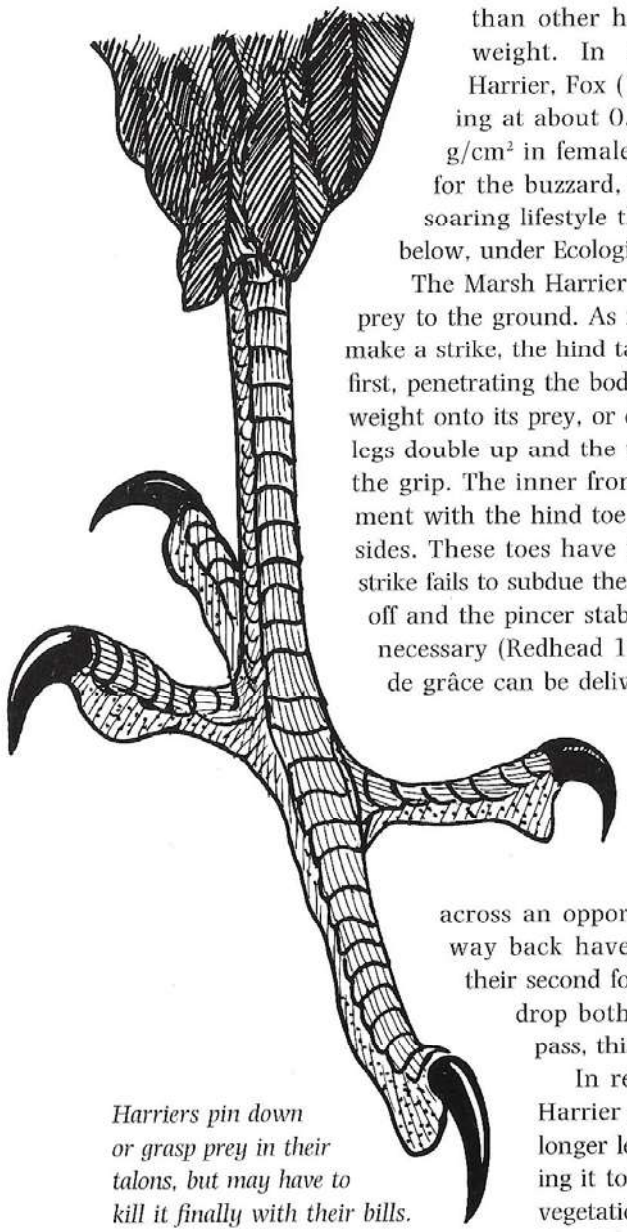
During the courtship and incubation periods, activity is concentrated on the breeding marsh. Territory size is at this stage typically small – a radius of 100–300 m around the nest – and the male spends a lot of time in early spring patrolling this and defending it against all perceived enemies such as crows and predatory mammals. The defence of territory against rivals varies in intensity, eliciting responses varying from threatening to escorting and to attacking. Moles are the most frequent defenders of territory against other Marsh Harrier but they are more tolerant of female intruders early in the season (Fernández and Azkora 1994b). Behaviour involving actual contact is rare. Escorting takes the form of following, chasing or 'pushing' the intruder up or away out of territorial airspace. Flying with legs lowered is a form of threat used to maintain territorial boundaries and if possible to avoid potentially damaging contact. This was reviewed in various territorial predatory

Territorial males push rivals up and away in an escorting flight from behind and below. Fights are rare.

birds by Barnard and Simmons (1986). Occasionally, this demonstration will escalate into a fight, and, as in play, an attacked bird's reaction is to flip over and present talons, and rarely the two will actually grasp each other by the talons and fall to the ground. Observing this in the African Marsh Harrier, Simmons (1991a) recorded that 'these encounters lasted 1–7 minutes, while the birds were presumed fighting or locked together on the ground'. At Horsey, Buxton found that some male Marsh Harriers were particularly pugnacious and one year he found the corpse of the first male to arrive in spring floating in the dyke under its preening post, 'no doubt slain by his rival who apparently lost a wing feather in the process'.

Once the young are hatched, the males abruptly extend their activities beyond the nesting territory by making long foraging flights into surrounding, often marginal or arable, land. The reason for this is very clear. Unless a particularly rich source of waterfowl is available, marshland hunting is not very productive. At Titchwell in one season, Sills (1983) observed that it took a male an average of 27 minutes to catch prey in the marsh, and it was likely to be a small item such as a fledgling passerine; prey was caught every 17 minutes on average on farmland and was usually a much heavier young Pheasant, Rabbit or Starling. Sills calculated that farmland was ten times more productive in terms of weight of food per minute of hunting. Elsewhere in East Anglia, Underhill-Day (1989) established that the size of

the hunting range of a male was very much larger during the nestling stage than it was earlier or later.



The males tend to hunt sectors of the compass based on their nest. Some researchers have found that such hunting territory is defended against other Marsh Harriers (Sondell 1970). Others maintain that it is not unusual for the hunting ranges of neighbouring males to overlap and that hunting territories are not defended.

How far might a harrier range from the nest? Maximum hunting distances from nests by male Marsh Harriers were recorded by Schipper *et al.* (1977) in Holland and France at only 1.5 to 3.1 km, females ranging only 1.4 to 1.8 km; they quoted other researchers as recording 5–8 km. In Cambridgeshire, where nesting pairs have had no near neighbours, I had one observation of the Wicken Fen male well away from the nest: one lunch-hour in 1985, at about the end of the harriers' incubation period I spotted him coursing low over the reeds of a marsh 12 km south of Wicken; he soon circled up in the sunshine and made off south, away from Wicken! There was no doubt that it was he – the same two inner primaries missing with no sign of regrowth and one or two tail feathers cut off short (shot damage acquired on migration?). On a separate occasion he was seen at another marsh 10 km east of Wicken.

The sizes of hunting ranges quoted by Schipper *et al.* vary from 250 to 680 ha for males and 80 to 370 ha for females. At Titchwell, hunting ranges out over arable farmland, inland of the coastal breeding marsh, were measured for individual males in 1982 and 1983 at a much larger 1250 ha and 1000 ha respectively (Sills 1988). Elsewhere in East Anglia, Underhill-Day (1989) calculated 217 ha during the courtship stage, 170 ha during incubation, 1112 ha during the nestling period and 310 ha during the fledgling period. In Poland, Witkowski (1989) calculated a far smaller mean area of 125 ha of arable fields and meadow plus 35 ha of fishpond used by each pair in a large semi-colony, with up to 50 pairs using 80 km^2. It seems clear that, so far as range sizes go, it all depends on the habitat, prey density and the stage of the breeding cycle.

Adaptations

The light structure and long wings of the harriers are adaptations to prolonged searching on the wing. Wing-loading measurements (weight of bird divided by wing area) for the harriers are much lower than those for raptors of similar size other than the kites, which are also very aerial birds. Harriers range from about 0.21 g/cm² in the smaller species to 0.30 g/cm² in the Marsh Harrier (Brown and Amadon 1968). Even a relatively heavy harrier such as the Marsh Harrier has a far lower wing-loading than, for example, the Common Buzzard at 0.45 g/cm². The Marsh Harrier has a shorter tail and smaller flight apparatus than other harriers, in relation to body-weight. In the New Zealand Swamp Harrier, Fox (1977a) calculated wing loading at about 0.39 g/cm² in males and 0.41 g/cm² in females, values approaching those for the buzzard, whose less active and more soaring lifestyle they were converging on (*see* below, under Ecological release and change).

Harriers pin down or grasp prey in their talons, but may have to kill it finally with their bills.

The Marsh Harrier normally kills by pinning its prey to the ground. As it pounces and reaches out to make a strike, the hind talon or talons generally arrive first, penetrating the body of the prey. Falling with its weight onto its prey, or clutching it to it, the harrier's legs double up and the tendons inside pull to tighten the grip. The inner front toe acts in a pincer movement with the hind toe to pierce the prey from both sides. These toes have the longest claws. If the first strike fails to subdue the prey, then a foot can be lifted off and the pincer stabbed in again, several times if necessary (Redhead 1969). Alternatively, the coup de grâce can be delivered with the bill, but not as a matter of course as the falcons do. In the breeding season, prey is generally carried back to the nest secured in one foot, and harriers that come across an opportunity to kill again on their way back have been known to strike with their second foot. If a male then proceeds to drop both prey to a female in a food-pass, this can cause problems!

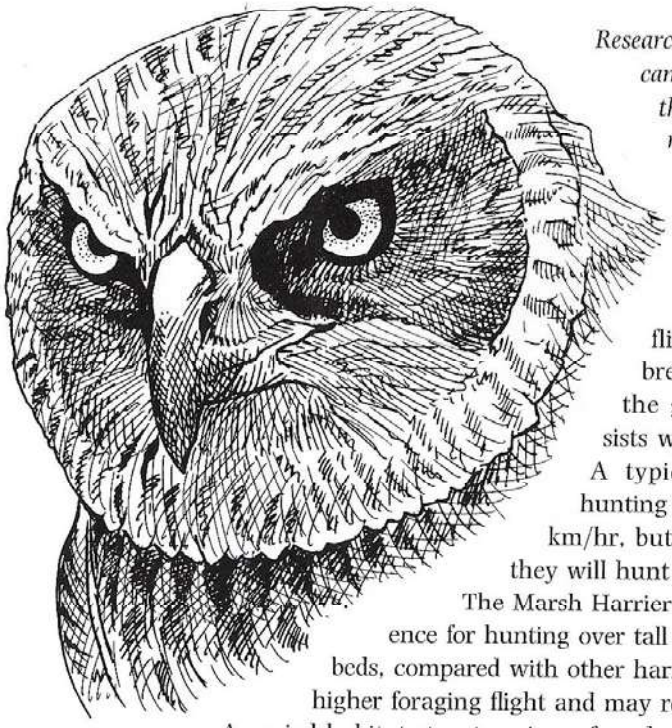
In relation to its size, the Marsh Harrier generally has larger feet and longer legs than other harriers, allowing it to reach down into long marsh vegetation for prey. The one exception

is leg length in eastern Asia of the Pied Harrier, which proportionately exceeds that of the Eastern Marsh Harrier there and is also thought to be an adaptation for reaching into deep marsh vegetation (Nieboer 1973). The large feet of the Marsh Harrier indicate greater killing capability for its body size. Comparison of the foot size of a male Montagu's Harrier and a female Marsh Harrier demonstrates the range of capabilities within a genus of birds which appear relatively similar in size in the field. This is a clue to their niche separation by size of prey.

The harrier bill reflects no special adaptation. It is again larger in proportion in the Marsh Harrier. This enables it to deal better with the larger prey its larger foot size allows it to catch, and with prey relatively difficult to tear or break open, such as fish, amphibians, reptiles and crustaceans. It also allows it to compete better at carrion. A side view reveals a very pronounced protruding hook to the upper mandible, which is used for tearing food.

Harriers hunt both by sight and by hearing. The forward-facing eyes allow good judgement of distance at the moment of pouncing on prey and major anatomical adaptations have enhanced the directional quality of their hearing, probably making it as important as their eyesight. It is this which determines much of their distinctive lifestyle and makes them harriers. For birds of their size, they have very large ear openings, set in facial discs. The supraorbital ridge forms the effective top to the half-disc, giving the face a fierce expression from some angles. The ridge may also protect the eye from glare, or when attacking prey. The external structure of the facial disc is very specialized. The ruff curves around just behind the ear opening and below the cheek. It is made up of a ridge of skin set densely with stiff perpendicular feathers, curved back with the general lie of the plumage only towards the end of their length. Highly specialized in form, the barbs are very dense and are knitted together by abundant barbules, giving these feathers a silky appearance which reflects light and makes the ruff conspicuous. In the male Marsh Harrier plumage, they are less pigmented and stand out all the more. Lifting the ear-coverts of a Marsh Harrier reveals an oval ear opening approximately 12 mm long and 9 mm wide. The opening begins about 15 mm behind the eye and the forward rim is raised, meaning that sounds tend to enter from behind, by reflection off the ruff of feathers. The ear-coverts lie back flat over a bare cheek and the ear opening, and are also finely adapted, with well-spaced barbs and blunt barbules, with the result that the vane does not knit together as in any normal feather, thereby allowing sound waves to pass through easily whilst still preventing the admission of particles of dirt borne on the wind. The feathers of the various parts of the disc are independently mobile, with their own musculature and nerves, allowing the harrier to direct sound into the ear by lifting feathers and altering the shape of the disc.

So, how exactly are these anatomical features used? In the owls, similar adaptations are for pinpointing prey in darkness, whereas in the harriers they are for pinpointing prey hidden by rank vegetation. The owls differ in that their ear openings are positioned asymmetrically and enable them accurately to gauge the source of a sound not only on the horizontal plane, by turning their head to equalize the amount of noise in each ear, but also on the



vertical plane. The lack of asymmetry in the harriers does not drastically cut down their directional hearing ability, however, and it may not be that critical, since in many situations the harrier can use its eyes at the last moment as it appears suddenly over the vegetation, on the correct horizontal course for the prey. An American scientist, William Rice (1982), tested the hearing of the Northern Harrier in laboratory conditions and found that it was almost equal to that of Short-eared and Barn Owls on the horizontal plane. Also working in the laboratory, Van Dijk (in Nieboer 1973) confirmed that the hearing abilities of Montagu's, Hen and Marsh Harriers were better than those of Common Buzzard, Goshawk and Kestrel. The Marsh Harrier therefore has these listening adaptations, but they may be less pronounced than in other harriers and the Marsh Harrier clearly must use them less because it tends to fly higher, giving better vision into tall vegetation but increasing the range for hearing purposes.

