Submission ID: S3256D0E6

I would like to make a statement about the impact that this proposed project has already had on our communities and my concerns about what will happen if it is given consent and constructed.
The well-being of our rural South-Norfolk communities is rooted in our strong sense of place and love of this ancient countryside environment. Residents are in nature daily and regard wildlife as a valued part of our shared spaces. Our hundreds of listed buildings root us to our past and create a strong sense of continuity. Many families have been here for multiple generations, tending to, farming, or cherishing this landscape. Many of our residents are elderly, and going out in nature is important to their health, identity and well-being.
The feelings of powerlessness and massive industrial change - fencing, enclosure, exclusion of wildlife - that this project is bringing is already having a serious impact on our communities' well-being. In practical terms it is already causing significant distress, uncertainty and financial problems for families unable to move, to downsize, to release money for retirement, who rely on tourism businesses or businesses supporting farming such as contractors etc. All of our lives and plans, which we thought were secure, have been thrown into complete disarray, with little recognition, consideration, respect or understanding by the applicant.
The applicant's approach to sending LIQs and posting CPO notices (frequently miles from the affected address) has been frightening to local residents and not accompanied by enough information for people to understand what the need for their land is or whether this will be temporary or permanent. There is no support for vulnerable residents on low incomes to seek legal advice. They neither know where to go for advice nor have the disposable income to pay for it up front.
Good renewable energy projects should be collaboratively designed with communities and bring a genuine benefit to them, and to the supporting landscape and ecology. This project has been none of those things. It is being imposed upon us, against our will. Our vulnerable residents have been frightened and contacted multiple times with documents they do not understand and to which they are unable to respond, with no offer of independent support for them.
We do not trust that IGP or Macquarie, as the previous owner of Thames Water, can be trusted as stewards of our landscape, ecology, chalk streams, aquifer, heritage or communities. They have so far not shown us any reason to believe that this project - pursued for 'optionality' and 'attrition' - is for any benefit other than their own and their shareholders' financial profit, or that any need will outweigh the significant harms that this project will cause in this location.

Submission ID: S468AE711

These land parcel objections for sites 3, 6 and 7 were researched and written by BEPS members impacted by the Scheme.
They are part of a group of 11 such land parcel objection documents, covering the entire scheme. The other land parcel objection documents are being submitted by individual Parish Councils.
All of these land parcel objection documents should be read in conjunction with BEPS's Written Representation (already submitted), the LVIA report compiled and submitted by Hempnall Parish Council, and the specialist reports on Barbastelles, Hydrology/Hydrogeology and Cultural Heritage submitted in the BEPS WR appendix.

Submission ID: SE0C00B48

These written representations have been compiled with residents of the village with BEPS-Great Moulton, who are part of BEPS.

DISCLAIMERS

Research Method and Use of AI

This document has been prepared from research undertaken by multiple human researchers using information available at the date of preparation. Sources include East Pye Solar application documents, Planning Inspectorate material, National Grid/NGET information, statutory consultee evidence, relevant government and regulatory material, guidance, best practice and, where relevant, peer-reviewed research.

Given the scale and complexity of the documentary record, BEPS Great Moulton also uses a closed-project bespoke GPT as a research and analytical aid. It assists with organising, cross-referencing and comparing material, identifying links between documents and topics, and supporting analysis of evidence already gathered by the research team.

The GPT is not treated as an independent source of evidence or as a substitute for human judgement. All submissions are reviewed, edited and checked by human members of BEPS Great Moulton. Material sources and significant factual propositions are checked against the underlying documents before reliance is placed upon them, and the authors determine the arguments and conclusions advanced.

This document is therefore a **human-reviewed submission, not an independent expert report**. Responsibility for its contents, accuracy and arguments remains with the authors. AI has been used only as an analytical, cross-referencing and document-management tool within a human-led research and review process.

Where this draft refers to National Grid Electricity Transmission plc (NGET) representations, it relies on the wording quoted in the source document unless the final submission team has separately checked the published Examination Library version.

The Ofgem material is used for a narrow purpose: it supports the proposition that BESS connection deliverability, queue credibility, battery oversupply and network-capacity allocation are live regulatory matters. It is not used to assert that East Pye has lost its connection or that the BESS cannot connect.

It is understood that East Pye Solar has continued to amend, supplement and update material submitted to the Planning Inspectorate during the examination process.

Accordingly, we respectfully ask the Examining Authority to read this submission in the context of the information reasonably available to us at the time it was prepared. Where subsequent Applicant submissions clarify, amend or supersede earlier information, any resulting discrepancy within this document is unintentional and should not be interpreted as an attempt to misrepresent the Applicant's case or evidence.

On behalf of the Village of Great Moulton we have sought throughout to present the Applicant's evidence accurately and fairly, while identifying those matters on which we consider further clarification, evidence or examination is required.

Initial Comments on Submission by the Writers of this Document

Great Moulton residents submit that the East Pye Solar application is unusually difficult for affected residents to understand because the principal effects on Great Moulton are split across multiple application documents, plans, appendices and outline management documents. The issue is not merely volume. It is the absence of one consolidated, parcel-specific explanation of the National Grid Substation, the 400 kV Project Substation, the BESS interface, overhead-line works, pylons, access, drainage, construction compounds, lighting, safety controls and retained infrastructure affecting Site 1.

This submission therefore asks the Examining Authority to test the Scheme as it will be experienced locally: as a concentrated western grid infrastructure hub on and around Site 1 and the BESS, not as a set of isolated technical components.

The Structure of East Pye's documents and lack of clarity, means that we are unable to obtain a full understanding of the design being proposed. From incorrectly labelled images and photographic co-ordinates making it impossible to actually ascertain what and where they have photographed - see document EN01110014, this document actually includes the National Grid Substation although labelled BESS.

The residents' position remains firm: renewable -energy policy does not remove the need to test whether the chosen BESS location is justified and whether its acknowledged impacts are acceptably controlled.

Oxford EN010147 Secretary of State Request

The Secretary of State request for further information in Botley West Solar Farm, EN010147, is not relied upon as a binding precedent. It is relied upon only as a recent comparator showing that, in a large solar NSIP, unresolved issues about alternatives, site selection, grid connection, design evolution, cumulative effects and mitigation can justify further information before determination.

The same type of scrutiny is appropriate here because Land Parcel 1 / Site 1 combines the National Grid Substation, 400 kV Project Substation, overhead -line works, cable routes, pylon works, access requirements, PRoW interactions, Grade 2 BMV land, private-water -supply risk, landscape harm and the functional relationship with the BESS.

EXECUTIVE SUMMARY

Great Moulton residents object to the concentration of the Scheme's principal western grid infrastructure at and around Land Parcel 1, particularly Sub-Site 1B. The submitted East Pye material confirms that the Scheme includes a new National Grid Substation and a 400 kV Project Substation, Grid Connection Infrastructure, including overhead-line and pylon works, cable routes and BESS infrastructure and associated access, drainage, security and mitigation works. These elements are functionally linked and should be assessed together.

The core objection is not that every topic is wholly unassessed, our objection is, that the acceptability of this locations depends on a transparent, criteria-led and enforceable justification for concentrating long-lived and permanent grid infrastructure close to Great Moulton village, that justification has not yet been provided with sufficient clarity.

The National Grid Substation and Grid Connection Infrastructure are materially different from temporary solar arrays. The East Pye material indicates that solar generation equipment and some project infrastructure would be removed at decommissioning, while the National Grid Substation and Grid Connection Infrastructure would remain in situ.

The planning balance must therefore distinguish temporary generation from retained transmission infrastructure, the effects cannot therefore be treated simply as temporary or reversible.

1. Need, Regional Oversupply and Proportionality

Great Moulton residents do not, in the main, dispute the national policy support for low-carbon generation. However, the issue is whether this particular 500 MW scheme, and especially the Site 1 grid hub and BESS interface, has been justified as necessary, proportionate and least harmful at this location.

The Applicant's own Statement of Need is said to acknowledge that the Site lies at the boundary of the Central England and East Anglia transmission regions and that NESO's Connections Reform process has already prioritised sufficient solar schemes to meet the relevant Clean Power 2030 regional capacity ranges for 2035. If those ranges are already met by prioritised schemes, regional necessity and proportionality cannot simply be assumed from national policy support for solar in principle.

The 2026 connections reform and Ofgem material materially strengthen the need for examination of deliverability and proportionality. Ofgem has stated that the battery queue is far beyond projected system need, with approximately 90 GW either operational or in the reformed queue compared with a projected 29 GW requirement by 2035. Ofgem is consulting on an Oversubscribed Technologies Commitment Fee intended to make the BESS queue more

credible and to ensure scarce grid capacity is held by projects that are serious about progressing.

This does not prove that East Pye cannot connect. It does mean that BESS connection status, connection offer assumptions, network-capacity allocation, likely attrition and the relationship between the solar and BESS components are material matters for the ExA. The Applicant should not be permitted to rely on general national need while avoiding detailed scrutiny of whether this BESS and grid hub are needed and deliverable in this location

Where permanent transmission infrastructure is proposed on high-quality agricultural land in a rural landscape close to Great Moulton, the quality of the site-selection and alternatives case is correspondingly important.

Source: APP/7.11 Statement of Need, including sections 5.3 and 7.2-7.3; APP/7.12 Grid Connection Statement.

2. DCO Certainty, Documentation and Post-Consent Controls

The submitted DCO and the outline plans must provide enough certainty for the ExA to reach a reasoned conclusion on likely significant effects. When critical matters are left to a later detailed ensign, the DCO must secure fixed parameters, approval triggers, standards, monitoring and corrective action, and monitoring obligations where they bear on likely significant effects or site suitability.

The section 51 advice identified the need for precision in document references, document dates, definitions and qualified commitments. This matters, because Site 1 impacts depend on construction access, drainage, firewater containment, noise control, protected species mitigation, utilities protection, PRoW management and decommissioning controls.

Great Moulton residents ask that all commitments bearing on likely significant effectors be converted from board wording such as “where practicable” or “where appropriate”, into binding requirements with approval bodies, objective standards and enforcement routes.

There also appears to be material inconsistency in the description of the BESS location. ES Chapter 4 states that Work No. 2 is the BESS compound “contained within Sub-Site 1B”, while the Non-Technical Summary and other scheme descriptions refer to a separate BESS Site. The Applicant should reconcile those descriptions and confirm that the Environmental Statement assesses the correct worst-case relationship between the BESS, Sub-Site 1B, the National Grid Substation and the Project Substation infrastructure.

Source: PINS section 51 post-acceptance advice, EN0110014-000275; APP/6.1.4 ES Chapter 4, para 4.2.7; APP/6.4 ES Non-Technical Summary.

3. Consultation Adequacy

The consultation concern is practical and substantive. Residents were required to respond to a large technical application whose most important local effects were spread across many documents and changed through design evolution.

Where the grid solution, substation voltage, BESS relationship, pylon works, access requirements or retained infrastructure have materially changed since earlier consultation, the Applicant should provide an auditable before-and-after schedule. That schedule should identify what changed, which receptors were newly or differently affected, what additional assessment was undertaken and why the Applicant says no new significant effects arise.

The ExA should treat consultation adequacy together with the clarity of the environmental information. A community cannot meaningfully engage with a grid hub if it must infer its true scale and operational effects from fragmented plans and outline documents.

The ExA should treat this statutory consultation with caution because consultees were asked to respond to a very large and evolving Scheme, including the BESS, National Grid substation, project substations, cable corridors, 400 kV overhead-line and pylon works, compulsory acquisition powers and a 60-year operational life.

The consultation documents were available electronically without charge and inspection copies were provided at specified locations. However, the section 46/48 consultation material stated that a requested printed copy of the PEIR and PEIR Non-Technical Summary could attract a charge of up to £750.

We do refute that the information was wholly unavailable; its concern is the practical accessibility of a large technical consultation for residents who could not readily use the electronic material, combined with subsequent design evolution and corrections.

Source: APP/5.9 statutory consultation notices/materials; Applicant Adequacy of Consultation material; PINS correspondence and section 51 advice concerning parish-council notification.

4. Land Parcel 1 as the Cumulative Infrastructure Choke-Point

Land Parcel 1 is not simply another solar field . It is the proposed point at which the National Grid Substation, the 400 kV Project Substation, Grid Connection Infrastructure and overhead-line/pylon, cabling, access, drainage, security, construction compounds, PRoW impacts and the BESS interface converge in a confined rural area.

We submit that this convergence produces a local cumulative effect. Residents, walkers, farmers, emergency services and PRoW users will experience the combined infrastructure, not separated topic chapters.

The ExA should therefore require a place-based Great Moulton / Site 1 cumulative assessment.

5. Site Selection - Unlawful or Inadequate Alternatives

Great Moulton's concern is not that the Applicant has produced no alternative material, the issue is whether the selected location has been tested transparently and consistently against environmental land-use, community and safety criteria.

When Norwich Main was discounted, the Applicant pursued a new 400kV connection along the Bramford to Norwich line. We accept that an alternative exercise was undertaken. The evidence does not yet demonstrate that Great Moulton was selected as the least harmful location.

We ask the Examining Authority to look carefully at the chronology, particularly the role of landowner willingness.

APP/7.20 paragraph 6.1.3 states that suitable land "with willing landowners wishing to participate in the Scheme" was identified at the same time as undertaking discussions with NGET about the grid connection.

Paragraph 6.1.7 confirms further that during Stages 2 and 3, land agents identified large landholdings with potentially willing landowners, which were then evaluated and taken forward to EIA Scoping.

This shows that landowner willingness was already influencing the process before the January 2025 EIA Scoping exercise.

APP/7.20 records the original National Grid Substation alternatives at Newton Flotman, Tharston/Tasburgh and Long Stratton — Options 1, 2 and 3 — before Great Moulton was introduced as the additional Option 4.

However, APP/7.20 does not clearly explain for Options 1, 2 and 3:

- whether the relevant landowners were approached
- when they were approached
- whether they were willing to participate
- whether those sites were available on the same voluntary basis as the Great Moulton land.

By January 2025, the EIA Scoping material showed both the southern Great Moulton location and the alternative location within what became Sub-Site 1B. APP/7.20 paragraphs **3.5.20–3.5.22** confirm that the southern location was initially the proposed site, with Site 1B as the alternative.

Paragraph 4.6.1 later confirms that the Applicant had established that landowners for the identified sites were willing to enter into voluntary agreements.

APP/7.20 paragraph **3.6.24** expressly records that alternative land within Siting Zone 2, south of Station Road and west of the railway, **was not selected because a willing landowner was not**

forthcoming. We would submit that this demonstrates landowner willingness was capable of determining whether potentially suitable land remained within the alternatives exercise.

We therefore ask the Examining Authority to require a clear chronology for Options 1, 2, 3, 4A and 4B, identifying:

- the date each option was first considered
- When landowners were first approached
- whether that landowner was willing to participate
- whether land availability was established **before or after** the environmental and technical assessment of that option.

Without that information, it is difficult to establish whether landowner willingness was simply a final deliverability check, or whether it **materially narrowed the alternatives before they could be compared on an equal basis.**

Source: APP/7.20 Site Selection Assessment, including the Norwich Main and Great Moulton option appraisal; Applicant references to the Horlock Rules.

6. Permanent Loss of Grade 2 BMV Agricultural Land

The agricultural-land case should be stated precisely. Site 1 and the National Grid infrastructure affect good quality BMV Grade 2 land, this infrastructure and project substation infrastructure are not comparable to raised solar arrays, because they involved hardstanding, foundations, access, drainage, operational compounds and retained infrastructure.

The Applicant should explain, when the early selection exercise relied on provisional Grade 3 land and later detailed ALC evidence identified Grade 2 land, why did this evidence not trigger reconsideration of the grid hub and BESS location, If it didn't the reason should be stated.

The ExA should require a field-by-field BMV schedule distinguishing temporary, long-term and permanent land take, including Site 1A-1D, the BESS Site, access, cabling, compounds, substations and mitigation land.

Source: APP/6.1.15 ES Chapter 15; APP/6.4 ES Non-Technical Summary; Outline Soil Resource Management Plan / detailed ALC evidence.

7. Groundwater, Private Water Supplies and Pollution Control

The water objection is not that East Pye has ignored water entirely. The remaining concern is the extent to which critical site-specific controls are deferred. The Outline CEMP provides for ground investigation before construction and states that a Foundation Works Risk Assessment will be undertaken post-consent for structures requiring deep foundations and/or piling, such as the Project Substations. A Hydrogeological Risk Assessment may also be required for trenchless crossings that interact with aquifers, watercourses or sensitive ecological receptors. For a permanent high-voltage installation involving transformers, oils, fuels, concrete works, impermeable areas and emergency/firewater considerations,

The ExA should require a single source-pathway-receptor note for Great Moulton / Site 1 and the BESS, covering baseline water-quality testing, private water supply identification, hydrogeological pathways, trenchless works, piling, oil containment, firewater containment, drainage exceedance, monitoring, response triggers and alternative supply arrangements.

Pollution-control measures should be secured through DCO Requirements and certified plans, not left as non-specific post-consent construction management.

Source: APP/6.1.9 ES water-environment assessment and appendices; APP/7.1 Outline CEMP, including ground investigation and Foundation Works Risk Assessment commitments; relevant consultation responses from the Environment Agency.

8. Compulsory Acquisition and Funding Evidence

Compulsory acquisition must be considered with alternatives and necessity. If the site-selection case is not robust, the case for acquiring or interfering with land and rights at Site 1 is correspondingly weakened.

The ExA should require the Applicant to show that each parcel and right within Site 1A-1D, Station Road, Frith Way, Hundred Lane and associated PRoW / utility land is necessary, proportionate and no more extensive than required for the authorised development.

Source: PINS section 51 post-acceptance advice, EN0110014-000275; Applicant Funding Statement and compulsory-acquisition documents.

9. Ecology and Barbastelle Deliverability

The Applicant's bat evidence records that the Order Limits fall within the Core Sustenance Zone of several known Barbastelle maternity colonies in surrounding woodland. The Ground Level Tree Assessment also identifies numerous trees with potential roosting features and states that, if bats are confirmed roosting in a tree that would be affected, an appropriate European Protected Species mitigation licence would be required before those works.

The Applicant seeks to avoid effects through retention of trees and hedgerows, buffers and lighting controls. BEPS's point is therefore one of deliverability: the final design of the 1B grid infrastructure and its associated lighting, access and construction disturbance should demonstrably maintain the ecological connectivity on which the assessment relies. If a licensable effect cannot be avoided, the statutory licensing tests, including the absence of a satisfactory alternative, become relevant.

PINS also noted at acceptance that the HRA material did not include the relevant Natura 2000/citation data sheets and recommended that these be supplied. That is an audit-trail issue that the competent authority should resolve; it is not, by itself, proof that the HRA conclusions are wrong.

If the final design requires a European Protected Species licence, the ExA should examine whether the no-satisfactory-alternative test can realistically be satisfied where the alternatives case for Site 1B remains contested.

Source: APP/6.1.8 ES Ecology and Biodiversity; APP/6.3.8.5 Ground Level Tree Assessment; PINS acceptance checklist / HRA observations.

10. Safety, Access, Rail and Aviation

Site 1 is a safety-critical infrastructure hub. Fire safety, transformer delivery, abnormal loads, emergency access, rail interface, aviation and glint / glare are not secondary construction details. They bear directly on site suitability.

The Applicant should provide one safety and emergency-response schedule for Site 1 and the BESS, including access widths, turning, cordons, smoke plume, water supply for firefighting, contaminated runoff, transformer incidents, battery incidents, road closures, railway interface, aviation safeguarding and emergency-service consultation outcomes.

10.1 Failure to Provide a Site-specific Norfolk Fire and Rescue (NFRS)

The NFRS have expressed their concerns regarding the proposed changes to the siting to the National Grid 400kV substation and the location change of the 132 kV substation upgraded to 400kV. They have particularly raised serious concerns given the close proximity to nearby residents in Great Mouton in the event of any fire or other emergency

The emergency-response assessment should be Site 1-specific and should include the National Grid Substation, 400 kV Project Substation, transformers, switchgear, oil containment, control buildings, cabling, access and firefighting water. It should not be limited to the BESS.

It should record NFRS consultation and secure any required controls.

BEPS-Great Moulton requested the ExA to require a site-specific Norfolk Fire and Rescue Service consultation schedule, showing what NFRS has requested, what the Applicant has accepted, what remains outstanding and how controls will be secured.

Source: APP/7.5 Outline Battery Safety Management Plan and related fire-emissions material; submitted drainage and emergency-management documents.

10.2 Abnormal Loads, Station Road and Rail Interface

Transformer delivery to the National Grid Substation and 400 kV Project Substation requires abnormal-load planning. Station Road, Frith Way, Lodge Road, Hundred Lane and the local railway interface should be assessed together for resilience, traffic management and emergency access.

The ExA should not accept that abnormal loads can be resolved solely through a later Construction Traffic Management Plan unless the critical route assumptions, structures, swept paths, verge protection, road closures and emergency arrangements are already fixed in principle.

Source: APP/6.3.11.1 Transport Assessment, including abnormal-load routing to Sub-Site 1B and the description of B1134 Station Road.

10.3 Aviation and Glint / Glare

Aviation and glint/glare effects are relevant to road safety, residential amenity and local aviation activity. The source material identifies Seething, Long Stratton, Hardwick, Topcroft Farm and Nut Tree Farm airfields, Norfolk Gliding Airfield, and consultation concerns relating to glint and glare, EFATO and thermal updrafts. For Land Parcel 1, these issues must be considered alongside solar panels, new overhead-line works, pylons, substations and associated construction activity.

The ExA should require confirmation that the final western infrastructure is within the aviation and safeguarding assumptions assessed, and that any consultant conditions are secured before operation.

Source: APP/6.1.18 ES Other Environmental Topics; submitted Glint and Glare and aviation / high-level investigative reports, including APP/7.27.

11. Overall Position

It is submitted that Land Parcel 1 / Sub-Site 1B has not been transparently justified as the location for the principal grid hub of the East Pye Solar scheme. Our case is that Land Parcel 1 / Sub-Site 1B remains the critical point at which the Scheme's alternatives, cumulative effects, permanent infrastructure, protected-species, groundwater, agricultural-land, access, safety and compulsory-acquisition issues come together. The Applicant has produced substantial assessment material, but the Examining Authority must be satisfied that the final configuration is justified by a transparent alternatives case and controlled by enforceable requirements that keep it within the assessed environmental envelope.

The cumulative impact of the scheme will crystallise in this area: Noise, lighting, traffic, 24-hour operational presence, security fencing, heavy plant, cable trenching, tower removal and replacement, transformer deliveries, residential amenity impacts, landscape effects and land-acquisition pressures all converge here. Yet the Applicant has not provided a focused cumulative-impact assessment for Great Moulton / Land Parcel 1 reflecting that exceptional concentration of infrastructure.

Nor has the Applicant provided a sufficiently neutral alternatives appraisal. Chapter 5 recognises that reasonable alternatives must be described with the main reasons for the chosen option, taking account of environmental, social and economic effects. However, the choice of

Sub-Site 1B is presented largely as a constrained outcome following the rejection of Norwich Main and a subsequent search along the Bramford–Norwich 400kV line. That does not demonstrate that this location is the least harmful or most appropriate site for a major rural grid hub.

We would further object that the Applicant relies on a flexible and deferred design envelope for critical infrastructure, including the National Grid Substation, Project Substations and Grid Connection Infrastructure. Flexibility may be acceptable for limited detailed design matters, but not where it prevents affected residents from understanding the likely effects of the Scheme's most intensive infrastructure on their homes, village, access, landscape, amenity and safety.

The ExA should require a consolidated Site 1 Grid Hub Statement, a revised alternatives appraisal, a National Grid / NESO / NGET delivery statement, a place-based cumulative effects assessment and a schedule of enforceable DCO controls before placing significant weight on the Applicant conclusions.

Examination Requests

On behalf of Great Moulton, Tivetshall and Wacton, we respectfully request that the Examining Authority require East Pye, and NGET where relevant, to provide a coordinated response to the matters set out below.

These requests are intended to test whether the Scheme is sufficiently defined, assessed and secured for determination. They do not seek to transfer the Applicant's design, assessment or evidential responsibilities to local residents.

- Provide a definitive Site 1 Grid Infrastructure Reconciliation Plan and Schedule covering Sub-Sites 1A–1D, the National Grid Substation, 400 kV Project Substation, Grid Connection Infrastructure, overhead-line and pylon works, underground cables, construction compounds, access routes, drainage, security infrastructure, mitigation land and the interface with the BESS. For each component, identify the relevant Work Number, maximum parameters, land requirement, temporary or permanent status, delivery body, operational responsibility and decommissioning position. [APP/6.1.4; APP/2.3; APP/7.12; APP/7.18]
- Confirm the final or presently assumed grid-connection solution and its deliverability, including the respective responsibilities of East Pye and NGET for design, construction, land, consent, operation and maintenance of the National Grid Substation, overhead-line works and associated Grid Connection Infrastructure. Identify which elements are fixed and which remain subject to NGET detailed design or further agreement, and demonstrate that any remaining flexibility cannot produce materially different environmental effects. [APP/7.12]
- Reconcile the current connection position for the solar and BESS components and explain the consequences for Site 1 if their connection rights, timing or configuration differ. This should include confirmation that the Site 1 land take, substation configuration, cable infrastructure and environmental assessment remain justified under each realistically deliverable connection scenario. [APP/7.11; APP/7.12]
- Provide a dated and auditable National Grid Substation alternatives chronology for Options 1, 2, 3, 4A and 4B, identifying when each option was identified, assessed, refined and discounted or selected; the evidence available at each decision point; and the technical, environmental, access, residential, land-use and planning criteria applied.
- Provide a common side-by-side comparison of Options 1, 2, 3, 4A and 4B, using consistent criteria and identifying the contemporary evidence supporting each assessment. Where different levels of technical investigation were undertaken—for example highway, abnormal-load, landscape, flood-risk, ecology, heritage or PRoW work—the Applicant should explain why the comparison remained robust. [APP/7.20]

- Explain transparently how land availability and landowner willingness influenced site selection. The Applicant should identify when those considerations entered the process, distinguish locations rejected on environmental or technical grounds from locations not progressed because land was unavailable, and demonstrate that reasonable alternatives were not excluded from meaningful comparison solely because voluntary land agreements were not available. [APP/7.20; APP/7.15]
- Provide a Horlock Compliance Schedule for the Site 1B Grid Hub, prepared with NGET input where appropriate, showing how the relevant principles influenced site selection and design, including local amenity, landscape and screening, residential proximity, noise, agricultural land, groundwater, ecology, PRoW, access and the concentration of infrastructure at Site 1B. [APP/7.20; APP/7.14]
- Provide a design-options statement for the National Grid Substation and 400 kV Project Substation, explaining the consideration given to AIS, GIS, hybrid or other compact arrangements and alternative layouts. Where an alternative was studied and rejected, provide the reasons; where it was not studied, explain why it was not considered a reasonable design alternative. Demonstrate that the retained design envelope represents the assessed worst case for footprint, height, visual effects, noise, drainage and land take.
- Identify every environmentally material matter remaining flexible under the Rochdale Envelope and provide a compliance schedule linking each matter to the relevant maximum parameter, ES worst case, certified document, DCO Requirement, approval body and verification mechanism. The Applicant should demonstrate that detailed design cannot exceed the environmental effects assessed. [APP/6.1.4; APP/7.18; APP/7.26]
- Provide a definitive statement on permanence and decommissioning. This should distinguish the infrastructure intended to be removed after the approximately 60-year operational period from the National Grid Substation and Grid Connection Infrastructure intended to remain, identify any secured end date for the retained infrastructure, and show the post-decommissioning Site 1 landscape including retained access, pylons, cables, drainage, fencing and mitigation planting. [APP/6.1.4; APP/7.3]
- Confirm the long-term management and legal control of mitigation associated with retained National Grid infrastructure, including which planting would transfer to NGET, the maintenance obligations applying after East Pye's decommissioning, and the mechanism securing those obligations for as long as the retained infrastructure remains.
- Provide a field- and component-specific Agricultural Land Classification and BMV schedule for Site 1A–1D and associated grid works, distinguishing temporary disturbance, long-term occupation and permanent loss caused by substations,

foundations, piling, access, drainage, construction compounds, pylon works and retained infrastructure. Explain whether the later identification of Grade 2 BMV land caused the earlier site-selection conclusions to be reconsidered and, if not, why not. [APP/6.1.15; APP/6.3.15.1]

- Provide a Site 1 landscape and residential visual reconciliation, assessing the combined National Grid Substation, Project Substation, solar arrays, pylons, fencing, security infrastructure, access and mitigation rather than treating those elements independently. Provide verified plans and representative visualisations from the most affected Great Moulton receptors and PRoW, with coordinates, camera position, lens/focal-length information and measured relationships to the development envelope. [APP/6.1.7; APP/6.3.7.9]
- Demonstrate the cumulative operational noise effects of the complete Site 1/BESS electrical infrastructure cluster, including the National Grid Substation, Project Substation, BESS, transformers, inverters, switchgear and cooling equipment. The assessment should identify the final or maximum plant assumptions, representative quiet night-time conditions, tonal and low-frequency characteristics, mitigation relied upon and the combined noise limit applying to the completed development. [APP/6.1.12; APP/7.2]
- Secure post-installation acoustic verification and corrective mitigation, so that compliance is demonstrated using the equipment actually installed and operated. The control should address tonal, low-frequency or otherwise distinctive noise as well as overall A-weighted sound levels and should prevent later plant replacement from exceeding the assessed envelope.
- Provide a consolidated Site 1 groundwater and Private Water Supply Source–Pathway–Receptor assessment, covering PWS identification, baseline water quality and yield where required, piling and deep foundations, cable trenches and trenchless works, transformer oils, contaminated runoff, drainage, monitoring, trigger levels and alternative-supply arrangements. [APP/6.1.9; APP/6.1.16; APP/7.1]
- Demonstrate before relevant works commence that deferred ground investigation and Foundation Works Risk Assessment requirements refine an environmentally acceptable design rather than determine post-consent whether an acceptable solution is achievable. Identify the limits on piling, foundation design and penetrative works that protect groundwater and PWS receptors. [APP/7.1]
- Provide a coordinated drainage, pollution-prevention and emergency-containment plan for the Site 1 Grid Hub, distinguishing clean surface water from potentially contaminated drainage and addressing transformer-oil containment, extreme rainfall, exceedance routing, containment-system failure and interaction with BESS firewater where relevant.

- Provide a definitive construction, abnormal-load and operational-access schedule for Site 1, reconciling Station Road, Frith Way, Lodge Road, Hundred Lane/RB19, A01/A02 and all other relevant accesses and haul routes. It should identify the purpose of each route, vehicle type, frequency, construction or operational use, temporary or permanent status, necessary highway works, PRoW crossings and emergency-access arrangements. [APP/6.1.11; APP/6.3.11.1; APP/7.6]
- Confirm the purpose and permanence of the Hundred Lane/RB19 crossing and any other retained maintenance access. Where an access is required for infrastructure intended to remain beyond the solar operational period, that potentially indefinite use should be identified and assessed accordingly; where it is not required after decommissioning, the restoration obligation should be secured.
- Provide a Site 1 PRoW reconciliation schedule covering FP13, FP14, RB19/Hundred Lane and all other affected routes, identifying closure periods, crossings, permanent access use, vegetation removal, safety controls, residual visual effects and restoration. The assessment should address the PRoW network as a connected recreational and landscape resource rather than only as individual route segments. [APP/6.3.7.9; APP/7.8]
- Demonstrate that the final Site 1 grid-infrastructure layout remains within the ecological assessment, including hedgerows, trees, ponds, ditches, bat flight lines and dark corridors, breeding birds, great crested newts and other protected species. Identify any licensing dependencies and demonstrate that access, drainage, lighting, fencing and final infrastructure locations do not undermine mitigation or ecological connectivity relied upon in the ES.
- Provide a coordinated operational-lighting and security plan for Site 1, showing permanent, maintenance and emergency lighting; CCTV locations and heights; switching and control arrangements; spill limits; ecological dark corridors; residential receptors and PRoW. Assumptions that lighting will be temporary, exceptional or inward-facing should be secured where relied upon by the environmental assessment.
- Provide an integrated Site 1 emergency-response statement, prepared with NGET and the relevant emergency services where appropriate, covering the National Grid Substation and Project Substation as well as the BESS interface. It should address transformer and electrical incidents, firefighting access, water supply, oil and contaminated-water containment, cordons, road restrictions, emergency access and the responsibilities of each operator.
- Demonstrate that EMF exposure from the final combined infrastructure remains within the assessment and applicable public-exposure standards, showing the relevant overhead lines, underground cables, substations and nearby residential and PRoW

receptors, and identifying any design assumptions or minimum separation distances relied upon.

- Provide a consolidated utilities and service-protection schedule identifying existing electricity, telecommunications, broadband, water, drainage and other infrastructure affected by Site 1 works, together with protection/diversion arrangements, responsible bodies, emergency repair procedures and service-continuity measures.
- Provide a place-based cumulative assessment for Great Moulton and the Site 1/BESS infrastructure cluster, bringing together landscape and visual effects, operational noise, lighting, access and traffic, PRoW, ecology, heritage, water, agricultural land, safety and residential amenity. The assessment should include construction, operation, foreseeable replacement activity, decommissioning and the retained National Grid infrastructure rather than limiting the assessment to individual technical chapters.
- Provide a whole-life infrastructure and replacement schedule identifying reasonably foreseeable replacement of transformers, switchgear, electrical plant, solar equipment and BESS equipment and demonstrating that associated abnormal loads, traffic, lifting operations, noise, temporary compounds and other construction-type effects remain within the assessed and secured envelope.
- Provide a consultation and design-change audit for Site 1, identifying material changes between Scoping, statutory consultation, targeted consultation and the DCO application, including changes to the National Grid Substation, Project Substation, pylon/OHL works, access, cable routes and the relationship with the BESS. For each material change, identify the affected receptors, additional assessment undertaken and consultation carried out.
- Demonstrate the necessity and proportionality of the land and rights sought for Site 1 and the Grid Connection Infrastructure, including land and rights required for permanent National Grid infrastructure, temporary works, access, PRoW, utilities and mitigation. Where the final NGET design remains flexible, explain how the compulsory-acquisition case remains no more extensive than reasonably required.
- Provide a change-control schedule requiring consequential documents to be updated where the Grid Hub design changes. Any material change to the National Grid Substation, Project Substation, BESS relationship, overhead-line/pylon works, cable routes, access, drainage or mitigation should identify whether revisions are required to the Works Plans, Land Plans, draft DCO, Book of Reference, Grid Connection Statement, LVIA/RVAA, noise assessment, drainage/FRA, water assessment, ecology/BNG evidence, heritage assessment, soils assessment, traffic assessment, aviation/glint-and-glare material, LEMP or compulsory-acquisition documentation.