It would appear that the harrier's facial discs gather sounds in much the same way as a parabolic reflector. Recent laboratory research on the coding of sound frequency and location in the brain of the Swamp Harrier, however, has found that the upper limit of response is to tones of about 4 kHz (Calford *et al.* 1985). Calculations of the point at which a facial disc of the size of the harrier's would become directional suggest that this would start only at about 4 kHz, meaning that the disc is too small to have a significant effect on the sound field in the harrier's audible frequency range. Although perhaps too much should not be read into this until it is confirmed by other studies, further research should prove very interesting indeed. The harrier's adaptations with regard to the facial disc and ruff are so similar to those of owls that it is almost inconceivable that they have a different function, but research has already found that the owls' methods of processing sounds in the brain may be quite different.

The sexual dimorphism in plumage of the Marsh Harrier may be significant from a hunting point of view. The much paler underside of the male may give better camouflage against the light sky in the more open situations where he encounters prey. Such camouflage could be less important for the female, as her hunting technique relies more on outright surprise in the more structured habitats in which she prefers to hunt.

Foraging techniques

Marsh Harriers typically fly over likely terrain at 2-6 m above ground level, cold-searching for prey beneath them. The height of flight seems to be linked to the height of the vegetation (Schipper 1977), with taller vegetation requiring higher flight to reduce the angle of vision for the harrier to be able to see down into it. Harriers use a low approach, screened by the vegetation or some other low obstacle. The technique is geared to surprising and closing on prey effectively at the first encounter. Marsh Harriers are not well adapted to give chase; they will go after running prey in the open with some expectation of success, but rarely pursue flying prey. The harriers' typical mode of flight, flapping for a few wingbeats but then gliding may be significant. This produces a rising and falling cadence to their

Research has shown that harriers can pinpoint prey solely from the noise it makes. The stiff ruffs of feathers behind the owl-like facial disks direct sound into large ear openings hidden by flimsy covert feathers.

flight, especially in a stiff breeze, and it may be that the glide on still wings assists with stealing up on prey. A typical flight speed for a hunting Marsh Harrier is 20–30 km/hr, but in some circumstances they will hunt more slowly.

The Marsh Harrier shows a greater preference for hunting over tall vegetation such as reedbeds, compared with other harriers. It has a noticeably higher foraging flight and may rely more on visual cues. A varied habitat structure is preferred, with abrupt changes in height of vegetation and other obstacles, giving more opportunities for surprise as they are flown over. Examples are ditches, verges, field edges etc., linear features that are followed by harriers. A harrier may hunt a promising patch of rank vegetation by the more thorough 'quartering' technique, changing direction frequently and flying over the patch several times. It may fly into the wind over part of the habitat, then rising up and quickly gliding back as its wings catch the wind; it then flies back low across the habitat into the wind again while carefully searching for prey concealed in the vegetation. A headwind allows the harrier to remain in control while reducing both its speed, to allow a more thorough search, and its altitude, to allow it to strike more quickly.

The heavier and less agile female Marsh Harrier appears to profit from the greater opportunity for surprise that really tall vegetation such as reeds gives her. Also, as a less manoeuvrable bird, she is not able to react so nimbly to catch prey that she comes upon at very close quarters. Dropping down into reeds that confine prey may give her more latitude, and combined with a slower speed of hunting flight at greater height, reedbed hunting is most typical of the female. Flying into the wind; at times the harrier seems to remain virtually at one spot, clumsily hovering where its interest is aroused. Males are more often seen hunting low and over shorter vegetation. The Marsh Harrier's slower hunting flight, especially that of females, means that it covers less ground than other harriers, but works it more thoroughly. In the breeding season, females hunt mainly on the nesting marsh, but males do tend to range further afield over the other habitats which they are better adapted to exploit.

Often, a Marsh Harrier will test a flock of waterfowl feeding out in the open, leisurely flying at and flushing them, in effect testing for the weak and slow. Hunting for passerine birds requires a fast approach. In Norfolk,

Male hunting over rough grassland. The rank vegetation helps to conceal his approach from potential prey and the light fore-edge to the wing breaks his outline.

flocks of juvenile Starlings feeding out on farmland in late summer are a favourite target. A male Marsh Harrier will fly fast and low towards them, if he is successful seizing one on the ground or in flight (Image 1991). Fast hunting, however, is not commonly used by the Marsh Harrier.

Flying low, harriers often cannot react to prey until they are already passing over it. A 'roll-pounce' as the harrier stalls, spreading its tail and cartwheeling back to dive feet-first at prey is typical; but the strike can also take the form of first hesitating or hovering, and then sideslipping through the air to drop straight down on to the prey, legs outstretched and wings held up. Hesitations in flight/feints occur at some height, but can be quickly checked if the harrier perceives that it has made a mistake or it has no chance of success because the prey has bolted. Stooping at prey and diving to flush it out are rarer, but tactics can become quite cheeky: a Marsh Harrier will occasionally knock a female Pheasant off her feet or even settle on her back, intent on stealing a chick. Harrying of waterfowl such as Coot is common. The waterfowl take to open water at the approach of a harrier and dive if necessary. Defensive behaviour such as grouping, turning on their backs and kicking out has been observed in Coots (Harris 1973). Deliberate holding-down or drowning of smaller waterfowl does occur, Hollands (1984) recounting how one determined Swamp Harrier forced a Coot to dive over and over again until it was exhausted and could be seized. The carcase then has to be retrieved from the water, but it may prove too heavy; in India I have watched Marsh Harriers attempt, unsuccessfully, to lift a waterfowl carcase out of a lake. Hunting prey in the water can also be dangerous, as shown by the drowned Swamp Harrier recovered with its talons embedded in a dead Australian Darter's neck (Vestjens 1972).

It is not generally in harriers' nature to still-hunt in the way that, for example, a Kestrel, Sparrowhawk or Buzzard will – sitting on a vantage point watching for prey and then going for it when it appears. Occasionally, especially where voles are numerous, harriers will 'ground-hunt' – sitting in quite short grass and then leaping on a vole when one appears (Schipper *et al.* 1975). At Minsmere, late one February, King (1961) observed a pair of Marsh Harriers jumping on to tussocks and eating small items in them. On another occasion at Minsmere, Clegg (1961) saw three juveniles attempt

ground-hunting, making short bounds with wings flapping, sometimes making a further hop and landing with wings spread, and appearing to miss small items of food. The description of this activity agrees with Cheke's (1987) description of a brood of young Réunion Harriers on the bed of a drying-out lake taking small unidentified items after a 'hop, skip and jump'. Ground-hunting was recorded by Baker-Gabb (1984) as a hunting method of very minor importance for the Swamp Harrier.

The harriers' cold-searching foraging methods and lack of chasing over long distances or stooping make them generally unsuitable for falconry,

To strike, a foraging Marsh Harrier typically spreads its tail to stall, cartwheels over and dives feet-first on prey.

A harrier may hesitate where it detects a potential prey which has taken refuge in deep vegetation, feinting strikes and choosing the moment to press one home.

although the Swamp Harrier has been successfully trained by traditional falconry methods and flown at Rabbits in New Zealand (Wheeldon 1981, 1992). A lot of effort was necessary, though, including selection of harriers which would concentrate on the matter in hand (found to be females 2–3 years old), training harriers to progress from easy young Rabbits to the adults, and flushing or successfully ferreting out Rabbits from their holes. Wheeldon remarked: 'countless hours were spent in the field, but successes were few'.

Strike success rates

Hostile accounts of birds of prey often give the impression that they easily kill everything they go after, well in excess of their food requirements. In actual fact, studies of hunting in a wide range of birds of prey have come up with rather low success rates, typically 5–10 per cent. Rates are difficult

to measure for the Marsh Harrier because the dense vegetation in which it hunts can conceal the outcome, although the birds usually soon fly up with prey and carry it at least a short distance to a place where they feel comfortable dealing with it. Schipper (1977), from observation of birds in Holland and France in the breeding season, calculated success rates ranging from 5 to 17 per cent; Underhill-Day (in Clarke in press a) calculated an unusually productive success rate of 27 per cent by six males and one female in the breeding season in East Anglia. Hunting activity is normally reduced or curtailed by rain. This and the effects of wind speed and temperature on success remain to be fully quantified. Schipper (1973) established that rain and stronger winds reduced the rate of prey supplied to the nest.

Kleptoparasitism

Marsh Harriers have stolen a fish from an Osprey (Persson 1971), a Teal from a Peregrine (Williams 1995) and robbed Hen Harriers of prey (Schipper 1977). At Horsey in 1947, Buxton noted a polygynous male Marsh Harrier stealing prey from a widowed female and a pair of Montagu's Harriers; it 'dashed at the hen Montagu and bagging her prey swept off with it in the direction of his own nests'. Baker-Gabb found that Australian Swamp Harriers were dominant in kleptoparasitic encounters, robbing Whistling Kites and a Peregrine Falcon, and repelling the great majority of attacks by Whistling Kites, Little Ravens and a Brown Falcon.

Monitoring food

In the breeding season, the diet of birds of prey is determined from observations of food brought to the nest or by identifying prey remains at plucking places and in pellets. Older studies sometimes relied on the stomach contents of shot birds.

Identification of the prey species by direct observation from a hide is not so easy as might be thought, because the action can be fast. Also, items brought to the nest may not be whole and a good view may not be obtained. Observation from greater distances may allow approximate classification of prey by size alone. The accurate identification of prey remains in harrier pellets requires skills in identifying principally feathers, fur and rodent teeth, but the greatest problem in the breeding season may be in obtaining enough pellets to give a large enough sample. In winter, harrier pellets can be obtained in good quantities from some communal roosts, but tides or winter floods can wash them away and flooded reedbeds can be impossible for a human to search.

Breeding-season diet

The accounts handed down to us by Buxton of food taken in Broadland indicate some specialization by individual harriers, but show that the commonest prey was Moorhen, with leverets and young Pheasants the next most frequent. Young Moorhens, partridges, Pheasants, buntings, a Blackbird, a Starling and a frog were all found over a period at one food

cache. In other years, adult Grey Partridges were found at one nest, small Coypus at another, and Moles were noted at a third.

Hosking (1943) made a useful record of the prey brought to a nest at Hickling in 1942, although he regarded it as incomplete since smaller items may have been immediately swallowed whole and gone unrecorded: 71 young birds comprised Pheasants (29), Grey Partridges (21), Red-legged Partridges (8), Meadow Pipits (7), Moorhens (2), Mallard (1), Lapwing (1) and unidentified passerines (2); the mammals comprised Rabbits (15), leverets (7), Field Voles (7), Water Voles (5) and a young rat (1). At Minsmere, Axell (1964) cited Rabbits, very small Coypus, Water Rail and young ducks, Moorhens, Coots, Lapwings, Snipe, partridges and small passerines (Starlings and Yellowhammers).

Recent studies of breeding-season diet in Britain have carried out by Norman Sills and colleagues at Titchwell Marsh, Norfolk, looking at two or three nests each year (Sills 1984), and by John Underhill-Day and volunteers on reclaimed farmland in East Anglia (Underhill-Day 1985). At Titchwell, prey seen to be taken by a male harrier were mainly Starlings one year, owing to the abundance of young Starlings feeding in flocks, and young Pheasants the next, the latter taken in situations where broods had wandered into a field, away from the hedgerow; young Rabbits were also a significant prey. The female took generally larger prey, which she brought to an area of rough, flattened grass for dissection before taking them into the nest. Observers were able regularly to collect remains from the place. A seasonal pattern was noticed with Field Voles taken in May, Moorhens in June

Marsh Harrier pellets from a winter roost on saltmarsh.

and July, and young Rabbits in July. A few partridges, ducklings and passerines, notably Skylark, were taken.

Underhill-Day's study showed a wide variety of prey; adult small passerines and mammals (mostly Field Voles and Rabbits) were predominant in the diet in April–May, but young gamebirds (mostly Pheasants) and waterbirds (mostly ducklings and Moorhens) increased in importance thereafter

In the breeding-season diet elsewhere, Schipper (1973) found that the important categories were young waders and Pheasants, and the larger mammals in Holland, but largely passerines with some waterbirds and larger mammals in northern France, and snakes and larger mammals in southern France. Observations were made of Marsh Harriers eating the eggs of ducks and gulls, but these were not of course visibly represented at the nest. In the Camargue, Thiollay (1970) found the principal foods to be frogs, fish and young waterfowl; eggs, reptiles, small mammals, rats, young Rabbits and, to a lesser extent, small passerines also featured. In Spain, González (1991) found that Rabbits made up 46 per cent of the breeding-season diet, with the rest spread over many categories, none of them approaching Rabbits in importance. Work in Poland, on three pairs of Marsh Harriers nesting at a Coypu farm, showed that the males fed mainly away from nesting marshes on rodents and open-country small passerines, whereas females fed mostly in marshes, on the birds there (Pinowski and Ryszkowski 1961). Predation on young Coypu was found to be negligible, as most hunting took place early in the day whilst Coypus were active in the evening. Witkowski (1989) recorded a significant amount of dead carp (10.5 per cent by number) in the diet at a complex of fishponds in western Poland, Common Vole (14.4 per cent) and Coot (12.4 per cent) among a very wide range of birds (60 per cent), mammals (28 per cent), fish (10 per cent) and frogs (2 per cent); eggs were important early in the season, but could not be quantified. Again, the females hunted the ponds and marshland for large prey and the males concentrated on the meadows and arable fields for smaller prey. In the post-fledging period, as the young of marshland prey species grew up, attention was shifted more to farmland for hunting, especially for voles. In Schleswig-Holstein, Bock (1978) found that the numbers of a wide range of largely small passerine birds taken fell dramatically in a good vole year in favour of the Common Vole. Other prey were negligible in importance, but again a taste for eggs was noted.

Witkowsi (1989) described how the shells of eggs eaten by Marsh Harriers were left with a small hole and claw marks. Egg-eating was actually witnessed by Tom and Pam Gardner (1984) in Australia, where Swamp Harriers were prospecting an ibis colony and a harrier dropped on a temporarily unattended nest, mantling the eggs and scaring neighbouring ibises away. Opening its gape wide, the harrier was able to pick up an egg and drop it on the others to crack it; it then opened it up with its bill and ate the contents. It treated all five eggs similarly and then did the same to a nearby clutch of four eggs, before wiping its bill on the nest and flying off.

These results demonstrate the wide spectrum covered by the breeding-season diet of the Marsh Harrier, tuned to the most profitable prey vulnerable at the particular place and at the time.

Access management

Although nest sites in reedswamp can be protected from human access relatively easily, the effect of open access to surrounding habitat is to reduce the usable hunting ranges for the harriers. This can be particularly detrimental if the areas affected contain optimum foraging habitat, and also later in the breeding season, when tourism increases at the same time as the food requirements of Marsh Harrier young reach their peak. In a study on the Neusiedler See in eastern Austria, which has one of the most important Marsh Harrier populations in central Europe, the harriers would fly no closer to visible tourist activity than an estimated 90 m in the open; routes frequently used by cyclists and walkers created a no-go corridor for Marsh Harriers 240 m wide, severely limiting the prime foraging habitat available to them (Gamauf 1993). Appropriate screening of paths and other areas of open access is therefore of paramount importance in reserve design. At Titchwell Marsh, a very heavily visited RSPB reserve in Norfolk with unscreened paths alongside the freshwater and tidal reedbeds, Sills (1983) found that Marsh Harriers would not build closer than 450 m to a path and on average sited their nests 600 m from the footpath to the west and 800 m from that to the east; this was in response to a regular and at times constant flow of people. Because of the proximity of so many nest sites to sea walls, the Marsh Harrier may be vulnerable to disturbance from leisure developments such as long-distance coastal footpaths.

Protection schemes

Although undoubtedly responsible for the total extinction of the species as a British breeding bird at the turn of the century, persecution is currently not a big problem for the Marsh Harrier in Britain, but it could become more of a limiting factor as numbers increase. In the ten years up to 1988, 22 incidents of persecution were recorded (Underhill-Day in Gibbons *et al.* 1993); most individuals were shot, trapped or were the victims of the indiscriminate use of poisoned baits. Two recovered at Snettisham in north Norfolk in 1985 were suffering from gunshot wounds. The species is prone to the illegal and careless use of poison, since it comes readily to both carrion and eggs, which are the principal vehicles used for poisoned baits. The setting of unprotected poison baits in the open is illegal in the UK. In 1980, the male of the first pair to attempt nesting in Scotland for many years was found poisoned (Buckland *et al.* 1990). Unrecorded persecution in the form of intentional disturbance of birds interested in breeding may be a problem in some areas.

Game interests are concerned with the impact of raptor predation on lowland gamebirds, which do form a proportion of the food of the Marsh Harrier. Calculations based on brood-size counts of Mallard, Pheasant and partridges in one study by Underhill-Day (1989) indicated that many of the chicks taken by Marsh Harriers would have died before reaching maturity. The number fledged was reduced by about 13 per cent for Mallard and 11 per cent for Pheasant. He recorded very few partridge chicks taken, perhaps because they stay closer to cover at field edges than Pheasants do. Delaying release until Pheasant poults are of a good size and the peak food demands of breeding Marsh Harriers

The interface of leisure activities and harrier breeding habitat requires careful management. Marsh Harriers are notoriously prone to deserting their nests.

are well past would be a good management strategy; effective cover for poults would also reduce predation. Calculating the losses of gamebirds to raptor predation entails a great deal of work in recording the large number of variables: food delivery rates in each phase of the breeding cycle, diet composition, hunting-range size, gamebird density, and brood sizes of both predator and prey.

Any prejudice against raptors cannot effectively be met by enforcement of the law alone. The requirements of the species in the modern landscape must be frankly discussed between landowners and ornithologists on the basis of sound scientific data and an acceptable position be reached by means of manipulation of the habitat.

In recent years, about half the British Marsh Harrier population has bred in nature reserves or under some form of wardening scheme. The RSPB has wardened a number of vulnerable sites off nature reserves, especially in west Norfolk (where a few pairs of Montagu's Harriers also breed), and in Somerset, for example, the Hawk and Owl Trust has combined with the county Wildlife Trust to warden Marsh Harriers. Routine farming operations are a threat to crop-nesting harriers, making it necessary to keep track of locations of nests and to liaise with the farms involved. Spraying during incubation appears to cause no harm if the nest is avoided by the tractor wheels! Later, the young have to be temporarily covered or removed or the spray turned off as the boom passes over the vicinity of the nest. Spray drift also has to be considered. Crops often grow unnaturally thick and can smother the nest and young, especially in wet weather; oilseed rape is a particular danger in this respect. The crop may have to be cut back at the nest to give the young a better chance.

The time of greatest danger is at harvest. Marsh Harriers nest earlier than Montagu's, and tend to have fledged by harvest time, but where they have not action has to be taken to protect nest from combining operations. It may be possible to agree a delay in harvesting until the young fledge. Otherwise the young should be temporarily removed in a ventilated cardboard box during

Chapter 8

Bat activity and back-tracking surveys

8.1 Introduction

This chapter provides information on carrying out bat detector surveys for bats. These bats may be commuting, foraging or exhibiting social behaviour (such as calling for mates during the mating season or swarming in the autumn). Acoustic surveys enable identification of species and provide an index of bat activity. Actual numbers of individuals can often not be established unless acoustic data is coupled with direct observations in the field by an ecologist, or through recordings made by an infrared or thermal-imaging camera.

These surveys may be required where development proposals are likely to impact on habitats suitable for bat commuting and foraging (see Section 2.2.2). Road and rail schemes can cause the specific impact of collision and it is good practice to carry out automated/static bat activity surveys of crossing points.

As with all surveys, survey design should be based around the questions that require answers. For the purposes of development and planning, the main questions with respect to bats in flight away from their roosts are generally as follows:

- Are bats present or absent?
- Which bat species use the site?
- What are the activity levels of bats on the site and can this tell us anything about the abundance (number) of bats using the site?
- What are bats using the site for?
- What is the temporal (both seasonally and in relation to time of night) and spatial distribution of recorded bat activity on site?
- Are peaks in bat activity associated with particular temporal and/or spatial locations, e.g. times of night or parts of the site?
- How are the habitats used on site connected to habitats in the surrounding area?

Answering some or all of these questions should allow an ecologist to carry out a robust impact assessment.

In order to answer these questions, bat activity surveys generally begin with the preliminary ecological appraisal, which includes a desk study and fieldwork (see Chapter 4). This provides existing data about bats in the area and identifies and assesses the suitability of habitats on site for bats. This information should be used to inform survey design, which should be iterative; each stage should inform the next.

The following sections describe **transect** and **automated/static bat activity surveys, back-tracking surveys** and **swarming surveys.**

8.2 Bat activity surveys – manual and automated/static

8.2.1 Description and aims

Manual bat activity **transect surveys** involve ecologists walking predetermined transect routes in order to observe, listen for and record bats in flight away from their roosts using hand-held bat detectors and recorders. **Automated/static activity surveys** involve bat detectors being deployed at fixed locations to record bat activity remotely. These are usually used in combination with transect surveys.

The aim of these surveys is to answer the questions posed in Section 8.1. The results of these surveys can then be used to inform the need for further surveys or to facilitate an impact assessment and the subsequent design of appropriate mitigation.

8.2.2 Equipment

Generic documentation/equipment required for field surveys for bats is provided in Section 2.5.2; survey-specific equipment is listed in Appendix 1.

8.2.3 Expertise and licences

Section 2.5.1 discusses expertise and Section 1.2.2 provides information on licences. Activity surveys are unlikely to disturb bats if carried out correctly; however, it is good practice for these surveys to be designed and carried out, or at least led, by licensed surveyors who have gone through a period of training and evaluation.

8.2.4 Methods

8.2.4.1 Transect surveys

Appropriate transect routes should be determined during the fieldwork carried out as part of the preliminary ecological appraisal (see Chapter 4). This survey should have identified the different habitats in the survey area that will be impacted by the proposed activities and may have assessed suitability (see Section 4.3.4). All habitats should be sampled but the habitats identified as having moderate or high suitability for bats are likely to be the main focus of the transect surveys.

The extent and arrangement of the different habitats on site should inform the number and arrangement of transects required to complete the survey. This is also influenced by ease of accessibility and navigation. Some habitat types (for example, wetlands or dense scrub/woodlands) may constrain transect surveys and increase the emphasis on collecting data from spot counts, timed searches (see Section 8.2.5) or automated/static surveys (see Section 8.2.4.2).

Ideally, ecologists should have the opportunity to walk transects during the daytime in order to avoid getting lost; to identify hedge or watercourse crossing points; and to identify any particular hazards. It is more appropriate for this work to be carried out in pairs; for ecologists to know where other colleagues will be on site; and for the method of communication to be identified. This may require two-way radios in the absence of mobile phone signal.

During transect surveys, an ecologist should walk at a fairly constant speed (so the sampling area is the same per unit time) along a planned route recording observations of bats such as number of bats, flight direction, flight height, behaviour (e.g. commuting or foraging – the latter can be identified through hearing feeding buzzes), appearance and relative speed. Much of this is qualitative information that cannot be recorded using the automated systems described in Section 8.2.4.2, although obviously constrained by light levels (more so in cluttered habitats). All echolocation calls should be recorded and subsequently analysed to species or genus (see Chapter 10) even if the ecologist has attempted to identify the species by ear in the field.

Technology is available to record each bat echolocation call and link it to a specific location (using GPS points) and time to enable the data to be easily mapped and presented in reports, although some ecologists still use paper recording forms to record time, location, species and behaviour.

Because an ecologist is only in one location at a given time, it is likely that bat activity will be missed. Repeating a short transect twice during the course of one evening, randomly varying the starting point through the season and/or supplementing transect surveys with automated/static detector surveys can help to overcome this limitation. Different methods facilitate different types of analysis. For example, randomising the start point across a suite of surveys facilitates the production of a kernel density plot of the activity along the transect (see Figure A7.6).

Ideally, all habitats represented on site should be sampled by transects during a single survey visit to allow a comparison of bat activity across the site. However, if few ecologists are available and the site is particularly large it may be necessary to visit the site (covering different transects each time) over several consecutive nights (collectively considered to be 'one survey visit') to cover all areas.

Transect surveys can be undertaken as:

- **dusk surveys only** – this is likely to be the most effective method in the spring and autumn when conditions are likely to deteriorate in the night and may cause bats to go back to their roosts and not emerge for a second time before dawn;

- **dusk and pre-dawn surveys with a break between the two** – this is a useful method if the conditions are appropriate for pre-dawn activity but long nights mean a dip in bat activity is experienced in the middle of the night;

- **dusk to pre-dawn surveys** – this is most useful on short summer nights when activity levels remain high, or where the aim is to record particular types of bat activity in the middle of the night such as mating or swarming along with dusk and dawn activity;

- **pre-dawn surveys only** – these may be used to record specific pre-dawn behaviours such as bats commuting back to a roost in a particular direction.

Where multiple transects are carried out at one site, they should all be approximately the same length. A good guide is 3–5km, but transects may be shorter than this depending on the site, ground conditions, whether or not stopping points are used and levels of bat activity.

8.2.4.2 Static/automated surveys

The use of static/automated detectors facilitates quantitative analysis of the data to supplement the often qualitative data collected during transect surveys. Some examples of strategies that can be used to identify bat detector locations are given below (please refer back to Section 2.2.6 on data analysis):

- **Random:** a random sampling strategy is a good method for not introducing bias (distortion) to the subsequent analyses. The survey area is divided up into a grid (10 × 10) of equal squares and rather than surveying all squares, 20 squares are chosen randomly from the 100. Each square is numbered from 1 to 100 and 20 numbers are generated randomly, between 1 and 100, and assigned to a square.

- **Systematic:** a systematic sampling strategy is a good method for not introducing bias (distortion) to the subsequent analyses. The survey area is divided up into a grid (10 × 10) of equal squares and rather than surveying all squares, every 5th square is chosen. Each square is numbered sequentially 1 to 100 and then squares 1, 5, 10, 15, 20, etc... are selected.

- **Judgemental:** sampling locations in the survey area are chosen subjectively. For example 20 sampling locations, using the example area above, are determined based on expert opinion (after the preliminary ecological appraisal; see Chapter 4) or historical information. The approach could be described as 'haphazard' and at the extreme can fall into 'convenience' (sampling at convenient places (or times)). Judgement sampling has inherent uncertainty, cannot be readily quantified and statistical methods cannot be applied. However, this approach may facilitate the chances of recording, for example, quieter calling bats (see Table 3.7 on page 31).