- Finally, provide one consolidated Grid Infrastructure Compliance Schedule identifying each material commitment relied upon to conclude that significant effects are avoided or mitigated, the document in which it appears, whether it is secured by the DCO, the approving authority, the stage at which approval is required, the objective standard to be achieved, monitoring and verification arrangements, and the corrective action required if the commitment is not achieved.

Concluding Request

BEPS-Great Moulton does not ask the Examining Authority or local residents to design the Scheme or to reconstruct the Applicant's case from dispersed documents. The Applicant, with NGET where relevant, should demonstrate through the coordinated information above that the Site 1 Grid Hub and associated Grid Connection Infrastructure are sufficiently defined, justified, assessed and secured within an enforceable environmental envelope.

Where information remains dependent upon later detailed design, East Pye should identify the assessed worst case and the binding DCO control that prevents the eventual design, construction or operation from producing effects greater than those examined. Where the final NGET connection solution could materially alter the land, infrastructure or effects now before the Examination, East Pye should demonstrate that the present consent and land powers remain justified before those powers are granted.

Where East Pye relies upon mitigation, a design assumption, an indicative layout, a future management plan or a later approval process in order to reach a “not significant” or otherwise acceptable conclusion, East Pye should identify precisely where that safeguard is secured, the assessment envelope within which it must remain, who is responsible for approving and implementing it, and how compliance will be demonstrated, monitored and enforced.

The central requirement is that East Pye and NGET should demonstrate the final proposition they seek consent for, show that it remains within the assessed worst case, identify the mechanism by which each material safeguard is secured, and provide an auditable means of verifying compliance.

Chapter 1 Introduction

Solar Sites 1a & 1b. (shaded in red)

Gt. Moulton (North)

1.1 Summary of the Historic Landscape of Great Moulton (Moulton St Michael)

Great Moulton should be understood as a historic rural settlement within an open agricultural plateau, not merely as a set of individual receptors. The lanes, PRoW, field boundaries, scattered farmsteads and views form part of the historic and community setting in which the Scheme would be experienced.

Hundred Lane – an Early Administrative Boundary

Hundred Lane reflects the boundary of Depwade Hundred and marks a long-standing territorial division. Medieval settlements were commonly positioned near such boundaries, and the proximity of Hundred Lane to The Sanctuary supports the identification of this area as the core of Little Moulton.

Narrowgate Way – the Medieval Street Line

Narrowgate Way preserves the original street line of the lost village. In Norfolk, gate derives from Old Norse gata, meaning street. Its narrow, bending alignment is characteristic of a medieval village street leading to a church or central cluster of dwellings. Its position directly adjacent to The Sanctuary confirms its role as the main route to Little Moulton.

Photos of the orchids that are prevalent on Hundred Lane this historic right of way.

Frith Way – the Woodland Edge

Frith Way preserves the line of the medieval woodland boundary. The name derives from Old English frith, meaning woodland or wooded pasture.

Broadgate Lane - The Wider Continuation of the Ridge Route

Broadgate Lane, Narrowgate Way, Frith Way, Hundred Lane, and The Sanctuary together form a well-preserved medieval landscape marking the site of Little Moulton and its vanished church, All Saints. Their historic alignments and enduring tranquillity give the area exceptional archaeological, spiritual, and heritage value, making any development here a serious risk to one of the parish's most significant historic environments.

The Lanes and Road Ways are not incidental features. They are part of the surviving rural route network, and their value lies in alignment, vegetation, quietness, openness, public use and relationship with the wider agricultural landscape. A retained legal PRoW line is not the same as retaining the character and amenity of the route.

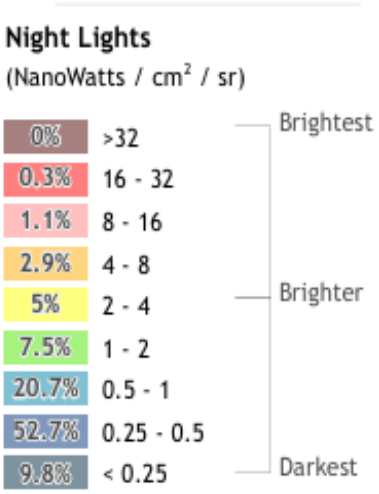
Where the Scheme proposes haul-route crossings, permanent maintenance access, vegetation removal, screening belts, fencing, lighting or operational traffic around these routes, the assessment should address the physical, visual, recreational and historic change together.

1.2 Great Moulton: Landscape, Heritage and Community

Great Moulton's rural character is defined by its unaltered medieval field patterns and routeways, sitting within the South Norfolk Claylands, it is one of only three Plateau Farmland areas in the district, giving it a landscape of exceptional distinctiveness and sensitivity. The plateau's flat, elevated form, large arable fields, open horizons and sparse settlement pattern create long views and a strong sense of exposure..

The lost settlement of Little Moulton survives through its landscape form—an exceptionally rare continuity that makes the area sacrosanct in heritage

terms. Visitors and pilgrims value its tranquillity, openness and sense of spiritual calm, consistent with NPPF § 174 (a) and (b) on conserving landscape character and heritage assets.



The parish's historic continuity is remarkable. It appears in the Domesday Book (1086) with over 70 households under Count Alan of Brittany. St Michael's Church retains Romanesque masonry from its early construction, and nearby timber-framed houses and moats such as Old Boyland Hall and Wacton Hall reflect the medieval landscape.

Great Moulton residents rely on the surrounding countryside for daily amenity, farming, access, walking, cycling, horse riding, wellbeing and community identity. The significance of harm therefore lies, not only in isolated views, but in the transformation of the village edge and its quiet rural setting.

Dark Skies and Amenity

Great Moulton Falls within England's Light Pollution and Dark Skies Zone B where policies require minimal light spill and protection of nocturnal species.

The proposed scheme's artificial illumination would conflict with these requirements, eroding the dark-sky quality and rural tranquillity that define the parish

The proposal would therefore fail to meet the tests of sustainable development under NPPF 8, § 174 and 185, and should be resisted on grounds of landscape, heritage and amenity impact.

The Site 1 grid hub would introduce an industrial energy character into a landscape currently defined by open farmland, low settlement density, long views, dark skies and a strong sense of rural separation.

This is a material planning consideration even where individual technical chapters predict no significant effect.

Chapter 2 Environmental Impact Assessment Methodology & Scheme Flaws

Introduction

The applicant states the EIA follows the usual sequence of baseline, embedded mitigation, assessment of likely effects, additional mitigation, residual and cumulative effects/in combination effects. It also uses the Rochdale Envelope approach because not all technical details have been determined at application stage. The methodological issue for Site 1A-1D is therefore not the absence of an EIA framework, but the final layouts remain controlled by maximum parameters, minimum offsets and later detailed design, whether the field-level baseline and design assumptions are sufficiently specific and secured for a worst-case conclusion to remain robust after detailed design.

The difficulty for Site 1 is that this broad methodology is only as reliable as the site-specific evidence beneath it. In several places, the ES identifies sensitive features at or close to Site 1, but then relies on generic design principles, future detailed design, outline management plans, or broad judgements of "not significant" without adequately explaining the local harm to Great Moulton residents, PRoW users, landscape character, bats, ponds, ditches and heritage setting is acceptable.

East Pye defines Site 1 comprising of approximately 73.6 ha (181 areas) comprising:

1A – 7.7 ha (19.02) acres – TM 16678 89158
1B – 48.2 ha (119.10 acres) – TM 17091 89199
1C – 13.9 ha (34.35 acres)– TM 16676 88715
1D – 3.8 ha (9.39 acres) – TM 17224 88509. **NSIP Documents**

There is no separate single centred NGR stated for the whole 73.6 ha Site 1 the Applicant provides one for each sub-site.

East Pye's own evidence establishes Site 1 as a large, open agricultural landscape on a flat elevated plateau, with expansive skies and a recognised PRoW network. It acknowledges nearby homes and the village edge of Great Moulton, predominantly Grade 2 agricultural land north of Hundred Lane, and a range of landscape, recreational and environmental constraints. NSIP Documents

East Pye then at the Targeted Consultation Site 1B became the location for the National Grid Substation, 400 kV Project Substation and associated OHL/grid infrastructure, with the Applicant explaining the choice principally through proximity to the 400 kV line, flood-risk and PRoW comparisons with Option 4A, existing vegetation and grid/technical requirements. NSIP Documents

Most significantly, East Pye's own landscape assessment concludes that the construction of Site 1 would cause a Major Adverse Significant effect, describing the development as a substantial change to the site's key landscape characteristics and identifying the scale of the proposed activity as uncharacteristic of its existing agricultural use.

(its difficult to write and research this document without understanding the rationale, behind the choice, to state categorically this will destroy our village but still go ahead)

The EIA should enable the ExA to understand the likely significant effects of the development as a whole. For Great Moulton, that requires integration across scheme description, alternatives, landscape, PRoW, ecology, water, transport, noise, safety, health, agricultural land and cumulative effects.

The principal flaw is fragmentation. Effects are divided across documents, while the village experiences one combined infrastructure hub.

The ExA should require The Applicant to provide a parcel-by-parcel infrastructure schedule for Site 1A-1D, with work number, component, maximum dimensions, footprint, temporary/permanent status, delivery body, decommissioning position and relevant control document and identify every **environmentally material parameter still flexible at site 1 and the exact requirement/commitment that prevents a later layout from creating effects outside the assessed envelope.**

2.1 Missing Private Water Supply Surveys and Consultation

This area falls under the Environmental Agency for Drinking Water Protection (Surface), Many of the the homes within the Great Moulton area rely on private wells and boreholes. Many of these supplies are shallow, not formally mapped, and don’t have much protection. That makes them especially vulnerable to anything that disturbs the ground — trenching, drilling, piling, or the construction of BESS compounds.

Private water supplies should be treated as sensitive receptors requiring positive identification, baseline condition and contingency planning where credible pathways exist. This is particularly important for cabling, piling, drainage, substation hardstanding, transformer oils, BESS firewater and construction compounds.

The ExA should require the Applicant to provide a PWS schedule for receptors within the relevant study area, including whether owners have been consulted, whether baseline quality and yield testing is proposed, and what alternative supply or compensation arrangements would apply if harm occurs.

2.2 Missing Ecological Surveys, Mapping or Consultation

Ecology must be assessed against the final infrastructure envelope, not only against broad solar-parcel assumptions. The final position of lighting, fencing, access roads, haul crossings, vegetation removals, drainage basins and operational areas can materially affect bats, newts, birds, hedgerows and dark corridors.

Where survey data is approaching expiry or does not cover revised areas, the Applicant should confirm how updated survey evidence will be secured before consent or before commencement.

2.3 Telecoms &Emergency Access

Telecommunications and broadband are community-resilience infrastructure in a rural parish. Damage or service loss affects home working, businesses, alarms, medical alerts, education and emergency contact.

The Applicant should provide a consolidated utilities protection plan covering Openreach, Gigaclear, BRN or any community fibre, electricity, water, drains and other affected services, with emergency repair contacts and minimum service-continuity commitments.

2.4 Climate Change

The EIA fails to provide a robust, site-specific assessment of the scheme's resilience to climate change or the potential for the development itself to exacerbate local climate risks. Great Moulton already experiences the effects of more intense rainfall, prolonged dry spells, and higher summer temperatures, and these pressures are projected to increase. A development of this scale must demonstrate how it will perform under future climate conditions, not just current baselines.The EIA also fails to consider whether the introduction of large-scale hard infrastructure could lead to localised overheating, changes in wind patterns, or drought vulnerability affecting adjacent farmland and communities. Great Moulton's agricultural land is already exposed to seasonal water stress, and any reduction in soil moisture or alteration of microclimates could have direct impacts on crop viability, hedgerow health, and the resilience of local wildlife.

The Scheme climate case should cover both greenhouse-gas benefits and adaptation/resilience. The relevant question for Site 1 is whether the grid hub and BESS remain safe and do not worsen local vulnerability under future rainfall, heat, drought and storm conditions.

The ExA should require climate-adjusted drainage modelling for substations, BESS hardstanding, tracks, compounds, cable trenches and panel areas, including exceedance routing and combined firewater / flood scenarios.

2.5 Missing Analysis of Views from Listed Buildings or Impacted Homes

The scale of the proposed changes is substantial, yet the submission significantly downplays the level of disruption and environmental harm that would be brought to the village of Great Moulton. The infrastructure would in some instances be circa. 25m from their garden/land boundaries, with increased pylon and substation heights, 4.5-metre solar panels, security fencing, lighting columns, and surveillance cameras.

This configuration appears to have been developed without meaningful consideration of the local community or the sensitivity of the surrounding landscape. The proximity and sheer massing of this industrial infrastructure would cause severe and long-term disruption to residents' daily lives, eroding residential amenity, tranquillity, and the rural character of the plateau.

The impacts extend beyond people. The plateau supports a range of wildlife that relies on its

Solar Sites 1a & 1b. (shaded in red) **Gt. Moulton** (North)

open, connected habitats. The introduction of tall, dense, and illuminated structures would fragment these habitats, displace species, and fundamentally alter the ecological function of the area.

Taken together, the proposal would transform a rural landscape into an industrialised zone, with consequences that have not been adequately assessed, mitigated, or justified. The community and its environment deserve far more rigorous consideration than this scheme currently provides.

The residential visual issue should be resident-led. A village-edge view toward a 400 kV grid hub, palisade fencing, security equipment, pylon works and substation plant is qualitatively different from a view toward solar panels alone.

The ExA should require verified photomontages or representative visualisations from Oak Lodge, Laburnham Farm, Potters Crescent, the south side of High Green, Frith Way, Hundred Lane and relevant PRoW locations.

2.5.1 Oak Lodge, High Green, Great Moulton

Oak Lodge should be assessed as a sensitive receptor potentially affected by proximity, outlook, construction activity, operational noise, lighting, security fencing and the perceived industrialisation of the village edge. A plan-only separation distance does not capture the actual residential experience.

The Applicant should identify whether this receptor is included in the Residential Visual Amenity Assessment, noise assessment, glint / glare assessment and construction traffic / dust assessment, and if not, explain why it was excluded.

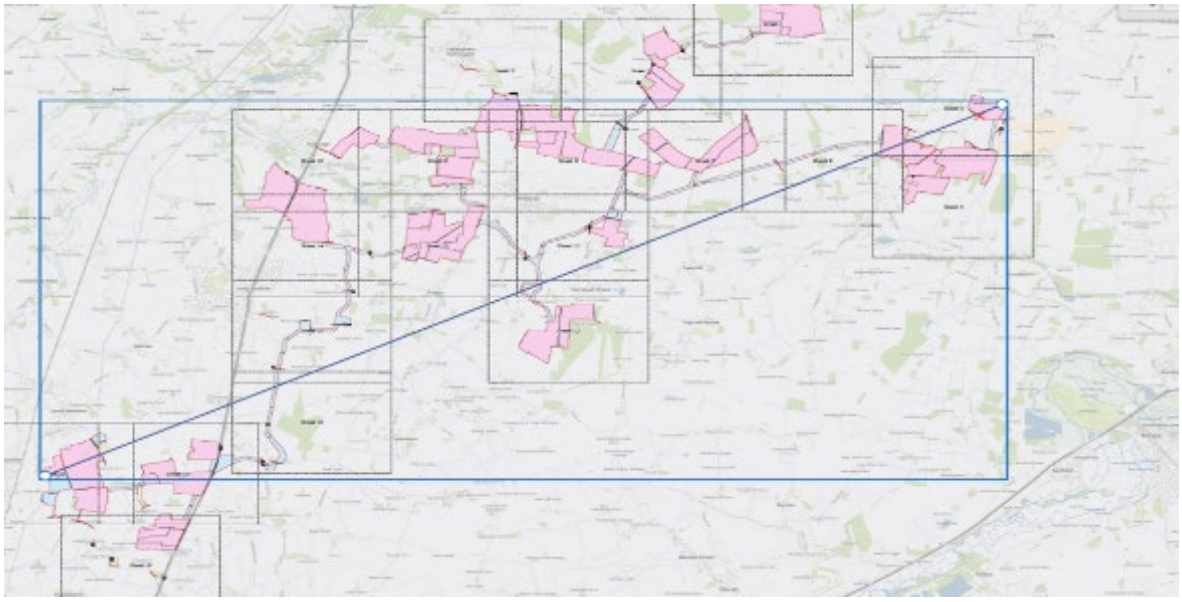
2.5.2 Laburnham Farm House, High Green, Great Moulton

Laburnham Farm House and associated land uses should be considered for visual, noise, amenity, ecological and agricultural effects, including impacts on gardens, outdoor use, apiaries, livestock or rural business activities where relevant.

The Applicant should identify whether this receptor is included in the Residential Visual Amenity Assessment, noise assessment, glint / glare assessment and construction traffic / dust assessment, and if not, explain why it was excluded.

2.5.3 Potters Crescent

Potters Crescent should be assessed not only by distance to the substation footprint but by the combined appearance and activity of the National Grid Substation, 400 kV Project Substation, pylons, access and construction phase.



Chapter 3 The Order Limits - Site and Surroundings

3.1 Site Selection, Retention and Reasonable Alternatives

East Pye Solar state in their Site Selection Assessment document APP/7.20 / APP215 sets out a site selection methodology and identifies policy preferences, therefore we do not state that East Pye did not undertake any site selection exercise.

Our issue is narrower, how that strategic methodology was then translated into later inclusion and retention and refinement of Site 1 and sub-sites 1A-1D following the change in the Point of Connection.

APP/7.20 records that The Applicant has not undertaken a detailed assessment of every unconstrained agricultural parcel. Instead, it focused in large part upon large landholdings identified through land agents as having potentially willing landowners and ultimately upon land which landowners were willing to make available.

APP/7.20 also records that the land originally coming forward for solar development comprised eight sites elsewhere and that Sites 1 and 2 were subsequently added after the Point of Connection had been identified on land south of Great Moulton. The Applicant further records that land availability was an important consideration and that some potentially suitable alternative land was not progressed because it had not been made available to the Applicant.

This may be a legitimate factor, for land availability, deliverability and commercial. However, this is not the same as environmental suitability. The examination issue is therefore not whether a site-selection exercise took place, but whether the submitted evidence allows the ExA to understand clearly:

- why each of Sub-Sites 1A, 1B, 1C and 1D was added once the Point of Connection changed;
- what environmental, technical, land-availability and commercial considerations were applied to each parcel;
- why each parcel remained necessary as the design evolved and environmental constraints became better understood; and
- whether reasonable opportunities to avoid or reduce effects through parcel deletion, whole-field removal, further reduction or use of other reasonably available land were considered.

We would submit that this distinction is particularly important because the level of explanation is not the same for all parts of Site 1.

Requested Examination Action

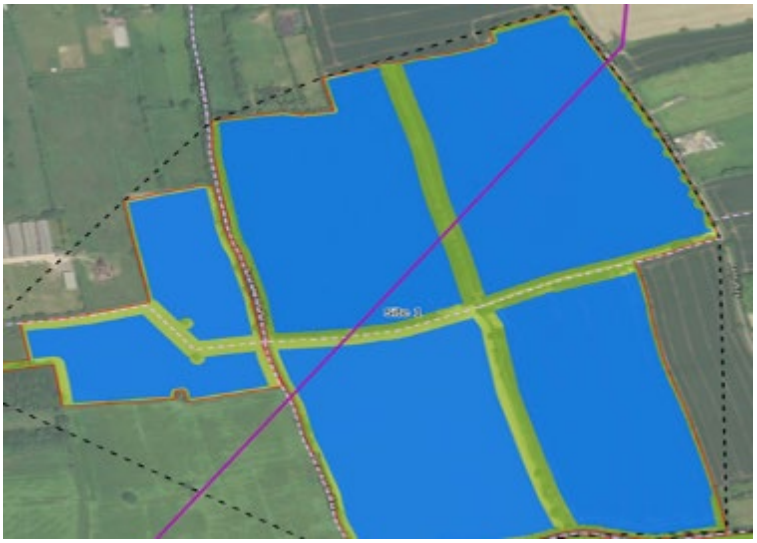
BEPS therefore asks the ExA to consider requiring the Applicant to provide one consolidated and auditable Site 1 selection and design-evolution schedule, drawing together information presently dispersed across APP/7.20, ES Chapter 5, the Design Approach Document and the relevant technical assessments.

The schedule should identify, for each of Sub-Sites 1A, 1B, 1C and 1D:

1. When and why the parcel entered the Scheme, including its relationship to the change in the Point of Connection.
2. The function and development proposed within the parcel, distinguishing solar generation land from National Grid infrastructure, Project Substations, Grid Connection Infrastructure, overhead-line works, cables, access, mitigation or other uses.
3. The environmental, technical, operational, commercial and land-availability criteria applied, together with sufficient explanation to understand how those considerations influenced the decision to select and retain the parcel.
4. The principal constraints subsequently identified through environmental assessment, consultation and design evolution, and the design changes made in response.
5. The reasonable design alternatives considered after those constraints became known, including where relevant further reduction, removal of individual fields or parts of fields, deletion of the parcel, relocation of infrastructure and use of other reasonably available land.
6. For Sub-Site 1B specifically, an integrated explanation of why the selected location remains appropriate when the cumulative presence of the National Grid Substation, Project Substation infrastructure, Grid Connection Infrastructure, overhead-line works,

access requirements and the adjoining BESS is considered together, rather than solely through the earlier comparison between National Grid Substation Options 4A and 4B.

7. A clear distinction between land which was environmentally or technically unsuitable and land which was potentially suitable but was not available to the Applicant.



This would not require the Applicant retrospectively to demonstrate that Site 1 was the theoretical “best” or “least harmful” site. Rather, it would allow the ExA to understand the Applicant's actual decision-making process and determine whether the reasonable alternatives that were studied, and the subsequent decisions to retain and refine Sites 1A–1D, have been explained with sufficient environmental and design justification.

Source basis: APP-215 / APP/7.20 Site Selection Assessment, particularly sections addressing the National Grid Substation and Point of Connection alternatives, solar site-search methodology, landowner availability, Potential Development Areas and Alternative Development Zones, and the later addition of Sites 1 and 2; APP-041 / APP/6.1.5 ES Chapter 5 – Reasonable Alternatives and Design Evolution; and APP-212 / APP/7.17 Design Approach Document.

3.2 Site Selection, Location and Context

The Order Limits create a long linear scheme, but the Great Moulton objection concerns the western concentration of infrastructure. Site 1 and the BESS cannot be understood by reading individual parcels in isolation.

Drone shot shows proximity of solar fields & national grid substation to Great Moulton

Sites 1A, 1B

Gt. Moulton - Looking North West

Red = Solar Sites
Yellow = Cable Route Corridors

3.3 National Grid Connection Point

The Grid Connection Statement describes a new National Grid Substation and associated 400 kV connection infrastructure. The source draft records NGET as qualifying the certainty of the final connection solution.

The NetG representation raises the doubt.

We would therefore ask the Planning Inspector to raise any concerns regarding NetG's response.

"Representation by Bryan Cave Leighton Paisner LLP on behalf of National Grid Electricity Transmission Plc Date submitted 10 June 2026

Netgrid state It is important to note in this context that it is NGETs understanding that the new connection agreement will not include the requirement for the Applicant to secure land or consent for the National Grid Substation.

National Grid remains committed to constructive engagement with the promoter as their project develops and the notification of a Gate 2 offer for their solar component of the project demonstrates that engagement will be ongoing to project delivery.

In the Applicant's Grid Connection Statement, it is stated that there are responsibilities for NGET to design and construct the National Grid Substation.

For the avoidance of doubt, should the Applicant receive consent for the National Grid Substation as part of the Order, this does not trigger or constitute any obligation for NGET to accommodate any connection to the national grid at such a substation. The wider regulatory and commercial context needs to be fully considered and worked through before the location of the new substation can be confirmed.

Although the Connection Reform process is still ongoing, all customers with a Gate 2 offers will, in part, influence the final size, design and location of the final point of connection solution. However, until those Gate 2 offers have been finalised, NGET cannot confirm what that solution will be but must always act in accordance with its statutory duties to provide an economic and efficient connection network."

This makes the precise scope, deliverability and responsibility for the grid works a central examination issue.

3.3.1 Connection status and consequences for Site 1B

The NGET material quoted above distinguishes the Gate 2 offer for the solar component from the wider connection solution. BEPS's Consolidated Summary of Written Representations records that the associated BESS remains at Gate 1, with no confirmed indicative connection date. That distinction does not establish that the BESS will not ultimately connect; it does mean that the solar generation and BESS should not be assumed to have identical connection rights, timing or delivery certainty.

This matters because the Application relies on the BESS for storage, flexibility and wider system benefits.

The Examining Authority should require the Applicant to identify separately the current connection status of the solar generation and BESS; the import and export rights presently secured for each; whether the BESS operating case assessed in the Application remains valid if it remains at Gate 1; and what changes if the BESS is delayed, reduced or does not secure the anticipated connection rights.

NGET's position also has a direct consequence for necessity. If the replacement connection agreement is not expected to require East Pye to secure land or consent for the proposed National Grid Substation, DCO consent would not oblige NGET to use that substation, and the final connection solution remains unresolved, **the Examining Authority should establish why permanent authorisation and land powers for this particular Site 1B solution are necessary now.**

The Applicant should therefore demonstrate that the environmental assessment, site-selection case, land take and compulsory acquisition case remain robust if NGET's eventual connection

solution differs materially from that currently shown.

3.4. Targeted Consultation - October 2025

The consultation undertaken for the East Pye Solar Project was not adequate because consultees were repeatedly asked to engage with a scheme that was neither stable nor accurately described. The statutory consultation proceeded on the basis of an incomplete and evolving design, with errors in parish identification, land-interest mapping, and scheme

description that were only corrected after the consultation had closed. The Applicant's subsequent targeted consultations—including Lime Down, Pulham Market, and Framingham Earl—demonstrate that significant areas and receptors were not properly identified at the statutory stage. These post-hoc exercises relied on short brochures and partial updates rather than a revised PEIR, materially limiting consultees' ability to understand the environmental significance of the changes. The consultation record therefore shows that affected communities were not given a fair or informed opportunity to comment on the actual scheme now before the Examining Authority. As a result, the Applicant cannot rely on its consultation history as evidence of compliance with the requirements of Chapter 2 of Part 5, and the adequacy of consultation remains a live and unresolved issue.

3.5 Key objection points arising from the Order Limits material

The Order Limits material supports the characterisation that Site 1 is not merely a solar field, but as a grid infrastructure hub.

Work numbers, land rights, access routes, pylon works and mitigation land should be scheduled together so the ExA can see what is temporary, permanent or retained.

3.6 Nearby Residential Dwellings – Sites 1A to 1D and the BESS

The Site and Surroundings chapter also identifies nearby homes at Great Moulton, individual dwellings close to Sub-Sites 1A and 1B. Nearby dwellings should be listed in one schedule showing distance to panels, substations, BESS, access tracks, cabling, haul routes, compounds, lighting and construction works. The absence of this environmental schedule makes the local effect harder to test.

3.7 Grade 2 BMV Land

The Order Limits record that all of Site 1 north of Hundred Lane is ALC Grade 2, that the National Grid Substation would permanently remove 6.1 ha of Grade 2 land, and that both the Project Substation in Sub-Site 1B and the Project Substation in the BESS Site would also be on Grade 2 land. The BESS itself is also proposed on Grade 2 land, with East Pye expressly acknowledging that the BESS Site is essentially all Grade 2 quality.

We submit that the Applicant should not rely on general renewable-energy needs to avoid a precise assessment of permanent and long-term agricultural land loss.

3.8. Plateau Farmland Sensitivity to Industrialisation

The Great Moulton plateau is sensitive because of openness, long views and low levels of built form, its character depends on uninterrupted skylines and the legibility of historic field patterns.. Once industrial elements are introduced into Plateau Farmland, the sense of openness and rural scale is permanently altered, and the landscape can no longer function as a coherent agricultural plateau.

Future planting may screen elements over time but will also alter the appearance, function, and cultural identity of Great Moulton's rural environment.open character. Screening is mitigation, not avoidance.

Views from local houses where both the 400Kv national grid substation and 400kv project substation are sited.

The final submission should include verified plans showing the relationship between the nearest property boundaries, gardens, PRoW and the National Grid Substation / 400 kV Project Substation envelope.

In the meantime the ExA has requested a plan showing an estimate of the proposed distances to the curtilage of properties whose boundaries are adjacent to the proposed POC Substation.

Chapter 4: The Scheme

4.1 Permanent versus Temporary Effects – Site 1 and the BESS

One of the central concerns is the repeated description of East Pye as a broadly temporary and reversible development, when East Pye's own documents establish an important distinction between the solar/BESS elements and the National Grid infrastructure.

ES Chapter 4 confirms that, following the approximately 60-year operational period, the solar generating infrastructure, BESS and Project Substations are intended to be decommissioned, whereas the National Grid Substation and **Grid Connection Infrastructure are to remain in situ.** Relevant mitigation planting associated with the National Grid infrastructure would also transfer to National Grid for continuing management.

That distinction matters.

An effect which ends because equipment is removed and agricultural land restored is fundamentally different from an effect created by major transmission infrastructure which remains beyond Year 60 with no equivalent decommissioning date identified.

The same issue arises at **Hundred Lane/Great Moulton RB19.** East Pye's PRoW Visual Amenity Assessment identifies a haul-route crossing which is also intended to provide permanent maintenance access. It records vegetation loss at the crossing and assesses effects on users as Major Adverse and Significant during construction and at Year 1, remaining Moderate Adverse and Significant at Year 15. Screening retained infrastructure is not the same as removing it.

BEPS therefore asks:

Can the ExA request the Applicant and NGET to confirm the anticipated operational life of the National Grid Substation and retained Grid Connection Infrastructure, and whether any decommissioning date is secured outside this DCO?

- If there is no secured end date, should the retained National Grid infrastructure and the access needed to serve it be assessed as a **permanent landscape presence**, rather than being presented within the wider narrative of a 60-year temporary Scheme?
- Has a post-Year-60 landscape assessment been provided which clearly shows what would remain once the solar panels, BESS and Project Substations have been removed?
- What landscape mitigation would transfer to NGET, for how long would it be maintained, and what mechanism would ensure that the retained infrastructure remained adequately screened?
- Finally, if the Hundred Lane/RB19 crossing is required only for infrastructure removed at Year 60, will it also be removed and the lane fully restored? If it is required for the retained National Grid infrastructure, its potentially indefinite effect should be clearly identified and assessed as such.

Relevant East Pye documents:

APP/3.1 Draft Development Consent Order; APP/6.1.4 ES Chapter 4 – The Scheme; APP/6.1.7 ES Chapter 7 – Landscape and Visual; APP/6.3.7.9 PRoW Visual Amenity Assessment; APP/6.4 ES Non-Technical Summary; APP/7.3 Outline Decommissioning Environmental Management Plan; APP/7.4 Outline Landscape and Ecology Management Plan; APP/7.8 Outline PRoW and Permissive Paths Management Plan; APP/7.18 Design Principles, Parameters and Commitments; APP/7.26 Commitments Register.

4.1.1 Whole-life replacement activity

The 60-year operational period should not be treated as one construction phase followed only by routine maintenance.

BEPS's consolidated evidence records that the Scheme permits complete panel replacement over a period of up to 24 months, up to five BESS replacement cycles, and major transformer and electrical replacement during the operational life.

For Great Moulton, those foreseeable replacement cycles may bring renewed abnormal loads, HGV movements, lifting operations, temporary compounds, noise, waste removal and construction-type disturbance. **The environmental assessment and DCO controls should therefore show how recurring whole-life replacement activity has been assessed and controlled, rather than treating the principal construction effects as a one-off event.**

4.2 Site 1B - National Grid Substation And 400kv Project Substation

Sub-Site 1B should be recognised as the principal grid hub for the western part of the Scheme. It contains the proposed National Grid Substation and 400 kV Project Substation and is functionally connected to Sites 1A–1D, the BESS, cable routes, pylon works and access infrastructure.

Our concern is that the Applicant has not yet demonstrated that the combined operational effects of this infrastructure will be acceptable for nearby residents, particularly in relation to **noise**.

Great Moulton has a very low rural background sound environment. The Applicant therefore needs to demonstrate clearly the cumulative effect of transformer hum, switchgear, BESS cooling equipment, inverters, fans and other electrical plant, including appropriate corrections for tonal or intermittent characteristics. The concern is not simply individual items of equipment, but their **combined 24-hour operational effect**, particularly at night.

The submitted material does not provide residents with a clear understanding of what this concentration of infrastructure will look and sound like once operational. There is also no single, easily understood plan or schematic showing the complete grid hub and its relationship with nearby homes.

This uncertainty is particularly important because the Scheme relies on a **Rochdale Envelope**. Where the final plant layout, technology, lighting, drainage, access or overhead-line works remain flexible, the worst-case effects must be clearly assessed and secured through the DCO so that the final development cannot create greater impacts than those examined.

We therefore ask the Examining Authority to require the Applicant to demonstrate, in one clear and auditable assessment, the combined operational noise and environmental effects of the National Grid Substation, Project Substation, BESS and associated electrical infrastructure on Great Moulton residents, together with the controls that will ensure those effects cannot increase at detailed design stage.