- **Stratified:** the survey area is divided unequally into sub-areas allowing a sub-area(s) of interest to be surveyed more intensively (identified during the preliminary ecological appraisal; see Chapter 4). Sub-areas can be analysed individually but care should be taken when looking at the area as a whole because a bias has been introduced; some areas have been surveyed more than others. One way of looking at the whole area, while surveying sub-areas more intensively, is to pair or group sample locations by factors and use the factors in the analysis. Factors are most useful when they are simple and easily defined:
  - Field 1 – Field 2 (adjacent to Field 1 and same area)
  - Hedgerow – Watercourse (same length)
  - Woodland – Open field (same area)

Random, systematic, judgemental and stratified sampling strategies also apply to the timing of surveys; the convention in bat surveying is to use timings that are systematic.

Ideally, the same model of automated/static bat detector should be used across the site, all detectors should be deployed with the same settings and all detectors should be subject to regular testing/calibration as appropriate to avoid the introduction of bias and to allow a meaningful comparison of the results.

The microphone should be positioned to maximise the amount of bat activity recorded – this requires knowledge and consideration of the directionality/sensitivity of the particular microphone used. The choice of microphone (uni- or omnidirectional) will depend on the objectives of the survey – both types have their uses.

Automated/static detectors may be deployed at varying heights depending on site and project-specific factors. It is not usually appropriate to deploy a detector on the ground because this will decrease the survey volume around the microphone. The microphone should be located so that the recording of ambient (e.g. wind, running water, rustling vegetation) or any other source of extraneous noise (e.g. electrical signals) is minimised. It is also important to consider whether solid objects nearby (e.g. vegetation, built structures, etc.) will impede the passage of sound to the microphone, and adjust its position accordingly. It may be appropriate to elevate the detector above the height of a hedgerow to enable recording on both sides or to deploy the detector just below or above the canopy of a woodland. It may also be necessary to fence the detector or have livestock moved from a field if surveying in open pasture is necessary.

Data from automated/static systems is limited because there is no observational context. One hundred bat passes could represent one bat passing 100 times or 100 bats each passing once. Reality is likely to be somewhere between these two extremes. In cases where high levels of activity are recorded it may therefore be necessary to contextualise the results (i.e. is it one bat or 100 bats) using a manual transect or spot count survey. These methods are complementary – each performs a different function.

Table 8.1 provides a summary of the comparative benefits and limitations of transect and automated/static surveys.

Table 8.1 A summary of the comparative benefits and limitations of transect and automated/static surveys.

Survey type	Benefits	Limitations
Transect	• Bats can be counted • Bat behaviour can be observed (more limited as light falls and in cluttered habitats)	• Snapshot of time only • Ecologist is only in one location at any given time so could miss activity elsewhere • Subjectivity of ecologist can limit consistency, repeatability and quantitative analysis • Security of ecologists • Difficult in some habitat types (e.g. dense woodland or scrub or open homogenous habitats) • Labour-intensive fieldwork • Can't be used at height
Automated/static	• Can be deployed for long periods to pick up variability in bat activity in the absence of ecologists • Can be deployed in different locations simultaneously • Large amounts of data generated • More objective and therefore consistent, repeatable and allows quantitative analysis • Full auto identification is possible with some models, although caution should be exercised in choice and accuracy of software and reliance on results • Can be used very effectively for at-height surveys	• Bats cannot be counted • Bat behaviour cannot be observed • Large amounts of data generated, requiring significant storage capability • Lots of data analysis • Variability of weather over longer periods (though evens out over longer periods) • Security of detectors • Need to change memory cards and batteries

The results of the surveys should be recorded in a standard format and survey design should be iterative, each survey informed by the previous one. This is particularly important for automated surveys, where issues with a particular site or piece of equipment that would not otherwise be apparent may need to be addressed.

8.2.5 Complementary/alternative methods

Transect surveys may be supplemented by **spot counts**, where ecologists remain stationary for short, set periods of time (3–5 minutes) at locations along a transect route selected to represent the different habitats in the survey area. It may be appropriate to only sample at the spot count locations (rather than also recording along the transect) in habitats that are difficult to navigate or walk such as dense woodlands, wetlands or on steep terrain. This can make hearing, observing and counting bats easier because there is no noise from footfall and the ecologist can focus on the survey rather than navigation and safety.

Timed searches allow ecologists to move freely around the survey area for a set amount of time responding to any visual or acoustic evidence of bats by moving towards it. Timed searches

can be used to standardise survey methods for bat species that are difficult to detect, or if bats are spread over a wide area that cannot easily be sampled using transects or spot counts. Timed counts provide a simple and effective means of obtaining estimates of relative bat activity in homogeneous or difficult terrain such as mountains or wetland bogs; landscapes with few features (moor, open farmland); and areas where it is difficult to walk around (e.g. in dense woodland, built-up areas, railway marshalling yards, etc.). Large sites can be subdivided into smaller areas; a random sample of these can be selected for sampling or each can be sampled on a different night. Searching for a set amount of time introduces an element of standardisation that can be repeated in subsequent surveys.

Vantage point surveys can provide information about the behaviour of early-emerging and high-flying bats such as noctule. Ecologists are located at vantage points around the site, so that all areas are covered. They then observe and listen for bats in flight while light levels allow, before and after sunset or sunrise. These surveys can provide information about numbers of bats and direction of travel, which gives an indication of the direction of the roost and the direction of early evening foraging grounds.

Transect surveys have been carried out using bikes or cars to cover more ground (or boats in aquatic habitats). However, the limitations of these methods should be recognised. Car surveys are particularly constrained because they focus the survey only on roads/tracks and the noise and lights of the cars could disturb some bat species (particularly species that avoid light). Quieter-calling species can easily be missed so these methods should not be used in isolation.

It may be necessary to capture bats using mist nets or harp traps in order to identify their species, gender and age to supplement activity survey information. The correct licence, skills and experience should be in place to carry out this activity and sensitive times of year should be avoided (such as the maternity and hibernation seasons). More information on capture and handling is provided in Chapter 9.

8.2.6 Timing

Recorded bat activity is dependent on the prevailing conditions at the time of the survey, which vary temporally (through the night, between nights, through the seasons and between years) and spatially (dependent on latitude, longitude, altitude, habitat, etc.).

Bat activity is also determined by what the bats are doing at different times of the year (although this is also dependent on prevailing conditions); the bat life cycle is given in Section 3.2.

The UK bat active period is generally considered to be between April and October inclusive, although April, September and October surveys are both weather- and location-dependent (October surveys are generally not acceptable in Scotland). Conditions may become more unsuitable in these months, particularly in more northerly latitudes, which may reduce the length of the survey season. Some useful data may be collected outside these months or weather conditions during these months may render surveys ineffective – professional judgement should be applied to determine the most effective activity survey period for a particular project.

It may be appropriate to survey for bat activity in the winter, particularly if there are hibernation roosts in, or close to, the survey area. Foraging habitats close to hibernacula may be particularly important because during the winter bats need to minimise energy used to gain food during milder weather conditions. Automated/static surveys are likely to be the most efficient way of collecting data on winter bat activity.

Table 8.2 gives recommended timings for activity surveys.

Table 8.2 Recommended start and end times for activity surveys.

Survey type	Start time	End time
Dusk survey – bat activity	Sunset[a]	2–3 hours after sunset
Dusk survey – swarming	2 hours after sunset	5 hours after sunset
Dusk to pre-dawn survey	Sunset	Sunrise or later if bats still active
Pre-dawn survey	2 hours before sunrise	Sunrise or later if bats still active
Automated bat detector survey	30 minutes before sunset	30 minutes after sunrise

[a] Adjust to earlier if in darker habitats such as woodland or if data justifies (e.g. if bats are already out by sunset on previous surveys or automated detectors show pre-sunset activity).

Timings may be adjusted (earlier or later) if necessary by the ecologist, bearing in mind the site-specific circumstances, although this should be fully justified in the survey report.

8.2.7 Survey effort

When planning surveys it is important to take a proportional approach. The number of transects, automated/static surveys and repeat visits decided upon should be proportional to the factors described in Section 2.2.5. To briefly recap, with particular reference to activity surveys, these are:

- likelihood of bats being present;
- likely species concerned;
- numbers of individuals;
- type of habitat affected;
- predicted impacts of the proposed development on bats;
- type and scale of proposed development.

An activity survey should provide a representative sample of the bat activity in all habitats present at the proposed development site (see Section 8.2.4.1). Sampling should be designed to provide a sufficient amount of data to assess the potential impacts of the development on bats.

Bat activity is inherently variable from night to night, with this variability not explained by weather conditions alone (Scott and Altringham, 2014), and so multiple consecutive nights of survey with automated systems are recommended.

Table 8.3 gives guidelines on the number of bat activity surveys recommended to achieve a reasonable survey effort on sites with low, moderate and high-quality habitat for bats (as defined during the preliminary ecological appraisal fieldwork; see Table 4.1 on page 35). Please note that the elements outlined in Section 2.2 should be considered alongside habitat suitability in designing surveys. In particular, the potential impacts of the proposals (Section 2.2.2) and proportionality (Section 2.2.5).

Table 8.3 Guidelines on the number of bat activity surveys recommended to achieve a reasonable survey effort in relation to habitat suitability.

Survey type	Low suitability habitat for bats[a]	Moderate suitability habitat for bats	High suitability habitat for bats
Transect/spot count/timed search surveys	One survey visit[b] per season (spring – April/May, summer – June/July/August, autumn – September/October)[c] in appropriate weather conditions for bats Further surveys may be required if these survey visits reveal higher levels of bat activity than predicted by habitat alone	One survey visit[b] per month (April to October)[c] in appropriate weather conditions for bats. At least one of the surveys should comprise dusk and pre-dawn (or dusk to dawn) within one 24-hour period.	Up to two survey visits[b] per month (April to October)[c] in appropriate weather conditions for bats. At least one of the surveys should comprise dusk and pre-dawn (or dusk to dawn) within one 24-hour period.
AND			
Automated/static bat detector surveys[d]	One location per transect, data to be collected on five consecutive nights per season (spring – April/May, summer – June/July/August, autumn – September/October)[c] in appropriate weather conditions for bats	Two locations per transect, data to be collected on five consecutive nights per month (April to October)[c] in appropriate weather conditions for bats	Three locations per transect, data to be collected on five consecutive nights per month (April to October)[c] in appropriate weather conditions for bats

[a] If the habitat has been classified as having low suitability for bats, an ecologist should make a professional judgement on how to proceed based on all of the evidence available. It may or may not be appropriate for bat activity surveys to be carried out in low suitability habitats. However, caution should be exercised in fringe areas (e.g. some areas of Scotland) where 'low suitability habitat for bats' may be extremely important to local bat populations due to the relative scarcity of better habitats. In such situations, bats are likely to also be more widely dispersed and may use a larger number of sites, therefore survey effort may actually need to be increased to detect use on the proposed site in question.

[b] A survey visit should aim to cover all habitats represented in the survey area that could be impacted by the proposed activities. This may consist of a single transect carried out on a single night for small sites (e.g. small housing developments) with low habitat diversity but could range up to multiple transects carried out over one or several nights (depending on number of ecologists) on a larger site (e.g. road schemes) with greater habitat diversity.

[c] April, September and October surveys are both weather- and location-dependent. Conditions may become more unsuitable in these months, particularly in Scotland, which may reduce the length of the survey season.

[d] Detector locations should be assigned to cover all habitats represented in the survey area that could be impacted by the proposed activities. This could mean a single detector location at a small site with only one habitat represented but could range up to many detector locations on larger sites. Automated/static surveys are particularly useful when assessing collision risk, e.g. detectors can be placed at crossing points on proposed roads or railways.

Note: Multiple survey visits should be separated by at least two weeks, preferably longer, to observe temporal changes in activity.

Survey data should be analysed as soon as possible and preferably before the next survey (see Section 10.2).

It is important to consider how effective the surveys are in recording species that are more difficult to detect (see Section 3.9) or exhibit highly variable or seasonal patterns of activity. It may be appropriate to adjust the survey methods, increase the number of survey nights or adjust the survey frequency to ensure these species are not under-recorded. Skalak *et al*. (2012) reported that relatively few nights are needed to detect common species but longer sampling periods may be necessary to detect rarer species. The same is true of those species that use quiet echolocation calls (see Table 3.8 on page 32).

Comparing transect and static data may also indicate that species are being recorded by one type of survey but not another, so that subsequent surveys can be adjusted accordingly.

8.2.8 Weather conditions
Please refer to Section 2.6.1 for guidance on weather.

8.2.9 Next steps
The next steps will depend on what has been recorded during the activity surveys. It may be necessary to carry out more targeted activity surveys in subsequent years or use alternative methods to gain specific information (e.g. using a trapping survey to distinguish between *Myotis* or *Plecotus* species or to define breeding status of the bats; see Chapter 9).

Where enough information has been collected, the data should be used to inform an impact assessment and the design of a mitigation strategy.

8.3 Swarming surveys – acoustic

8.3.1 Description and aims
Swarming surveys are carried out to identify if a site is used by bats for autumn swarming, which was described by Fenton (1970) as 'the flight of bats through hibernacula in late summer and early fall'. This usually occurs in the UK from August to October inclusive and activity peaks 3–4 hours after sunset (Rivers *et al.*, 2006; Glover and Altringham, 2008): observations made during the first 2–3 hours after sunset may not detect it. Autumn swarming should not be confused with what is commonly termed 'dawn swarming', where one or more bats fly around outside their roosts prior to entry at dawn.

Autumn swarming behaviour has been recorded mostly at the entrances to and outside underground sites such as caves, mines and tunnels but has also been observed around other structures such as castles, and large barns. Evidence from the Netherlands shows mass swarming events of common pipistrelle bats in the autumn followed by mass hibernation in a diverse range of building types in urban environments (Korsten *et al*., 2015). This phenomenon requires some research in the UK but ecologists should be aware of the potential for larger numbers of this species to be present during the autumn and winter in large buildings in highly urbanised environments.

Swarming behaviour is common among *Myotis*, *Plecotus* and *Barbastella* species. Swarming probably has several important functions: mating, transfer of information about hibernation sites to young, collection of information on the condition of hibernation sites prior to hibernation and migration stopover, but as yet most lack direct evidence to support them. There is, however, good behavioural and genetic evidence to show that mating is an important function (Thomas *et al.*, 1979; Kerth *et al.*, 2003; Rivers *et al.*, 2005; Furmankiewicz and Altringham, 2007).

Rivers *et al.* (2006), in a study of four North Yorkshire caves, found that Natterer's bats undertook seasonal migration between the caves and their nursery sites over at least a 60km radius area. Between 300 and 400 bats visited the caves each night, with many more at the peak of the season. Numbers of bats vary between sites and from night to night at the same site. Activity typically starts in August and rises to a peak in September or early October before slowly declining. Many thousands of bats may visit some sites, but swarming behaviour may involve no more than a few bats each night at minor sites.

Swarming sites can therefore be important mating sites for large numbers of bats and are important for gene flow (Kerth *et al.*, 2003; Rivers *et al.*, 2005; Furmankiewicz and Altringham, 2007). Many underground swarming sites are also hibernation sites and it is likely that those bats swarming at a site go on to hibernate in the same site (Glover and Altringham, 2008). Individual bats show very high fidelity to a single swarming site (Rivers *et al.*, 2005, 2006; Glover and Altringham, 2008) and few bats are recaptured at other sites, even those close by.

The impact of destroying or changing a swarming site for development purposes is likely to be severe, so it is particularly important to investigate further whether swarming is a possibility. The aim of carrying out acoustic bat activity surveys at potential swarming sites is to establish actual use of the site by swarming bats and understand how bats use the site. If a site likely to be impacted by development does support swarming bats it is possible that further surveys will be necessary (see Chapter 9).

8.3.2 Equipment
Generic documentation/equipment required for field surveys for bats is provided in Section 2.5.2; survey-specific equipment is listed in Appendix 1.

8.3.3 Expertise and licences
Section 2.5.1 discusses expertise and Section 1.2.2 provides information on licences. Acoustic swarming surveys are unlikely to disturb bats if carried out correctly; however, it is good practice for these surveys to be designed and carried out, or at least led, by licensed surveyors who have gone through a period of training and evaluation. If disturbance to bats is likely (e.g. because an ecologist needs to deploy a detector in the entrance to a roost), then a survey licence is required.

8.3.4 Methods
The simplest and most efficient way to investigate whether bats are swarming at a site is to deploy an automated/static bat detector and recorder to record swarming bats just outside or within the entrance to an underground site (or complex structure). Repeated peaks in ultrasonic activity, reaching a maximum 3–4 hours after sunset, indicate the site is used by swarming bats and the echolocation calls recorded can be analysed to species or genus after the survey. This method is likely to generate a large amount of data at a swarming site because of the high levels of activity generally observed. However, it is unlikely to be necessary to scrutinise all recordings made, depending on the aims and objectives of the survey. Alternatively, data collected could be reduced by recording for only a few hours during the middle of the night (e.g. 2–5 hours after sunset).

8.3.5 Complementary methods
It may be appropriate to trap bats at a swarming site if it is necessary to confirm species, particularly if Annex II species such as barbastelle and Bechstein's bat may be present. Wherever and whenever possible, harp traps should be used in preference to mist nets due to the possibility of catching large numbers of bats. More information on trapping is provided in Chapter 9. With the evolution of more reliable software for automated identification from echolocation calls, trapping to determine species only may eventually become unnecessary.

Trapping to establish gender is unnecessary because the pattern of use at swarming sites is well documented: both sexes are present, but males outnumber females, consistent with mating behaviour during swarming (Thomas *et al.*, 1979; Kerth *et al.*, 2003; Parsons *et al.*, 2003a; Rivers *et al.*, 2005; Furmankiewicz and Altringham, 2007; Glover and Altringham, 2008).

8.3.6 Timing

Swarming surveys should be carried out from mid-August to October inclusive, but if only a limited survey period is available mid-September to early October is best. Species composition varies throughout the swarming season, with *Plecotus* and most *Myotis* species either peaking early or showing no discernible peak, and Natterer's bat peaking late in the season (Parsons *et al.*, 2003b; Rivers *et al.*, 2006; Glover and Altringham, 2008). Bechstein's bat, Alcathoe bat and barbastelle also swarm, but numbers caught are too low to reveal temporal patterns. Most sites have a similar mix of species: brown long-eared bat and the *Myotis* species expected in the area. It is typical for Natterer's bat to greatly outnumber all other species, particularly from mid-season onwards. Non-swarming species may also be recorded, particularly horseshoe bats, depending upon the nature of the adjacent habitat.

8.3.7 Survey effort

At least five nights of survey with an automated/static detector (in appropriate weather conditions for bats; see Section 2.6.1) in each month of the swarming season of mid-August to the end of October is recommended to establish whether a site is used for swarming or not.

If trapping is undertaken, then recommendations on survey effort are provided in Chapter 9.

8.3.8 Weather conditions

Please refer to Section 2.6.1 for guidance on weather.

Many studies have noted that bat activity at swarming sites varies markedly from night to night: bat activity is significantly suppressed by rainfall and positively correlated with residual maximum ambient temperature. Grubb (2012) also found high winds depressed activity. Moon phase does not appear to influence swarming activity (Parsons *et al.*, 2003a), but a bright moon has been known to lower capture success (if trapping) at exposed locations. Swarming activity appears to be more likely when weather conditions are more stable so targeting periods of high pressure may be appropriate.

8.3.9 Next steps

See Chapter 9 regarding trapping bats at swarming sites. This is only likely to be necessary if Annex II species may be present. If the presence of Annex II species is unlikely, then trapping is less appropriate because species assemblages using swarming sites are well documented from other studies (Parsons *et al.*, 2003b; Rivers *et al.*, 2006; Glover and Altringham, 2008).

Swarming sites are also used for hibernation so it may be necessary to also carry out hibernation surveys as described in Section 5.3.

8.4 Back-tracking surveys

8.4.1 Description and aims

Back-tracking surveys involve ecologists making visual observations of bats commuting away from their roosts at sunset or commuting back to their roosts at sunrise then attempting to track back to the roost based on these observations. Bat detectors are also used to record echolocation for identification of species, where possible. This technique was first developed in the Netherlands and is based on four principles:

- The earlier a bat is seen after sunset or the later it is seen before sunrise, the closer it is likely to be to its roost (the exact time depends on the species).
- Bats fly away from their roost at sunset, so ecologists should move in the opposite direction as the bats at this time to locate the roost.
- Bats fly towards their roost at sunrise, so ecologists should move in the same direction as the bats at this time to locate the roost.
- At sunrise, some bats species swarm at roost access points for between 10 and 90 minutes before entering.

The aim is to find roosts by making observations of commuting bats. These surveys are often used after a bat activity survey if numbers of bats were seen all commuting in one direction and follow-up is required or in situations with lots of potential roosts sites that are difficult to survey using alternative methods (e.g. in woodlands or highly urbanised areas).

8.4.2 Equipment

Generic documentation/equipment required for field surveys for bats is provided in Section 2.5.2; survey-specific equipment is listed in Appendix 1.

8.4.3 Expertise and licences

Section 2.5.1 discusses expertise and Section 1.2.2 provides information on licences. Back-tracking surveys are unlikely to disturb bats if carried out correctly; however, it is good practice for these surveys to be designed and carried out, or at least led, by licensed surveyors who have gone through a period of training and evaluation. If disturbance to bats is likely (e.g. because an ecologist would needs to investigate the roost when found using a torch or endoscope), then a survey licence would be required.

8.4.4 Methods

Ecologists should be deployed on potential or actual commuting routes close to roost sources (identified during the preliminary ecological appraisal, see Chapter 4, or during activity surveys, see Section 8.2) and note the time and direction of travel of each bat encountered on a detailed plan of the site. The ecologists should move in the opposite direction to the bats at sunset and in the same direction as the bats at sunrise. As ecologists approach potential roosts they should watch for bats emerging or dawn swarming at roosts.

If multiple ecologists are used they should be in constant contact via hand-held radio to communicate their observations. The data from multiple ecologists can also be pooled for a bigger picture of bat activity across the site, which can be used to design subsequent surveys where necessary.

In theory, back-tracking surveys work best for species with loud echolocation calls which form large roosts, but they can potentially be used to locate the roosts of any bat species.

8.4.5 Complementary methods

Back-tracking surveys are rarely used in isolation; they are most effective when combined with roost (Chapters 5 to 7) and bat activity surveys (Section 8.2).

8.4.6 Timing

As back-tracking surveys are most effective for larger roosts, the best time to carry them out is between May and August, when maternity colonies are gathered. However, results may be gained if carried out in April, September or October, depending on the individual situation (although October surveys are not considered appropriate in Scotland). See Section 8.2.6 for further comments on timing of activity surveys through the year. Table 8.4 gives recommended timings for back-tracking surveys during the night.

Table 8.4 Recommended start and end times for back-tracking surveys.

Survey type	Start time	End time
Back-tracking survey at dusk	15 minutes before sunset	When it is too dark to observe bats or when the source roost has been found
Back-tracking survey at dawn	2 hours before sunrise	When bats cease to be active or when the source roost has been found

Timings may be adjusted (earlier or later) if necessary by the ecologist, bearing in mind the site-specific circumstances, although this should be justified in the survey report.

8.4.7 Survey effort

The survey effort for back-tracking surveys is not fixed. These surveys have the specific aim of locating roosts using commuting bats for guidance and should be continued until this aim is reached unless alternative methods are considered more appropriate.

8.4.8 Weather conditions

Please refer to Section 2.6.1 for guidance on weather.

8.4.9 Next steps

If a roost is found during a back-tracking survey it may be necessary to follow up with a roost characterisation survey (see Section 7.2) to count the numbers of bats present at the roost.

COUNCIL OF EUROPE
COMMITTEE OF MINISTERS

RESOLUTION (79) 13

ON THE AWARD OF THE EUROPEAN DIPLOMA TO THE MINSMERE NATURE RESERVE (UNITED KINGDOM)

(Adopted by the Committee of Ministers on 13 September 1979 at the 307th meeting of the Ministers' Deputies)

The Committee of Ministers, under the terms of Article 15.*a* of the Statute of the Council of Europe,

Having regard to Resolution (65) 6 instituting the European Diploma ;

Having regard to the proposals of the European Committee for the Conservation of Nature and Natural Resources ;

Having recorded the agreement of the Government of the United Kingdom ;

After deliberation,

Solemnly awards the European Diploma, Category A, in accordance with the regulations for the European Diploma, to the Minsmere Nature Reserve (United Kingdom) ;

Places the aforesaid reserve under the patronage of the Council of Europe until 13 September 1984.

COMMITTEE OF MINISTERS
COMITÉ DES MINISTRES
1949.2019
COUNCIL OF EUROPE
CONSEIL DE L'EUROPE

MINISTERS' DEPUTIES Resolutions CM/ResDip(2019)5 4 September 2019

Resolution CM/ResDip(2019)5 on the renewal of the European Diploma for Protected Areas awarded to the Minsmere Nature Reserve (United Kingdom)

(Adopted by the Committee of Ministers on 4 September 2019 at the 1352nd meeting of the Ministers' Deputies)

The Committee of Ministers, under the terms of Article 15.*a* of the Statute of the Council of Europe,

Having regard to Resolution Res(65)6 instituting the European Diploma for certain protected landscapes, reserves and natural features, as amended by Resolution CM/ResDip(2008)1 on the revised regulations for the European Diploma for Protected Areas;

Having regard to Resolution Res(79)13 on the award of the European Diploma to the Minsmere Nature Reserve (United Kingdom);

Having regard to Resolution CM/ResDip(2009)9 on the renewal of the European Diploma for Protected Areas awarded to the Minsmere Nature Reserve (United Kingdom);

Taking into consideration the expert's report presented at the meeting of the Group of Specialists on the European Diploma for Protected Areas on 5 and 6 March 2019;

Having regard to the proposals of the Standing Committee to the Bern Convention;

Noting that holding the European Diploma implies the maintenance of exceptional European interest, the continuance of exemplary management and compliance with the provisions of Resolution CM/ResDip(2008)1, especially with regard to the obligations to report annually and to give appropriate visibility to the European Diploma;

Renews the European Diploma for Protected Areas awarded to the Minsmere Nature Reserve, until 13 September 2029;

Attaches the following condition to the renewal:

with regard to the project for a third reactor at the Sizewell nuclear power plant (project Sizewell C), carry out a proper Strategic Environmental Assessment and an Environmental Impact Assessment according to international standards; the results of these assessments should ensure that the construction of the new reactor will not be to the detriment of the Minsmere Nature Reserve;

Attaches the following four recommendations to the renewal:

1. control, wherever possible, the invasion of bracken with mechanical means, as opposed to the use of herbicides; in cases of restoration of big areas, the use of chemical products should be limited to the minimum possible extent and a careful record of this practice should be kept in order to assess and cope with possible undesirable side effects; specific scientific research on this issue should be carried out;

2. pursue efforts to mitigate the effect of the rise in the sea level; explore the possibility of restoring the lost habitats in other parts of the reserve; envisage compensatory measures; carefully monitor indicative plant and fauna species and duly register and scientifically characterise the changes observed;

3. continue the land purchase policy; in the absence of opportunities to acquire new plots, establish long-term agreements with the land owners of selected areas to improve their contribution to biodiversity conservation and/or restoration;

4. maintain the surveillance of alien species of flora, especially controlling and managing the pirri-pirri bur (*Acaena novae-zelandiae*) and pursue the control of the American mink (*Mustela vison*).