4.2.1 Rochdale Envelope- scenario testing

The relevant test should not be confined to whether the Applicant's preferred configuration falls within the assessed envelope. The Applicant should demonstrate that every realistically permitted implementation scenario - including solar-only operation, delayed or reduced BESS, altered National Grid connection works, different detailed substation layouts and replacement technologies - remains within the environmental effects actually assessed and secured by the DCO.

Where a permitted scenario could alter land take, access, noise, lighting, drainage, fire safety, landscape effects or compulsory acquisition requirements, the Examining Authority should be shown the assessed maximum case and the specific DCO control that prevents the detailed design from exceeding it.

4.3 Area and location

- Sub-Site 1B forms part of Site 1. Site 1 totals approximately 73.6ha;
- Sub-Site 1B is approximately 48.2ha, centred on NGR TM 17091 89199.

The ExA should require The Applicant to provide a parcel-by-parcel infrastructure schedule for Site 1A-1D and the BESS, with work number, component, maximum dimensions, footprint, temporary/permanent status, delivery body, decommissioning position and relevant control document.

MAIN OPERATIONAL USE

The operational use is not merely electricity generation; it includes transmission-interface infrastructure, monitoring, export, import for BESS charging, switching, maintenance and retained grid works.

New National Grid Substation

The new National Grid Substation is the element that makes Site 1 a long-term grid node

- The new National Grid Substation is located within Sub-Site 1B and would be owned/operated by National Grid.
- It is required at the Point of Connection to connect the 400kV Project Substation to the National Grid.
- It monitors and manages exports of electricity.

The ExA should require clarity on NGET responsibility, final connection solution, scope of works, delivery programme and what happens if the connection solution changes.

NATIONAL GRID SUBSTATION PARAMETERS

Parameters should include footprint, building heights, busbar/gantry heights, fence height, access-track width, lighting, drainage, transformer oil containment, temporary works, construction duration and operational maintenance requirements. Including the following:

- maximum compound area 6ha
- access track up to 8m wide
- relay/control rooms up to 7m x 19m and 4.2m high
- foundations may be raft or piles to 12m with 1m pile cap
- 3m palisade fencing.

400KV PROJECT SUBSTATION IN SUB-SITE 1B

The 400 kV Project Substation should be assessed cumulatively with the National Grid Substation. Residents will not experience the two as separate planning effects.

- 400kV Project Substation is proposed in Sub-Site 1B,
- with electrical infrastructure to allow electricity to be exported to the National Grid Substation
- It may include control/relay rooms
- 33kV switch room
- monitoring/maintenance equipment
- welfare/office facilities

400KV PROJECT SUBSTATION PARAMETERS

- Compound perimeter:
- 3m palisade fencing
- plus 2.5m deer-type wire mesh/wooden post fencing outside;
- access up to 6m wide;
- relay/control room
- 33kV maximum compound area 1.1ha

- maximum height 15m to top of busbars
- foundations up to 1m concrete base or piles up to 12m.

The ExA should require confirmation whether gas-insulated or air-insulated switchgear is proposed or retained as an option, and how the worst case for height, footprint, noise, visual clutter, drainage and operational risk has been assessed.

GRID CONNECTION / OVERHEAD LINE WORKS

Overhead-line works and pylon changes are integral to the grid hub. The Applicant should show all proposed tower works, temporary scaffolding, netting, pull zones, outages, construction compounds, access routes and permanent changes on one plan.

- Grid Connection Infrastructure will connect the National Grid Substation to the existing 400kV Norwich Main - Bramford overhead line.
- Chapter 4 refers to a double turn-in of both circuits into the National Grid Substation within Sub-Site 1B,
- up to four new pylons across the Scheme, up to 61m high.

SECURITY AND CAMERAS

Security infrastructure should be assessed for visual effect, lighting, privacy, ecology and rural character. CCTV locations and heights should be fixed or controlled.

- National Grid Substation
- BESS
- Project Substations
- 3m palisade fencing
- Pole-mounted, internal-facing CCTV will be installed around the perimeter of the Sites; maximum CCTV/pole height is 3m generally, but 4.2m for the National Grid Substation.

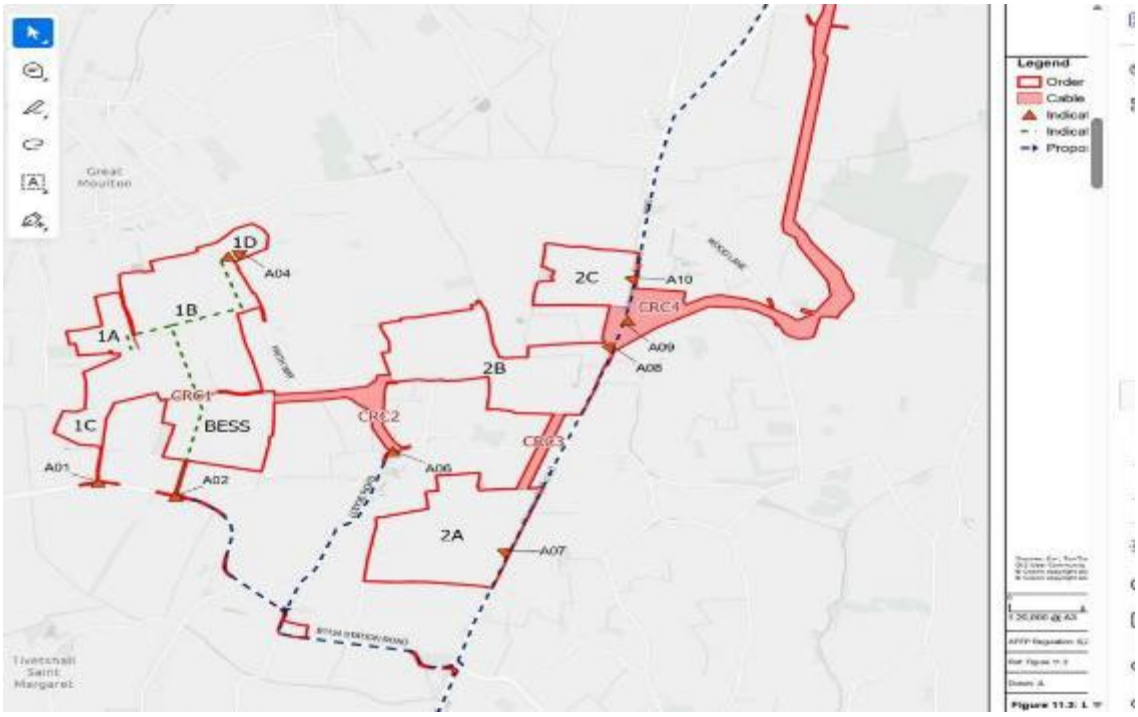
LIGHTING

Lighting should be assessed against dark skies, bats, PRoW users, nearby homes, aviation and emergency scenarios. A "temporary maintenance lighting" assumption should be secured and enforceable

- National Grid Substation lighting is to comply with National Grid standards.
- External components are not expected to require dedicated external lighting
- If maintenance lighting is needed, temporary lighting is used.
- Control-room entrance lighting should emit no upward light.
- National Grid Substation access road will not be illuminated.

DRAINAGE / ATTENUATION

Drainage design should identify clean and contaminated water systems, firewater isolation, penstock failure scenarios, testing, tankering, discharge limits and emergency exceedance routing.



- National Grid Substation drainage is proposed to be lined with an impermeable membrane with controlled discharge.
- Indicative attenuation volume is 7,308-9,246m3, refined to 8,256m3.
- 400kV Project Substation in Sub-Site 1B has revised attenuation of 1,511m3.
- Localised surface-water flood risk around the National Grid Substation and 400kV Project Substation is acknowledged, with a detailed-design solution deferred.

TEMPORARY CONSTRUCTION COMPOUNDS

Construction compounds in Site 1 should be assessed for land take, traffic, noise, dust, lighting, welfare drainage, fuel storage, security and restoration.

- Chapter 15 states two construction compounds are proposed within Site 1B, both on Grade 2 agricultural land. It says almost all of Site 1 is Grade 2 so this is considered unavoidable by the Applicant.
- When the construction work complete, what is the proposed restoration for each of these

ACCESS / HGV ROUTE

HGV and abnormal-load routes should be shown with swept paths, structures, verge protection, traffic management, PRoW controls, railway-level-crossing interaction and emergency access arrangements.

- Sites 1A-D and BESS use accesses A01 and A02 via A140/B1134 roundabout, B1134 westbound, then northbound on A01/A02. B1134
- Station Road is described as the key link for access to the National Grid Substation, Project Substation in the BESS Site and Project Substation in Sub-Site 1B.

The Applicant should clarify why document AP095, page 2 it shows Lodge Road as a 2 way Proposed Vehicle Routeing, The map also shows A02 the access point to the BESS and the Indicative 2-way.Internal Routeing. Indicative site access on the red CRC2. A09, A10, A08, A07 as access from the A140 into 2A, 2B and 2C, Route A01 from Station Road in 1C access to the pylons, A04 crossing over Frith Way. Frith Way has no indicative traffic, but the CRC2 highlights definitive use as access. The documents state the cable routes will be used for traffic movements.

LANDSCAPE / PROW CONTEXT

The PRoW network should be assessed as a connected recreational and heritage network, not only as isolated paths.

4.4 Grid connection / pylon works

Pylon and overhead-line works should be included in all landscape, heritage, aviation, transport, EMF, ecology and construction assessments.

GRID CONNECTION / PYLON WORKS

- Chapter 3 states underground and/or overhead lines including new pylons between the National Grid Substation and Point of Connection will be located within Sub-Sites 1A-D. Appendix 9.1 states OHL works within Sub-Site 1C comprise
- modification and reconfiguration of the existing OHL, including new pylons
- dismantling of existing overhead lines and pylons

PYLONS

The maximum pylon heights and temporary works should be represented visually from Great Moulton homes and PRoW

- Up to four new pylons are assessed across the Scheme,..Three are associated with repositioning existing pylons and up to one is new.
- Pylons may be up to 61m above ground level.

SOILS / LAND ASSUMPTIONS

Unsurveyed or assumed land should be treated conservatively, but the Applicant should not use assumptions to avoid field-specific restoration obligations.

- Chapter 15 records that parts of mitigation/enhancement areas in Sub-Sites 1C and 1D were not surveyed for ALC.
- Works No.5 relates to reconfiguring and installing new overhead lines
- The non-surveyed land is assumed worst-case Grade 2.
- It also says Sub-Sites 1C and 1D are areas within which pylons may be relocated.

SECURITY / LIGHTING

Grid connection work areas should be controlled for temporary lighting, fencing, generator use and overnight security.

- No separate permanent security or lighting regime is described for Sub-Site 1C in the available text, beyond the scheme-wide position
- infrastructure work areas may be fenced during construction
- PV arrays, if present, would use deer fencing/CCTV.
- OHL/pylon works would not normally imply operational lighting.

LANDSCAPE CONTEXT

The landscape context includes the plateau, historic lanes, PRoW, village edge and intervisibility with surrounding settlements.

- Appendix 7.2 states Sub-Site 1C spans two fields
- one directly south of 1A
- one south of Hundred Lane/Great Moulton 19,west of the BESS Site.
- Hundred Lane / Great Moulton 19 crosses its centre, and Tivetshall St Margaret FP1/FP2 run north-south.

4.5 Proposed Solar Panels

The solar panels are part of the cumulative visual, hydrological and access effect even if their direct construction differs from substations.

OPTION A: SINGLE-AXIS TRACKER PANELS

If single-axis tracker panels are retained as an option, the assessment should address maximum height, movement, glint / glare, mechanical noise, maintenance and visual appearance during tilted positions.

- Solar PV array area. Chapter 5 states maximum solar PV arrays were considered at Stage 1, then reduced along the southern boundary to increase the Hundred Lane buffer, respond to PRoW views and provide landscape/ecological mitigation.
- Arrays were also reduced to accommodate hedgerows, trees, field margins and a pond in the northwest corner.
- 4.5m above ground level at greatest inclination
- 2.5m when horizontal
- 0.4m minimum clearance above ground

4.6 Site 1C&1 D

The Applicant's documents appear to identify Sub-Sites 1C and 1D principally in connection with the grid connection, including overhead-line works, potential pylon relocation, underground and/or overhead cabling, construction access and mitigation or enhancement of land. However, the precise purpose and extent of development within each parcel remains unclear.

This is significant because the National Grid Substation and 400kV Project Substation are proposed within Sub-Site 1B, while associated grid-connection works, including cables, overhead lines and potentially new or relocated pylons between the substations and the Point of Connection, may extend across Sub-Sites 1A–1D. **Sub-Sites 1C and 1D must therefore be assessed as integral parts of the same grid-infrastructure package, rather than as minor or residual land.**

The Applicant should clearly identify, for each of Sub-Sites 1C and 1D:

- the exact works proposed and their maximum extent;
- whether pylons, overhead lines, underground cables, access routes or construction compounds would be located within the parcel;
- which works and land-use changes would be temporary and which would remain permanently or be subject to retained rights;
- the construction period, access arrangements and likely disturbance;
- why each parcel is necessary and what reasonable alternatives were considered; and

- the residual and cumulative effects when considered alongside Sub-Site 1B, the National Grid Substation, the 400kV Project Substation, the BESS and associated connection infrastructure.

Without that information, the effects on landscape and visual amenity, residential outlook, PRoW, agricultural land, drainage and private water supplies, ecology, construction traffic, lighting and cumulative infrastructure cannot be properly understood or tested.

Great Moulton residents therefore submit that the present information for Sub-Sites 1C and 1D is insufficiently clear and parcel-specific. If these parcels are required for pylon relocation, overhead-line reconfiguration, cabling, access, construction works, mitigation or retained grid rights, those works and their consequences must be expressly identified, assessed and justified.

Before reliance is placed on the Applicant's conclusions, the Examining Authority should require a clear parcel-by-parcel explanation of **what is proposed in 1C and 1D, why the land is required, how long each use will last, what alternatives were considered, and how the individual and cumulative environmental effects have been assessed and secured.**

4.7 Noise Intrusion into rural Rural Character, Cumulative Effects and Assessment Uncertainty

Great Moulton and Tivetshall residents have employed their own Consultant - his comments are included under each relevant chapter. BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf - Oakridge Environmental Services) - (see full report following & Appended to this document

Great Moulton is a quiet rural environment, not an existing industrial soundscape. The significance of operational noise therefore cannot be judged simply by whether a predicted figure falls below a general numerical limit. The important questions are how noticeable the new sound would be, its character, how long it would occur, and the extent to which it would change the existing rural acoustic environment, particularly during evening, night-time and early-morning periods.

The Applicant has undertaken a substantial baseline survey, these were unattended acknowledges that it was not possible to identify the dominant sound sources throughout the monitoring periods. At the Great Moulton monitoring locations, (these have never been identified), so the road traffic may in fact refer to the B1134, which is not in the vicinity of Great Moulton, the road traffic was identified during attended observations, but the technical review questions whether traffic provides a reliable and continuous masking effect at the nearest homes, particularly during quiet night-time periods. **East Pye also identifies the relevant Great Moulton residential receptors as high-sensitivity receptors.**

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf

Page 5 2.1 Baseline Sound Survey The Environmental Statement on noise and vibration prepared by Stantec provides a baseline noise survey taking data from 51 noise monitoring positions that effectively ...(see full report following & Appended to this document

Page 6 The submitted ES Chapter 12 identifies MP41, MP42 and MP43 as the associated measurement positions for residential receptors in and around Great Moulton, including dwellings on Broadgate Lane and Station Road. The ES also identifies these (see full report following & Appended to this document

This is important because the proposed development would introduce a substantial new cluster of electrical infrastructure into that rural setting, including the **BESS, National Grid Substation, Project Substation, transformers, inverters and associated electrical plant**. These are operational effects capable of occurring over the lifetime of the development, including during the quietest periods of the night.

We would ask the ExA to be aware of Great Moulton's concern that the omission by the Applicant not to identify that the POC substation has no decommissioning date, so the proposed temporary changes to the environment are NOT temporary.

The concern is increased because the operational noise assessment is **not based on final plant specifications or a final equipment layout**. East Pye states that detailed plant specifications are not yet available and that potential noise emissions have therefore been assessed using **example equipment data and an example plant layout**. The final number, type, location and operating regime of BESS containers, transformers, inverters and cooling equipment may materially affect both the overall noise level and its acoustic character.

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf

Page 8 2.2 Noise modelling and calculations 2.2.1 Assessment Assumptions and Limitations The authors have stated that "Detailed plant specifications are not available at this stage and potential noise emissions baked on example equipment data have been assessed using an example plant layout which has been based on an indicative plant layout) (see full report following & Appended to this document

There is also significant reliance on mitigation. The assessment includes a **4-metre-high acoustic barrier around parts of the BESS**, while reduced fan duty is assumed as part of the BESS noise mitigation. The technical review identifies uncertainty over matters including the number of BESS units represented in the model, barrier location and performance, source heights, frequency response, plant layout and the effectiveness of the mitigation over the lifetime of the development.

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf

Page 9 This introduces a level of uncertainty that is difficult to evaluate. The authors have prudently used a conservative approach assuming the plant operates simultaneously, continuously, and at maximum output. However, there is no indication as to the number of battery storage units (see full report following & Appended to this document

Particular concern arises from **tonal and low-frequency noise**. Electrical infrastructure does not necessarily produce sound that is adequately described by a single broadband A-weighted figure. The review identifies insufficient disclosed frequency data to independently verify the modelling of low-frequency sound from the BESS, inverters and substations, or the effectiveness of barriers at those frequencies. Such components may be more noticeable during quiet night-time conditions.

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf

Page 9 The sound source data have only been given in broadband A-weighted sound power levels and thus, if the noise model has been calculated in accordance with ISO 9613-2, has used the 500 Hz octave-band frequency to estimate ...

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf

Page 10 ... frequency propagation, barrier performance at low frequencies or the potential prominence of transformer hum and cooling plant noise at night. This is particularly relevant as the development includes both BESS infrastructure, ...(see full report following & Appended to this document

East Pye itself recognises that high-voltage transformers can generate a **100 Hz hum**, but concludes that this would be masked by broadband noise from the BESS inverters and containers. The technical review questions whether that assumption has been sufficiently demonstrated. If a BESS cooling plant operates at reduced duty during the night, or plant loading and operating conditions change, the relative prominence of transformer noise may also change. Without the underlying one-third-octave data, the absence of an appropriate BS 4142 acoustic-feature correction cannot presently be independently verified.

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf

Page 11 2.2.3 BS 4142 Acoustic Feature Rating Corrections The authors have concluded that neither the BESS nor the National Grid Substation produce any tonal sound, despite stating:.... ".(see full report following & Appended to this document)

This is therefore **not an argument that unacceptable noise has already been conclusively demonstrated**. The concern is that the Applicant has not yet provided sufficient certainty to rule it out. The review identifies continuing uncertainty over final plant specification, source spectra,

modelling assumptions, mitigation performance and whether the measured residual sound environment is representative of the most affected homes.

The issue must also be considered **cumulatively**. Residents around Site 1 and the adjoining BESS would not experience the National Grid Substation, Project Substation, BESS, inverters and other electrical plants as separate planning exercises. They would experience the combined acoustic effect of an infrastructure cluster operating within the same rural environment. Any assessment and noise limits must therefore control the **combined operational effect**, rather than allowing individual items of plant to be considered in isolation.

For Site 2 and other solar parcels containing operational electrical equipment, the same principle applies: the assessment must demonstrate that inverter, transformer or other plant noise remains acceptable at the relevant receptors. However, the attached technical review is principally directed to the BESS and National Grid infrastructure around Great Moulton and should not be presented as a parcel-specific assessment of Site 2.

What should be required

Before reliance is placed on the Applicant's conclusion of no significant operational noise effects, East Pye should be required to demonstrate, on a secured worst-case basis:

- the final or maximum plant numbers, specifications, locations and operating conditions;
- cumulative operational noise from the BESS, National Grid Substation, Project Substation, transformers, inverters and associated plant;
- representative night-time background conditions at the most affected homes;
- appropriate assessment of **tonality, low-frequency sound and other distinctive acoustic characteristics**;
- the specification and effectiveness of acoustic barriers, enclosures and other mitigation;
- enforceable cumulative noise limits applying to the completed development; and
- post-installation verification, together with a clear requirement for corrective mitigation if operational noise proves more intrusive than predicted.

The central concern is that a long-term industrial acoustic character should not be introduced into a quiet rural environment on the basis of example equipment, indicative layouts, assumed masking and mitigation that has not yet been finally specified and demonstrated.

The Applicant must therefore establish not merely that predicted broadband noise can meet numerical criteria, but that the **final development, operating cumulatively and during the quietest periods, will avoid significant adverse effects and minimise other adverse effects on residential amenity and quality of life.** The technical review concludes that the present information does not yet provide sufficient certainty to make that judgment.

BEPS-GMPC -Review of the NIA - East Pye Solar V2.pdf Page 14

However, it is not possible to validate this assessment due to the degree of uncertainty in the submitted assessment. This is due to: • The lack of detail in plant selection, both for the BESS and National Grid ...(see full report following & APPENDIX 2)

Article, regarding the issue of Noise associated with large NSIP developments. Daniel Clare is managing director at RSK Acoustics – 2 April 2025

APPENDIX 3

4.8 Information Required from East Pye Regarding Deferred Design, Noise and Access Details

Due to the complexity of the scheme, and the extent to which East Pye relies on maximum design parameters, outline assumptions and later detailed design, with detailed access layouts deferred, concerned residents ask the ExA to ensure that East Pye provide the following information:

1. Provide a full operational noise assessment for Site 1, Site 2B, the BESS, the National Grid Substation and the 400kV Project Substations, based on the final or current assumed equipment layout, equipment specifications, transformer locations, inverter and cooling plant locations, BESS container positions, acoustic enclosures, tonal characteristics, low-frequency noise, night-time operation and cumulative plant noise. This should explain how operational noise would affect an extremely quiet rural soundscape where background sound levels may fall below 25 dB, and should include clear, enforceable limits, post-installation monitoring and corrective-action requirements if noise proves audible, tonal or intrusive at residential receptors, gardens, public rights of way or other quiet rural receptors.
2. Provide a single parcel-by-parcel infrastructure schedule for Sub-Sites 1A, 1B, 1C, 1D and the BESS Site, identifying every permanent and temporary component by Work Number, maximum dimensions, likely location and whether it is temporary or permanent.
3. Confirm whether any solar PV arrays are proposed in Sub-Sites 1C and/or 1D, or whether those parcels are limited to overhead line, pylon, cabling, mitigation, access or ancillary works.

4. Provide the final or current assumed number and location of CCTV cameras for Site 1A–1D, the Project Substations and the National Grid Substation, including pole heights and whether infrared lighting is proposed.
5. Provide a lighting plan showing operational lighting columns, emergency lighting, motion-sensor zones, switching arrangements and bat/ecology buffers for the BESS, National Grid Substation and 400kV Project Substations.
6. Provide a combined plan showing the National Grid Substation, 400kV Project Substations in Sub-Site 1B, pylon works, cable trenches, drainage infrastructure, access roads, palisade fencing and deer fencing.
7. Provide a construction-phase plan for Site 1A–1D showing construction compounds, laydown areas, temporary fencing, haul routes, welfare/office areas, lighting locations, vegetation removals and visibility-splay works.
8. Provide a clear drainage and firewater-containment note explaining how firewater from Site 1A–1D, the BESS, the National Grid Substation and the 400kV Project Substations would be contained, tested and removed, and how failures of penstock, shut-off or containment systems would be prevented.
9. Demonstrate how these infrastructure elements have been assessed together for residential amenity, public rights of way, landscape, dark skies, tranquillity, ecology, traffic, drainage, agricultural land and cumulative effects, rather than considered only as separate topic elements.

Visual Image to try and show proximity of site 1B to Great Moulton, site boundaries of peoples homes (c.25m) & PRoW

Chapter 5: Reasonable Alternatives and Design Evolution

5.1 National Policy on Site Selection and the Point of Connection

The 2025 EN-1, EN-3 and EN-5 policy suite came into force on 6 January 2026. EN-5 recognises the urgent need for electricity network infrastructure, but still requires The Applicant to justify the siting, design and mitigation of associated infrastructure such as substations.

National Policy EN-5 2.2.5-2.2.9 states The identification of a grid connection does not remove the Applicant's responsibility to justify the particular land selected for the associated electricity infrastructure.

The Applicant should transparently compare each reasonable alternative against topography, existing screening, community, environmental constraints, land use, BMV land quality, access, safety and alternatives.

The 400kV transmission network constrained the general area in which East Pye could connect, but it did not dictate that the National Grid Substation had to be located specifically within Sub-Site 1B. East Pye considered more than one possible substation location before selecting Option 4B (subsite 1B).

The selection of Sub-Site 1B was therefore a separate decision which the Applicant must justify on the grounds within the National Policy. The policy question is not merely whether the effects of Site 1B can be mitigated, but whether another site could have avoided or reduced them.

EN-5 recognises that the initiating and terminating points of network infrastructure may be constrained, but paragraphs 2.2.5–2.2.9 also make clear that applicants retain control over routing and site selection within the development zone, are not exempt from balancing site-selection considerations, and should carefully consider the location and design of substations, including local topography and opportunities for screening. The question is therefore not whether a grid connection constrained the broad search area, but how the Applicant selected the particular land within that area."

In ExQ1 Q1.3.1 the ExA asks why the Scheme remains a reasonably practicable and robust solution following the transition to the Great Moulton point of connection and what evidence shows that a fresh site-selection exercise centred on Great Moulton would not have produced a materially different scheme. Q1.3.2 separately asks the Applicant to explain the relative influence of environmental assessment, engineering requirements, grid connection considerations, landowner willingness and land availability. Chapter 5 addresses those two questions."

The Applicant should therefore show how the topographical and screening of Options 1, 2, 3, 4A & 4B were compared before selecting Option 4B (subsite 1B) was selected.

East Pye EIA scoping describes Site 1 topography as predominantly level,

We would submit this is not an accurate description as described by Broadland District Council, South Norfolk - South Norfolk landscape character assessments describes it as follows:

E2: GREAT MOULTON PLATEAU FARMLAND DESCRIPTION 17.1. Location and Boundaries:

The Great Moulton Plateau Farmland character area comprises an area of elevated plateau above the 50m contour in the southern part of South Norfolk District. To the north, south and west lower lying Tributary Farmland slopes away from the plateau towards the rivers of the Tas and Waveney. Its western edge is formed by the boundary of South Norfolk District, although the plateau character extends into Breckland District.

E2: GREAT MOULTON PLATEAU FARMLAND DESCRIPTION 17.1. Location and Boundaries: The Great Moulton Plateau Farmland character area comprises an area of elevated plateau above the 50m contour in the southern part of South Norfolk District. To the north, south and west lower lying Tributary Farmland slopes away from the plateau towards the rivers of the Tas and Waveney. Its western edge is formed by the boundary of South Norfolk District, although the plateau character extends into Breckland District.

The simplicity of the Plateau Farmland landform is a reflection of the uniformity of the underlying geology comprising a thick layer of chalky glacial till (Lowestoft Till). Landform, Topography. The flatness of the plateau landform and lack of enclosure affords a strong sense of openness with expansive skies and distant views, both internally within the plateau and across the adjacent landscapes from the plateau edge. Land Cover and Biodiversity This is a simple and uniform landscape, dominated by arable farmland with largescale, regular, geometric fields. There has

been wide-scale removal of boundary vegetation to accommodate modern farm machinery and the scarcity of hedgerows accentuates the scale and openness of the plateau. Where hedgerows do occur as field boundaries they tend to be fragmented https://www.southnorfolkandbroadland.gov.uk/planning/future-development/supplementary-planning-documents/south-norfolk-landscape-character-assessments

Did East Pye demonstrate why Site 1B was the appropriate location for the grid infrastructure after environmental, community, agricultural, access and technical considerations were compared with reasonable alternatives?

5.2 National Grid Substation Alternatives - Options 1,2,3,4A &4B

The chronology matters because the Scheme was not selected in its present form at one point in time. The Applicant's Site Selection Assessment records that the earlier solar-site search was undertaken while Norwich Main was being considered and that Sites 1 and 2 were subsequently added after the Point of Connection was identified south of Great Moulton. The National Grid Substation search also evolved: the initial alternatives were followed by a Great Moulton option south of the village and a further alternative within Sub-Site 1B. By EIA Scoping both Great Moulton locations were still under consideration.

The Examination therefore needs to be able to follow not only the final reasons given for Site 1B, but the evidence available when each successive decision was made.

APP/7.20 states that Options 4A and 4B were subjected to the **"same RAG rating"** using the identified site-selection criteria. However, BEPS has been unable to identify sufficient evidence to establish whether the later options were subjected, at the relevant decision-making stage, to the **same depth of option-specific scrutiny and supporting technical investigation** as Options 1–3.

For example, APP/7.20 expressly refers to swept-path analysis in the consideration of Options 1 and 3 and provides detailed reasoning concerning highway constraints. The assessment of Option 4 and subsequently Options 4A/4B is described principally as a desk-based review. It is therefore unclear whether equivalent highway, abnormal-load, landscape, heritage, flood-risk, ecology, PRoW and other technical work had been undertaken for 4A/4B at the point at which those options were compared and the preferred location selected.

BEPS therefore respectfully requests that the Applicant be asked to provide the **contemporaneous audit trail** for the National Grid Substation site-selection exercise, including:

- The date on which each of Options 1, 2, 3, 4A and 4B was first identified, assessed, refined and rejected or selected; the option-appraisal matrices, RAG worksheets and decision records which existed at those respective dates; the technical studies and

specialist advice relied upon for each option; clarification of whether the assessment now presented in Tables 3.1 and 3.2 of APP/7.20 was prepared contemporaneously with the decisions or subsequently consolidated for the DCO application; and an explanation of how comparability between the earlier and later options was maintained where the evidence available at the respective assessment stages differed.

- BEPS also asks the Applicant to identify any option-specific swept-path or abnormal-indivisible-load assessment undertaken for Options 4A and 4B, or, if none was undertaken before the preferred location was selected, to explain why that level of highway assessment was considered necessary for some of the earlier options but not for the later alternatives.
- It would additionally assist if the Applicant provided a **single side-by-side comparison of Options 1, 2, 3, 4A and 4B against a common set of criteria**, identifying the evidence available at the date each decision was made rather than relying solely upon the later summary contained in APP/7.20.
- Finally, BEPS asks for confirmation of the relationship between Options 4A/4B in APP/7.20 and the locations subsequently described during consultation as the National Grid Substation "Option 1" and "Option 2", so that the complete site-selection chronology can be followed without ambiguity.

BEPS is not asserting that the later options were necessarily inadequately assessed. The concern is that the submitted evidence does not presently allow Interested Parties, or potentially the Examining Authority, to verify whether the alternatives considered at different stages were subjected to a **consistent and reasonably comparable level of scrutiny before the preferred Great Moulton location was selected**.

The submitted material shows a process driven heavily by grid availability, proximity to the Bramford to Norwich 400kV overhead line, access, landowner willingness, commercial deliverability and the need to accommodate a very large 500MW export/import scheme. This may explain why East Pye prefers the chosen land. East Pye have not proven that the Great Moulton and Tivetshall locations are environmentally, socially or agriculturally acceptable, or that less harmful alternatives were properly examined.

APP/7.20 and APP/6.3.2.1 establish the change from the earlier Norwich Main strategy to Great Moulton, the addition of Sites 1 and 2, and the existence of alternative National Grid Substation locations at scoping.

Reconstructed comparison: Compiled by BEPS - Great Moulton Options 1–3 against Site 4A or 4B??

We would submit that Option 4A or (B), would have varying results based on which site was evaluated

Conclusion

BEPS does not suggest that no assessment was undertaken. Our concern is that **East Pye has not provided a clear and transparent like-for-like comparison of National Grid Substation Options 1, 2, 3, 4A and 4B from which the Examination can readily understand why Site 1B ultimately emerged as the preferred location.**

The wider alternatives assessment itself indicates that Site 1B was not the only technically feasible location. For example, the Applicant records that parts of Siting Zone 3 **"could represent a feasible area to construct a National Grid Substation"**, but that those areas were not progressed because a location closer to the solar sites was preferred. Likewise, factors such as shortening connections or diversions may reduce construction impacts and capital costs. These are legitimate considerations, but they are not the same as demonstrating that Site 1B was environmentally preferable when all effects are considered together.

The evidence therefore suggests that the selection of Site 1B reflected a combination of considerations, including **proximity to the existing 400kV line, access, proximity to the Applicant's solar sites, engineering and connection efficiency, competing development constraints and land availability**. The issue for BEPS is whether those considerations were applied consistently across all of the Land Parcels

5.3 Design Evolution - Site 1 B

Norwich Main chronology, NGET capacity advice, the requirement for a new substation, the Bramford to Norwich 400kV overhead line and the 500MW export/import connection offer.

Norwich Main was discounted on NGET capacity advice and East Pye was advised to look for a new site on the Bramford/Norwich Line. Three options were originally reviewed during October/November 2024 , Option 1 – Newton Flotman, Option 2 – Tharston/Tasburgh, Option 3 – Long Stratton. In Late 2024 but prior to 15 January 2025 Option 4A (formerly option 4) - Great Moulton was included. In January 2025 a further option was added, namely Option 4B - Great Moulton APP/7.20 paragraphs 3.2.3-3.2.9:

The January 2025 Scoping material treats Site 1 as one of the locations for solar PV arrays, separately identifying the BESS and National Grid Substation. Current ES/LVIA material records solar arrays, National Grid Substation, 400kV Project Substation and grid connection works within/around Site 1

APP/7.20 records Sites 1 and 2 being added under the **Applicant's assessment of suitable solar development sites**. The Applicants documents show an evolution from Site 1 being introduced as solar-generating land to Site 1B subsequently becoming the principal location of a substantial electrical infrastructure

East Pye's documentation shows the commercial and technical pathway by which it arrived at the present scheme.