BETA TEST

1: Introduction

The rationale for using a metric

1.1. Biodiversity is the term that is used to describe the variety of all life on earth. It includes all species of animals and plants – and everything else that is alive on our planet. Habitats are the places in which species live. These species and their habitats contribute to the ecosystems services that provide substantial benefits to people and the economy. For example, woodlands and saltmarsh can help prevent flooding whilst parks and greenspaces make our towns and cities healthier and more attractive places in which to live and work. However, biodiversity is under threat, globally and at home. Habitats are being damaged or disappearing and species are declining. This is not just bad news for nature but also for our own health and well-being and that of future generations. Biodiversity and healthy habitats are vital for a well-functioning planet but their value is often not taken into account in decision-making.

1.2. In this user guide we introduce and explain how to use the **biodiversity metric 2.0**. This metric provides a way to measure biodiversity and the impact that developments or land management practices may have upon it. Biodiversity metric 2.0 can help developers, ecologists, planners, communities, land managers and many others take biodiversity into account. The metric provides a way to measure biodiversity loss and gain in a consistent and robust way. It can also predict the likely effectiveness of creating new or enhancing existing habitats. Used in combination with appropriate professional advice the metric can help to reduce biodiversity losses and increase gains resulting from development or land management.

Introducing the biodiversity metric 2.0

1.3. Biodiversity metric 2.0 is an updated version of the original Defra biodiversity metric[1]. This version builds upon the knowledge and experience gained across a variety of different sectors since the original Defra biodiversity metric was first launched as part of Defra's biodiversity offsetting pilots.

1.4. Biodiversity metric 2.0 balances robustness with simplicity. The metric uses habitat as a proxy for wider biodiversity with different habitat types scored according to their relative biodiversity value. This value is then adjusted depending on the condition and location of the habitat, to calculate '**biodiversity units**' for that specific project or development. Biodiversity metric 2.0 incorporates similar but separate calculations for habitats that require a different method of measurement such as hedgerows, lines of trees, rivers and streams and street trees.

1.5. The metric can be used to measure both on-site and off-site biodiversity changes for a project or development. The metric also accounts within it for some of the risks associated whenever new habitat is created or existing habitat is enhanced. In calculation terms, the change in biodiversity units is determined by subtracting the number of **pre-intervention** biodiversity units (i.e. those originally existing on-site and off-site) from the number of **post-intervention** units (i.e. those projected to be provided). It is important to note that achieving gains in biodiversity from the

[1] DEFRA. 2012. Biodiversity offsetting pilots. Technical paper: the metric for the biodiversity offsetting pilot in England. Defra. March 2012. https://www.gov.uk/government/collections/biodiversity-offsetting (Accessed 20-06-2019)

BETA TEST

calculation does not necessarily mean a development meets any wider requirements of planning policy or law relating to nature conservation or biodiversity.

1.6. All biodiversity unit calculations come with some 'health warnings'. The outputs of the metric are not absolute values but provide a proxy for the relative biodiversity worth of a site pre- and post-intervention. The quality and reliability of outputs will depend on the quality of the inputs. This user guide provides advice on how to use the biodiversity unit approach and where and when it is appropriate for use. The metric is not a substitute for expert ecological advice. The metric does not override or undermine any existing planning policy or legislation, including the mitigation hierarchy (see section 1.11 below), which should always be considered as the metric is applied.

1.7. Biodiversity metric 2.0 does not include species explicitly. Instead, biodiversity metric 2.0 uses broad habitat categories as a proxy for the biodiversity 'value' of the species communities that make up different habitats. The metric does not change existing levels of species protection and the processes linked to protection regimes are outside the scope of the metric.

1.8. To simplify and streamline the calculation process, the biodiversity metric 2.0 comes with a free tool to calculate biodiversity units. A shortened user guide for the calculation tool is also available.

The mitigation hierarchy and the metric

1.9. Planning policy[2][3] supports the application of the **mitigation hierarchy** (see Figure 1-1). When using the metric application of the mitigation hierarchy might mean looking to retain habitats in situ or avoiding habitat damage. In the metric biodiversity gains are easier to achieve where habitat impacts are avoided due to the way that habitat creation or enhancement risks are accounted for.

BETA TEST

Key process steps

2.19. The key steps you need to follow to make practical use of the metric are outlined in Figure 2-1.

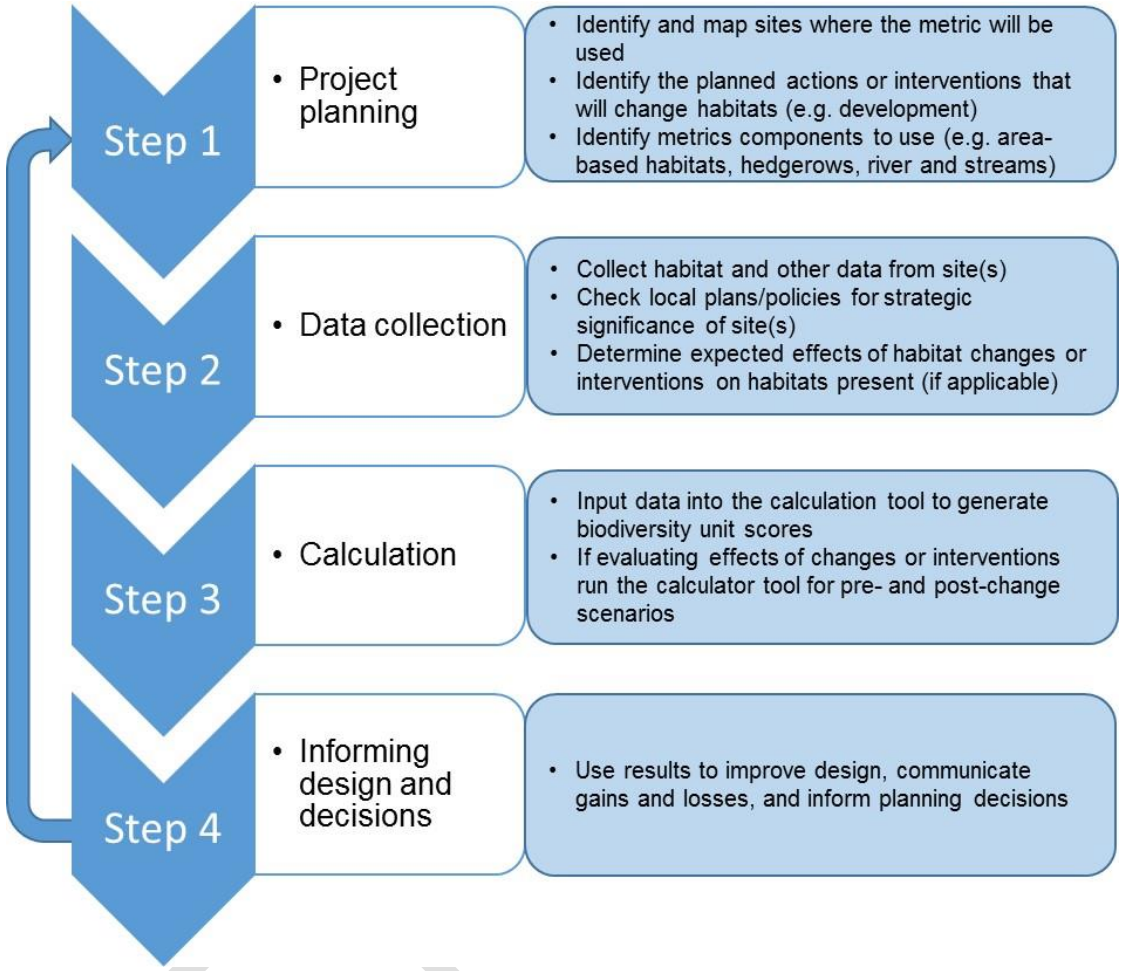

FIGURE 2-1: The 4 key steps to using biodiversity 2.0

Principles and rules for using the metric

2.20. The metric is a tool that can be used to help inform plans and decisions. Used properly, it incentivises actions that are expected to benefit biodiversity and discourages actions that harm biodiversity. It is important, however, to be aware of its limitations and to follow some important principles.

2.21. The metric uses habitat categories as a proxy for biodiversity. Although this is rational, it is an oversimplification of the real world. Furthermore, while the scoring of habitats is informed by ecological reasoning and the available evidence, the outputs of biodiversity unit calculations are not scientifically precise or absolute values. The generated biodiversity unit scores are proxies for the relative biodiversity worth for the state of a place.

2.22. The metric and its outputs should therefore be interpreted, alongside ecological expertise and common sense, as an element of the evidence that informs plans and

decisions. The metric is not a total solution to biodiversity decisions. The metric, for example, helps you work out how much new or restored habitat is needed to compensate for a loss of habitat, but it does not tell you the appropriate composition of plant species to use.

2.23. Users wanting to apply the metric properly should conduct their assessments with regard to a set of **key principles and rules** for its use. These are set out below:

- **Principle 1: The metric does not change the protection afforded to biodiversity.** Existing levels of protection afforded to protected species and to habitats are not changed by use of this or any other metric. Statutory obligations will still need to be satisfied.

- **Principle 2: Biodiversity metric calculations can inform decision-making where application of the mitigation hierarchy and good practice principles[6] conclude that compensation for habitat losses is justified.**

- **Principle 3: The metric's biodiversity units are only a proxy for biodiversity.** While it is underpinned by ecological evidence the metric is only a proxy for biodiversity and to be of practical use has been kept deliberately simple. The numerical values generated by the metric represent relative, not absolute, values.

- **Principle 4: The metric focuses on widespread species and typical habitats.** Area based habitats are considered a suitable proxy for widespread species found in typical examples of different habitat types.
    - Protected and locally important species needs are not considered through the metric,
    - Impacts on protected (e.g. SSSIs) and irreplaceable habitats are not adequately measured by this metric, and will likely require separate consideration.

- **Principle 5: The metric design aims to encourage enhancement, not transformation, of the natural environment.** Where possible, habitat created to compensate for loss of a natural or semi-natural habitat should be of the same broad type (e.g. new woodland to replace lost woodland) unless there is a good ecological reason to do otherwise (e.g. to restore a heathland habitat that was converted to woodland for timber in the past).

- **Principle 6: The metric is designed to inform decisions**. Decisions and management interventions need to take account of available expert ecological advice and not just the biodiversity unit outputs of the metric.

- **Principle 7: Compensation habitats should seek, where practical, to be local to the impact.** They should aim to replicate the characteristics of the habitats that have been lost, taking account of the structure and species composition that give habitats their local distinctiveness. Where possible

[6] CIEEM, CIRIA, IEMA. 2016 Biodiversity Net Gain – Good Practice Principles for Development. https://www.cieem.net/data/files/Publications/Biodiversity_Net_Gain_Principles.pdf

BETA TEST

compensation habitats should contribute to England's ecological network by creating more, bigger, better and joined areas for biodiversity

- **Principle 8: The metric does not enforce a mandatory minimum 1:1 habitat size ratio for losses and compensation.** A difference can occur because of a difference in quality between the site impacted and the compensation provided. For example, if a habitat of low distinctiveness is impacted and is compensated for by the creation of habitat of high distinctiveness, the area needed to compensate for losses can potentially be less than the area impacted. Consideration should be given to whether reducing the size of compensation is an appropriate outcome.

Rules	
Rule 1	Where the metric is used to measure change biodiversity unit values need to be calculated prior to the intervention and post-intervention for all parcels of land / linear features affected.
Rule 2	Compensation for habitat losses can be provided by creating new habitat, by restoring or enhancing existing habitats, or by accelerating successional processes. Measures to improve existing habitats must provide a significant and demonstrable uplift in distinctiveness and/or condition to record additional biodiversity units.
Rule 3	'Trading down' must be avoided. Losses of habitat are to be compensated for on a "like for like" or "like for better" basis. Ideally, new or restored habitats should aim to achieve a higher distinctiveness and / or condition than habitats lost.
Rule 4	Biodiversity unit values generated by biodiversity metric 2.0 are unique to this metric and cannot be compared to unit outputs from the original Defra metric or any other biodiversity metric. Furthermore, the units generated by the each module of biodiversity metric 2.0 (for area, hedgerow and river habitats) are unique and cannot be summed.
Rule 5	It is not the area of habitat created that determines whether ecological equivalence or better has been achieved but the net change in biodiversity units. Risks associated with enhancing or creating habitats mean that it may be necessary to enhance or create a larger area of habitat than lost to fully compensate for impacts on biodiversity.
Rule 6	Deviations from the published methodology of biodiversity metric 2.0 need to be ecologically justified. While the methodology is expected to be suitable in the majority of circumstances it is recognised that there may be exceptions. Any local or project-specific adaptations of the metric must be transparent and fully justified.

5: Detailed description of the biodiversity metric 2.0

5.1. This chapter provides explanations of the different components of biodiversity metric 2.0. The aim is to give a sense of the values used for different multipliers, why those multipliers are being used, and the assumptions and limitations around them. This chapter also outlines some the considerations that might be taken into account when designing a project underpinned by the metric.