The ExA must establish whether land availability narrowed the pool before environmental comparisons were sufficiently complete

Source note: APP/7.20 sections 4.6 and 4.7, and the solar site assessment material, show that land availability and willingness to participate were material to the filtering of potential development areas and alternative development zones.

5.4 Parcel-specific justification for Sub-Sites 1A–1D

The Applicant's documents clearly identify Site 1 as comprising four separate sub-sites, 1A, 1B, 1C and 1D [APP/6.1.3; APP/6.3.7.2]. They are therefore not unexplained parcels of land, and each has an identified function within the Scheme.

Sub-Site 1A accommodates solar PV arrays and associated infrastructure. Sub-Site 1B accommodates solar PV arrays together with the principal grid infrastructure, including the National Grid Substation and 400kV Project Substation. Sub-Sites 1C and 1D have a particular role in accommodating the Grid Connection Infrastructure and Overhead Line Works associated with connecting the Scheme to the existing 400kV network. APP/6.3.7.4 expressly explains that 1C and 1D are included to represent the Overhead Line Works, while APP/6.3.7.7 identifies Grid

Connection Infrastructure within Sub-Site 1C and assesses views in which the BESS, Site 1B and National Grid Substation would be experienced together.

There is also evidence of design evolution and mitigation within Site 1. For example, the Applicant identifies changes affecting Sub-Site 1A arising from access, PRoW, landscape and planting considerations, and the visual assessment records solar arrays within 1A and 1B together with associated mitigation. The National Grid Substation within 1B was also reorientated and its relationship with the Project Substation changed during design development.

The issue for BEPS is therefore not whether Sites 1A–1D have a stated purpose, but whether the Applicant has provided a sufficiently clear parcel-specific justification for why each was originally selected and subsequently retained. Design evolution demonstrates how impacts have been mitigated after the land entered the Scheme, but it does not necessarily explain why that particular parcel was preferable to reasonable alternatives.

For each of Sites 1A–1D, the Examination should therefore be able to identify clearly: its purpose within the Scheme, the reasonable alternatives considered, the reasons for its selection and retention, the design changes subsequently made, and the residual environmental and community effects. This would enable the ExA to have confidence that the overall selection and continued use of Site 1 has been robustly justified.

Source note: The reviewed APP/6.1.5 / APP/7.20 material provides more detail for 1B and some design-evolution material for 1A, but much less parcel-specific explanation for 1C and no clear equivalent design-evolution entry for 1D in the material reviewed.

5.5 The BESS- Site Selection &Risk Specific Alternatives

APP/7.20 states that the BESS Site was selected principally because of its proximity to the Point of Connection and access from Station Road, with landscape, visual, heritage and noise effects also considered. It also identifies operational advantages from locating the BESS close to the National Grid Substation. Those are relevant considerations.

East Pye also identifies distances to residential property, a listed building and PRoW, a site may be convenient for electrical efficiency and still be inappropriate when judged against residential proximity, fire safety, rural road capacity, private water supplies, emergency response and cumulative infrastructure impacts.

The alternatives question is nevertheless wider. A BESS brings a different risk and operational profile from solar arrays. A site may be convenient for electrical efficiency and still be inappropriate the site-selection record should therefore show how residential separation, emergency access, fire and thermal-event response, firefighting and contaminated runoff, groundwater and private water supplies, noise, lighting, landscape, ecology and cumulative interaction with the substations were considered when the BESS location was selected and

retained. The remaining question is whether the BESS's distinct safety, drainage, emergency-access, noise, lighting and residential considerations were given sufficient weight when the location was selected and retained, rather than being addressed principally through later mitigation

BEPS is not suggesting that the BESS must be remote from the Point of Connection. The request is for a transparent record showing how network efficiency was balanced against the site-specific environmental and safety consequences of concentrating the BESS next to the principal grid hub.

5.6 Design Evolution – Mitigation After Selection versus Avoidance Through Selection

The Applicant's site-selection material refers to willing landowners, voluntary agreements and the availability of land as relevant considerations. BEPS does not object in principle to those factors forming part of a site-selection exercise. The question is whether they were balanced alongside a sufficiently broad and comparative consideration of the environmental, planning and technical effects of the reasonable alternatives.

This distinction is important when considering subsequent design evolution. Mitigation can reduce an effect after a location has been selected, but successful mitigation does not, by itself, demonstrate why that location was preferable to another reasonable location where the effect might have been avoided or reduced at the outset.

Site 1 and Sub-Site 1B contain a substantial concentration of infrastructure and are subject to a number of identified constraints, including landscape and visual effects, nearby residential receptors, public rights of way, rural highway access, ecological and heritage considerations, Grade 2 Best and Most Versatile agricultural land, water-environment considerations and interaction with the BESS and associated grid infrastructure. The Applicant's documents show that the design has evolved in response to constraints, including changes to infrastructure locations, setbacks, access arrangements and environmental mitigation. Those changes are relevant and should be recognised. However, they also raise a separate site-selection question: **were the constraints that required those changes sufficiently considered when the reasonable alternatives were compared and when the Site 1/Site 1B configuration was subsequently retained?**

The relevant distinction is therefore between **mitigating effects within the selected site** and **avoiding or reducing effects through the choice of site itself**. The Applicant should demonstrate not merely that individual effects can be mitigated, but that the environmental

consequences identified through design evolution were taken into account when deciding whether the selected location remained justified when compared with reasonable alternatives.

Detailed consideration of the individual effects is addressed in the relevant BEPS topic chapters. The Chapter 5 issue is whether those identified constraints and effects are fed back into the alternatives and site-selection process.

"Mitigation can reduce an effect after a location has been selected, but successful mitigation does not, by itself, demonstrate why that location was preferable to another reasonable location where the effect might have been avoided or reduced at the outset." Do these changes demonstrate successful design evolution, or do they also show that significant constraints existed in the selected land which should have been considered when alternatives were compared?

5.7 Later BMV Evidence and Reconsideration of Site Selection

The discovery of higher-quality land than assumed at early stages should trigger a clear explanation of whether and how the alternatives appraisal was revisited. If not revisited, the Applicant should justify that position.

The Applicants documents show that early provisional ALC mapping suggested mostly undifferentiated Grade 3 land, but the later detailed ALC survey found the land quality was generally higher than expected, including substantial Grade 2 and Grade 3a Best and Most Versatile land. A subsequent detailed ALC survey confirmed much of the land was BMV.

This is especially important for Site 1. East Pye states that all of Site 1 north of Hundred Lane is Grade 2 land. It also accepts that the National Grid Substation would be located on Grade 2 land, that project substation infrastructure would be on Grade 2 land, and that the BESS would also be located on Grade 2 land. The National Grid Substation would cause permanent loss of Grade 2 land, and East Pye accepts that if deep piling is required for the BESS, restoration to comparable ALC grade is unlikely to be achievable.

That is not a minor issue. BMV Grade 2 land forms part of the nationally important Best and Most Versatile resource. The later ALC evidence raises a clear question as to weather and how the earlier selection was reconsidered. The current case appears to be that Grade 2 land cannot be avoided because of the chosen grid connection location. That is circular reasoning. East Pye relies on the chosen location to justify the harm, rather than proving that the chosen location remains justified despite the harm.

5.8 Private Water Supplies

East Pye has undertaken assessment of private water supplies and existing lawful water users in the Ground Conditions Assessment and Water Resources Assessment. The Chapter 5 issue is therefore not the absence of any PWS assessment. It is whether the receptor-specific information obtained through those later assessments was capable of affecting the selection or retention of Site 1/BESS and, if so, whether that feedback into the alternatives/design-evolution process is documented. The detailed source–pathway–receptor and mitigation issues are addressed in the Water Environment and Human Health chapters."

The Examining Authority should require East Pye to identify precisely what is proposed, how it interacts with private water supplies, and why this land is necessary. Without that information, the assessment remains incomplete.

Source note: APP/7.20 Site Selection Assessment; APP/7.5 Outline Battery Safety Management Plan; APP/6.1.18 Other Environmental Topics; relevant water, noise and transport assessments

5.9 Cumulative Site 1/BESS Infrastructure Cluster

When choosing between reasonable locations, the Applicant should consider the consequences of concentrating the principal infrastructure elements within the same Site 1/BESS cluster.

East Pye has undertaken topic-specific and cumulative assessments which identify a range of effects arising from the BESS, National Grid Substation, Project Substations, overhead-line works, cabling, access, lighting and associated infrastructure. The relevant question for site selection is whether the significance of those combined effects was taken into account when the Site 1/BESS location was selected and subsequently retained.

The issue is therefore not simply whether the effects of each individual component can be mitigated. It is whether, having regard to the combined environmental and community effects identified through the Applicant's own assessments, the continued concentration of this infrastructure in this location was reconsidered and remains justified.

These effects are considered in more detail in the relevant BEPS topic chapters, including landscape and visual effects, noise, water environment, transport and access, human health and residential amenity.

5.10 National Grid Infrastructure and Delivery Uncertainty

The relationship between the promoted National Grid Substation and NGET's final connection solution is now expressly before the Examination. ExQ1 Q1.2.15 asks NGET to clarify why its relevant representation states that the new connection agreement will not require the Applicant to secure land or consent for the National Grid Substation, whether significant additional NGET

infrastructure may be required, whether the substation might need to be located differently, and the expected delivery timescale. APP/7.11 also records different Connections Reform positions for the two components of the Scheme: the solar component has Gate 2 Phase 2 prioritisation, while the BESS has Gate 1 prioritisation and no confirmed indicative connection date. These matters do not of themselves determine the acceptability of Site 1B, but they are relevant to whether the land, infrastructure envelope and environmental assessment now promoted remain appropriately justified."

Source note: NGET Relevant Representation/grid-connection material; Planning Act 2008, s.122.

5.11 Conclusion

BEPS does not contend that East Pye failed to undertake a site-selection exercise. The Applicant has provided the Site Selection Assessment [APP/7.20], the Environmental Statement chapter addressing reasonable alternatives and design evolution [APP/6.1.5], the Design Approach Document [APP/7.17] and associated environmental assessments and plans.

The issue is whether that evidence provides a clear and auditable explanation of why the Site 1/BESS configuration now before the Examination remains justified as a whole.

APP/7.20 records that the original solar land was identified while a connection at Norwich Main was being considered and that Sites 1 and 2 were subsequently added after the Point of Connection moved south of Great Moulton. It also records that the solar-site search focused upon larger landholdings identified through land agents and landowners willing to make land available.

The Applicant subsequently compared Options 4A and 4B for the National Grid Substation and selected Option 4B within Sub-Site 1B, The BESS was also located principally by reference to proximity to the Point of Connection and access from Station Road, alongside environmental considerations.

Those explanations are relevant, but the Examination should be able to understand how the individual decisions came together to produce the wider Site 1/BESS infrastructure cluster and whether later environmental, technical and grid information caused the Applicant to reconsider its earlier conclusions.

In particular, the outstanding matters can be grouped as follows:

- Site-selection chronology and comparison: how the move from Norwich Main to Great Moulton altered the site-selection exercise; what changed between Scoping, PEIR, targeted consultation and the DCO application; and whether reasonable alternatives were reconsidered as the Scheme evolved.

- Site 1 and the Sub-Sites: why Sites 1A–1D remain required in their present form and how changes to the National Grid Substation, Project Substations, cabling, overhead-line works, access and associated infrastructure affected that justification.
- BESS and the combined infrastructure cluster: why the BESS remains appropriately located alongside the substations and other grid infrastructure, and whether the significance of the identified BESS-specific and combined effects informed the selection and subsequent retention of that location.
- Later evidence and design evolution: whether later information, including the detailed identification of substantial Grade 2 and Grade 3a BMV agricultural land and other environmental constraints, caused the earlier site-selection conclusions to be revisited. Mitigation introduced after selection may reduce an effect, but does not by itself explain why the selected location remained preferable to another reasonable location.
- Grid connection and delivery: whether the National Grid Substation and connection solution are sufficiently defined for the Examination to understand the infrastructure actually required within Site 1B, and whether any material change in the connection arrangements could affect the layout, land take or environmental assessment.
- Land, rights and retained infrastructure: which land and rights are required for the Scheme now proposed, which infrastructure is temporary or permanent, and whether those requirements remain consistent with the final configuration and connection solution.

These matters closely reflect the issues already raised by the ExA in ExQ1 Q1.3.1 and Q1.3.2: whether the Scheme remains robust following the change to a Great Moulton-centred solution, and the relative influence of environmental assessment, engineering considerations, grid connection, landowner willingness and land availability upon the Scheme that ultimately emerged.

“BEPS therefore asks that the Examination obtain the evidence identified above before reaching conclusions on whether the Site 1/BESS configuration, the associated grid infrastructure and the related land and rights sought are adequately justified in the form proposed.”

Note: “The Botley West EN010147 Secretary of State request is useful because it demonstrates the importance of a clear audit trail where a solar NSIP has changed or evolved around grid-connection options. It is not relied upon as binding precedent, but it is a persuasive comparator. In Botley West, the Secretary of State requested additional information on alternatives and site selection, including grid-connection options,

search radius, environmental/social/economic considerations, technical and financial feasibility, BMV land, flood zones and grid infrastructure timing.”

Chapter 6 Site Selection Compliance/Audit Trail, Horlock Compliance and Grid Hub Design

BEPS does not suggest that East Pye failed to undertake a site-selection exercise. The Applicant has provided a Site Selection Assessment [APP/7.20], an Environmental Statement chapter dealing with alternatives and design evolution [APP/6.1.5], the Design Approach Document [APP/7.17] and a substantial range of environmental assessments.

Our concern is more specific.

The Examination needs to be able to follow a clear audit trail showing **how the National Grid Substation location developed, why Site 1B was ultimately selected, when land availability and landowner willingness entered that process, how environmental constraints were applied between competing locations, and whether the final grid-hub design reflects the Horlock Rules.**

This is particularly important because Site 1B is no longer simply part of a solar site. It has become the main grid-infrastructure hub for the western part of the Scheme, containing or directly associated with the National Grid Substation, the 400kV Project Substation, overhead-line and pylon works, cable connections, access infrastructure and the adjoining BESS and 4.5m high tracking solar panels.

The site-selection evidence should therefore be capable of explaining the choice of this location **as a combined infrastructure cluster**, rather than only explaining the location of individual components.

6.1 Audit Trail – Options 1 to 4A and 4B

The Applicant's documents show that the National Grid Substation site-selection process developed over time. The original options did not include the final Site 1B location in the form now proposed. A further Great Moulton option was subsequently identified and the process developed into Options 4A and 4B.

APP/7.20 records that due to another solar planning and the loss of site 4A, Option 4B within Sub-Site 1B was ultimately targeted. We submit that the site was simply the easiest choice, undertaken by a desktop analysis, We would suggest no site visits were made, BEPS-Great Moulton have requested a site visit but these were refused.

The Applicant then confirmed through the targeted consultation between 22 October and 26 November 2025 that Option 4B would be taken forward. There is nothing inherently wrong with a site-selection process evolving. Major projects frequently develop as technical information, land arrangements and environmental information become available.

The difficulty for residents and, we suggest, for the Examination is that the assessments of the different options were undertaken at different stages and are spread across several documents.

BEPS therefore considers that a clearer audit trail is required showing:

- when each National Grid Substation option was first identified;
- what environmental and technical information was available when each option was considered;
- what criteria were applied to Options 1, 2 and 3;
- whether the same criteria and level of scrutiny were subsequently applied to Options 4A and 4B;
- when Option 4A was introduced and when Option 4B was first identified;
- when NGET became involved in assessing the Great Moulton alternatives;
- when the decision was made to prefer Option 4B and relevant site visits undertaken;
- what role land availability and landowner willingness played at each stage; and
- whether any environmental assessment undertaken before the final Site 1B configuration remained appropriate after the design changed.

The purpose of this request is not to reopen the entire site-selection exercise. It is to allow the Examination to understand and test the reasoning that led to the particular grid-hub configuration now before it.

6.2 Land Availability and Willing Landowners

Land availability is plainly a relevant consideration for a project of this scale.

APP/7.20 expressly records that the Applicant identified suitable land with landowners willing to participate in the Scheme while discussions concerning the grid connection were taking place. It also explains that land agents were used to identify larger landholdings with potentially willing landowners. [APP/7.20, including paragraph 6.1.3 onwards]

BEPS does not object to that approach simply because willing landowners were involved. A scheme cannot realistically be developed without considering whether land can be secured.

The important question is how much influence land availability had on the alternatives that were actually examined.

There is a difference between:

- first identifying technically and environmentally reasonable alternatives and then considering their deliverability,
  and
- allowing the availability of particular land to determine the alternatives that receive detailed environmental consideration.

The Applicant's Policy Compliance Document itself recognises landowner willingness and commercial and technical feasibility as part of its approach to alternatives. [APP/7.15]

BEPS therefore asks for clarification rather than making an assumption about the process.

- The Applicant should explain whether potentially suitable locations were excluded because land was not voluntarily available and, if so, at what stage. Where this occurred, it should distinguish clearly between an option being rejected because it was environmentally or technically unsuitable and an option not being pursued because of land ownership or commercial deliverability.

That distinction matters because Site 1B itself contains significant constraints which have subsequently required assessment and mitigation:

- These include landscape and visual effects, nearby residential receptors, public rights of way, agricultural land, water and drainage issues, ecology, heritage, rural access and the cumulative effects of concentrating the National Grid Substation, Project Substation, BESS, cables, overhead-line works and associated development in this part of the Scheme.

The Examination should therefore be able to see that comparable constraints were considered consistently when the competing locations were assessed.

6.3 Horlock Rules and Site 1B

The Horlock Rules are particularly important to the National Grid Substation.

The current NPS EN-5 states that environmental considerations should be addressed from the earliest stage of substation development and that technical and capital-cost requirements should be balanced against environmental effects so as to keep adverse effects to a reasonably practicable minimum.

The principles include protecting local amenity, important habitats and landscape features, historic hedgerows and surface and groundwater sources; taking advantage of existing landform and screening; minimising visual, noise and other environmental effects; considering land-use effects; and considering the form of equipment, buildings and ancillary development appropriate to the individual location.

National Grid similarly describes its substation siting process as considering matters including proximity to transmission infrastructure, access, topography, distance from residential areas and environmental, cultural and visual constraints.

Those principles are directly relevant to Site 1B.

The location is within a rural landscape and the final proposal represents a substantial concentration of electrical infrastructure. Although planting, hedgerow reinforcement and other mitigation are proposed, the Horlock approach places considerable importance on the initial choice and design of the site itself, including use of landform, existing screening, layout and levels.

The issue is therefore not simply whether Option 4B performed better than Option 4A in relation to flood risk or the public right of way.

The wider question is:

Has the Applicant demonstrated that the siting and design of the complete Site 1B grid hub keeps the resulting environmental effects to a reasonably practicable minimum?

BEPS considers that this would be much easier for the Examination to determine if the Applicant and NGET provided a simple Horlock Compliance Schedule for Site 1B.

That schedule should identify each relevant Horlock principle and explain:

- how it influenced site selection;
- what alternatives were considered;
- what environmental constraints were identified;
- what design response followed;
- where effects could not be avoided;
- what mitigation is relied upon; and
- why the final location and design were considered preferable.

Particular attention should be given to the open rural setting, proximity to homes, landscape and visual effects, noise, public rights of way, agricultural land, groundwater/private water supplies, access requirements and the cumulative presence of the associated BESS and Project Substation.

This would provide a much clearer basis for assessing Horlock compliance than requiring the Examination to reconstruct the reasoning from numerous separate documents.

6.4 AIS, GIS and Lower-Impact Substation Design

BEPS also considers that the Applicant should explain the technology and design alternatives considered for the 400kV infrastructure.

The present proposal appears to be based upon air-insulated switchgear (AIS). National Grid describes AIS as its standard arrangement for new substations, while GIS can be used in particular circumstances and has the advantage of being more compact, although generally more expensive.B

BEPS does not suggest that GIS must automatically be used at Site 1B, or that GIS would necessarily have lower environmental effects in every respect.

The question is whether a more compact arrangement could materially reduce some of the particular effects experienced at this location.

The Infrastructure Planning (Environmental Impact Assessment) Regulations require the Environmental Statement to describe reasonable alternatives studied by the developer, which can include alternatives relating to design, technology, location, size and scale, together with the main reasons for choosing the preferred option.

EN-1 similarly requires information about reasonable alternatives actually studied by the Applicant, while recognising technical and commercial feasibility.

BEPS therefore asks the Applicant and NGET to explain:

- whether GIS was considered for any part of the National Grid or Project Substation infrastructure;
- whether hybrid AIS/GIS arrangements or other compact layouts were considered;
- whether those alternatives could reduce the overall footprint, height or spread of equipment, agricultural land take or visual exposure;
- what technical disadvantages or operational constraints would arise;
- the comparative implications for construction, maintenance, cost and future expansion; and
- why the configuration within the current Rochdale Envelope represents the appropriate design for this particular rural location.

If GIS or another compact design was considered and rejected, an explanation would resolve the issue..

If it was not considered, BEPS asks the Applicant to explain why it was not regarded as a reasonable design alternative for Site 1B.

6.5 Consistency in the Treatment of Constraints

A recurring concern throughout the site-selection evidence is whether constraints were applied consistently. APP/7.20 records reasons for discounting various locations including flood risk, access, public rights of way, environmental constraints, land availability and interaction with other development.

Many of those same types of constraint are also present to some degree around Site 1B.

That does not mean that Site 1B should necessarily have been rejected. It does mean that the Examination should be able to understand why a constraint regarded as important at one location was considered capable of mitigation at another.

BEPS therefore asks for a short comparative schedule showing the principal criteria applied to Options 1, 2, 3, 4A and 4B and the Applicant's assessment against each criterion.

This need not become another lengthy environmental report. A transparent table would be sufficient, provided that it identifies the supporting document and assessment date.

6.6 Information Requested from the Applicant and NGET

BEPS considers that much of the uncertainty could be resolved through one consolidated response rather than further information being scattered across separate submissions.

We ask the Examining Authority to consider requesting a Site 1B Grid Hub Site-Selection and Design Audit Statement, prepared by the Applicant with input from NGET where appropriate.

It should contain:

1. A dated chronology of Options 1, 2, 3, 4A and 4B, including when each was identified, assessed and discounted or selected.
2. A common comparison table showing the environmental, technical, access, land, residential and planning criteria applied to each option.
3. A land-availability statement explaining when willing-landowner considerations entered the process and whether any otherwise reasonable alternatives were excluded because land was unavailable.
4. A record of NGET involvement, explaining what assessment NGET undertook or reviewed in relation to the Great Moulton options and when.
5. A Horlock Compliance Schedule for the final Site 1B location and design.
6. An AIS/GIS and design-options statement explaining whether more compact technology or layouts were considered and why the proposed arrangement was selected.

7. Confirmation of the current grid-hub configuration, including the National Grid Substation, Project Substation, BESS relationship, overhead-line/pylon works, cable connections, access and any infrastructure intended to remain permanently.
8. Confirmation that the environmental baseline remains applicable to the final configuration. If material elements of the layout, access arrangements, cable routes, substation design or associated works change, the Applicant should identify which environmental assessments and plans require updating.

The purpose would not be to create another large body of evidence. It would provide a single document through which the Examination, Interested Parties and local residents can follow the development of the Site 1B decision from the early alternatives through to the final proposal.

6.7 Conclusion

BEPS's concern is therefore not that East Pye undertook no site-selection work.

The concern is that the route from the earlier alternatives to the present Site 1B grid hub is difficult to follow because the process evolved over time, the evidence is spread between different documents, land availability formed part of the selection process, and the scale and role of Site 1B itself developed substantially.

The National Grid Substation is permanent infrastructure and Site 1B now forms the centre of a much wider cluster involving the Project Substation, BESS, overhead-line works, cables, access and associated development.

For a decision of that importance, the Examination should be able to follow a clear evidence trail showing:

- why this location was selected;
- what alternatives were genuinely considered;
- how landowner willingness affected that process;
- whether the same constraints were applied consistently;
- how the Horlock Rules influenced the decision; and
- whether a less extensive or less intrusive substation design was reasonably available.

BEPS therefore asks the Examining Authority to require the Applicant, with NGET where appropriate, to provide the consolidated audit information identified above before the close of Examination.

That would allow the final Site 1B grid-hub proposal to be considered on the basis of a clear and transparent site-selection and design record, rather than requiring the reasoning to be reconstructed from a number of separate documents.

Chapter 7 Climate Change

Residents object to the adequacy of East Pye's climate-change assessment for Great Moulton, Site 1A–1D and the BESS / grid-hub area.

East Pye should demonstrate climate resilience of the Site 1 grid hub and BESS under future rainfall, heat, drought and storm conditions. The assessment should include climate-adjusted runoff modelling, soil compaction and infiltration, drainage exceedance, firewater containment, emergency access during extreme weather and local microclimate effects on hedgerows, fields and receptors.

Our objection to an Environmental Impact Assessment that relies on the climate benefits of solar generation while failing to demonstrate that this particular development, in this particular rural location, is resilient to the climate pressures now expected over its operational lifetime.

Chapter 8 Landscape and Visual

Great Moulton and the surrounding Plateau Farmland are defined by open agricultural views, historic field patterns, quiet lanes, public rights of way and rural tranquillity. The proposed National Grid substation, project substation, BESS-linked infrastructure, fencing, lighting, access tracks and associated works would introduce a permanent industrial character into a landscape whose value lies in openness, continuity and low levels of built form.

The harm is not limited to individual viewpoints. Residents, walkers, cyclists, horse riders and neighbouring parishes would experience the combined effect of panels, substations, pylons, lighting, security infrastructure and construction access as a single infrastructure cluster. Screening would not remove that harm; it would itself alter the open rural character of the landscape.

The LVIA should be receptor-led for Great Moulton and should assess the combined appearance of solar arrays, National Grid Substation, 400 kV Project Substation, BESS, pylons, fencing, lighting, access and mitigation planting. Screening cannot be treated as a complete answer because it can itself alter openness and the historic plateau character.

8.1 Applicant's own LVIA findings

The existence of substantial landscape harm is not simply BEPS's interpretation. BEPS's consolidated review of the Applicant's LVIA records Major Significant effects at Site 1 during construction, at Year 1 and continuing at Year 15, together with a description of a "total change" to key landscape characteristics. The BESS also remains Moderate Significant at Year 15.

Those findings are directly relevant to alternatives and site selection. Where the Applicant's own assessment identifies enduring significant effects from the selected Site 1 grid hub.

The ExA should address not only how the infrastructure will be screened, but why this location was selected and retained in preference to reasonable less harmful alternatives.

8.2 Misrepresentation of images

We ask the ExA to request the Applicant to provide coordinates, camera height, lens information and the receptor represented for any disputed image.

8.2.1 Clarification of where this image was taken?

We submit this photographic image **is not** part of Great Moulton Landscape

View Location Reference: Site 1/National Grid Sub Station - VL2 (b)

Site Context Photograph (2 of 2)

This panorama is not to scale. For contextual information only

8.2.2 Site 1B - Distortion of site looking towards Village Boundary

The panoramic photo creates a huge distortion of the actual distance between the properties and field boundaries of Oak Farm and Laburnham Farm and even Potters Crescent

Where wide-angle images are used, we request verified visualisations or equivalent images at standard focal lengths and from agreed receptor locations.

EAST PYE WIDE ANGLE LENS

Photographic Image taken from same location using normal lens

The Boundary to beginning of Village Boundary

8.2.3 Site 1B - Distortion of site looking towards Broadgate Lane from Frith Way

This Image shows the National Grid positioning, (the image appears to have been taken with a wide angle lens, distorting the depth of the landscape. The image is taken from Frith Way looking towards Broadgate Lane. This image does not reflect that its boundary is close to other residential boundaries or Narrow Gate Lane PRoW

We submit that the Applicant should supply close-up images - giving the proposed perspective of the POC Substation at all four views within sub-site 1B, using a normal lens. Giving clear measurements at each boundary.

Extent of Maximum
Development Parameter

Chapter 9 Ecology and Biodiversity

The ecological concerns around Great Moulton are not marginal. Site 1 and the surrounding landscape sit within a sensitive network of hedgerows, ditches, ponds, ancient woodland edges, dark corridors and field margins used by Barbastelle bats, other bat species, birds, great crested newts, mammals and notable verge flora.

The proposed infrastructure would fragment this network through fencing, lighting, trenching, access works, noise, construction disturbance and long-term land-use change. The particular concern is the combined effect of the National Grid substation, project substation, BESS-related infrastructure, solar arrays, cable routes and maintenance activity on functional ecological connectivity.

The ecological case should address the final grid-hub layout, including bat corridors, dark corridors, hedgerows, ponds, ditches, great crested newts, birds, botanical interest and BNG baseline.

The ExA should require updated survey validity and licensing deliverability evidence before relying on deferred mitigation.

Chapter 10 Water Environment

Great Moulton has a sensitive rural water environment and the water assessment should be consolidated into a Site 1 / BESS source-pathway-receptor model, with private water supplies, groundwater, ditches, drainage, transformer oils, BESS firewater, sediment control, baseline monitoring and alternative supply commitments secured in enforceable requirements.East Pye has identified and assessed private water supplies and other lawful water users, including through APP/6.3.16.1 and APP/6.3.9.3. The remaining issue is whether the assessment and proposed controls provide sufficient protection for individual receptors potentially affected by the Site 1/BESS development.

The assessment should therefore be considered on a receptor-specific source–pathway–receptor basis, having regard to the local geology and groundwater environment, construction activities, foundations and piling where applicable, drainage arrangements and the potential movement of contaminants.

Particular consideration should also be given to the management of contaminated runoff and firewater associated with the BESS, including how such water would be contained and prevented from reaching groundwater, surface-water features or private abstractions.

BEPS considers that the Examination should establish whether appropriate baseline information, receptor-specific monitoring and clearly secured mitigation are in place before

relevant construction activities commence, together with an appropriate response procedure should water quality or supply be affected.

10.1 Independent hydrogeological review

The water objection is further reinforced by the independent H Fraser Consulting review summarised in BEPS's consolidated evidence. HFCL identifies 15 technical deficiencies concerning the conceptual hydrogeological model, WFD assessment, water resources, private supplies, groundwater-dependent terrestrial ecosystems, firewater, foundations and other pathways, and concludes that there is a "significant lack of confidence" that impacts on the water environment are properly understood or capable of mitigation.

This is particularly relevant at Site 1, where substations, BESS infrastructure, hardstanding, transformers, foundations, drainage and firewater controls are concentrated. It strengthens the case that later Foundation Works Risk Assessments, drainage details and construction method statements should refine an already demonstrated acceptable solution, rather than determine after consent whether an acceptable solution exists.

Chapter 11 Cultural Heritage

Heritage should be assessed as a landscape-wide setting issue, including historic lanes, field patterns, archaeological sensitivity, listed buildings, Wacton and Tivetshall context, dark skies and tranquillity, not as isolated asset impacts. The effect of a permanent grid node on historic landscape legibility should be specifically addressed.

The DCO should not proceed without a full cumulative heritage-setting assessment, receptor-specific dark-sky and lighting evidence, archaeological safeguards and a clear explanation of why less harmful locations have not been selected.

Chapter 12 Transport and Access , Public Rights of Way and Glint/Glare

Great Moulton, Tivetshall and surrounding villages rely on narrow rural lanes with soft verges, deep ditches, limited passing places and little or no pedestrian infrastructure. The Transport and PRoW assessment should cover rural-lane suitability, abnormal loads, HGVs, worker traffic, verge/ditch damage, Station Road, Frith Way, Lodge Road, Hundred Lane, Narrowgate Way, emergency access, cyclists, equestrians and walkers. Glint / glare should be receptor-specific for homes, PRoW, roads, rail and aviation.

The ExA should require a definitive Frith Way and Station Road access-management schedule, including phasing, closures, PRoW, emergency access and simultaneous restriction controls and proposed Haul Routes

Chapter 13 Noise and Vibration

Great Moulton is a quiet rural parish with very low background sound levels, particularly at night. In that context, construction noise, HGV movements, reversing alarms, piling, generators, transformers, inverters, cooling fans and BESS equipment would be highly noticeable and intrusive. The concern is both temporary and permanent..

East Pye has not demonstrated that the evidence it has presented on the anticipated noise and vibration studies are accurate and well defined.The purpose of requesting a private study is to bring to the attention of the Planning Inspectorate this fact. See Appendix 2.

Noise should be assessed for construction, decommissioning and operation against a very quiet rural baseline, The Applicant should demonstrate how LOAEL and SOAEL thresholds have been applied to this rural baseline, how low-frequency and tonal noise have been assessed, how night-time impacts will be controlled, and how cumulative noise from Site 1, Site 2B, BESS and National Grid infrastructure will be prevented from causing unacceptable harm.

The unaddressed issue of the permanence of the National Grid POC and the proposed haul Road across The Bess Site and Site 1 needs to be resolved.

13.1.1 Great Moulton - Private Consultants - Noise Analysis

The Oakridge review will be retained as Appendix 2 and used to identify the technical questions for East Pye: source sound levels, locations, tonal corrections, low-frequency assessment, night-time levels, cumulative plant and post-installation monitoring.

The evidence presently before the Examination does not justify the siting of permanent, large-scale transmission infrastructure on Grade 2 agricultural land within an exposed rural landscape close to homes, public rights of way, ecological receptors, heritage assets, and private water supplies. Nor has East Pye demonstrated that the Great Moulton location represents the least-harm or most appropriate option when compared with reasonable alternatives.

Chapter 14 Air Quality

Great Moulton currently benefits from clean rural air and has no comparable industrial emission source.

Air-quality controls should include dust, diesel emissions, construction traffic, soil disturbance and BESS / transformer incident emissions.

The BESS also raises a distinct air-quality and safety concern because thermal events can release toxic gases, combustion products, particulates and contaminated residues. In a rural location surrounded by arable fields, hedgerows and dry vegetation, the risk of secondary fire spread and emergency access constraints must be assessed as part of the environmental case.

The definition of “maintain” in the DCO must be tightly constrained so future replacement or refurbishment works do not create new environmental effects without proper assessment. and controlled for dust, emissions, construction traffic, operational maintenance, fire response, contaminated runoff, monitoring and decommissioning.

Chapter 15 Socio-Economics

The socio-economic harm is wider than direct construction employment or landowner benefit. Great Moulton’s local economy is tied to productive agriculture, rural contractors, tourism, quiet lanes, heritage visits, pilgrimage routes, equestrian use, country pursuits, local accommodation and the broader appeal of an unspoilt rural landscape.

The proposed infrastructure would reduce the attractiveness and usability of the area by replacing tranquillity, open views and historic rural character with substations, BESS compounds, fencing, lighting, traffic and operational noise. It would also remove productive farmland and reduce demand for agricultural contracting, machinery, seasonal labour and related rural services.

East Pye should be required to assess these local economic losses, including impacts on rural businesses, tourism, equestrian activity, agricultural contractors, property amenity and long-term confidence in the area. The benefits of the scheme should not be overstated unless they are compared transparently with these local and cumulative harms.

Chapter 16 Soils and Agriculture

The land around Great Moulton contains high-quality agricultural soils, including Grade 2 Best and Most Versatile land. The Applicants s own material identifies Grade 2 land within Site 1, the National Grid substation area, the project substations, the BESS site and assumed areas of Site 2B. This is not marginal land; it is productive agricultural land with long-established soil structure and historic agricultural continuity.

APP/6.3.15.1 – ES Volume 3, Appendix 15.1: Agricultural Land Classification Report. This contains the detailed survey undertaken by Amet Property Ltd and the maps showing the distribution of the agricultural land grades, including Grade 2, Grade 3a and Grade 3b land.

The proposal would cause temporary, long-term and permanent harm through compaction, trenching, foundations, access tracks, hardstanding, substations, BESS infrastructure, altered drainage, contamination risk and potential panel degradation. The National Grid substation and other fixed infrastructure cannot be treated as reversible solar occupation because they permanently remove or alter agricultural land.

The Applicant should provide a field-by-field ALC/BMV schedule distinguishing temporary, long-term and permanent land take, compaction, trenching, foundations, hardstanding, drainage change, restoration

Chapter 17 Ground Conditions

Great Moulton's ground conditions reflect centuries of agricultural use with limited deep disturbance.

The risks include compaction, altered drainage, localised flooding, subsurface barriers, ground instability, contamination from oils or fire residues, and long-term degradation from infrastructure remaining in place for decades. These risks are particularly important where homes, lanes, ditches, water supplies, archaeological remains and productive fields sit close to the proposed works.

The Applicant Ground condition assessments should cover geotechnical stability, piling, trenching, compaction, contamination pathways, UXO where relevant, drainage stability, archaeological sensitivity and remediation. Baseline and monitoring commitments should be secured before intrusive works.

Without these, the Examining Authority cannot be confident that ground integrity and agricultural viability will be protected.

Chapter 18 Electromagnetic Fields

The proposal would introduce new EMF sources into a rural parish with no comparable baseline, including the National Grid substation, project substations, high-voltage cabling, inverters, transformers and BESS infrastructure. The relative increase in exposure is therefore material for nearby homes, gardens, PRoW and sensitive receptors.

Children, residents, wildlife and aviation receptors require particular consideration. The concern is not simply whether generic public exposure limits are met.

The EMF assessment should map receptors, cable routes, overhead lines, substations, PRoW and homes. The issue is not only generic compliance with public exposure limits but the

cumulative infrastructure layout and the adequacy of separation and shielding. Until this evidence is provided, the EMF assessment should be treated as incomplete.

Chapter 19 Other Environmental Matters

The utilities assessment does not yet demonstrate that the scheme can be delivered without unacceptable risk to existing services and community resilience, this is particularly important in a rural parish where residents may rely on private wells, shallow utility routes, broadband connections, emergency medical alarms and constrained local access. Loss of connectivity, water supply, access or service reliability would have serious consequences for daily life and public safety.

Utilities, broadband, telecoms, glint/glare, waste, materials and human health should be assessed in a way that reflects rural community resilience. The Applicant should provide utility surveys, diversion/protection plans and service-continuity commitments.

These matters should not be left to unresolved post-consent detail.

Chapter 20 National Grid Infrastructure Cluster

The National Grid substation, project substations, BESS-related infrastructure, transformers, inverters, cabling corridors, access roads, fencing, lighting and associated works form a permanent industrial cluster. This cluster would remain as a long-term grid node even if solar elements were later removed, and it should be assessed as a single operational and cumulative development with a clear permanent legacy.

The combined impacts include operational noise, low-frequency hum, lighting, visual intrusion, fire and major accident risk, emergency access requirements, firewater containment, contamination pathways, glint and glare, rail and aviation safety concerns, and long-term landscape industrialisation. These impacts fall on a rural parish with private water supplies, narrow lanes, sensitive ecology and valued PRoW.

Chapter 21 Cumulative and In-Combination Effects

The central planning issue is cumulative harm. Cumulative effects should include overlapping construction, operation, maintenance/replacement, decommissioning, future grid-node effects and other energy proposals. The assessment should address the lived experience for Great Moulton, Tivetshall and Wacton.

Cumulative effects include loss of rural quiet and dark skies, visual industrialisation, ecological fragmentation, heritage harm, repeated construction traffic, ongoing maintenance and

replacement traffic, noise, air quality impacts, loss of BMV land, pressure on utilities and private water supplies, glint/glare effects, and mental health impacts from long-term uncertainty and loss of place.

Chapter 22 Human Health and Wellbeing

The Human Health assessment should consider the consequences for residents and other users who rely upon private water supplies if construction or operation of the Scheme were to affect water quality, quantity or reliability.

East Pye has undertaken assessment of private water supplies and lawful water users. The relevant human-health question is therefore whether the proposed prevention, monitoring and response measures provide adequate protection for households dependent upon those supplies.

This includes consideration of potential contamination arising from construction activities and, in relation to the BESS, the consequences of an abnormal incident involving contaminated runoff or firewater. The detailed hydrogeological pathways and mitigation are addressed in the Water Environment chapter; the Human Health chapter should address the resulting exposure and welfare implications for affected receptors and the measures available to maintain a safe and reliable alternative supply if required.

Human health and wellbeing are material considerations under EN-1 and EN-5. Great Moulton's health and wellbeing baseline is defined by rural quiet, clean air, dark skies, safe walking routes, access to countryside, social cohesion and the daily use of lanes and PRoW as the parish's functional green space. Human health and wellbeing should assess sensory and community effects: noise, lighting, traffic, loss of safe recreation, glint/glare, EMF concern, uncertainty, rural isolation, access disruption and vulnerable residents.

The Applicant must now scope back in the "Human Health and Wellbeing" as specified by the ExA at the ISH on September 17

Chapter 23 Great Moulton Specific Issues

Great Moulton should be treated as a place-based receptor. The central issue is whether the village edge can absorb a permanent and high-voltage grid hub without unacceptable harm to amenity, safety, landscape, water, ecology, PRoW, agriculture and heritage.

The Applicant's own site-selection narrative shows that the project became driven by the need to find a new 400 kV connection location after Norwich Main was unavailable. That history makes it essential to test whether the chosen Great Moulton/Tivetshall location is genuinely least harmful or merely grid-convenient.

The proposal raises unresolved concerns on site selection, reasonable alternatives, Horlock Rules compliance, Grade 2 BMV land, GIS alternatives, fire safety, private water supplies,

drainage, long-term landscape change, lighting, bat activity, great crested newts, access routes, Frith Way, Lodge Road, Hundred Lane, PRoW, FP13, residential amenity, glint and glare, and the proportionality of imposing permanent infrastructure on a small rural community.

East Pye should be required to provide updated and integrated documents where layout, access, grid works, tower works, substation design, BESS relationship or mitigation has changed. This should include updated works plans, land plans, draft DCO, Book of Reference, grid connection statement, LVIA, RVAA, drainage and flood-risk material, ecology and BNG evidence, heritage and settings assessment, soils evidence, LEMP, decommissioning plan, traffic/access assessment, glint/glare/aviation assessment and any compulsory-acquisition or protective-provisions material affected by the change.

The Planning Inspectorate should not allow these matters to be deferred or treated as minor. The residents of Great Moulton, Tivetshall and Wacton require a clear, evidence-based explanation of why this location has been selected, why less harmful alternatives have been rejected, and how the full cumulative effects of the National Grid substation and associated infrastructure.

Chapter 24 Core position.

BEPS and residents do not dispute the national need for renewable electricity generation or the important contribution that solar generation can make.

Our objection is more specific. **East Pye must demonstrate that the particular land, infrastructure and configuration now proposed across Great Moulton, Tivetshall and Wacton are appropriately justified, having regard to the reasonable alternatives considered, and that their environmental and community effects have been adequately assessed and secured.**

This is particularly important for **Sites 1A–1D, Site 2B and the BESS/Site 1 grid-infrastructure cluster**, where solar generation is combined with, or affected by, major electrical infrastructure, access, cabling, substations, overhead-line works, drainage, mitigation and associated development.

East Pye states in its Site Selection Assessment that previously developed land, brownfield land, industrial land and commercial rooftops were considered, but that no suitable land of sufficient scale was identified for the proposed 500 MW utility-scale solar development. [APP/7.20, paras 4.4.9–4.4.14; APP/7.14]

The Examination issue is therefore not whether those alternatives were mentioned, but whether the Applicant has demonstrated that the exercise was sufficiently robust and remains applicable to the Scheme now proposed.

East Pye should therefore explain:

- the geographical extent and date of the brownfield and previously developed land search;
- the basis for excluding sites below the thresholds used in APP/7.20;
- whether combinations of smaller sites and commercial or other suitable roofspace were meaningfully considered;
- why the assumptions concerning the scale and distribution of land required were reasonable;
- whether that assessment was revisited after the Point of Connection moved to Great Moulton and Sites 1 and 2 were subsequently added;
- how the preference in EN-3 for suitable previously developed, brownfield, contaminated and industrial land was applied;
- how the later identification of substantial Grade 2 and Grade 3a Best and Most Versatile agricultural land affected the continued selection and retention of the agricultural land now proposed; and
- whether reasonable opportunities to reduce the overall agricultural-land requirement, remove individual fields or relocate particular infrastructure were reconsidered as the Scheme evolved.

BEPS does **not** suggest that East Pye is required to pursue every conceivable alternative method of producing renewable electricity, nor that rooftop solar elsewhere is automatically a substitute for this 500 MW NSIP. The relevant question is whether the **reasonable location, scale, layout and design alternatives capable of meeting the objectives of the proposed development** have been transparently identified and adequately considered.

The burden remains upon East Pye to explain why the particular Scheme now before the Examination remains justified in light of the environmental information subsequently obtained, the evolution of the grid connection, the concentration of infrastructure around Site 1 and the BESS, the use of BMV agricultural land and the significant effects identified in its own assessments.

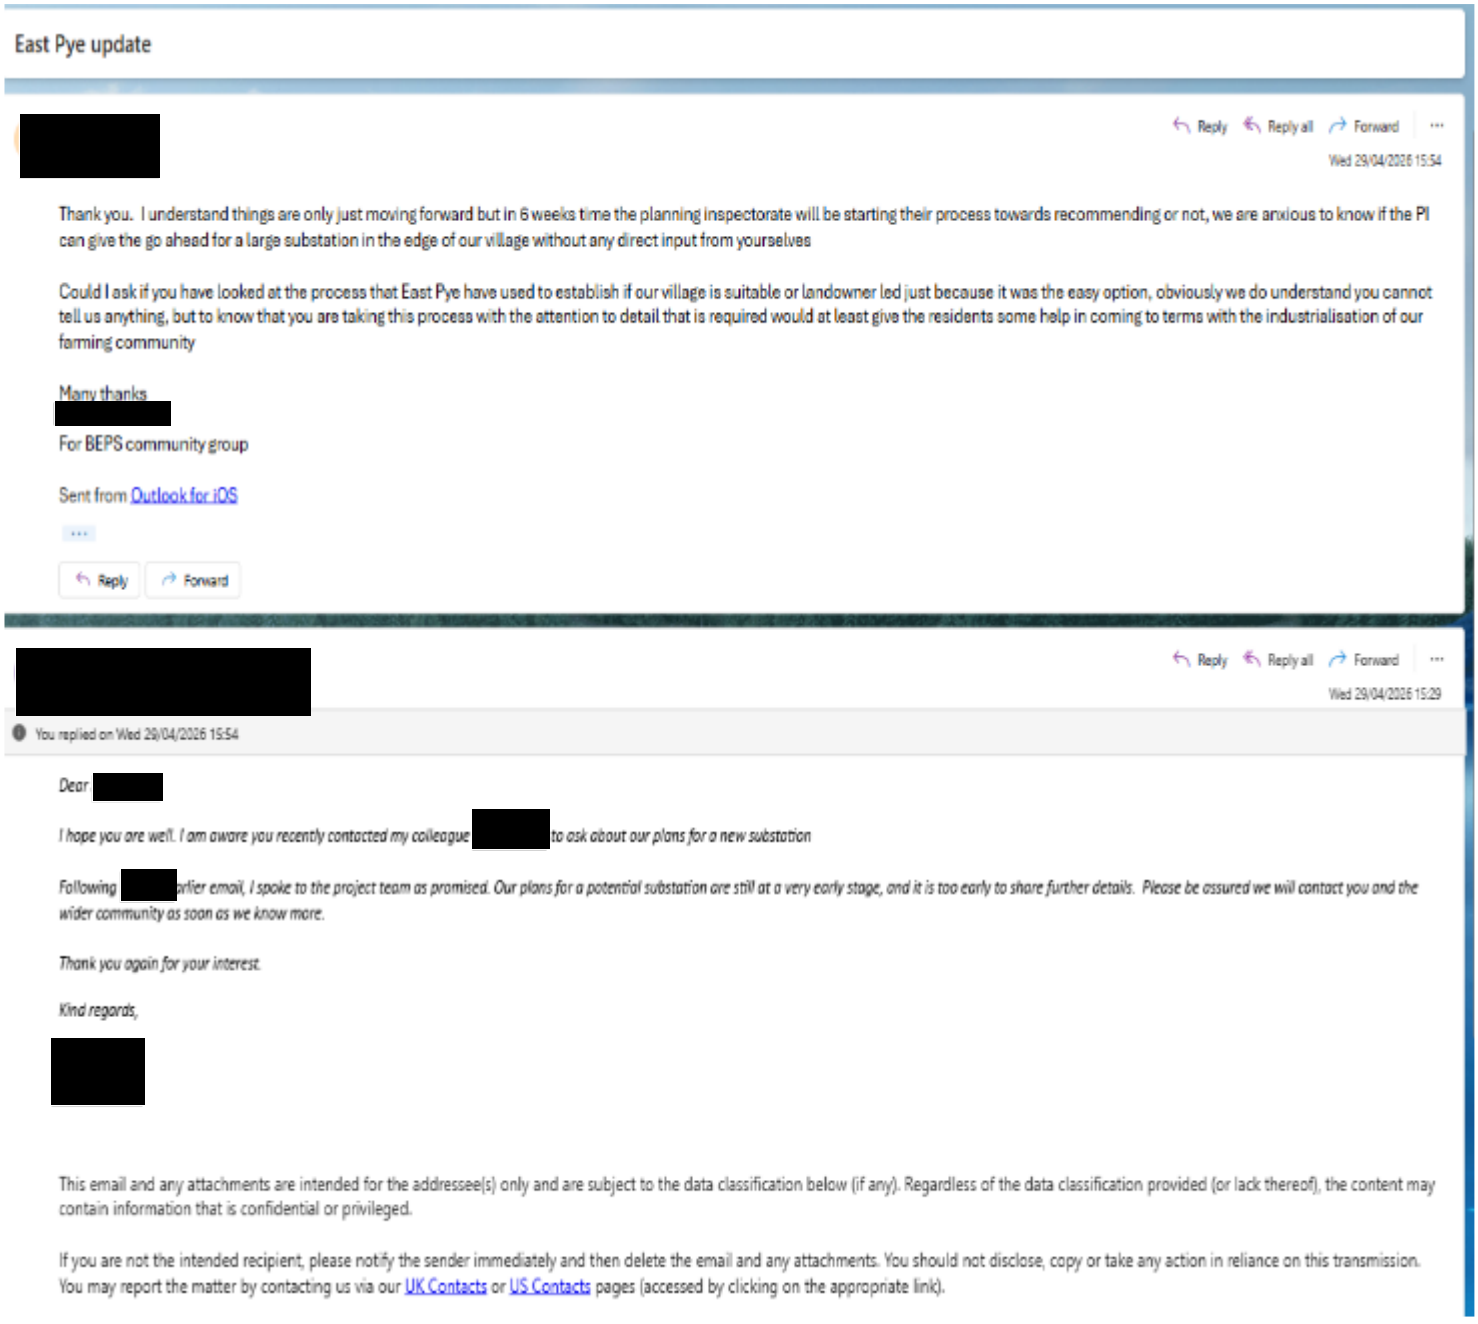
Concluding Request

Great Moulton, Tivetshall and Wacton residents respectfully ask the Examining Authority to require East Pye, and NGET where relevant, to provide the outstanding evidence, reconciliations and secured controls identified in this representation before conclusions are reached on the acceptability of the Scheme.

The residents do not seek to undertake the Applicant's design exercise, identify alternative sites on its behalf or reconstruct its environmental case from dispersed application documents. **It is**

for East Pye to demonstrate that the particular siting, land take, infrastructure and design for which consent and associated powers are sought are adequately justified, sufficiently assessed, deliverable and subject to effective and enforceable mitigation.

Where the Applicant relies upon later detailed design, East Pye should demonstrate the assessed worst case and identify the binding control which prevents the eventual development from exceeding that environmental envelope. Where the final NGET connection solution, BESS connection arrangements or other material infrastructure remain uncertain, East Pye should demonstrate that the land, powers and environmental conclusions now sought remain justified under the realistically foreseeable outcomes.



Until those matters are satisfactorily resolved, BEPS submits that the Examining Authority should not assume that the particular Site 1/Site 2B/BESS configuration, associated permanent grid infrastructure and related land requirements have been adequately justified merely from the established national need for renewable energy.

I think this is **stronger for Examination purposes** than the original. It avoids three arguments East Pye could otherwise make immediately: that national need is already established by the NPS, that brownfield/rooftops were in fact considered, and that the policy test does not require East Pye to prove its site is literally the “least harmful” possible location.

The useful challenge is instead: **show us how robust your brownfield/rooftop exercise actually was; show us why its assumptions remained valid after the Point of Connection and Scheme changed; and show us why later Grade 2/BMV and other environmental evidence did not alter the land-selection conclusions.** That keeps the evidential burden where you want it—on East Pye.

Thank you. I understand things are only just moving forward but in 6 weeks time the planning inspectorate will be starting their process towards recommending or not, we are anxious to know if the PI can give the go ahead for a large substation in the edge of our village without any direct input from yourselves

Could I ask if you have looked at the process that East Pye have used to establish if our village is suitable or landowner led just because it was the easy option, obviously we do understand you cannot tell us anything, but to know that you are taking this process with the attention to detail that is required would at least give the residents some help in coming to terms with the industrialisation of our farming community

Many thanks

Dear [redacted]

I hope you are well. I am aware you recently contacted my colleague [redacted] *to ask about our plans for a new substation*

Following [redacted] *earlier email, I spoke to the project team as promised. Our plans for a potential substation are still at a very early stage, and it is too early to share further details. Please be assured we will contact you and the wider community as soon as we know more.*

Thank you again for your interest.

Kind regards,

[redacted]

Good morning [redacted]

Thank you for this info and the promise of an update if things change.

I have taken the liberty of sending a copy to the contact at Great Moulton Parish Council, [redacted], so she has a direct link to you for the future.
Many thanks,
[redacted]

[redacted]
Thank you for you response
We were aware that East Pye Solar is preparing a Development Consent Order which they propose to submit in February and as part of this is the proposal for a parcel of land as a potential site for the possible National Grid Substation, what we as a village are concerned about is the proximity of this to the village, some 25 metres from property boundaries and public bye-ways and given the fact that Norfolk Fire Service have reported that the proposed location is unsafe due to its proximity to homes and it would cause an existential threat to Tibenham Airfield, given the gravity of this situation and this decision on siting for local residents and businesses transparency about how the decisions are made we feel is extremely important and although this scheme has not reached planning it has unexpectedly been given a Gate2 connection (we assume as it has Secured Land Rights), but:

You state that 'The scheme's grid connection agreement requires East Pye Solar to source suitable land for the substation connection and to consent it on our behalf.' Therefore, could you clarify whether National Grid has any say in whether this is a suitable location and if this location is found to be unsuitable due to the various issues highlighted previously at what stage will the National Grid require a new location to be found?
East Pye state they have a Gate 2 connection but I am confused as having read the Queue Management Milestone M1 – Planning Submission - What M1 now requires (updated under CMP434):

If validation has not yet occurred at the time of Gate 2 application, the submitted application itself may be provided temporarily —but the planning reference number must be provided before the Gate 2 Offer is issued."
Therefore as East Pye have not achieved the Gate2 criteria why are the National Grid considering this application?
I look forward to your thoughts
Kind regards

Subject: RE: [EXTERNAL] Urgent Concerns and Clarification Required: Proposed National Grid Substation at East Pye Solar Park

Dear [redacted]
Happy New Year and apologies for the delayed response. Below is an update which I hope answers your questions.
As you are aware, East Pye Solar Limited (a subsidiary of Island Green Power) is preparing a Development Consent Order application. The scheme includes proposals for a parcel of land which has been identified as a site for a possible National Grid substation which will connect the solar farm to the high voltage network.
The scheme's grid connection agreement requires East Pye Solar to source suitable land for the substation connection and to consent it on our behalf. We have reviewed the proposals and will continue to work with East Pye Solar, and provide feedback, during their examination process this year.
At National Grid we continually review site selection for potential connections to ensure network needs are met and to support our customers. I am not sure if you are familiar with Connections Reform but for awareness, it is an overhaul of the grid connection process which prioritises projects that are ready and needed to help maintain a reliable network. As part of this, the process will determine if the proposed substation site for East Pye Solar is the most suitable solution when considering other projects progressing through Connections Reform.
Once all these factors have been considered, and the associated work is complete, we will be able to share more information with you and the local community about our plans.
Best wishes

Hello [redacted]
Further to my email of the 6 November, I was wondering if you have been able to ascertain anything relating to this new substation that East Pye Solar are proposing?
We as a village are very anxious about the proximity of this to our village and also as East Pye have managed to obtain a Gate 2 connection with NESO, even though they are not meeting the criteria that NESO have set, we are more concerned about this substation, the build timelines and any consultations that may or not be required before this sub-station is built. Our local councils, both South Norfolk and Norfolk CC, have both expressed their concern about the access routes to build this structure and how they would be able to manage to contain any incidents that may occur.
Also we would like to raise the following points to raise the seriousness of this proposed development.
'The proposed new East Pye Solar National Grid substation is located within a groundwater Source Protection Zone in the catchment of a sensitive river, in a landscape containing multiple private drinking water supplies, immediately adjacent to the London–Norwich main railway line and within the safeguarding influence of Tibenham airfield. The local road network is incapable of accommodating the required abnormal indivisible loads, such that access would depend on constructing new haul routes across clay fields, with significant geotechnical intervention, drainage disruption and increased pollution risk to the underlying aquifer and water environment. The site is also located approximately 100 metres from existing homes in and around the village of Great Moulton, and the fire and rescue service has advised that this separation distance is dangerously small for a substation of this scale and type, creating an unacceptable level of residual risk to nearby residents in the event of fire, explosion or major incident. Taken together,

these constraints indicate that the selected site is inherently unsuitable for a substation of this nature, and that the promoter has not demonstrated a realistic, environmentally acceptable or safe means of construction and operation when reasonable alternative locations are clearly available.'

Thank you [redacted] and I look forward to hearing from you shortly.

Kind regards

[redacted]

Subject: [EXTERNAL] Urgent Concerns and Clarification Required: Proposed National Grid Substation at East Pye Solar Park

CAUTION: This email originated from outside of the organisation. Do not click links or open attachments unless you recognise the sender and know the content is safe. If you suspect this email is malicious, please use the 'Report Phish' button.

Dear [redacted]

I didn't think I would have to bother you so soon, but we have just received a Targeted Consultation document from East Pye Solar Park. East Pye Solar - Targeted Consultation Document. This highlights significant changes regarding the siting of a substantial National Grid Substation, new pylons up to 61 metres, and a 400kV substation up to 13 metres which have caused significant distress among residents. I am sure you are aware it is imperative that electricity network developments avoid unacceptable impacts on residential amenity, noise and lighting.

The proposed Sub-Site 1B and the additional site 1D allocated for the National Grid 400 kV substation would place major industrial infrastructure just 300 metres from homes and less than 900 metres from the heart of Great Moulton village. This site is entirely situated within an Environment Agency Drinking Water Safeguard Zone and Source Protection Zone 2, encompassing numerous private wells. This raises serious risks to residential amenity, groundwater quality, and public health, especially given the presence of oil-filled transformers and the risk of fire-water run-off posing contamination threats that contravene the Water Resources Act 1991 s.93.

The proposed substation site is directly north of the main London–Norwich railway line, where electromagnetic interference, subsidence from cable trenching, and restricted emergency access present operational and safety concerns for Network Rail.

The site is also located approximately 4 km from Tibenham Airfield, an active glider base, and thus falls inside the CAA CAP 168 ten-kilometre safeguarding consultation zone. The planned 20–25-metre-high gantries and lightning masts would disrupt glider flight paths and necessitate aviation-lighting mitigation.

Also, it may be of interest to you that the developer of Tasway Energy Park has publicly stated an intention to connect to the National Grid at or near Great Moulton. However, the East Pye Solar Targeted Consultation materials do not address this possibility.

Key Concerns:

1. Transparency and Due Process:

- Why is East Pye proposing a substation of this scale without clear backing or detailed input from the National Grid?
- You previously clarified that there has been no formal communication or agreement between National Grid and East Pye regarding this location. Is this still the case? The lack of detail regarding the National Grid is leaving the community deeply unsettled and we are concerned that East Pye's documents allude to an agreement between them and yourselves.

2. Suitability of Location:

- Would National Grid contemplate placing a substation of this scale in a rural area where the road infrastructure is insufficient?
- Is it acceptable for such infrastructure to be sited so close to homes in a historic farming community, referenced in the Domesday Book?

3. Environmental and Strategic Considerations:

- We understand National Grid takes a holistic view of environmental impacts when planning new substations. Can you confirm this remains the case, and how such considerations would be applied here?

4. Alignment with Local Policy:

- The South Norfolk plan explicitly states that the Great Moulton Plateau should not be industrialised due to its heritage and landscape value. We believe these proposals constitute industrialisation and urge National Grid to respect local policy and community sentiment.

Our Requests:

- Please clarify National Grid's current position regarding the East Pye proposal.
- If National Grid has not endorsed this location, when and how will East Pye be informed, and if appropriate, what steps will be taken to ensure a more suitable site is identified?
- Could we ask that National Grid engage directly with our community to address our concerns and ensure full transparency throughout this process.

We hope National Grid will act with sensitivity and uphold its commitment to environmental stewardship and community engagement.

We look forward to your response and to working together to protect the heritage and wellbeing of our village.

Thank you.

Yours sincerely,
[redacted]

We would Steering Group

Subject: RE: [EXTERNAL] Urgent Concerns and Clarification Required: Proposed National Grid Substation at East Pye Solar Park

Dear [redacted]

Thank you for your recent email and patience. I have been liaising with the wider project team before coming back to you with the latest information.

Island Green's gated position is being determined by the independent National Energy Systems Operator and will be communicated to us in due course along with the customer. Once we know more, we will be in touch to explain next steps. I hope you can appreciate we are unable to share any further insight until this process is concluded and cannot comment on individual customer outcomes.

I appreciate you are also seeking some generic substation images. Substation designs are unique to their location and the volume of customers we are connecting so I don't feel this will help in terms of showing what a potential connection could look like. But please be assured we will keep the local community informed regarding any potential plans.

Best wishes

1. Introduction

1.1 Introduction

This report is prepared on behalf of Great Moulton Parish Council in support of refusal of the planning application EN0110014 for the erection of a battery energy storage facility (BESS) and a National Grid substation within the parish of Great Moulton, Norfolk. The BESS and National Grid substation will serve a proposed solar farm which is also part of the application. However, it is the BESS and substation that have the potential to cause significant adverse effects to the residents of Great Moulton. The grounds for refusal include consideration of potential noise impacts stated as follows:

This report is a technical review of the applicant's submitted Noise Impact Assessment and supporting information. It does not purport to provide a complete new operational noise assessment of the scheme.

Rather, it considers whether the submitted information is sufficiently detailed, transparent and robust to allow the decision-maker to conclude that unacceptable adverse noise effects would be avoided. Where the applicant's information is incomplete, uncertain or not capable of independent verification, this report identifies those limitations and the implications for decision-making.

1.2 Summary

The case is not that the BESS and National Grid substation development is inherently unacceptable in noise terms. Rather, the concern is that the submitted information does not provide sufficient information and therefore introduces a high level of uncertainty as to whether adverse noise effects would be avoided or capable of being mitigated effectively once the site becomes operational, particularly having regard to:

- BS 4142 assessment methodology, context and uncertainty;
- The very quiet rural night-time acoustic environment;
- Potential low-frequency and lack of information on tonal characteristics;
- Uncertainty over the final plant specification; and
- Limited information on modelling inputs and scale of uncertainty of the noise propagation model for a large collection of noise sources with a low frequency character

acoustic character, mitigation assumptions and receptor background conditions remain uncertain, the decision-maker cannot be confident that the proposed development would be acceptable in noise terms.

While it is acknowledged that grid-scale battery energy storage systems (BESS), substations and associated electrical infrastructure can often be made acceptable in noise terms, it is respectfully submitted that the current submission does not provide sufficient certainty to conclude that this particular development would not give rise to

adverse or significant adverse effects on residential amenity, particularly during the night-time period and in relation to low-frequency and/or tonal noise.

The BESS is considered in some detail because it appears to be one of the potentially dominant operational noise sources, but the same issues of specification uncertainty, source data, acoustic character, mitigation assumptions and receptor context are also relevant to the National Grid substation and other noisy operational elements of the scheme.

Environmental Statement Vol. 3: Appendix 12.2 – Noise Modelling and Calculations	Stantec	March 2026
Statutory Nuisance Statement Revision 1	Stantec	March 2026

Table 1 - Reports examined

2. Stantec Environmental Statement – Noise and Vibration

2.1 Baseline Sound Survey

The Environmental Statement on noise and vibration prepared by Stantec provides a baseline noise survey taking data from 51 noise monitoring positions that effectively covers the number of noise-sensitive receptors across this vast site. The survey durations were 6 to 8 days at each location and provide a good representative snapshot of the ambient and background sound levels in terms of broadband A-weighted $L_{eq,T}$, $L_{90,T}$ and $L_{F\,Max,T}$.

However, the report states that as this was an unattended survey, it is not possible to accurately comment on the dominant noise sources or specific noise events during the entire survey period. Comments were given on the on-site environmental sound climate at the time of set-up and collection and these included "on-site sound levels dominated by vehicular movements on the surrounding road network" for the majority of the survey positions and in all 4 of the survey positions reported for Parcel Group 1 which covers Great Moulton.

These are MP41 to MP44. Since no octave or third-octave band data have been published, it is not possible to determine whether road traffic noise is the dominant source of noise in this isolated rural area. The presence of road traffic noise can be indicated by comparing the spectral content of the measured levels with the typical road traffic spectrum set out in BS EN 1793-3 and referenced in BS 8233:2014. This is a concern, as the subsequent noise model and specific sound level assessments rely somewhat on the masking effect of road traffic sound. The DEFRA-funded strategic noise maps produced by Extrium (http://www.extrium.co.uk/noiseviewer.html) shows that the A140 to the east of Great Moulton does not appear to have a significant noise impact on the area. (See ***Figure 1*** to ***Figure 3***).

These strategic road traffic noise maps are not a substitute for receptor-specific background sound measurements, but they provide useful context when considering whether road traffic is likely to provide a consistent masking influence at Great Moulton, particularly during the night-time period.

The submitted ES Chapter 12 identifies MP41, MP42 and MP43 as the associated measurement positions for residential receptors in and around Great Moulton, including dwellings on Broadgate Lane and Station Road. The ES also identifies these receptors as high sensitivity receptors.

This reinforces the need for particular caution when applying generic assumptions about the residual acoustic environment at Great Moulton, because the acceptability of the operational assessment depends on whether the measured baseline is genuinely representative of the receptor locations and whether the assumed masking environment is present during the most noise-sensitive periods.

The principal concern at this time is not whether the background sound levels reported by the applicant are numerically correct at the monitoring locations. Rather, it is whether those measurements and the acoustic conclusions drawn from them are representative of the nearest and most affected residential receptors.

The submitted assessment relies upon assumptions regarding the residual acoustic environment, including the degree to which existing background sounds like road traffic, would mask operational noise from the BESS, National Grid substation and associated infrastructure. If those assumptions are not representative of the receptor locations, the conclusions of the BS 4142 assessment may be materially affected. This uncertainty could then be further exacerbated by tonal and character assumptions informing the selected Noise Rating level on which judgement is made as to whether or not there are significant impacts.