5.2. This chapter focuses on the core components of the metric. Specific area habitat and urban tree components are detailed in chapters 6 and 7 respectively. Chapter 8 provides similar details and explanations for the additional supplementary metric modules covering hedgerows, lines of trees and rivers and streams.

Components of biodiversity quality

Distinctiveness

5.3. Habitats are assigned to distinctiveness bands. These are based on an assessment of the distinguishing features of a habitat or linear feature, including the consideration of species richness, rarity (at local, regional, national and international scales), and the degree to which a habitat supports species rarely found in other habitats.

5.4. The distinctiveness band of each habitat is preassigned in biodiversity metric 2.0. The bands are based upon the UK habitat classification system. A combination of simple rules and expert judgement have been used to assign each habitat type to the appropriate distinctiveness band. The distinctiveness categories used are tailored to habitat type and are explained later in this chapter for Area Habitats and in chapter 8 for habitats with supplementary modules.

Condition

5.5. Parcels of habitat will be in different ecological conditions In addition, interventions to improve habitats will not always involve taking a habitat in poor condition and improving it to good condition. The metric therefore takes account of variants in habitat condition.

5.6. The approach to condition assessment is tailored to habitat type and is explained later in this chapter for Area Habitats and in chapter 8 for habitats with supplementary modules.

Strategic significance and connectivity

5.7. ‘The spatial location of a habitat is treated as a component of the quality of a habitat parcel in the same way as distinctiveness or condition. Two distinct spatial components are used strategic significance and connectivity. These are explained in more detail in section 5.29.

Dealing with risk

5.8. There are uncertainties and a risk of failure in any endeavour to create or improve the biodiversity unit value of a habitat. One way to deal with these risks is to complete the habitat improvements works in advance of the habitat losses occurring.

5.9. Where this is not possible risks can be mitigated by reducing the number of units generated by a unit of compensation habitat. This is done by using a **multiplier** in the metric to correct for disparity or risk. The use of multipliers to account for the risks associated with habitat restoration or creation has several benefits:

BETA TEST

- it **provides flexibility** by allowing activities impacting habitats to proceed in advance of compensation being either provided or attaining its target quality in exchange for an increase in the magnitude of compensation provided;
- it **incentivises** the creation of compensation habitat in advance of loss. If the habitat is established before the impact then there is no need to apply risk multipliers to manage delivery risks or to take account of time differences. More units will therefore be available from a specific parcel of land, and
- it **creates a disincentive** for damaging habitats that are difficult or take a long time to recreate or restore (the case for many habitats in the Very High and High distinctiveness band), by increasing the area of habitat needed to compensate for the loss.

5.10. A typical consequence of applying risk multipliers is to increase the size (e.g. area or length for linear features) of habitat required as compensation such that it exceeds the size of habitat lost or damaged. This is necessary:

- to preserve the incentives and disincentives referred to above;
- to compensate for temporal losses of biodiversity (e.g. where there is a period of diminished biodiversity between the point in time when a habitat is impacted and it is replaced by habitat of equivalent biodiversity value);
- to protect against situations where habitats that are created, enhanced or restored fail to adequately compensate for the lost biodiversity. This is necessary because there is no requirement to provide additional compensation if interventions ultimately fail to deliver the predicted biodiversity outcome.

5.11. The following three risks are recognised in this metric.

Difficulty of creation and restoration

5.12. This risk associated with delivery of biodiversity creation or enhancement due to uncertainty in the effectiveness of management techniques used to restore or create habitat.

5.13. The level of risk differs between habitat types because of ecological factors (e.g. the different challenges posed by creating different habitat types) and due to the availability of techniques or know-how to create habitats in a realistic time-frame. Uncertainty in achieving the target outcome for each habitat is addressed by a habitat-specific 'difficulty' multiplier based on available science and expert opinion.

5.14. There is a growing body of experience and expertise associated with habitat creation and enhancement[11]. Nevertheless, it is important to recognise that it is impossible to exactly replicate habitat losses because of the unique physical and ecological features of every place. This point is of particular relevance to impacts on well-established semi-natural habitats and emphasises why it is so important that the mitigation hierarchy is adhered to so that impacts on such habitats occur only when there is no alternative.

5.15. The difficulty and uncertainty of successfully creating, restoring or enhancing a habitat is recognised in this multiplier.

[11] As the evidence base on the effectiveness of creation and restoration techniques grows and is reviewed the risk multipliers may be modified. A timetable for future updates/revision to the metric will be published.

BETA TEST

Difficulty categories	
Category	**Multiplier**
Very High	0.1
High	0.33
Medium	0.67
Low	1

Temporal risk

5.16. In delivering compensation there may be a mismatch in the timing of the impact and compensation, i.e. the difference in time between the negative impact on biodiversity and the compensation reaching the required quality. This results in lower levels of biodiversity for that period of time.

5.17. This issue can be managed by the creation of compensation habitat ahead of the impact taking place: e.g. by starting the offset work well ahead of the development for projects with a long lead in or through the creation of a bank of habitat units.

5.18. However, this is not always possible and even where the management to create compensation habitat starts in advance, the time taken for habitats to mature means that there will almost inevitably be a time lag. Where a time lag does occur, a risk multiplier is applied. This is referred to as the '**Time to target condition'** multiplier.

5.19. The time period to use in applying the Time to Target Condition multiplier to a metric calculation is the length of time (in years) between the intervention and the point in time the habitat reaches the pre-agreed target quality (i.e. distinctiveness, condition, area). This time will vary between habitat types, between change scenarios (e.g. creation typically takes longer than enhancement) and due to way the habitat is managed. Time to target condition values – based on based on good practice and typical conditions are provided for all habitats used in biodiversity metric 2.0. These values are set out in detail in the Technical Supplement.

5.20. These time to target condition values then need to be discounted. Discounting over time is an economic technique used to compare costs and benefits that occur in different time periods based around the principle that, generally, people prefer to receive goods and services now rather than later. Where time discounting is used in compensation schemes a standard discount rate is typically used. The biodiversity metric 2.0 uses 3.5%, which is the value recommended in the Treasury Green Book[12](Table 5-2 shows the multipliers for a number of time periods using a discount rate of 3.5 %. It is important to use precise figures (at least to 3 decimal places).

5.21. To be practical, the metric:

- **assumes that there is a quality 'jump' from the baseline condition to the target condition** once the relevant number of years has elapsed. Metric

[12] more details on discounting can be found in the Treasury Green Book Guidance, HM Treasury, 2011).

BETA TEST

calculations do not take into account incremental increases in quality of the habitat and do not need to be re-done annually, and

- **sets a limit on the discount rate used for temporal risk**. The metric sets a multiplier limit of x0.320 to take account of temporal risk. This equates to approximately 32 years, which is about the maximum time frame that most projects and plans can realistically plan ahead.

Monitoring is, however, recommended to confirm the actual number of biodiversity units delivered matches what was predicted.

TABLE 5-2: Time to target condition: multipliers for different time periods using a 3.5% discount rate.

BETA TEST

Off-site risk multiplier

5.22. There are both ecological and social drivers for compensation habitat to be provided local to where losses occur: e.g. the cultural ecosystem services provided by an area of land to a community. When off site compensation is within the local planning authority area (LPA) or the same National Character Area (NCA)[13] it is considered

[13] Further information on NCAs can be found at: http://publications.naturalengland.org.uk/category/587130

that those drivers have been addressed. However there is a risk of compensation being delivered at distance from the impact site. Where this is the case the off-site risk multiplier is applied to those compensation parcels outside of the relevant LPA or NCA. This risk is applied to area habitat, hedgerow and river elements of biodiversity metric 2.0. Note – for rivers and streams different off-site risk multipliers called riparian loss. See Chapter 8 for more details.

TABLE 5-3: Off-site risk categories

Off-site risk categories			
Category	**Score**	**Point applied to calculation**	
		Pre-impact	**Post-impact**
Compensation inside LPA or NCA of impact site	1.0	No	**Yes**
Compensation outside LPA or NCA of impact site but in neighbouring LPA or NCA	0.75	No	**Yes**
Compensation outside LPA or NCA of impact site and beyond neighbouring LPA or NCA	0.5	No	**Yes**

Biodiversity change scenarios

5.23. Different biodiversity change scenarios carry different levels of risk and the multipliers are applied differently to reflect this. Three distinct biodiversity habitat change scenarios (illustrated in Figure 3.1) are recognised in the biodiversity metric 2.0:

- **Habitat creation or recreation.** Where one habitat type is replaced by another or the habitat is destroyed (e.g. by development works) and the same habitat is recreated.
- **Habitat restoration or enhancement** of an existing habitat to improve its distinctiveness and / or condition. An example of restoration would be the transformation of a derelict chalk grassland dominated by scrub and coarse grasses to a continuous area of chalk grassland with isolated woody species and an abundance of fine-leaved grasses.
- **Accelerated habitat succession**. This recognises that certain interventions are comparable with ecological succession processes which result in a more distinctive habitat type (for example, grassland changing into scrub and ultimately woodland).The biodiversity value of the original habitat is not abruptly lost, but gradually changes as the new habitat type emerges. Accelerated succession interventions are subject to 'trading down' principles. Accelerated succession is a purposeful sustained intervention and it is envisaged that there are a limited number of situations where this would apply. For example, the planting of an existing grassland with thorny shrubs to facilitate natural tree regeneration to establish a woodland without removing the grassland.

5.24. Under the above scenarios different portions of the biodiversity value of a habitat may have different risk multipliers applied to it. So, as illustrated in Figure 5-1, in the

BETA TEST

case of a straightforward habitat creation, you lose all the original habitat, so the risks apply to the whole value of the habitat being created. Whilst in the case of restoration or enhancement the habitat starts with and retains a certain biodiversity value that interventions increase. The risk multipliers are applied to this uplift (improvement) of the habitat. In accelerated succession the situation is more complex. Recognising that the original habitat retains a biodiversity value while the new habitat emerges the metric applies risk only to the uplift in value resulting from succession.

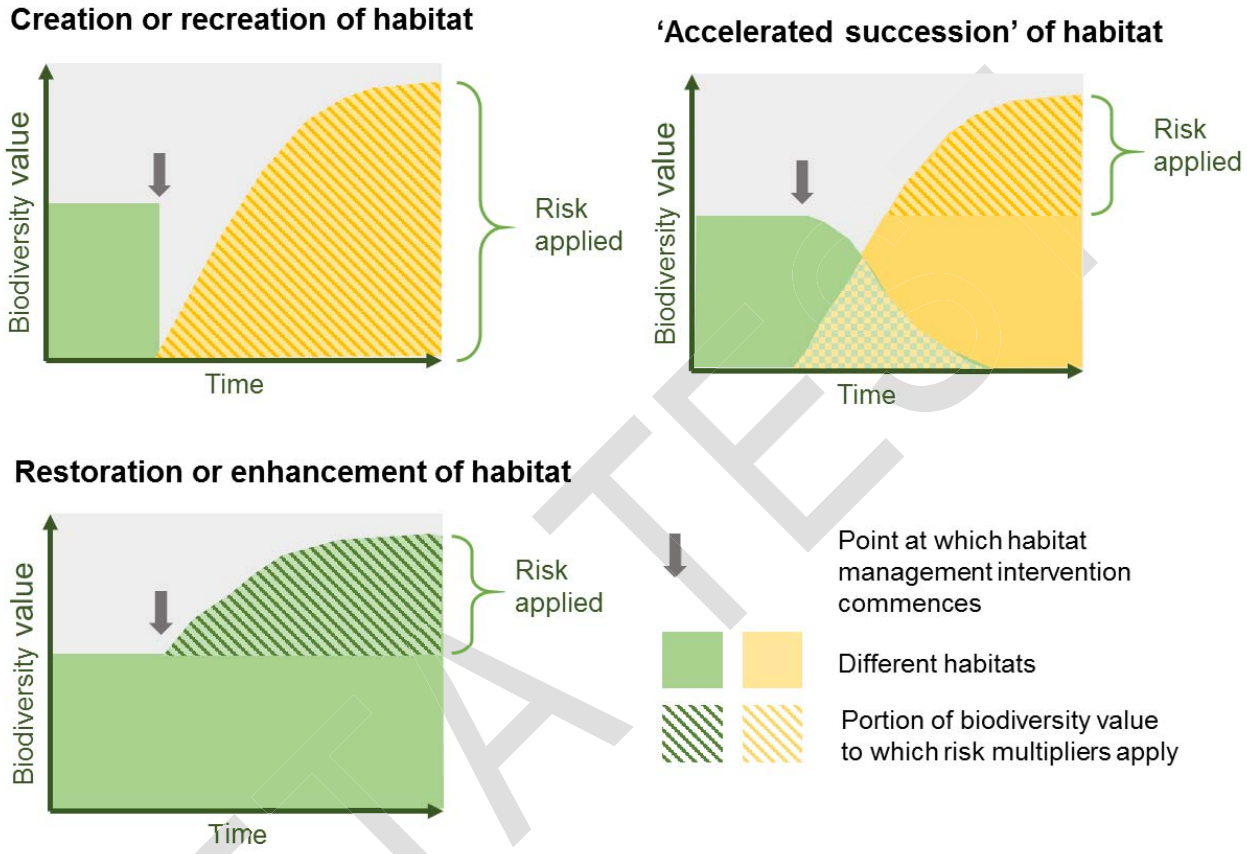

FIGURE 5.1: The biodiversity habitat change scenarios recognised in the metric

5.25. This leads to three different equations being used to generate biodiversity unit values pre and post intervention.

5.26. It is important to select the appropriate change scenario for each management intervention. This choice is an ecological judgement and is determined by the ecological consequences of the change, not where the habitat is located.