Figure 1- Lden Road traffic noise levels from Extrium

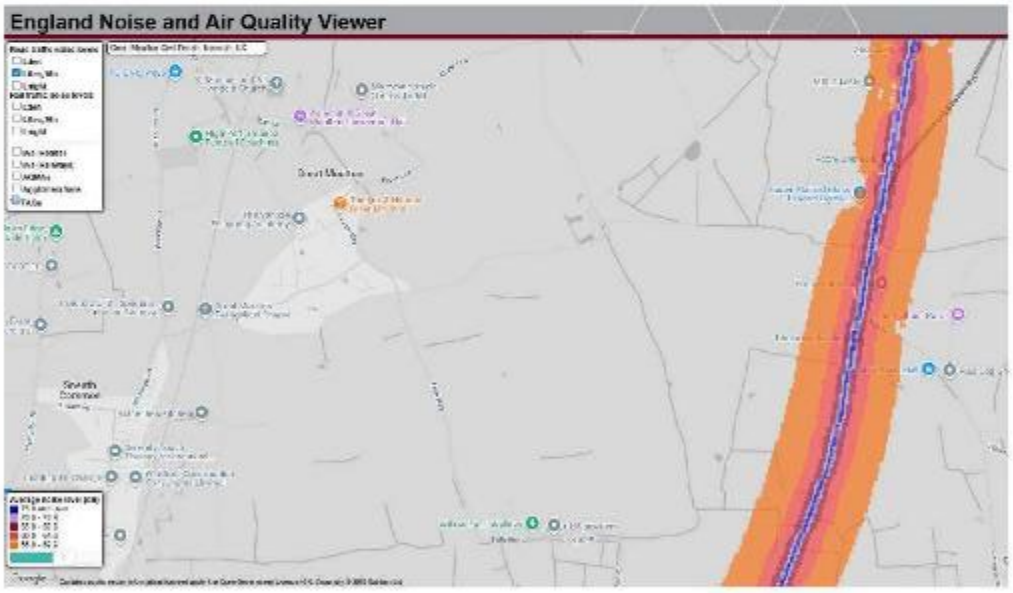

Figure 2 LAeq,16hrs road traffic noise levels (daytime) from Extrium

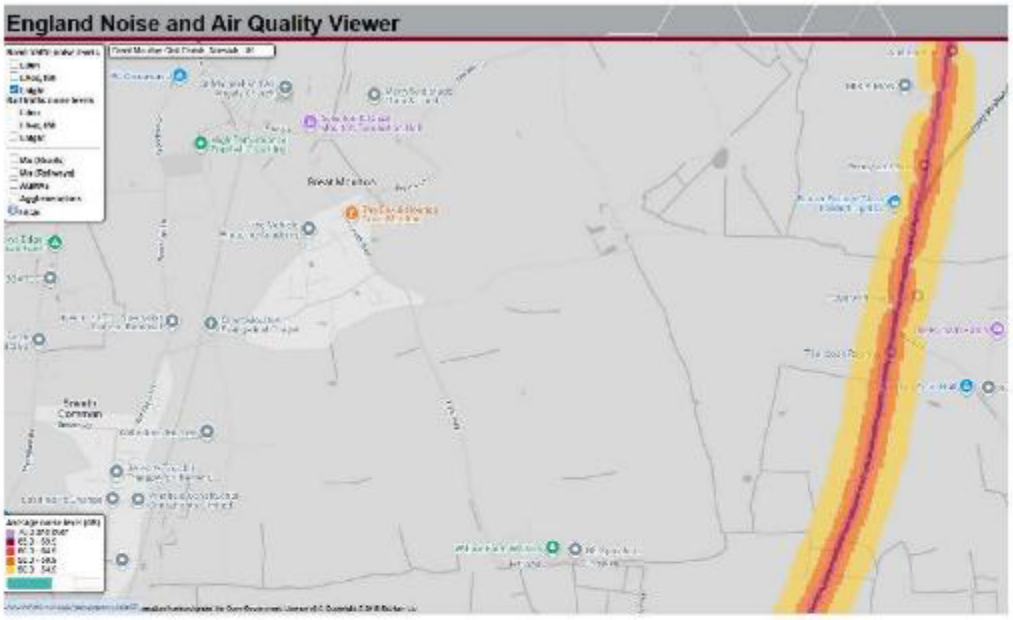

Figure 3 Lnight road traffic noise levels from Extrium

2.2 Noise modelling and calculations

2.2.1 Assessment Assumptions and Limitations

The authors have stated that:

> *"Detailed plant specifications are not available at this stage, and potential noise emissions based on example equipment data have been assessed using an example plant layout which has been based on achieving the Outline Operational Environmental Management Plan….. noise requirements "*

The ES Chapter 12 states that the operational assessment has been informed by scheme information but also identifies assessment assumptions and limitations. The submitted information therefore appears to rely on an indicative plant layout and example plant data at this stage.

This is important because the final number, type, layout and operating regime of BESS containers, inverters, transformers and associated cooling plant may materially affect both the overall rating level and the acoustic character of the installation. In a BS 4142 assessment, such uncertainty is not simply a matter of calculation refinement; it affects the confidence that can be placed on the predicted outcome and on the conclusion that no significant effect is anticipated.

This introduces a level of uncertainty that is difficult to evaluate. The authors have prudently used a conservative approach assuming plant operates simultaneously, continuously, and at maximum output. However, there is no indication as to the number of battery storage units to be installed and the authors have made an exception with the BESS by assuming reduced sound levels associated with lower fan duty as a method of mitigation. It is not clear from the report how many units have been used in the calculation of noise from the BESS.

The calculation includes the provision of a 4m high acoustic barrier in areas around the BESS with a surface density of 15kg/m2 and an absorptive side facing the battery storage containers.

The inclusion of a 4 m high acoustic barrier as part of the modelled mitigation indicates that operational noise requires material mitigation in order to achieve the assessment conclusions. The effectiveness of that mitigation is therefore central to the reliability of the assessment and should be supported by clear assumptions regarding barrier location, height, surface density, absorption, source heights, frequency performance and long-term deliverability.

Consideration could be given to an earth bund around the BESS and substation site that provides sound and visual screening.

The need for a 4 m high acoustic barrier as embedded or additional mitigation is itself a material indicator that operational plant noise is capable of being significant if not carefully controlled.

The ES Chapter 12 includes operational plant noise assessment tables and residual operational assessment tables, but the robustness of those conclusions depends on the performance assumptions for the barrier, the assumed source heights, source directivity, plant layout and the frequency content of the source data. If any of these assumptions change at detailed design stage, the modelled screening performance and receptor levels may also change.

The sound source data have only been given in broadband A-weighted sound power levels and thus, if the noise model has been calculated in accordance with ISO 9613-2, has used the 500 Hz octave-band frequency to estimate sound attenuation. However, there are concerns regarding low-frequency sound from the BESS, inverters and substations, which will not be addressed by A-weighted broadband levels, and attenuation over distance in the lower frequencies such as 50 Hz and 100 Hz is less than that in the mid to high frequencies.

The ES Chapter 12 reports operational sound power data in tabulated form and concludes that residual effects would not be significant. However, without the supporting octave-band or one-third-octave source data, it is not possible to independently test whether the model has appropriately accounted for low-

frequency propagation, barrier performance at low frequencies or the potential prominence of transformer hum and cooling plant noise at night. This is particularly relevant as the development includes both BESS infrastructure, inverters and a National Grid substation, as these source types can include tonal, low-frequency or otherwise distinctive acoustic components.

The practical implication for nearby residents is that the likely audibility, character and intrusiveness of operational noise cannot be confidently determined from the information currently provided.

This is particularly important at night, when residual sound levels in rural areas may be low and when tonal or low-frequency components may be more noticeable than would be suggested by broadband A-weighted levels alone.

The absence of transparent source spectra and detailed modelling inputs therefore prevents a robust assessment of whether operational noise would be inconspicuous, clearly audible, adverse, or potentially significant at the most affected dwellings.

When considering background noise levels and statements in the applicants noise reports suggesting reliance on traffic noise to provide masking of operational sound, the accuracy and consideration of spectral make-up of the ambient noise is a key consideration to ensure any consideration of impact is as accurate as possible.

2.2.2 Operational Assessment of Low Frequency Noise

The authors of the noise model have provided a calculated 1/3 octave band façade incident external sound level from estimated noise from both the National Grid Substation and the BESS site.

However, it is not clear how the one-third-octave-band sound power levels from the plant have been determined. For example, manufacturer's data or measurements taken from existing sites. Although the authors state that they have used manufacturers' sound power levels of similar plant, this is not documented and only the A-weighted sound power levels are reported.

Without this information it is not possible to check the validity of the estimated sound levels.

The ES Chapter 12 includes operational plant assessment outputs for high sensitivity residential receptors and identifies residual operational effects as not significant. However, the ability to reach that conclusion is dependent on the accuracy of the assumed source spectra and propagation model. If the underlying frequency data are not provided, the assessment cannot be independently checked against the low-frequency criteria or the tonal audibility method in BS 4142. This is a material limitation because a broadband A-weighted level can mask the presence of a pronounced low-frequency component which may be more noticeable inside dwellings, particularly during the night-time period.

This issue is particularly relevant to electrical infrastructure such as transformers and substations, where tonal or low-frequency components may form an important part of the perceived acoustic character. The assessment should therefore demonstrate not only compliance with broadband noise limits, but also that the frequency content and acoustic character of the predicted sound would not give rise to adverse perceptibility or disturbance at nearby dwellings.

It is also not clear how much absorption from the proposed noise barriers located around the BESS has been estimated in the model, but the effective absorption at low frequencies will be affected by the depth of the absorptive layer. This is due to the length of the soundwave, which is equal to the speed of sound in air (m/s) divided by the frequency of the sound (Hz). This can range from 13.7 m at 25 Hz to 2.1 m at 160 Hz. (See ***Table 2***.) The use of earth bunds, which have a wider footprint as mitigation, would address some of these concerns.

Frequency (Hz)	25	31.5	40	50	63	80	100	125	160
Wavelength (m)	13.7	10.9	8.6	6.9	5.4	4.3	3.4	2.7	2.1

Table 2 – Typical wavelength values (m) for low frequency 1/3 octave bands (Hz).

2.2.3 BS 4142 Acoustic Feature Rating Corrections

The authors have concluded that neither the BESS nor the National Grid Substation produce any tonal sound, despite stating:

> *"High voltage transformers can generate a 100Hz hum due to vibration of the transformer coil. The acoustic modelling exercise indicates that the specific sound level from the high voltage transformers, including the 100Hz tone, is unlikely to be distinguishable at the receptor as it will be masked by other broadband sound relating to the BESS inverters and BESS Containers."*

Annexe C of BS 4142:2014+A1:2019 provides a 1/3 octave band method for assessing the audibility of tones. If the 1/3 octave band data used in the noise model were provided, this would prove/disprove the likelihood of tones and the value to be added to the Rating Level.

In the absence of disclosed one-third-octave data, it is not possible to confirm whether the transformer 100 Hz component would be sufficiently masked at the receptor, or whether it would remain perceptible during periods of low residual sound.

This is important because the assessment appears to rely on the assumption that broadband BESS-related sound will mask any transformer tone. That assumption may not be robust where the BESS cooling plant is operating at reduced night-time duty, or where weather, plant loading or operating mode changes the relative contribution of the transformer and cooling plant sources.

The authors also state:

> *"BESS are designed without any noticeable acoustic features due to the broadband nature of the sound. Noise from the proposed development is not likely to be readily distinctive against the residual sound environment. Therefore, no rating penalty has been applied for 'Other Sound Characteristics'."*

Section 11 of BS 4142:2014+A1:2019 states:

> *"The character and level of the residual sound compared to the character and level of the specific sound. Consider whether it would be beneficial to compare the frequency spectrum and temporal variation of the specific sound with that of the ambient or residual sound to assess the degree to which the specific sound source is likely to be distinguishable and will represent an incongruous sound by comparison to the acoustic environment that would occur in the absence of the specific sound. Any sound parameters, sampling periods and averaging time periods used to undertake character comparisons should reflect the way in which sound of an industrial and/or commercial nature is likely to be perceived and how people react to it."*

If one-third-octave-band or at least one-octave-band data were available from the baseline sound survey, this could be used to show whether the specific sound level is in fact indistinguishable against the residual background. The authors may be relying on the presence of road traffic noise, particularly in the 80 Hz to 160 Hz one-third-octave bands. However, it has not been demonstrated that road traffic is the dominant noise source in all areas, particularly in Great Moulton where the BESS and National Grid substation are proposed. Road traffic in this rural area is sporadic and there are long periods, particularly at night, when there is very little traffic.

The same concern applies to any reliance on road traffic or general residual sound to mask tonal or low-frequency components from the proposed plant. Masking cannot be assumed from short attended observations or from broadband A-weighted sound levels alone. It should be demonstrated using representative night-time frequency data for the residual sound environment and the predicted plant noise. Without that comparison, there remains uncertainty as to whether tonal components, particularly around 100 Hz, would be perceptible at residential receptors during quiet night-time periods.

In the absence of this information, it is not possible to determine whether the operational sound would be appropriately characterised as acoustically neutral, or whether rating penalties for tonality, intermittency, distinctiveness or other acoustic features may be required. T

his is a material issue because even relatively small changes to the rating level may alter the BS 4142 outcome, particularly where representative night-time background sound levels are low.

2.3 Implications for residential receptors

The implications for residents are not that unacceptable noise effects have been conclusively demonstrated at this stage. Rather, the submitted information does not allow those effects to be confidently ruled out. This distinction is important.

Where a proposed development includes substantial operational electrical infrastructure in a quiet rural environment, the assessment should provide sufficient information to demonstrate that noise from the BESS, National Grid substation, transformers, inverters, cooling plant and associated infrastructure would not result in unacceptable effects at the nearest and most affected dwellings.

The current assessment does not provide sufficient transparency regarding final plant specification, source spectra, modelling assumptions, mitigation performance or the representativeness of receptor background sound levels.

As a result, it is not possible to determine with confidence whether operational noise would be insignificant, acceptable subject to mitigation, or potentially adverse at individual residential receptors. This uncertainty is itself material to the planning decision, because the decision-maker must be satisfied that significant adverse effects on health and quality of life would be avoided before consent is granted.

3. Conclusion

Paragraph 4.43 of the Statutory Nuisance Statement states:

> *"A noise assessment has been undertaken and is reported in ES Volume 1, Chapter 12 - Noise and Vibration [EN0110014/APP/6.1.12]. This chapter focuses on an assessment of the likely significant effects on noise and vibration as a result of the Scheme. The noise and vibration assessment concludes that no significant noise or vibration effects are anticipated."*

However, it is not possible to validate this assessment due to the degree of uncertainty in the submitted assessment. This is due to:

- The lack of detail in plant selection, both for the BESS and National Grid substation;
- Operational assumptions such as reduced fan duty at night and the suggestion of acoustic enclosures without details/specifications;
- Lack of spectral data for both the assumed plant noise and the residual/background sound survey;
- Lack of detail regarding the acoustic barrier performance and the propagation of low frequency noise (<160Hz) over distance;
- Insufficient evidence supporting the decision not to add a feature correction to the specific sound level.

Taken together, the available information does not demonstrate that the development would avoid adverse or significant adverse noise impacts with sufficient certainty. The conclusions of the submitted assessment are therefore not robust, as they are dependent on assumptions which have not been substantiated by project-specific data. Accordingly, the Council's position remains that insufficient information has been provided to demonstrate that acceptable noise levels can be achieved and maintained. The absence of confirmed plant specification, lack of frequency-based source and survey data and limited transparency of the modelling approach collectively introduce a substantial level of uncertainty into the assessment. This is not a minor or isolated uncertainty, but one which has the potential to materially alter the outcome of the BS 4142 assessment.

Relatively small changes in the underlying assumptions — including acoustic character corrections and spectral content — may reasonably result in rating levels within a range indicative of adverse or significant adverse impact. In the context of an exceptionally quiet rural environment, such outcomes may be particularly difficult to mitigate effectively through design or operational controls once the site is constructed.

The ES Chapter 12 records that operational plant noise has been assessed against defined LOAEL and SOAEL thresholds and concludes that residual operational effects would not be significant. However, those conclusions are only as reliable as the assumptions on which they are based. The present review identifies several areas where the submitted information does not allow independent verification of the assessment outcome, including the absence of confirmed plant specification, incomplete disclosure of source spectral data, uncertainty over acoustic feature corrections, limited transparency over barrier performance, and uncertainty regarding the representativeness of the residual acoustic environment at Great Moulton.

If the applicant subsequently provides confirmed plant specifications, source sound power spectra, detailed modelling assumptions, mitigation specifications and representative receptor-based background data, it may then be possible to undertake a more definitive assessment of likely operational impacts. Until that information is available, any attempt to quantify the precise degree of impact at individual dwellings would be subject to significant uncertainty.

This raises fundamental concerns regarding reliance on pre-commencement or pre-operational planning conditions to resolve these issues at a later stage. Paragraph 198 of the National Planning Policy Framework requires planning decisions to ensure that development avoids significant adverse impacts on health and quality of life arising from noise.

Where the submitted information does not allow the decision-maker to confidently conclude that unacceptable noise impacts would be avoided, the appropriate conclusion is not that the matter can simply be deferred, but that the assessment is presently insufficient. The associated Planning Practice Guidance sets out the concept of the Significant Observed Adverse Effect Level (SOAEL), above which adverse effects should be avoided. The potential for adverse or significant adverse noise effects cannot be ruled out with the degree of confidence required.

On the information currently submitted, the proposed development has not demonstrated compliance with Policy ENV2 or national planning policy in relation to noise.

On the information currently submitted, the applicant has not demonstrated with sufficient confidence that adverse or significant adverse noise effects would be avoided, particularly at night and in relation to low-frequency and/or tonal operational plant noise.

Noise is a material consideration in the national Planning Framework. Refusal of the application is therefore justified unless and until the applicant provides sufficient project-specific evidence to demonstrate that the BESS, National Grid substation, Inverters and associated noisy infrastructure can operate without causing unacceptable noise impacts at affected residential receptors.

Appendix 3

Article, regarding the issue of Noise associated with large NSIP developments. [redacted] is managing director at RSK Acoustics – 2 April 2025 -

The sound of solar: Noise in a sustainable world | New Civil Engineer

The noise associated with solar farms, particularly large developments, can be significant and compounded by their rural locations. In these settings, any additional noise can be noticeable and can have an impact on people using and living in the area, as well as local wildlife.

It is often assumed that solar farms don't make any noise, that they are silent generators of clean energy. While the panels themselves make no noise, the infrastructure surrounding solar farms that enables energy to reach our homes does create residual noise. It is important to design for this noise at the start of the process to avoid surprise mitigation further down the project's development that could increase costs and delay planning approvals.

When considered at the scale of solar farm installations that we see in the UK, the electrical infrastructure that enables these large-scale connections to the grid can have an impact on existing noise environments if noise is ignored. Typically developed in rural locations where there is sufficient land to house solar photovoltaic (PV) panels, these naturally quieter environments can often mean that low-level noise emissions that would often go unnoticed in an urban environment have the potential to be disruptive. Managing this is regulated closely by planning policies to ensure any noise brought by the infrastructure is not harmful to wildlife or residents.

National policies such as the National Planning Policy Framework (NPPF) and the Noise Policy Statement for England (NPSE) both provide specific overarching requirements to protect residents and communities from noise associated with developments and promote its effective management for good health and quality of life. At a local level, individual councils and authorities will have their own policies, resulting in some national variation and making it crucial to understand what applies to a specific site. An understanding of acoustics is vital to delivering new projects in line with these regulations and for positive community outcomes. Dispelling myths around sound and solar means appropriately anticipating the impact of an installation and designing mitigation early on.

On a solar farm, it is the supporting infrastructure, such as battery storage, transformers and substations, that produces noise. The significance of that audible noise is relative to the existing environment and the plant chosen. Identifying the right products for the development and working closely with the manufacturers allow for greater control over potential noise. Engaging with the manufacturers at this stage also enables collaborative work on designing the plant for greater noise control and quieter operation when installed

Ambient sound levels typically fluctuate through the course of the day – it is usually quieter overnight than during the day – and vary by location. The bustle of a city will create much more noise than rural countryside. This means that a low-level sound generated by a battery energy storage system or transformer may not be noticeable during the day in the middle of a city, but in the countryside it would be. It is also important to bear in mind the cumulative effect of multiple plants and machines running together; it is unlikely that a solar farm will have a single source of noise.

When there is an understanding of these specific environmental factors, and their relationship with the infrastructure to be installed, it becomes possible to manage noise. To most effectively mitigate potential significant noise, incorporating actions into the design is vital. It means not only cost savings against implementing measures later on but also issues can be removed in their entirety.

Layout is particularly important on large sites where significant infrastructure is needed. It is possible to design in a way that is sympathetic to acoustics, moving sources away from receptors such as residents or wildlife or creating noise barriers with needed site structures. These intelligent designs make use of the natural noise-managing properties of terrain, structures and buildings. If this is considered at the design stage, buildings such as offices and substations that are an integral part of the site can be positioned in a way that they serve as these needed noise barriers.

Making these design elements as effective as possible comes down to accurate early estimations of source noise levels. Preparing models that simulate the acoustics of the site means that mitigation can be designed from the beginning. Like in many construction and engineering disciplines, it's always the case that action to eliminate will be taken before action to insulate. The accuracy of models and plans makes this possible. Engaging acoustic specialists early on enables mitigation to be optimised. Working on the early planning and design stages of the project also means that it is possible for cross-discipline collaboration, opening opportunities for solutions to be found together.

Ultimately, by incorporating acoustic considerations from the outset and integrating noise reduction strategies into the design, we not only align with regulations but also foster harmonious relationships with local communities and protect wildlife. Effective noise management is not an afterthought but a crucial element of sustainable solar farm development that ensures long-term success and minimal environmental impact.

acoustics solutions to the energy generation and transmission sector around the globe and is a Chartered Environmentalist and Member of the Institute of Acoustics.

APPENDIX 4 : East Pye Solar Application Documents Referenced

East Pye Solar – Planning Inspectorate Reference EN0110014

Scope and method. This appendix identifies East Pye Solar application documents that are expressly cited, named or clearly relied upon as source material in the objection. References have been normalised to the Applicant's official EN0110014/APP numbering. The "How referenced / relied upon" column preserves the shorthand or alias used in the objection where relevant. Official titles and numbering have been checked against East Pye Solar, Guide to the Application, APP/1.3 (Revision 1, March 2026).

A. Source Based Used

Issue	Source / factual anchor	Technical submission point
East Pye ES Chapter 4 and Grid Connection Statement	Scheme description, grid connection, National Grid Substation, Project Substations and retained infrastructure.	Used to define Site 1 as a grid infrastructure hub.
East Pye ES Chapter 5 and APP/7.20 Site Selection Assessment	Reasonable alternatives, design evolution, Option 4A/4B and siting zones.	Used to frame alternatives and Horlock critique.
East Pye ES Chapters 7-18 and appendices	Landscape, ecology, water, transport, noise, soils, ground conditions, EMF and other environmental matters.	Used to identify topic-specific control gaps.
NGET Relevant Representation and National Grid correspondence	Connection deliverability and National Grid role as recorded in the source draft.	Used to request a formal grid delivery statement.
Ofgem, 17 September 2026 press release and DESNZ/Ofgem April 2026 letter	BESS queue oversupply, Gate 2 context, proposed OTCF and battery surplus risks.	Used to strengthen proportionality and deliverability scrutiny.

Botley West EN010147 Secretary of State request	Recent comparator for further information on solar NSIP alternatives, grid, design and cumulative effects.	Used as persuasive context, not precedent.

Written Representations submitted in response to East Pye Solar
PINS Reference: EN0110014

Volume 1: Chapters 1 –7

Submitted by BEPS (Block East Pye Solar [redacted])

Table of Contents

Objection 15

East Pye Solar is the wrong project, at the wrong scale, in the wrong place 15

Preliminary Chapter – CPO and DCO 18

Part I – Purpose and legal framework 18

P.1 The purpose of this Preliminary Chapter 18

P.2 The distinction between development consent, DCO powers and compulsory acquisition 19

P.3 The statutory threshold for compulsory acquisition 20

P.4 The DCO must authorise the Scheme assessed and secure the mitigation relied upon 21

Part II – Is there a sufficiently defined and deliverable Scheme to which the powers can attach? 23

P.5 The DCO powers attach to a Scheme whose final form remains materially uncertain 23

P.6 Gate 1 BESS and the identity of the Scheme 24

P.7 Partial implementation and unused statutory powers 25

P.8 The Applicant should provide a Scheme-to-powers schedule 26

Part III – Legal plans and certainty of the land and Works authorised 27

P.9 Inconsistent mapping and legal-plan reliability 27

P.10 The Works Plans, Land Plans and Book of Reference must reconcile 27

P.11 Plan hierarchy and precedence 28

Part IV Compulsory Acquisition and Land Rights: Whether the Applicant Is Seeking More Than the Scheme Requires 29

P.1 Principal objection 29

P.2 The statutory question is not simply whether the Scheme needs land 30

P.3 Compulsory freehold powers materially alter the bargaining position in ongoing land negotiations 31

P.4 The Applicant must explain what happens to the landowner's contractual bargain if freehold powers are exercised 33

P.5 Decommissioning makes the distinction between leasehold and freehold still more important 34

P.6 Other solar NSIPs demonstrate that permanent freehold acquisition is not inherent to large-scale solar 35

P.7 The Applicant must distinguish project necessity from commercial convenience 36

P.8 The Applicant's own alternatives evidence makes the inconsistency sharper 36

P.9 The Statement of Reasons does not yet demonstrate why lesser powers are insufficient for Work No. 1 37

P.10 Contractual risk does not, without more, justify acquisition of a greater interest 38

P.11 Compensation does not answer the necessity objection 38

P.12 Other categories of land require the same interest-specific scrutiny 39

P.13 National Grid land and the unresolved connection solution 39

P.14 National Gas and other statutory undertaker interests 41

P.15 The human-rights analysis must address the intensity of the interference 43

P.16 The compulsory-acquisition objection stands independently of the wider need case 43

P.17 The Applicant should be required to state its intentions unequivocally 44

P.18 The comparative evidence makes a generic answer inadequate 44

P.19 Overall conclusion 45

P.20 Remedy sought 46

P.21 Confidentiality and non-objection obligations: landowners must remain free to participate... 47

Part V – DCO controls: genuinely cross-cutting issues 48

P.22 Preliminary works and commencement must not precede essential safeguards 48
P.23 Staging, phasing and token commencement 50
P.24 The Requirements must be precise, mandatory and testable 51
P.25 Post-consent approvals must not determine questions of principle 52
P.26 Requirement discharge, consultation, amendments and deemed approval 53

Part VI – Whole-life powers and liabilities 54

P.27 Maintenance, replacement and repowering 54
P.28 The 60-year period must not be capable of indefinite extension 55
P.29 Cessation, abandonment and partial failure 56
P.30 Decommissioning security 57
P.31 Transfer of the benefit of the Order 58

Part VIII – Overall CPO/DCO consequences 59

P.33 The cumulative problem: the Applicant seeks the widest powers before resolving the Scheme 59
P.34 The compelling case for compulsory acquisition has not been established 59
P.35 The draft DCO does not yet provide an adequate control mechanism 61
P.36 Remedies sought 62

Chapter 1 64

1.1.1 The central question for the Examination 64

1.1.2 Good design: the appropriate examination framework 66

1.1.3 The critical distinction: designing for the place or fitting the project into it 67
1.1.4 Good design requires an integrated solution 68
1.1.5 Good design must be demonstrated by design evolution 68
1.1.6 The examination test 69
1.1.7 The Application was required to be environmentally coherent before Examination 70
1.1.8 Residual harm cannot be identified until avoidance and mitigation are exhausted 71
1.1.9 Precautionary assumptions are not a substitute for avoidance design 72
1.1.10 The Examination should follow receptors across chapter boundaries 72
1.1.11 Selective land removal does not demonstrate a consistently applied mitigation hierarchy .. 73

1.2 Regional Need and Public Interest (NPS EN-1 §4.2.3; §4.1.2) 75

1.2.1Consumer Cost and System Risk (NPS EN-1 §4.1.2) 77

1.2.2 Inconsistency with CP2035 Objectives 78

1.2.3 Congestion, Curtailment and Strategic Positioning Risk 79

1.2.4 East Pye is one project within the Applicant's much larger development portfolio 81

1.3 BESS undeliverability 83

1.4 Deliverability Challenges of large-scale standalone solar 85

1.5 Negative Pricing 86

1.6 Compulsory Acquisition and Protected-Species Licensing: Consequences of Unproven Locational Necessity 86

1.6.1 Compulsory Acquisition – No Compelling Case in the Public Interest 86

1.6.2 European Protected Species licensing – no satisfactory alternative and unresolved favourable-conservation-status test 87

1.6.3. Proportionality and the separate statutory tests 89

1.6.4. Conclusion 90

1.7 Availability of Alternative Regions with Unmet Capacity Envelopes 90

1.8 Grid Capacity, Gate 2 Allocation and Deliverability Failure 91

1.9 Deliverability Risks 93

1.9.1 Deliverability Risk: European Protected Species Licensing 93

1.9.2 Deliverability Risk: Water Environment and WFD Compliance 94

1.9.3 Deliverability Risk: Private Water Supplies and Aquifer Protection 95

1.9.4 Deliverability Risk: Major Accidents and Disasters – Site 1 Infrastructure Cluster 95

1.9.5 Deliverability Risk: Aviation Safeguarding and Glint/Glare 96

1.9.6 Deliverability Risk: Heritage Harm and Setting 97

1.9.7 Deliverability Risk: Construction Access and Abnormal Indivisible Loads 97

1.9.8 Deliverability Risk: Soils, Heavy Clay and Irreversibility 98

1.9.9 Deliverability Risk: Replacement and Lifecycle Assessment 99

1.9.10 Deliverability Risk: Decommissioning and Financial Security 99

1.9.11 Cumulative Infrastructure Nexus – Site 1 99

1.11 Failures of East Pye Solar's Chapter 1 102

1.12 Identified mitigation is not the same as secured mitigation 103

1.13 Chapter 1 overstates the adequacy and continuity of the consultation-stage environmental information 104

1.14 The introductory description obscures the 500 MW design premise 105

1.15 Chapter 19 cannot cure interactions missed in the underlying assessments 106

Chapter 2: EIA Methodology 107

2.1 Introduction: why methodology is a substantive issue 107

2.2 Applicable EIA principles and the applicant's own stated framework 108

The ES must therefore be tested against both the applicable legal and policy framework and the Applicant's own stated standards. It is insufficient merely to cite CIEEM guidance, Water Framework Directive requirements, Historic England guidance or the National Policy Statements if the underlying baseline is incomplete, the receptor hierarchy is inconsistent, the reasonable worst-case design is not defined, or the mitigation relied upon remains subject to later determination. 109

2.3 Failure to provide a site-specific, ecosystem-led methodology 109

2.4 Failure to apply a landscape-scale ecological framework 109

2.4.1 The central methodological problem: cross-topic inconsistencies and interactions 110

2.4.10 Design changes and mitigation displacement across environmental topics 117

2.4.11 Consequence: the residual-effect conclusions require cross-topic reconciliation 119

2.5 Incomplete, uneven and untimely baseline data 121

2.5.1 White-clawed crayfish and aquatic ecology 122

2.5.2 Bat survey coverage and maternity-colony function 123
2.5.3 Botanical baseline 124
2.5.4 Other baseline omissions identified by consultees 125
2.5.5 Consultation consequences of incomplete baseline information 125

2.6 Generic significance matrices are not calibrated to site-specific ecological sensitivity 125

2.7 Generic mitigation assumptions do not demonstrate ecological functionality 126

2.8 Cumulative and functional-connectivity underassessment 127
2.8.1 Barbastelle Core Sustenance Zones 127
2.8.2 Hydrological connectivity 127
2.8.3 Combined effects of the Scheme 127
2.8.4 External cumulative schemes 128

2.9 Temporal methodology and ecological timescales 128

2.10 Future baseline and climate-dependent ecological change 129

2.11 Professional judgment and unexplained ecological conclusions 129

2.12 Rochdale envelope and changing ecological effects 130

2.13 Outline controls and excessive deferral 130

2.14 Consequences for consultation, HRA and EPS licensing 131
2.14.1 Consultation 131
2.14.2 Habitats Regulations Assessment 132
2.14.3 European Protected Species licensing 132
2.14.4 Planning balance 132

2.15 Wider cross-topic manifestations of the same defect 133

2.16 Methodological consequences and overall finding 134

2.17 Examination questions 135

2.18 Remedies sought 135

Chapter 3: The Order Limits 137
3.2 Fragmentation of the Receiving Environment 137
3.3 Failure to Describe Interrelationships 138
3.4 Understatement of Environmental Sensitivity 138
3.5 Failure to Treat the Area as a Living Historic and Environmental Landscape 139
3.6 Consequences for the EIA as a Whole 139
3.7 Historic Settlement Pattern, Heritage Context and Rural Character 140
3.8 Water Environment, Drainage Connectivity and Private Water Supplies 144
3.9 Ecology, Woodland Networks and Functional Habitat Connectivity 146
3.10 Public Rights of Way, Rural Amenity and the Experience of the Countryside 147
3.11 Cumulative Infrastructure Pressure and the Transformation of Rural Character 149
3.12 Site-by-Site Fragmentation and the False Neutrality of Parcel Descriptions 150
3.13 Site 1, the Grid Hub and the Cumulative Industrial Nexus 151
3.14 BESS Site, National Grid Substation Site and Grid Connection Infrastructure 152
3.15 Cable Route Corridor, Uncertainty and Concealed Effects 153
3.16 Settlement Proximity, Residential Receptors and Village-Edge Harm 154