5.27. Compensation habitats can be created, restored or enhanced, or subject to accelerated succession on-site as well as off-site. Measures taken to generate biodiversity units by improving existing habitats must provide a significant and demonstrable uplift in distinctiveness or condition.

5.28. Good management practice does not, by itself, constitute restoration or enhancement, or accelerated succession.

BETA

The spatial component

5.29. In biodiversity metric 2.0 there are two core spatial components. First, the **strategic significance** of a place for biodiversity, its geography. Second, ecological **connectivity**, the relationship of a habitat in a defined place to its immediate surroundings in respect of biological and ecosystem flows. While these concepts are not completely independent of each other they do represent different qualities of a habitat.

Strategic significance

5.30. The idea of strategic significance works at a landscape scale. It gives additional unit value to habitats that are located in preferred locations for biodiversity and other environmental objectives. Ideally these aspirations will have been summarised in a local strategic planning document which articulates where biodiversity is of high priority and the places where it is less so. Strategic significance utilises published local plans and objectives to identify local priorities for targeting biodiversity and nature improvement, such Nature Recovery Areas, local biodiversity plans, National Character Area[14] objectives and green infrastructure strategies. Table 5-5 shows the multiplier scores for both impact and compensation sites based on its place in a strategic plan.

5.31. In the absence of a locally or nationally relevant strategic documentation indicating areas of significance for biodiversity, the value of **1** should be used in pre and post development calculations. Use of a score of 1 does not penalise a proposal.

TABLE 5-5: Strategic significance categories and scores

Strategic Significance categories			
Category	**Score**	**Point applied to calculation**	
		Pre-impact	**Post-impact**
High strategic significance High potential & within area formally identified in local policy	1.15	**Yes**	**Yes**
Medium strategic significance Good potential but not in area defined in local policy	1.1	**Yes**	**Yes**
Low Strategic Significance Low potential and not in area defined in local policy	1	**Yes**	**Yes**

Connectivity

5.32. The focus of connectivity in biodiversity metric 2.0 is the relationship of a particular habitat patch to other surrounding **similar** or **related** semi-natural habitats. These help facilitate flows of species and ecosystem services increases habitat resilience.

[14] For more details of National Character Areas see: https://www.gov.uk/government/publications/national-character-area-profiles-data-for-local-decision-making/national-character-area-profiles

By **similar** habitats we mean, for example, multiple patches of calcareous grassland. By **related** habitats we mean habitats often found in association as part of a dynamic complex, for example lowland heath and scrub. The same approach is applied to impact and compensation sites.

5.33. In the beta version of biodiversity metric 2.0 all High and Very High distinctiveness habitats should be assigned a Medium connectivity multiplier, other habitats a Low connectivity multiplier (see Table 5-5).

5.34. A connectivity tool will be published in an updated version of biodiversity metric 2.0. which will use an approach based upon the habitat fragmentation or 'structural connectivity' model with the National Biodiversity Climate Change Vulnerability Model (NBCCVM)[15] to assess connectivity and will generate connectivity categories from highly connected to low connectivity. It encompasses the ideas of:

- Larger habitat patches being less susceptible to extreme events;
- Accommodation of a wider range of soil types, topography and microclimate affords greater niche variation;
- Potential for species dispersal and local re-colonisation to be facilitated; and
- Patch size and permeability of surrounding landscape being important for persistence of biodiversity.

TABLE 5-5: Beta version Connectivity multipliers assigned by habitat distinctiveness.

Connectivity Multipliers		
Habitat distinctiveness	**Connectivity**	**Multiplier**
Very high distinctiveness	Medium	1.1
High distinctiveness	Medium	1.1
Medium and low distinctiveness	Low	1

Moderating the influence of spatial components

5.35. So that strategic significance and connectivity elements do not have a disproportionate effect on the calculation outputs the specific scores are restricted in range in the beta version of biodiversity metric 2.0 to: strategic significance 1 – 1.15, and connectivity 1 – 1.1.

6: Area Habitat biodiversity unit calculations

6.1. Areas habitats are perhaps the most familiar ecological currency in the UK, they are the woodlands, grasslands, wetlands and other types that are widely recognised by ecologists and the public alike. The habitats we recognise comprise a community of different species populations living in a place. There is usually a sub-group of those

[15] For more information about the NBCCVM see: TAYLOR, S., KNIGHT, M. & HARFOOT, A. 2014. National biodiversity climate change vulnerability model. Natural England Research Report NERR054. Natural England. ISBN 978-1-78354-084-6.

Abstract: Military helicopter training over the Lincoln National Forest (LNF) in southcentral New Mexico has been severely limited to protect nesting Mexican spotted owls (*Strix occidentalis lucida*). To evaluate nesting and nonnesting spotted owl responses to helicopter noise, we measured flush frequency, flush distance, alert behavior, response duration, prey delivery rates, female trips from the nest, and nest attentiveness during manipulated and nonmanipulated periods, 1995–96. Chain saws were included in our manipulations to increase experimental options and to facilitate comparative results. We analyzed stimulus events by measuring noise levels as unweighted one-third-octave band levels, applying frequency weighting to the resultant spectra, and calculating the sound exposure level for total sound energy (SEL) and the 0.5-sec equivalent maximum energy level ($LEQ_{max\ 0.5\text{-}sec}$) for helicopters, and the 10-sec equivalent average energy level ($LEQ_{avg.\ 10\text{-}sec}$) for chain saws. An owl-weighting (dBO) curve was estimated to emphasize the middle frequency range where strigiform owls have the highest hearing sensitivity. Manipulated and nonmanipulated nest sites did not differ in reproductive success ($P = 0.59$) or the number of young fledged ($P = 0.12$). As stimulus distance decreased, spotted owl flush frequency increased, regardless of stimulus type or season. We recorded no spotted owl flushes when noise stimuli were >105 m away. Spotted owls returned to predisturbance behavior within 10–15 min after a stimulus event. All adult flushes during the nesting season occurred after juveniles had left the nest. Spotted owl flush rates in response to helicopters did not differ between nonnesting (13.3%) and nesting seasons (13.6%; $P = 0.34$). Spotted owls did not flush when the SEL noise level for helicopters was ≤102 dBO (92 dBA) and the LEQ level for chain saws was ≤59 dBO (46 dBA). Chain saws were more disturbing to spotted owls than helicopter flights at comparable distances. Our data indicate a 105-m buffer zone for helicopter overflights on the LNF would minimize spotted owl flush response and any potential effects on nesting activity.

JOURNAL OF WILDLIFE MANAGEMENT 63(1):60–76

Key words: chain saws, disturbance, flush response, helicopters, Mexican spotted owls, noise, response thresholds, sound measurements, *Strix occidentalis lucida.*

To maintain tactical proficiency for low-level search-and-rescue missions, military air crews require frequent training. Recently, low-level training flights have come under scrutiny for their potential effects on wildlife, which has led to reductions in military access to potential training areas (Holland 1991). Holloman Air Force Base (HAFB), located in southcentral New Mexico, lacks sufficient area and habitat diversity to conduct effective helicopter training operations, but the Sacramento Ranger District of the LNF in the Sacramento Mountains contains the habitat diversity necessary to conduct such training operations. However, to avoid potential effects on nesting Mexican spotted owls (hereafter, spotted owl), military helicopters have been precluded from flying over the LNF during the February–August nesting season. To gain year-long access to the forest for training of the 48th Rescue Squadron (48 RQS), HAFB had to determine if and to what extent their activities might affect nesting spotted owls.

Much of the information about noise effects on raptors is anecdotal and fails to quantitatively measure either the stimulus or a behavioral response related to the animal's fitness. Predictive models for the relation between disturbance dosage and quantifiable effects are even more scarce (Awbrey and Bowles 1990, Grubb and Bowerman 1997). Although many types of human disturbance can affect birds of prey (Fyfe and Olendorff 1976), very little research has addressed the effects of human activity on owls (Wesemann and Rowe 1987; J. C. Bednarz and

[1] Present address: U.S. Army Construction Engineering Research Laboratories, P.O. Box 9005, Champaign, IL 61826, USA.
[2] E-mail: d-delaney@cecer.army.mil

T. J. Hayden. 1988. The Los Medanos cooperative raptor research and management program, unpublished. Final Report 1985–87 for Department of Energy and Bureau of Land Management. University of New Mexico, Albuquerque, New Mexico, USA.). Presently, there is no published research available on the possible effect of noise on spotted owls.

The objectives of this study were (1) record, characterize, and quantify helicopter overflights at spotted owl roost sites during a post- or nonnesting season (1995) and at active nest sites during the nesting season (1996); (2) develop a dose-response threshold relation for quantifying spotted owl behavioral responses to variation in noise levels and stimulus distances; (3) determine if helicopter overflights affect spotted owl reproductive success (successful nests) or productivity (young fledged); and (4) develop disturbance-specific management guidelines to minimize potential effects from helicopter overflights on the LNF.

STUDY AREA

This study was located within the Sacramento Ranger District of the LNF in southcentral New Mexico, Otero County. This area was chosen for its large population of spotted owls and its importance as a potential training site for the 48 RQS. Vegetation is primarily Rocky Mountain conifer forest (Brown and Lowe 1980) dominated by Douglas-fir (*Pseudotsuga menzii*) with some southwestern white pine (*Pinus strobiformes*) and ponderosa pine (*P. ponderosa*; Alexander et al. 1984). Elevation in the mountainous terrain ranges between 1,372 and 2,957 m.

METHODS

Surveys and Territory Selection

Territories were surveyed between 15 June and 6 July 1995 and between 15 March and 15 April 1996. We selected territories for our study based on (1) presence of mated pairs of spotted owls, and (2) no captures or manipulations prior to our research. During the 1996 nesting season, a third criterion required pairs to be reproductively active. Seven female and 6 male spotted owls were tested in the nonnesting season. During the nesting season, we concentrated on testing females because of their nest fidelity. Sample sizes in both the nonnesting and nesting seasons were limited by the number of pairs that fit the foregoing criterion.

Vocal imitations of spotted owl calls (Forsman 1983) were used during nocturnal and diurnal point surveys to locate both nonnesting and nesting spotted owls. During nocturnal surveys, we determined initial spotted owl locations between dusk and 2200 (all times reported as Mountain Standard Time). Spotted owl positions were triangulated by plotting compass bearings on topographic maps so that each area could be visited for diurnal surveys (predawn to 0800), when we followed spotted owls to a daytime roost. During the 1995 nonnesting season, we then radioed the location to the 48 RQS for an overflight later that day or conducted a chain saw manipulation. Upon finding a spotted owl during the 1996 nesting season, we attempted to determine its reproductive status by feeding it live mice. Nesting spotted owls take prey back to the nest, while nonreproductive spotted owls either cache or eat the prey (Forsman 1983). Once a territory was determined to be reproductively active, the nest location was recorded for future testing. To minimize interactions with spotted owls, we used the least number of mice necessary to determine reproductive activity.

Spotted Owl Behavior and Response Measures

We documented spotted owl behavior during manipulated and nonmanipulated periods by direct observation (camouflaged blinds 25–30 m from nest or roost) and through video surveillance. To evaluate spotted owl response behavior to helicopter and chain saw manipulations and contrast it with pre- and postmanipulated behavior, we measured the following: (1) flush frequency = proportion of manipulations that elicited a flight response; (2) flush distance = distance (m) flown by a spotted owl in response to a sound stimulus; (3) alert behavior = number of head movements averaged per 5-min block, before, during and after manipulations; (4) time to alert = minutes between start of a manipulation and when a spotted owl initially responded with a head movement in the direction of the manipulation; (5) response duration = minutes following a noise stimulus until a disturbed spotted owl returned to prestimulus behavior; (6) prey deliveries = number of prey deliveries recorded at each nest site (calculated per hour for diurnal, nocturnal, and 24-hr periods); (7) trips = number of times the attending female left the nest (calculated per hour for diurnal, nocturnal, and 24-hr periods); and (8)

nest attentiveness = proportion of time the adult female spotted owl spent on the nest through the nesting season (calculated for diurnal, nocturnal, and 24-hr periods, as well as for nesting phases; see Delaney et al. 1999).

Video Surveillance

Because our use of video was a new and unique application of the various hardware components, we had to design, construct, test, and modify our video surveillance system before applying it in the field (Delaney et al. 1998). We used Marshall black-and-white, miniature video cameras (Marshall Electronics, Culver City, California, USA) with night vision to monitor spotted owl behavior. (Use of trade names does not imply endorsement by the U.S. Forest Service Rocky Mountain Research Station, U.S. Air Force, U.S. Army Construction Engineering Research Laboratories, or Northern Arizona University to the exclusion of other potentially suitable products.) In addition to the 6 infrared light-emitting diodes (LEDs) on the camera board, 9-LED supplemental light sources were constructed to approximately double night-vision capabilities. Panasonic industrial-grade video recorders provided up to 24-hr coverage/VHS tape (Panasonic Corporation of America, Secaucus, New Jersey, USA). Between 9 April and 27 May 1996, cameras were placed at 20 nest sites in adjacent trees, averaging 6.9 m from nests (range = 3.0–10.3 m). A 15-m, power-line-and-coaxial-cable down line and a 60-m trunk line were used to minimize potential disturbance to spotted owls by offsetting the recorder and batteries to an out-of-sight tarpaulin blind. Between 25 April and 3 July 1996, video surveillance systems at 19 successful nests yielded >2,655 hr of spotted owl behavior coverage. All cameras and related equipment were removed after the 1996 nesting season.