3.17 Surrounding Infrastructure, Airfields, Rail and Baseline Change 155
3.18 Baseline Deficiency 156
3.19 Description of the Site and Surroundings / The Receiving Environment as it Truly Exists 157
3.20 The Applicant's Baseline Is Contradicted by Its Own Statutory and Specialist Consultees ... 160
3.21 The Scheme Is Located in a Landscape 'Dense with Nature', Not Generic Agricultural Land 161
3.22 The Order Limits Directly Contain and Adjoin Ecologically Sensitive Sites 163
3.23 Roadside Verges Are Part of the Ecological Baseline, Not Expendable Highway Margins 165
3.24 The Applicant Has Failed to Describe a Nationally Important Bat Landscape 166
3.26 Protected-Species Uncertainty Remains Embedded Within the Order Limits 169
3.27 The Agricultural Baseline Remains Incomplete Across the Order Limits 170
3.28 Ancient Woodland, Veteran Trees and the Inadequacy of Inconsistent Buffers 172
3.29 Historic England Confirms That This Is a Heritage-Sensitive Rural Landscape 173
3.30 Cumulative Effects Are Already a Concern to Ecological and Heritage Consultees 175
3.31 The Consultees' Qualified Positions Cannot Be Converted into a Finding of Environmental Acceptability 177
3.32 The Consequences for Scheme Design and the Mitigation Hierarchy 178
3.33 Overall Conclusion: Chapter 3 Conceals the Constraints That Should Have Shaped the Scheme 180
3.34 Remedies Sought 181
Summary: Why the Application Should Be Refused 182

Chapter 4: The Scheme 185

4.1 The statutory importance of an accurate scheme description 185
4.1.2 Legitimate detailed-design flexibility 189
4.1.3 Uncertainty concerning the essential nature of the development 189
4.1.4 The breadth of the authorised works 190
4.1.5 South Norfolk Council's concern about excessive flexibility 191
4.1.6 Norfolk County Council's concern about unclear works descriptions 192
Norfolk County Council's concern about unclear works descriptions and inconsistent mapping . 192
4.1.7 The Environment Agency's concern about incomplete and uncertain controls 194
4.1.8 Consequences for the Examination 195

4.2 Authoritative description of the development applied for 196
4.2.1 Solar photovoltaic generating station 196
4.2.2 Battery Energy Storage System 198
4.2.3 Project substations 199
4.2.4 National Grid substation and associated grid works 201
4.2.5 Cable Route Corridors 202
4.2.6 Accesses, haul roads and construction infrastructure 203
4.2.7 Operational period, replacement and repowering 204
4.2.8 Decommissioning and retained infrastructure 204
4.2.9 Consolidated description and identified uncertainties 205

4.3 Material design evolution after statutory consultation 207
4.3.1 Selection of the Site 1B National Grid substation 208
4.3.2 Abandonment of the southern substation alternative 209
4.3.3 Upgrade and relocation of the project substation from 132 kV to 400 kV 209
4.3.4 Taller new 400 kV pylons 210
4.3.5 Additional solar panels at Site 7D 211
4.3.6 Additional land for overhead-line and grid connection works 211

4.3.7 Additional land for AILs, visibility splays and highway alterations 212
4.3.8 Changes to construction traffic and AIL routes 213
4.3.9 The Applicant's decision not to revise the PEIR 213
4.3.10 A general assertion of unchanged significance was insufficient 214
4.3.11 Landscape and visual consequences 215
4.3.12 Heritage consequences 215
4.3.13 Noise and residential amenity 216
4.3.14 Fire, emergency response and public health 216
4.3.15 Drainage and flood-risk consequences 216
4.3.16 Aviation safeguarding consequences 217
4.3.17 Archaeological and ecological consequences 217
4.3.18 Cumulative effects 218
4.3.19 Conclusion 218

4.4 Solar and BESS are not aligned as one confirmed connection project 219
4.4.1 Physical co-location does not establish co-deliverability 220
4.4.2 The BESS has no demonstrated Gate 2 route on the evidence presently available. 220
4.4.3 The draft DCO must be tested for severability 221
4.4.4 Solar-only development 221
4.4.5 Delayed BESS construction 222
4.4.5A Claimed co-location benefits must be tested against timing 222
4.4.6 Partial or reduced BESS 223
4.4.7 Different battery technology at initial construction or replacement 223
4.4.8 Construction of BESS infrastructure without a confirmed connection 224
4.4.9 Environmental consequences of the connection mismatch 225
4.4.10 The planning balance must not assume benefits which are not demonstrated as deliverable 226
4.4.11 Required works-severability schedule 227
4.4.12 Required connection-status schedule 228
4.4.13 Required technical and legal confirmation 228
4.4.14 Required DCO controls 228
4.4.15 Conclusion 229

4.5 The proposed National Grid substation is not a confirmed connection solution 230
4.5.1 The infrastructure for which consent is sought 230
4.5.2 NGET has not confirmed that Site 1B is the final solution 231
4.5.3 Strategic network planning and North Anglia Node A 232
4.5.4 Consequences for Scheme definition and deliverability 233
4.5.5 The assessed envelope cannot accommodate an unknown transmission solution 234
4.5.6 Compulsory acquisition cannot precede confirmed necessity 235
4.5.7 Responsibility, ownership and enforceability 236
4.5.8 Information required during Examination 236
4.5.9 DCO controls required 237
4.5.10 Conclusion 238

4.6 The change from a 132 kV to a 400 kV project substation 238
4.6.1 Comparison of the consulted and applied-for designs 239
4.6.2 The voltage change altered the physical project 241
4.6.3 The project and National Grid substation parameters must be kept distinct 242
4.6.4 Landscape and visual effects 242
4.6.5 Heritage effects 243

4.6.6 Operational noise 243
4.6.7 Air quality and construction emissions 244
4.6.8 Fire, oil and major-accident consequences 244
4.6.9 Drainage and impermeable area 245
4.6.10 Groundwater and foundation effects 245
4.6.11 Aviation consequences 246
4.6.12 Construction traffic and abnormal loads 246
4.6.13 Audit required of the final Environmental Statement 246
4.6.14 Conclusion 247

4.7 Uncertainty over the boundary between Applicant works and NGET works 248
4.7.1 The DCO authorises the transmission works themselves 248
4.7.2 The delivery model remains insufficiently defined 248
4.7.3 Detailed-design approval must be legally identifiable 249
4.7.4 NGET engineering flexibility must remain within the assessed envelope 250
4.7.5 Transfer of the Order must transfer the obligations as well as the powers 250
4.7.6 Land ownership and compulsory powers must reflect the actual delivery model 251
4.7.7 Long-term ownership creates continuing environmental obligations 251
4.7.8 Enforcement responsibility must be unambiguous 252
4.7.9 Decommissioning and permanent retention must be divided expressly 253
4.7.10 Information and DCO controls required 253
4.7.11 Conclusion 254

4.8 Unresolved interaction with National Gas Transmission infrastructure 254
4.8.1 The FM05 feeder main is a fixed operational constraint 255
4.8.2 Cathodic-protection infrastructure must also be protected 255
4.8.3 The easement restrictions engage a wide range of East Pye works 256
4.8.4 Ground levels, loading and access require specific control 256
4.8.5 Cable and drainage crossings must be fixed and controlled 257
4.8.6 Landscaping and BNG cannot conflict with pipeline safety 257
4.8.7 Protective provisions remain unresolved 258
4.8.8 Compulsory-acquisition powers require particular scrutiny 258
4.8.9 The interface must remain safe for the whole life of the Scheme 259
4.8.10 Information and controls required 259
4.8.11 Conclusion 260

4.9 Cable Route Corridors and unresolved connection geography 261
4.9.1 Cable works authorised by the DCO 261
4.9.2 Number and voltage of cables 262
4.9.3 Trench width and depth 263
4.9.4 Overall working width 263
4.9.5 Freedom to route cables anywhere within the corridors 264
4.9.6 Joint bays 265
4.9.7 Fibre chambers and link boxes 266
4.9.8 Trenchless crossings and HDD 266
4.9.9 Fixed crossing locations 267
4.9.10 Cable thermal properties 268
4.9.11 Preferential groundwater pathways 268
4.9.12 Dewatering 269
4.9.13 Spoil and soil storage 269
4.9.14 Haul roads and access 270

4.9.15 Is the cable network fixed to Site 1B? 271
4.9.16 Could cables be constructed before the NGET solution is confirmed? 271
4.9.17 Duplicate or stranded cable infrastructure 272
4.9.18 What happens if the connection point moves? 272
4.9.19 Are the powers wider than the assessed alignment? 273
4.9.20 Cumulative below-ground effects 273
4.9.21 Cable lifespan and replacement 274

4.10 The Rochdale Envelope is insufficiently defined or controlled 274
4.10.1 The Applicant's reliance on a design envelope 274
4.10.2 Consolidated assessment of the retained flexibility 276
4.10.3 The uncertainties cannot be considered independently 292
4.10.4 Discipline-specific worst cases may not produce a controlled whole-project worst case 293
4.10.5 The final ES may not consistently use the final design 293
4.10.6 The envelope cannot cure uncertainty over the identity of the connection solution 294
4.10.7 The envelope cannot cure severability 295
4.10.8 Broad associated-development powers increase the uncertainty 295
4.10.9 The Works Plans do not provide an adequate geographical control 296
4.10.10 The Design Principles cannot substitute for absent parameters 296
4.10.11 'Substantially in accordance with' weakens the control further 297
4.10.12 Required parameters, assessment and control schedule 298
4.10.13 Required DCO controls 299
4.10.14 Evaluative conclusion 299

4.11 Aviation-sensitive design parameters and Site 1 300
4.11.1 Scope of this section 300
4.11.2 Relationship between Site 1 and Tibenham Airfield 301
4.11.3 The original glint-and-glare work pre-dated meaningful engagement 302
4.11.4 Norfolk Gliding Club's allegation concerning Pager Power 302
4.11.5 Wider operational risks identified by NGC 303
4.11.6 The photographic and mapped evidence 303
4.11.7 Was the emergency-landing environment incorporated into Site 1 design? 304
4.11.8 No defined aviation-safe maximum panel extent 305
4.11.9 Is there a panel-free corridor? 305
4.11.10 Tracking panels must be assessed expressly 306
4.11.11 Panel orientation and movement require binding controls 306
4.11.12 Reflectivity is not adequately controlled by colour alone 307
4.11.13 Fencing and obstacles within emergency areas 307
4.11.14 Pylons and substations must form part of the aviation envelope 308
4.11.15 Later design changes could worsen aviation risk 309
4.11.16 The Examination has now treated aviation as a wider safety issue 309
4.11.17 Required aviation design evidence 310
4.11.18 Required DCO controls 310
4.11.19 Conclusion 311

4.12 Construction description and missing quantities 311
4.12.1 Programme, phasing and simultaneous construction 312
4.12.2 Construction sequencing must reflect environmental and safety dependencies 313
4.12.3 Workforce and traffic assumptions require reconciliation 313
4.12.4 Abnormal-load construction remains insufficiently quantified 314
4.12.5 Solar piling is not sufficiently quantified 314

4.12.6 Deep foundations for BESS and substations require the same discipline 315
4.12.7 Concrete and civil works need a quantified maximum 315
4.12.8 Cable excavation and below-ground works are not fully quantified 315
4.12.9 HDD and trenchless construction remain underdefined 316
4.12.10 Dewatering is a potentially material but unquantified activity 316
4.12.11 Earthworks, compounds and hardstanding require clearer limits 317
4.12.12 Haul roads and temporary access also need a defined envelope 317
4.12.13 Pollution-control infrastructure cannot remain generic 318
4.12.14 Welfare and water demand should reconcile with the workforce case 318
4.12.15 Materials, spoil and waste remain only partially quantified 318
4.12.16 Vegetation removal should be quantified as part of construction 319
4.12.17 Construction lighting and working hours require enforceable limits 319
4.12.18 Commissioning is a separate construction-stage effect 320
4.12.19 A consolidated Construction Parameters Schedule is required 320
4.12.20 DCO controls required 321
4.12.21 Conclusion 321

4.13 Unresolved end-to-end transport and AIL deliverability 322
4.13.1 Purpose of this section 322
4.13.2 The route must be assessed from port to final compound 323
4.13.3 National Highways had not agreed the strategic AIL route 323
4.13.4 Strategic-road constraints must be identified before consent 324
4.13.5 Junction effects require assessment 325
4.13.6 Greater granularity is required for cumulative construction traffic 325
4.13.7 Traffic limits must be enforceable 326
4.13.8 Norfolk County Council rejects important parts of the local routeing strategy 327
4.13.9 Hall Lane and Fairstead Lane 327
4.13.10 Other minor rural routes 328
4.13.11 Routes for Sites 7–10 remained unresolved 328
4.13.12 AILs should use approved haul routes 329
4.13.13 No complete route to the BESS has been established 329
4.13.14 No complete route to each project substation has been established 330
4.13.15 No complete route to the National Grid substation has been established 331
4.13.16 Pylon and overhead-line construction access 331
4.13.17 Swept-path assessments 331
4.13.18 Structural assessments 332
4.13.19 Highway works and vegetation removal 332
4.13.20 Conservation areas and sensitive rural roads 333
4.13.21 Fallback routes 333
4.13.22 Land and rights within the Order Limits 334
4.13.23 Required AIL and transport deliverability schedule 334
4.13.24 Required DCO controls 335
4.13.25 Conclusion 336

4.14 Operational replacement and repowering 337
4.14.1 Replacement is a foreseeable part of the authorised development 337
4.14.2 Complete panel replacement resembles a second construction phase 337
4.14.3 Meaning of ‘replacement’ 338
4.14.4 Maximum simultaneous replacement area 339
4.14.5 Re-establishment of compounds and laydown areas 339

4.14.6 Re-establishment of haul roads and accesses 340
4.14.7 Replacement traffic limits 340
4.14.8 Updated transport information may be required 341
4.14.9 Updated noise controls 341
4.14.10 Updated soil and agricultural controls 341
4.14.11 Updated ecological controls 342
4.14.12 Updated drainage controls 343
4.14.13 BESS replacement up to five times 343
4.14.14 Storage of removed batteries 343
4.14.15 Damaged batteries 344
4.14.16 Different battery chemistry 344
4.14.17 Environmental-performance equivalence 345
4.14.18 Transformer replacement 346
4.14.19 Replacement of conversion units and other electrical plant 346
4.14.20 Cable replacement 347
4.14.21 Waste calculations 347
4.14.22 Carbon and materials calculations 348
4.14.23 Required Replacement Management Plan 348
4.14.24 Required DCO controls 349
4.14.25 Conclusion 350

4.15 Decommissioning, permanent infrastructure and restoration security 351
4.15.1 The 60-year description does not define the whole life of the development 351
4.15.2 The post-decommissioning development must be defined now 352
4.15.3 The National Grid infrastructure is permanent development 353
4.15.4 Permanent infrastructure requires permanent environmental assessment 353
4.15.5 Agricultural restoration is not established by equipment removal 354
4.15.6 'As far as reasonably practicable' is not an adequate restoration standard 354
4.15.7 The new private decommissioning securities alter, but do not resolve, the financial-security issue 355
4.15.8 Private landowner security may fragment a Scheme-wide liability 355
4.15.9 The security must cover restoration, not merely equipment removal 356
4.15.10 Consistency, insolvency protection and public enforcement remain unproven 356
4.15.11 Responsibility must survive transfer and permanent retention 358
4.15.12 Evidence and DCO controls required 359

4.15.13 Conclusion 359

4.16 Severability and materially different implementation scenarios 360
4.16.1 The DCO must be tested against what it permits, not only what the Applicant presently intends 360
4.16.2 Construction of only some solar sites 361
4.16.3 A reduced total generating capacity 361
4.16.4 Solar without BESS 362
4.16.5 Delayed BESS 362
4.16.6 Omission of some project substations 363
4.16.7 Omission of the National Grid substation 364
4.16.8 A different NGET connection solution 364
4.16.9 Cables constructed but not used 365
4.16.10 Staged implementation over many years 365
4.16.11 Abandonment of works after commencement 366

4.16.12 Biodiversity net gain and ecological mitigation 366
4.16.13 Landscape mitigation 367
4.16.14 Drainage and flood-risk mitigation 367
4.16.15 Construction traffic under prolonged phasing 367
4.16.16 Claimed benefits may not arise 368
4.16.17 Compulsory-acquisition powers may outlast the need for individual works 368
4.16.18 Required severability evidence and controls 369
4.16.19 Conclusion 369

4.17 Consequences for the Environmental Statement 370
4.17.1 Introduction 370
4.17.2 Worst-case assessment 371

4.18 Remedies sought 373
4.18.1 Consolidated scheme definition 373
4.18.2 Grid connection and NGET responsibilities 374
4.18.3 Solar and BESS severability 375
4.18.4 Design parameters 375
4.18.5 Cable and below-ground works 376
4.18.6 Statutory undertakers 377
4.18.7 Aviation safeguards 377
4.18.8 Construction and transport 378
4.18.9 Replacement and decommissioning 379
4.18.10 Updated environmental assessment 379
4.18.11 Consequence if the remedies are not satisfied 381

Chapter 5: Reasonable Alternatives and Design Evolution 382

5.1.1 Introduction 382
5.1.2 The applicable alternatives requirement 383
5.1.3 The land search preceded confirmation of a viable grid connection 384
5.1.4 Failure to restart the site-selection exercise after Norwich Main failed 384
5.1.5 Land availability was a materially conditioning factor 385
5.1.6 The Great Moulton point of connection was selected to preserve the land package 386
5.1.7 The site-selection process was not ecologically led 387
5.1.8 Agricultural-land constraints were relaxed to preserve the Scheme 388
5.1.9 The Applicant fixed the scale before assessing alternatives 389
5.1.10 No demonstrated regional need for East Pye in T7 389
5.1.11 The position is particularly adverse for transmission solar 390
5.1.12 The BESS does not cure the absence of a regional solar need case 391
5.1.13 The Applicant's own development portfolio reinforces the absence of demonstrated locational necessity 391
5.1.14 The 'do nothing' alternative is material and should be prioritised 394
5.1.15 Design evolution does not cure the site-selection defect 395
5.1.16 Overall conclusion 395
5.1.17 Remedies sought 396

5.2 Legal and policy framework 396
5.3 The original site search was tied to Norwich Main 398
5.4 Failure to restart the site search when Norwich Main failed 399
5.5 Land availability materially conditioned site selection 400
5.6 The Great Moulton substation was selected to preserve the assembled sites 402

5.7 The site-selection process was not ecologically led 404
5.8 The agricultural-land methodology confirms that project delivery overrode environmental screening 405
5.9 The project scale was fixed before alternatives were assessed 408
5.10 No evidence of regional need for East Pye Solar in T7 410
5.11 The Applicant has not demonstrated a separate locational necessity for this configuration . 412
5.12 The BESS does not cure the absence of a solar need case 413
5.13 The Applicant's own development portfolio reinforces the absence of demonstrated locational necessity 415
5.14 The environmental consequences of selecting this extensive area of South Norfolk are exceptionally severe 418
5.15 The future baseline and the no-development scenario 420
5.16 Failure of design evolution to cure the site-selection defect 422
5.17 Overall conclusion 425
5.18 Remedies sought 426

Chapter 6: Climate Change 429
6.1 Introduction 429
6.2 Independent application of the Great North Road methodology 431
6.3 Failure to assess water vulnerability and water-resource resilience 431
6.4 Failure to assess runoff, flood intensification and groundwater effects under future climate conditions 432
6.5 Failure to provide a reliable whole-life GHG assessment 433
6.6 Failure of the headline calculation to reconcile 434
6.7 Material arithmetic and unit errors 434
6.8 Static use of the 2031 grid factor 435
6.9 Uncertain commencement and operational date 435
6.10 Failure to assess curtailment and useful exported electricity 436
6.11 Failure to assess the Scheme without BESS 436
6.12 The BESS dominates lifecycle emissions 437
6.13 Unassessed BESS charging and operational emissions 437
6.14 Unsupported replacement and repowering assumptions 437
6.15 Failure to assess land-use change and soil carbon 438
6.16 Omitted infrastructure and operational demand 438
6.17 Failure to include water-supply and tankering emissions 438
6.18 Unsupported downstream benefits 439
6.19 Failure to provide a secured GHG Reduction Strategy 439
6.20 Failure to assess cumulative climate effects 439
6.21 Failure to assess combined climate and ecological effects 440
6.22 Loss of ecological connectivity under climate change 441
6.23 Climate effects on bats and other mobile species 441
6.24 Climate effects on ponds, ditches and aquatic ecology 441
6.25 Failure to test whether ecological mitigation is climate-resilient 442
6.26 Climate change and the mitigation hierarchy 442
6.27 Heat, BESS parasitic demand and fire risk 443
6.28 Drought-related failure of landscape and ecological mitigation 443
6.29 Agricultural resilience and displacement of food production 444
6.30 Cumulative loss of permeable and climate-resilient land 444
6.31 Climate consequences of repeated mid-life replacement works 445
6.32 Consequences for the significance conclusion 445

6.33 Remedies sought 446
Summary: 447
Chapter 7: Landscape and Visual 449
7.1 Executive Summary and Principal Objection 449
7.2 Policy and Assessment Framework 451
7.3 The Applicant's Own Assessment Establishes Extensive Significant Harm 452
7.4 The Landscape Has Been Assessed as Separate Development Parcels Rather Than as a Coherent Landscape 453
7.5 Underassessment of Historic Landscape Character and Artificial Separation from Heritage 454
7.6 Landscape Sensitivity Has Been Systematically Understated 455
7.7 Site 1, BESS and Great Moulton: the Scheme's Most Serious Landscape Conflict 457
7.8 The Scale and Industrial Character of the Solar Arrays Are Understated 458
7.9 Inadequate Study Area and Overreliance on Distance 459
7.10 Visualisations Do Not Adequately Represent the Worst-Case Seasonal Effect 460
7.11 Night-Time Character, Dark Skies and Tranquillity Have Not Been Properly Assessed 461
7.12 Tranquillity Is Treated as a Descriptor Rather Than a Receptor of Harm 462
7.13 Public Rights of Way and Sequential Landscape Experience Are Underassessed 463
7.14 Residential Visual Harm Is Materially Understated 464
7.15 Trees, Hedgerows and Woodland: the Existing Landscape Framework Is Itself Under Pressure 465
7.16 Mitigation by Screening Does Not Preserve Landscape Character 466
7.17 The Year 15 Case Is Over-Optimistic and Does Not Remove the Harm 467
7.18 Site 7 and Site 8: High Tranquillity, Dark-Sky and Recreational Sensitivity 468
7.19 Site 10: C2, Ditchingham, the Broads Interface and Parkland Context 469
7.20 Fritton and St Catherine's Church 470
7.21 Cable Corridors, Lanes and the Structural Landscape 470
7.22 Aviation and Airfield Landscape Cross-Effects 471
7.23 Ecology and Landscape Are Functionally Interdependent 471
7.24 Cumulative Landscape Industrialisation 472
7.25 Replacement Cycles and Decommissioning Are Not Truly "Temporary" 473
7.26 Good Design: Screening Harm Is Not the Same as Avoiding Harm 474
7.27 Overall Planning Weight 475
7.28 Remedies and Requirements Sought 476

Objection

East Pye Solar is the wrong project, at the wrong scale, in the wrong place

BEPS objects to East Pye Solar in its entirety. The objection is not to solar generation or to the transition to a low-carbon electricity system. It is to the proposition that this particular 500MW-scale, transmission-connected development, dispersed across approximately 1,200 hectares of solar fields and 54 square miles of South Norfolk, is necessary or proportionate when weighed against the exceptional and largely irreversible harm it would impose on the place in which it is proposed.

The starting point must be need. The Applicant presents East Pye as part of the national imperative for additional solar generation. That proposition is materially more complicated than the application suggests.

NESO's original December 2024 Clean Power 2030 Action Plan envisaged that 90% of solar capacity would be provided through smaller projects connected to the **distribution network,** [1] with only 10% connected at transmission level.

For the T7 East Anglia transmission region, the original solar allocation was only **900MW** for the relevant 2031–35 period. East Pye Solar and Island Green Power's other Norfolk NSIP, The Droves, would together exceed that amount without even taking into consideration the multiple other solar NSIPS proposed across East Anglia.

In April 2025, the separate transmission and distribution allocations were replaced with combined Tx+Dx regional capacity limits. The effect was to remove the previous constraint on the proportion of solar capacity that could be delivered through very large transmission projects.

That was not simply an abstract technical adjustment. The documentary material before BEPS records that Island Green Power was among a group of solar developers that wrote to the Secretary of State on 3 December 2024 seeking changes to the regional connection methodology, including removal of the distinction between transmission and distribution projects. Extensive lobbying by Macquarie and private meetings with DESNZ followed, including the detailed discussion of East Pye Solar as one of the projects that would not be required under NESO's existing methodology. Macquarie also proposed combining Dx+Tx capacity limits to enable their pipeline of projects to receive grid connections. DESNZ subsequently wrote to NESO on 7 April 2025, saying that it had decided to combine Tx+Dx regional capacity limits for 2031-5 due to the increased transmission-connected solar pipeline not being reflected adequately in NESO's earlier assumptions.

BEPS does not ask the Examining Authority to infer impropriety merely from the existence of industry engagement. But where the promoter of this DCO was among those seeking a policy change that subsequently improved the position of large transmission-connected projects, and the Secretary of State who heads the Department responsible for that intervention will ultimately determine this application, the sequence gives rise to a serious **appearance-of-bias**

[1] 'The distribution network will play an important role in the deployment of renewable generation, with 29% of onshore wind and 90% of solar capacities connected to the distribution network in our pathways.' (NESO, Clean Power 2030, p. 27.)

and procedural fairness issue which warrants transparent examination. More fundamentally, it undermines any attempt to treat the revised Gate 2 allocation as independent proof that East Pye itself is regionally necessary.

The DESNZ policy change appears to have accommodated the existing transmission solar pipeline rather than demonstrated that the original system assessment had underestimated consumer need. A large queue of transmission projects is evidence of developer interest; it is not, by itself, evidence that all of that capacity is needed, that it is needed in East Anglia, or that transmission-scale solar represents the most efficient or least harmful means of meeting national solar objectives.

There is also a wider public-interest question. The benefits of a transmission-connected NSIP should not be expressed as though its electricity will preferentially 'power local homes'. Electricity exported at transmission level enters the wider electricity market. Statements that a project could power the 'equivalent' of a particular number of homes describe generation volume at maximum generating capacity; they do not identify the ultimate purchaser of that electricity or establish a direct benefit to the communities hosting the infrastructure. The commercial reality may include substantial corporate offtake. Cleve Hill Solar Park provides a clear example: Tesco has contracted for **65% of its generation** under a 15-year corporate power purchase agreement. Many of these vast NSIP solar plants will go on to power data centres – which will bring further development pressure and environmental degradation.

BEPS therefore submits that the Examination must distinguish between a general national need for renewable electricity (predominantly on the distribution network) and the alleged specific need for **East Pye Solar at this scale, in this transmission region and in this location**. The former does not automatically establish the latter.

This distinction matters because the environmental price of East Pye is extraordinary.

This is not development on a degraded industrial site. It is proposed across an ancient, settled and intensely interconnected South Norfolk landscape: productive arable farmland; medieval churches and historic timber-framed farmsteads; ancient hedges, woodland and veteran trees; nationally important bat habitat; chalk-stream catchments; historic sunken lanes lined with vanishingly rare assemblages of botany, historic commons and greens; conservation area rural settlements; fragile private water supplies; cherished public rights of way; and landscapes whose cultural and ecological structures have developed together over thousands of years.

The Applicant's own evidence confirms much of that sensitivity. Its bat surveys identify a nationally important assemblage. Its archaeological work reveals extensive evidence of prolonged human occupation. Independent heritage assessment identifies less-than-substantial harm from the principal built development to 36 designated heritage assets and adverse effects upon 41 designated heritage assets overall, compared with the substantially narrower harm identified by the Applicant (two). Statutory consultees have raised unresolved concerns about ecology, water, archaeology, transport, landscape and infrastructure. The Scheme requires extensive road intervention, cable corridors, substations, BESS infrastructure, fencing, access tracks, security measures and planting designed not to preserve or enhance the existing landscape but to conceal the industrial infrastructure inserted into it – some on a permanent basis.

Our central objection is that East Pye does not seek to fit respectfully within this landscape. It requires the landscape to be **re-engineered around the project**. Open fields become power-

generation compounds. Historic views are screened rather than preserved. Hedgerows become infrastructure boundaries and crossing points. Rural lanes become construction routes. Productive soils become the platform for a 60-year industrial use. Quiet approaches to churches and villages become settings for tracker arrays, substations and associated infrastructure. Ecological connectivity is expected to adapt around fencing, cabling, roads and repeated construction disturbance. New planting is then presented as enhancement even where its function is to screen development that should not have been placed within that historic open setting in the first place.

BEPS strongly rejects that approach to environmental planning. This approach sits uneasily with the NSIP good-design principles in EN-1, which require infrastructure to be designed as an integral part of the landscape and place within which it sits, with adverse environmental effects avoided or reduced through good design rather than merely concealed after the event. Good design is not achieved by first imposing the maximum engineering footprint and then using buffers, screening belts and later mitigation to make the consequences less visible. BEPS submits that East Pye represents mitigation-led concealment of harm, not the genuinely integrated, place-responsive and environmentally sensitive design expected of an NSIP.

This landscape is not empty space awaiting a nationally significant use. It is already **nature-dense, history-dense and community-dense**. Its value lies precisely in the accumulated relationships between farmland, water, wildlife, historic settlement, buildings, lanes, woods and the people who live within it. Those relationships cannot be recreated by biodiversity units, landscape screening, later management plans or the promise that the Scheme may ultimately be removed after sixty years. Some infrastructure will remain in perpetuity, as will the new screening planting which will permanently alter the wide-open spaces and views across our landscape on which our specific current ecology depends. The issue for the Examination is whether the harm presented by this project, on this scale, in this location is outweighed by need.

The original NESO framework did not envisage this concentration of transmission-scale solar in East Anglia. The subsequent expansion of the available transmission envelope followed direct industry pressure – including from Macquarie specifically about East Pye Solar – and accommodated a pipeline that already exceeded the earlier transmission assumptions. That substantially weakens the proposition that this particular Scheme represents an unavoidable national necessity.

Against that weakened needs case stand extensive and interacting harms to landscape, ecology, cultural heritage, agriculture, water, tranquillity, transport and community life.

BEPS submits that those harms are not incidental costs of an otherwise appropriate project. They are evidence that the Scheme is fundamentally misplaced. The planning system should require renewable infrastructure to respect and work with the places in which it is located. East Pye instead asks South Norfolk to be reshaped to accommodate it. The result would be the progressive industrialisation of a cherished and still remarkably intact area of already ‘nature dense’ ancient countryside for a ‘temporary’ project whose specific regional necessity has not been demonstrated independently of a connections framework altered to accommodate the transmission pipeline.

BEPS therefore asks the Examining Authority to reject the proposition that national support for solar generation is sufficient to justify East Pye. It is not. The proper question is whether the benefits properly attributable to this Scheme justify its particular environmental effects and

whether its scale, location and configuration are acceptable under the applicable policy framework. On the evidence before the Examination, BEPS submits that the answer is no.

Preliminary Chapter – CPO and DCO

Part I – Purpose and legal framework

P.1 The purpose of this Preliminary Chapter

This Preliminary Chapter addresses the legal consequences of the objections developed in Chapters 1–20. It does not repeat the detailed evidence concerning need, alternatives, scheme definition, ecology, water, transport, heritage, soils, ground conditions, noise, EMF, major accidents, cumulative effects or decommissioning. Those matters are addressed in the substantive chapters of this Written Representation.

Its purpose is narrower and more fundamental. The Applicant seeks two exceptional statutory outcomes. First, it asks the Secretary of State to make a Development Consent Order authorising the Scheme and conferring extensive statutory powers for its construction, operation, maintenance, replacement and decommissioning. Secondly, it seeks compulsory powers over land and third-party interests, including permanent acquisition, acquisition of rights and restrictions, temporary possession and interference with existing rights.

Those powers cannot properly be considered in isolation from the evidential deficiencies identified elsewhere in this Written Representation. The question in this Preliminary Chapter is therefore not whether individual environmental effects are unacceptable; those matters are addressed in the substantive chapters. The question is whether, in light of the uncertainties and defects identified there, the Applicant has demonstrated a sufficiently defined, deliverable and legally controlled Scheme to justify the powers contained in the draft DCO and the compulsory acquisition of private interests.

That distinction is important. Chapters 1 and 5 address the claimed need for East Pye and the alternatives available. Chapter 4 demonstrates extensive uncertainty concerning the physical identity, severability, grid connection, BESS, National Grid infrastructure, cable network, construction arrangements, replacement and decommissioning of the Scheme. Chapters 8–18 identify important environmental controls that remain dependent upon later surveys, detailed design, management plans, licences, permits and approvals. The present chapter asks what follows from those findings when the Applicant seeks statutory authority to implement the Scheme and coercive powers over third-party property.

The central proposition is simple. Statutory powers should follow a demonstrated and sufficiently defined need for those powers. They should not be granted at maximum breadth first, leaving the Applicant to determine later which development will actually proceed, which land will actually be required, which environmental controls will ultimately apply and which powers will in practice be exercised.

P.2 The distinction between development consent, DCO powers and compulsory acquisition

Three separate questions arise and they should not be collapsed into a single planning balance.The first is whether East Pye Solar is acceptable in principle under the relevant statutory and policy framework. That question engages the claimed need for renewable generation, alternatives, environmental effects, good design and the overall planning balance. It is addressed principally in Chapter 1 and the substantive environmental chapters.

The second is whether the draft DCO is an adequate legal instrument for the development that has actually been assessed. A decision that a solar project is acceptable in principle does not itself establish that every power contained in the draft Order is properly drawn. The DCO must define what is authorised, identify the geographical and physical limits of those powers and secure the controls upon which environmental acceptability depends.

Current Government guidance on DCO content emphasises that the draft Order is the legal instrument through which the authorised development and the powers required to implement it are established. It is not merely a description of the Applicant's present intentions. The Planning Inspectorate's drafting advice similarly requires the DCO itself to be prepared and submitted as part of the application; the Examination is therefore concerned with the legal powers actually sought, not only with the design the Applicant currently says it expects to construct.

This distinction is particularly important at East Pye. Chapter 4 identifies uncertainty concerning the relationship between solar and BESS, the severability of principal Works, the final National Grid connection solution, the number and configuration of major substations, cable-route flexibility, replacement and repowering, and what infrastructure would remain after decommissioning. The draft DCO must therefore be tested against the full range of development it legally permits, not merely against the Applicant's preferred present configuration.

The third question is different again: whether the Applicant has justified each compulsory power and each property interest sought. A conclusion that East Pye is desirable in planning terms would not automatically establish that permanent acquisition of a particular freehold is necessary. Nor would it establish that acquisition of a permanent right is justified where temporary possession would suffice, or that land should remain subject to compulsory powers where the Work requiring it may never be constructed.

That distinction is inherent in the Planning Act 2008. Section 122 does not provide that compulsory acquisition follows automatically from development consent. It imposes an additional statutory condition: there must be a compelling case in the public interest for the land to be acquired compulsorily.

Accordingly, even if the Examining Authority were ultimately to reject some of BEPS's substantive objections to the Scheme, two independent questions would remain.

First, does the Order precisely and effectively control the development which may lawfully be implemented?

Secondly, has the Applicant demonstrated that the particular compulsory acquisition powers sought are necessary and proportionate to that development?

BEPS submits that neither question can be answered simply by pointing to the national need for renewable energy.

P.3 The statutory threshold for compulsory acquisition

Section 122 of the Planning Act 2008 permits compulsory acquisition to be authorised only where the statutory purpose condition is satisfied and where there is 'a compelling case in the public interest for the land to be acquired compulsorily'. The latter is a substantive statutory condition, not a procedural formality. The Applicant must therefore do more than establish that East Pye would use land. It must justify the compulsory taking of the particular land or interest concerned.

The Government's Planning Act compulsory-acquisition guidance is directed specifically to DCO applications involving compulsory acquisition of land or rights over land. Its underlying approach is consistent with the general compulsory-purchase principle that compulsory powers require a compelling public-interest justification and should be pursued alongside reasonable attempts to secure land by agreement. For East Pye, the correct enquiry has several distinct elements.

First, there must be a sufficiently clear purpose for which the relevant land or right is required. It is difficult to demonstrate necessity where the corresponding Work remains optional, severable, capable of substantial relocation or dependent upon an unresolved connection solution.

Secondly, the interest sought must be no more extensive than the Scheme reasonably requires. The relevant question is not only whether a parcel is needed, but what interest in it is needed. Permanent freehold acquisition represents a materially greater interference with property rights than a lease, permanent right, restrictive covenant or temporary possession. The existence of statutory power to acquire the greater interest does not establish that the greater interest is necessary.

Thirdly, reasonable alternatives to compulsory acquisition must be properly considered. Those alternatives include not only different geographical parcels but, where relevant, less intrusive forms of land control.

Fourthly, the interference must be proportionate to the public purpose relied upon. That requires the strength and certainty of the public benefit to be weighed against the nature and extent of the private interference. The distinction matters particularly where a project is presented as temporary but the property interest sought is permanent.

Fifthly, the Applicant should be able to demonstrate that there is a reasonable prospect of the Scheme for which the land is sought actually proceeding. Compulsory powers should not be granted merely to preserve commercial optionality over land which may prove unnecessary if a BESS, substation, cable route, access arrangement or grid solution does not proceed.

These considerations are especially important here because Chapter 4 identifies extensive uncertainty over which parts of the authorised development are essential and which may be omitted, delayed or delivered differently. Chapter 11 identifies unresolved access and construction-deliverability matters; Chapter 8 identifies unresolved ecological and protected-species issues; Chapters 9 and 16 identify unresolved water, groundwater and ground-condition controls; and Chapter 15 identifies potentially long-lasting consequences for agricultural land and restoration.

The compulsory-acquisition case cannot be insulated from those uncertainties. If an essential Work is not presently demonstrated to be deliverable, the case for permanently taking the land required solely for that Work is correspondingly weakened. If the final configuration is not settled, the Applicant must demonstrate why the entire area and the full interest sought are nevertheless necessary.

The statutory sequence is therefore important: the Applicant must identify the development that is capable of proceeding; identify the land genuinely required for it; identify the minimum interest necessary to secure that land; and only then demonstrate why compulsory acquisition of that interest is justified by a compelling case in the public interest.

It would reverse section 122 to grant the widest powers now and allow necessity to be determined later through detailed design, commercial negotiation or implementation choices.

P.4 The DCO must authorise the Scheme assessed and secure the mitigation relied upon

The same discipline applies to the draft DCO itself. A DCO is not merely permission for the general concept of a solar farm. It defines the development which may legally be carried out and the powers by which that development may be implemented. The Order must therefore correspond with the Scheme assessed in the Environmental Statement and must secure those design limits and mitigation measures necessary to support the Applicant's conclusions.

Government guidance treats DCO control documents as instruments intended to provide specific and detailed practical controls over the proposed development. The 2024 pre-application guidance expressly describes control documents named within DCO Requirements as documents providing such controls and expects mature outline control documents to accompany the application. That approach is inconsistent with using outline documents merely as placeholders for environmental solutions yet to be worked out after consent.

Five principles follow.

First, the authorised development must be defined with sufficient certainty.

Chapter 4 demonstrates why this is a material issue at East Pye. The Scheme retains substantial flexibility concerning the solar/BESS relationship, BESS connection status, principal substations, the National Grid connection solution, cable routing, associated development, construction arrangements, replacement and decommissioning. The DCO must establish the boundaries of that flexibility. It cannot leave open such a broad range of implementation outcomes that it becomes uncertain which development has actually been assessed.

Secondly, the authorised development must remain within the environmental envelope assessed.

The Rochdale Envelope permits legitimate design flexibility where the parameters and reasonable worst case are properly defined. It does not permit the identity or essential environmental consequences of the project to be settled later. Chapter 2 identifies methodological concerns about whether a coherent whole-project worst case has been assessed; Chapter 4 develops that objection in relation to the actual design envelope.

The Order should therefore contain effective limits ensuring that subsequent detailed design cannot produce a materially different environmental outcome from that examined.

Thirdly, mitigation relied upon in the Environmental Statement must be legally secured.

This is particularly important because the substantive chapters repeatedly identify conclusions of limited or non-significant effect which depend upon measures not yet finally designed. Chapter 8 identifies extensive reliance on the Outline LEMP, later protected-species measures, future lighting design, CEMPs and later licensing. Chapter 11 identifies dependence on later construction traffic arrangements and highway controls. Chapter 15 identifies future soil-management and restoration controls. Chapter 16 identifies deferred intrusive investigations, Foundation Works Risk Assessments and HDD hydrogeological assessment.

Where the Applicant's significance conclusion assumes that a measure will occur, that measure cannot remain merely aspirational. A mitigation measure that may subsequently be omitted because it is considered impracticable, modified through a loosely worded final plan or displaced through later detailed design is not equivalent to secured mitigation.

Fourthly, later maintenance, replacement and repowering must remain within the assessed envelope.

This is especially important because Chapter 4 records that the Scheme contemplates complete replacement of the solar panels and repeated replacement of the BESS during the operational period. Those are foreseeable construction-like events involving new equipment, traffic, waste, ecological disturbance, noise and potentially different technology.

A broadly drafted power to "maintain" must not become a mechanism through which a materially different generating or storage project can be installed without further environmental assessment. The Order must distinguish ordinary maintenance from major replacement and from repowering, and it must prevent later technology or capacity changes from producing materially new or different effects.

Fifthly, material post-consent decisions must be subject to enforceable controls.

The application relies extensively upon later detailed design and discharge of Requirements. Some post-consent refinement is inevitable and legitimate. But there is a fundamental distinction between deciding how an already acceptable mitigation measure will be implemented and deciding after consent whether an environmentally acceptable solution exists at all.

That distinction is particularly important at East Pye because the substantive chapters identify unresolved matters concerning access, drainage, protected species, groundwater, foundations, archaeology, operational noise, BESS safety, soil restoration and other matters that go directly to environmental acceptability.

The DCO must therefore ensure that later approvals cannot be used to relax the environmental case examined, transfer harm from one receptor to another or substitute materially different mitigation without appropriate scrutiny.

These principles are not an attempt by BEPS to eliminate legitimate detailed-design flexibility. They are the minimum controls necessary if development consent is to operate on the basis of the Environmental Statement before the Examination.

The Applicant must ultimately be able to demonstrate a clear chain:

assessed effect → relied-upon mitigation → binding DCO mechanism → approval and consultation procedure → monitoring → remedial action → enforcement.

Where that chain is absent, the Environmental Statement's conclusion and the legal control of the authorised development become disconnected. That concern is not theoretical at East Pye. The Planning Inspectorate's own post-acceptance advice has already raised questions concerning the scope of preliminary works, the definitions governing commencement and maintenance, the precision of design parameters and the use of vague qualifiers in documents intended to control the development. The detailed DCO hearing issues identified by BEPS reflect precisely the same problem.

The proper starting position for the remainder of this Preliminary Chapter is therefore that the DCO must authorise no more than the development actually assessed, while securing every measure necessary to keep the development within that assessed case. Where the Applicant cannot demonstrate that correspondence, greater drafting flexibility is not the answer. The power must be narrowed, the control strengthened or, where the uncertainty concerns the acceptability of the development itself, the matter must be resolved before consent is granted.

Part II – Is there a sufficiently defined and deliverable Scheme to which the powers can attach?

P.5 The DCO powers attach to a Scheme whose final form remains materially uncertain

The draft DCO does not attach to a single, fully settled implementation case. Chapter 4 identifies material uncertainty over the relationship between the solar and BESS elements, whether principal Works are mandatory or severable, the final National Grid connection solution, the extent of cable-routing flexibility, the possibility of partial build-out and the sequencing of construction.

That uncertainty is not confined to secondary detail. Norfolk County Council’s LLFA has already identified that supporting infrastructure such as trenching, swales, drainage, services, access,

security measures and private-track improvements is grouped under generic associated-development descriptions rather than clearly allocated to individual Work Nos. It also records inconsistent use of the term “associated development” and uncertainty over what the Applicant means by flexibility in the “arrangement” of major components. Those are matters capable of affecting land take, environmental effects and the scope of statutory powers.

The same problem arises at the grid interface. The Applicant’s own material records that discussions with National Grid remain ongoing concerning the configuration and layout of the proposed National Grid substation and the associated overhead-line reconfiguration, with illustrative material capable of further revision through micrositing and orientation. Chapter 4 also identifies uncertainty over whether Works Nos. 4 and 5 are indispensable components of the Scheme, whether they could be constructed but not used, and what would occur if NGET adopted a different final connection solution.

Construction is similarly not a single fixed operation. The Applicant anticipates a 24-month programme but acknowledges that the programme may vary, while the application does not consistently provide scheme-wide maxima for simultaneous work fronts, compound area, piling activity, haul-road length, dewatering or other construction parameters. That uncertainty matters where different sequencing choices may change the duration, location and cumulative intensity of disturbance and the land required at any particular time.

These matters are analysed in detail in Chapter 4. Their relevance here is narrower: compulsory and statutory powers should not be granted more widely than is necessary for a development whose essential configuration and implementation pathway have been demonstrated.

The Applicant therefore needs to identify the minimum Scheme to which the claimed public benefits and compulsory powers attach, distinguish mandatory from optional Works and explain what powers remain necessary under every realistically permitted implementation scenario. A DCO should not operate as a portfolio of powers from which the undertaker may later select a materially different project.

P.6 Gate 1 BESS and the identity of the Scheme

The solar and storage components do not presently have equivalent connection status. The Applicant’s material records Gate 2 prioritisation for the solar component, whereas the BESS has only Gate 1 status. The Applicant has not demonstrated an equivalent Gate 2 position for the storage element. The DCO hearing material records the position more specifically: solar has Gate 2 Phase 2 prioritisation, whereas the BESS has Gate 1 status and no confirmed indicative connection date. The June 2026 Gate 2 Criteria Methodology materially sharpens that distinction. A project must satisfy both the Gate 2 Readiness Criteria and one Gate 2 Strategic Alignment criterion. For batteries, the potentially relevant routes are protection under Clause 2b, 3a or 3b, ordinary alignment with available CP2030 capacity, or Project Designation. Batteries are within the CP2030 framework and cannot rely upon the separate route for technologies outside CP2030.

On the presently available evidence, East Pye does not appear to satisfy Clause 3a or 3b because its DCO application post-dates the relevant planning cut-offs, and BEPS has identified no qualifying Clause 2b contract or regulatory approval and no Project Designation. Ordinary

CP2030 alignment is itself materially constrained by the existing T7 battery oversupply. The Applicant has therefore not demonstrated which Strategic Alignment route the BESS is expected to satisfy. That is directly relevant to the identity of the authorised development.

East Pye is promoted and environmentally assessed as a combined solar-and-storage Scheme. The BESS forms part of the project description, occupies land, requires associated electrical infrastructure and contributes to the Applicant's claimed flexibility and system benefits. Yet the draft DCO must be tested against what it legally permits if that storage component is delayed, reduced or never progresses beyond Gate 1.

The Applicant should therefore state unequivocally whether the BESS is a mandatory component of the authorised development, an independently severable Work or an optional component which may simply not be constructed. It should also explain whether the solar generating station may lawfully proceed and operate without it, whether the BESS may be constructed years later, and whether the associated electrical and land requirements change in those circumstances.

This is not an argument that Gate 1 status itself prevents development consent. The narrower point is that a component without the same connection certainty as the solar element cannot automatically justify permanent land and statutory powers on the assumption that the integrated Scheme will be delivered exactly as promoted.

That concern is reinforced by the Applicant's own analysis, which accepts that if the BESS is delayed, reduced, omitted or unable to obtain Gate 2 status, the Scheme may in practice operate principally as a 500 MW solar generator. The DCO therefore needs to identify the legal and land consequences of that scenario now.

No compulsory power should be justified by reference to a BESS or associated infrastructure whose need for the particular land interest has not been demonstrated under the implementation scenario actually capable of proceeding.

P.7 Partial implementation and unused statutory powers

The draft DCO must also address what happens where only part of the authorised development is implemented.

Chapter 4 identifies several realistic implementation scenarios: construction of only some solar Sites, solar without BESS, delayed or reduced BESS, omission of some project substations, a different National Grid solution, unused cable infrastructure and prolonged staged implementation. Those scenarios matter directly to compulsory acquisition because the need for land and rights is not necessarily constant across them.

If only some generating Sites proceed, it is not apparent why compulsory powers over land required solely for omitted Sites should continue. If the BESS does not proceed, land and rights required only for BESS infrastructure should not remain available indefinitely. If NGET adopts a materially different connection solution, the Applicant must explain whether land sought for Work No. 4 or related works remains necessary. If cable alignments are refined or particular

corridors become redundant, compulsory powers over unused corridor land should not simply survive because they appeared in the original Order.

The same applies to construction powers. A broad temporary-possession or access power should not remain capable of exercise over land once the Work for which that power was justified has been abandoned or definitively omitted.

The current application structure creates a risk that the DCO confers a wider reserve of land powers than any final version of the Scheme actually requires. That is inconsistent with the principle that compulsory acquisition must correspond to demonstrated need, not future optionality.

BEPS therefore submits that the DCO should include express expiry or release mechanisms. Where a principal Work is not commenced within a defined period, is formally omitted from the approved phasing plan or becomes unnecessary because another connection or design solution is adopted, the associated compulsory acquisition, rights and temporary-possession powers should cease to be exercisable except where separately justified.

Without such a mechanism, partial implementation could leave third-party land burdened by statutory powers for infrastructure that the undertaker no longer intends or is no longer able to construct.

P.8 The Applicant should provide a Scheme-to-powers schedule

The uncertainties identified above can be tested efficiently through a single Scheme-to-powers schedule. The Applicant should be required to provide, for every principal Work and material associated component, a definitive schedule identifying:

- whether the Work is mandatory, optional or severable;
- its present connection and deliverability status;
- the land required for it;
- the property interest or statutory power sought over that land;
- why that particular interest is necessary rather than a lesser one;
- the other Works upon which it depends;
- whether it may proceed independently;
- and whether the relevant land power survives if the Work is not implemented.

The schedule should include at least the solar generating Sites, BESS, project substations, National Grid substation, overhead-line works, cable corridors, access and highway works, habitat land and other land subject to permanent or temporary powers.

This would not create new information. It would force the Applicant to reconcile information currently dispersed across the draft DCO, Works Plans, Land Plans, Statement of Reasons, Book of Reference, Grid Connection material, Design Principles and Environmental Statement.

That reconciliation is necessary because the present application does not consistently identify which Works are indispensable to the Scheme and which merely preserve implementation options. Where the Applicant cannot identify a clear implementation purpose for a Work, it cannot simply assume that the corresponding compulsory power remains justified.

The Scheme-to-powers schedule should therefore be treated as a prerequisite to determining both the adequacy of the draft DCO and the section 122 compulsory-acquisition case.

Part III – Legal plans and certainty of the land and Works authorised

P.9 Inconsistent mapping and legal-plan reliability

The legal plans must provide a reliable geographical definition of the development and the land over which statutory powers are sought. At East Pye, that requirement is not presently satisfied consistently.

Chapter 4 records that the Works Plan and other application figures do not all use the same contemporary mapping baseline. Norfolk County Council's targeted-consultation response identified outdated mapping in relation to additional land areas 8 and 9 because the plans did not show or consider the operational Long Stratton Bypass. The LLFA concluded that the relevant assessment had not been undertaken using the latest available information and required further work.

The inconsistency persists across the application material. BEPS's review records that Figure 4.2 and the Works Plan use a pre-bypass base, while Figure 4.3 uses a more contemporary mapping base. The final Chapter 4 transport material may refer to the Long Stratton Bypass/Parker's Lane roundabout, yet the certified Works Plan still retains the older mapping.

That is not merely a cartographic defect. The Works Plan is one of the central legal instruments defining where numbered Works may be carried out. The bypass altered the physical and highway baseline, movement patterns, access relationships and drainage context. An obsolete map can obscure the relationship between authorised Works and existing highways, cable crossings, access points, receptors and land interests.

The problem is compounded by NCC's identification of inconsistencies between ES Chapter 4 and the Works Plans and by different depictions of infrastructure elsewhere in the application. Where different documents use different geography, the Examining Authority cannot safely assume that the land assessed, the land shown on the Works Plans and the land subject to compulsory powers are identical.

BEPS therefore asks for corrected Works Plans on an up-to-date base, together with confirmation that every environmental assessment and land document has been checked against the same geography. Where correction changes routeing, access, drainage, land take or receptor relationships, the consequential assessment must also be corrected.

The legal plans must define the Scheme that exists in the real landscape, not the landscape as it appeared before material infrastructure was constructed.

P.10 The Works Plans, Land Plans and Book of Reference must reconcile

The problem is not confined to the age of the base mapping. The DCO can safely confer land powers only if the documents defining the Works, plots and powers reconcile with one another.

Chapter 11 already demonstrates the problem in relation to highways. The Applicant is required to reconcile proposed highway interventions against the Order Limits, Works Plans, Land Plans, Streets Plan, Access and PRoW Plans, Book of Reference and draft DCO powers. A passing place, visibility splay, oversail area, vegetation-clearance zone or other intervention cannot be treated as secured if the necessary land or power is absent from the legal documents.

The same principle applies across the whole Scheme. For every numbered Work, the Applicant should be able to demonstrate a direct correspondence between:

- the geographical area shown on the Works Plan;
- the affected plot shown on the Land Plan;
- the ownership or interest recorded in the Book of Reference;
- the power sought in the draft DCO;
- and the development or right actually required.

NCC's LLFA has already identified inconsistencies between the works descriptions in ES Chapter 4 and references on the Works Plans and has called for reconciliation of the narrative description, Table 4.1, Works Plans, Land Plans, Design Principles, draft DCO and Commitments Register. That is strong evidence that reconciliation cannot presently be assumed.

The transport chapter gives a practical example of the form required. It calls for a consolidated schedule identifying for each access or intervention the Work No., Works Plan sheet, Land Plan plot, Streets Plan provision, Access and PRoW Plan reference, Book of Reference entry, landowner, DCO power and environmental assessment reference. That approach should be extended to every material Work involving compulsory acquisition or temporary possession.

Any mismatch matters because the DCO cannot lawfully make missing land appear after consent. Nor should the ExA grant compulsory powers over a plot where the Work said to justify those powers is not clearly and consistently shown.

BEPS therefore submits that a complete plan-and-land reconciliation exercise should be required before the compulsory-acquisition case is determined.

P.11 Plan hierarchy and precedence

The Applicant must also identify which document prevails where the application documents do not align. At present, the Scheme is described and controlled through multiple overlapping instruments: the Works Plans, Land Plans, Design Principles and Parameters, Environmental Statement figures, outline management plans, Schedule 1 works descriptions and other certified documents. NCC's evidence already demonstrates that those documents are not invariably consistent. That creates a legal-control problem.

If a Works Plan permits a wider area than the environmental figure assessed, which governs? If a Design Principle allows flexibility inconsistent with a more precise ES assumption, which prevails? If a final management plan departs from an indicative layout but remains said to be "substantially in accordance with" an outline document, does the plan or the original assessed

assumption control the development? If a Land Plan and Works Plan are inconsistent, which determines the geographical extent of the power?

The answer cannot depend upon the Applicant's intention after consent. The hierarchy must be apparent from the Order itself. This matters particularly because different documents perform different functions. A Land Plan identifies interests and plots; it does not necessarily define the precise physical extent of every Work. An ES figure may describe what was assessed but may not itself limit the statutory power. Design Principles may impose parameters but may also retain flexibility. Unless the Order identifies how those instruments interact, a narrow environmental assumption may be displaced by a broader legal power.

BEPS therefore asks the Applicant to provide an express document hierarchy and conflict provision identifying which certified document controls in the event of inconsistency. As a minimum, the hierarchy must ensure that no wider plan, parameter or later approval can override a more restrictive environmental limit or mitigation commitment relied upon in the ES.

The governing principle should be straightforward: where two certified documents conflict, the provision that affords the greater environmental protection and the narrower authorised envelope should prevail unless the DCO expressly provides otherwise following a justified and assessed change.

Without a clear hierarchy, the Examination cannot be certain that the development ultimately authorised will remain the development actually assessed.

Part IV Compulsory Acquisition and Land Rights: Whether the Applicant Is Seeking More Than the Scheme Requires

P.1 Principal objection

Before the environmental merits of East Pye Solar are considered, there is a more fundamental question about the powers the Applicant asks the Secretary of State to confer over other people's land.

The Applicant seeks compulsory powers across Order Limits extending to 1,212.3 hectares. The draft DCO includes power to acquire all interests in land, including freehold, under Article 21; to acquire new permanent rights under Article 24; to take temporary possession under Articles 31 and 32; and to suspend or override existing rights. The Applicant says that compulsory freehold acquisition is sought over parts of Work Nos. 1, 2, 3, 4, 7, 10 and 11. Work No. 1 is the ground-mounted solar generating station itself.

BEPS' objection begins with a simple question which the Statement of Reasons does not presently answer:

If the Applicant's intended commercial arrangement for the solar fields is a lease for the life of the Scheme, why does it require compulsory power permanently to acquire the freehold of those fields?

That question arises from the Applicant's own evidence. The Statement of Reasons confirms that Option Agreements have already been entered into with the relevant landowners for the Solar PV Sites, BESS, Project Substations and National Grid Substation. More importantly, paragraph 4.1.3 explains why compulsory powers are sought despite those agreements. One of the examples given is the possibility that a freeholder might fail to grant the Applicant a **lease** in accordance with a completed Option Agreement. The Applicant says compulsory powers are therefore required as protection against contracts not being performed or being disrupted by matters such as death, divorce or insolvency.

That evidence indicates that the underlying land bargain contemplated by at least the relevant Option Agreements is leasehold occupation, yet the DCO seeks a statutory power capable of replacing the existing owner altogether through permanent acquisition of the freehold.

The need for a statutory backstop and the need for permanent ownership are not the same thing. The Applicant may have a legitimate interest in ensuring that a project cannot be frustrated by failure to complete a contractual land agreement. But that does not establish that the appropriate statutory response is acquisition of a greater and permanent property interest than the 'temporary' Scheme actually requires.

This distinction goes directly to section 122 of the Planning Act 2008. Compulsory acquisition may only be authorised where the statutory land-purpose condition is satisfied and where there is a compelling case in the public interest for compulsory acquisition. The Applicant itself accepts that the Secretary of State must be satisfied that the land is needed, that no more land is acquired than is reasonably required, that reasonable alternatives to compulsory acquisition have been explored, and that the interference with property rights is necessary and proportionate. Current Government application guidance likewise requires the Statement of Reasons to explain why there is a clear and compelling case for the compulsory powers sought and why that case outweighs the potential private harm to landowners.

Those requirements demand more than proof that the 'temporary' East Pye Solar project needs permanent access to land. They require scrutiny of the **nature and extent of the interest** that the Applicant says it needs. For the solar fields, that scrutiny is presently missing.

P.2 The statutory question is not simply whether the Scheme needs land

The Applicant's Statement of Reasons correctly identifies the section 122 test and states that compulsory powers must be necessary, proportionate and no more extensive than reasonably required. It also accepts that there must be a clear idea of how the land is to be used, that reasonable alternatives must have been explored, and that the public benefits must outweigh private loss.

BEPS does not dispute that a 60-year solar project requires secure land control. The Applicant would plainly require sufficiently durable arrangements for construction, operation, replacement, maintenance, access and eventual decommissioning. That does not answer the present objection.

There are two separate questions. The first is whether the Scheme requires control of a particular parcel. The second is what legal interest in that parcel is actually required to provide

that control. A need to occupy land for a defined operational period does not automatically establish a need to own it permanently. A need to run a cable does not automatically require ownership of the surface. A need to maintain habitat does not automatically require the freehold. A need to preserve access does not automatically require permanent acquisition of the underlying land.

The Applicant itself implicitly recognises this distinction because the draft DCO contains a graduated range of powers: permanent freehold acquisition, acquisition of new rights and restrictions, subsoil rights and temporary possession. It further states that freehold acquisition has only been included where lesser powers would not be 'sufficient or appropriate'. That is therefore an assertion the Applicant must prove, not a conclusion the Examination should assume.

For each area of solar-field land over which Article 21 freehold powers are sought, the Applicant should demonstrate precisely why a lesser land interest would not secure the authorised development for its entire life.

P.3 Compulsory freehold powers materially alter the bargaining position in ongoing land negotiations

There is a further and more immediate proportionality concern. The Applicant is not merely seeking compulsory powers as a remote contingency after voluntary negotiations have failed. It is continuing to negotiate land agreements while simultaneously asking the Secretary of State to confer powers capable of compulsorily acquiring the freehold of the same land. That fact materially changes the bargaining position between the Applicant and affected landowners.

The Applicant's Statement of Reasons is explicit. It states that Option Agreements have already been entered into with relevant landowners for the Solar PV Sites, BESS, Project Substations and National Grid Substation, but that negotiations concerning land and rights remain ongoing. It says compulsory powers are nevertheless required even where agreement has been reached because, for example, a freeholder might not grant the lease required by the completed Option Agreement. In that event, the Applicant says it would be in the public interest for the Scheme to proceed and for the affected interests to be 'effectively converted into a claim for compensation'.

That is a significant statement. It means that a landowner negotiating the final terms of occupation is doing so in the knowledge that, if agreement is not reached or the contractual arrangements fail, the Applicant is seeking a statutory power not merely to secure the lease contemplated by the bargain but potentially to acquire the underlying freehold.

The Government's compulsory-purchase guidance expressly recognises the leverage inherent in that process. It permits compulsory-acquisition procedures to proceed in parallel with voluntary negotiations and observes that commencement of the formal process makes the seriousness of the acquiring authority's intentions clear and can encourage affected owners to enter more readily into negotiations. Once compulsory powers have been confirmed, the Government's public guidance states even more plainly that negotiations may continue in the

knowledge that, if they fail, the acquiring authority can secure ownership through compulsory acquisition.

BEPS does not suggest that parallel negotiations are unlawful merely because compulsory powers are being pursued. The statutory system expressly contemplates them. The concern at East Pye is more specific: **the bargaining leverage being sought appears potentially wider than the property interest which the Applicant's own commercial arrangements require.**

If the contemplated voluntary transaction is a 60-year temporary or similar project lease, the landowner's negotiating position should ordinarily concern the terms on which that temporary interest is granted: rent, indexation, access, liability, agricultural use, succession, restoration, decommissioning, taxation, insurance, environmental obligations and the condition in which the property will ultimately be returned.

Those negotiations are materially altered if the Applicant is simultaneously able to say, in substance, that failure to agree can result instead in permanent acquisition of the landowner's freehold and substitution of a statutory compensation claim.

A landowner deciding whether to accept a lease amendment, revised rent provision, decommissioning covenant, access right or other contractual term is not negotiating from the same position if refusal may expose the entire freehold interest to compulsory acquisition. The Examining Authority should therefore scrutinise whether the breadth of the compulsory powers sought is itself exerting leverage beyond that justified by the Scheme's actual land requirements.

The issue becomes especially important because the Applicant's own documents indicate that leasehold arrangements are expected where the Option Agreements operate normally. If the lease is sufficient where a landowner agrees voluntarily, the Applicant must explain why a substantially greater interest—the permanent freehold—is necessary merely because agreement is not ultimately reached. A compulsory-acquisition power should not be used to improve the Applicant's bargaining position beyond what is necessary to deliver the authorised development.

The current Planning Act application guidance requires the Applicant's Statement of Reasons to explain why the particular compulsory powers sought are necessary and proportionate, why there is a clear and compelling public-interest case for them, how that case outweighs private harm, and why the powers sought over each identified plot are justified. Those requirements become particularly important where the powers themselves materially affect the negotiations through which the Applicant says it is attempting to avoid compulsory acquisition.

The Examination should therefore establish not merely whether negotiations are continuing, but **what is being negotiated and against what compulsory alternative**.

For each solar-field landowner, the Applicant should identify whether the voluntary transaction contemplated is a lease, a freehold sale, permanent rights or some combination of interests; whether the form of transaction has changed since the Option Agreement was signed; and whether the Applicant has told the landowner that compulsory freehold acquisition may be pursued if agreement is not reached. It should also explain whether the commercial terms

currently being negotiated would be different if the DCO authorised only compulsory acquisition of the leasehold or other rights actually required to operate the Scheme.

This is relevant to the weight the Examination should give to subsequently concluded agreements. An agreement reached while the land is subject to proposed compulsory acquisition powers cannot simply be treated as evidence that the breadth of those powers was therefore uncontroversial or unnecessary to examine. Government guidance itself recognises that the existence of the compulsory process provides leverage which encourages agreement.

That is especially so here because the alternative confronting the landowner may not be equivalent to the voluntary bargain. The voluntary bargain appears, from the Applicant's own Statement of Reasons, to contemplate a lease. The compulsory alternative potentially permits acquisition of the freehold. The ExA should therefore require the Applicant to answer a basic question:

Why should a landowner negotiating a temporary lease for a temporary solar development have the permanent loss of the freehold hanging over those negotiations if permanent ownership is not actually necessary to construct, operate and decommission the Scheme?

Until that question is answered, it cannot safely be concluded that the freehold powers are the minimum proportionate interference with private property rights.

P.4 The Applicant must explain what happens to the landowner's contractual bargain if freehold powers are exercised

The relationship between the Applicant's Option Agreements and the compulsory powers also requires clarification because the economic consequences are potentially very different.

Under the voluntary model apparently contemplated by the Applicant's own Statement of Reasons, the landowner remains the freeholder and grants the Applicant a lease. Unless the actual agreements provide otherwise, the obvious commercial structure is therefore one in which the owner retains the reversionary title and receives the contractual consideration associated with the lease during the project period.

If the Applicant instead compulsorily acquires the freehold, that is a fundamentally different transaction. A general vesting declaration can transfer title itself to the acquiring authority. Government guidance confirms that compulsory acquisition can acquire existing freehold or leasehold interests and that compensation is then assessed under the compulsory-purchase compensation code. The overriding principle is financial equivalence, with compensation generally based upon the value of the interest taken together with any applicable disturbance, loss, severance or injurious-affection claims.

What is not clear from the East Pye Statement of Reasons is how that statutory compensation outcome interacts with the Applicant's existing Option Agreements. If the freehold is compulsorily acquired before the contemplated project lease is granted, is the landowner still entitled to the contractual stream of lease payments which would otherwise have been received over the Scheme's operational life? Is the option agreement terminated, overridden or

otherwise modified? Is loss of the contractual bargain separately compensatable? Is any compensation assessed by reference to the agricultural freehold in the statutory 'no-scheme' world rather than by reference to the solar lease consideration? Does the Applicant intend the option agreement itself to prescribe what happens upon exercise of compulsory powers?

Those questions cannot responsibly be answered without the actual contractual terms. The Applicant should answer them. Its Statement of Reasons says only that, in the event described, the landowner's interests would effectively be converted into a claim for compensation. That formulation conceals a potentially profound economic difference between the two outcomes. A landowner who expected to remain owner of the land, receive lease income throughout the operational period and recover unencumbered possession at the end of the lease may instead lose the freehold permanently in return for a compensation claim assessed under a different statutory regime. The ExA should know whether that is genuinely possible under this DCO before authorising the power.

BEPS is not required to establish what each confidential Option Agreement provides. The burden lies on the Applicant to demonstrate that the powers it seeks are necessary and proportionate. It should therefore disclose sufficient information about the standard commercial structure to enable the Examination to understand the consequences of compulsory acquisition without requiring publication of commercially sensitive individual rents.

P.5 Decommissioning makes the distinction between leasehold and freehold still more important

There is no general rule under which a solar-field freehold acquired compulsorily automatically revests in its former owner when the authorised solar development ends. The Crichel Down Rules do not provide such a mechanism. They are non-statutory arrangements principally concerning surplus government land. Where they apply, the normal principle is an opportunity for the former owner to **repurchase** qualifying surplus land, not automatic restoration of title. The Rules are recommended to local authorities and statutory bodies and are only commended in certain private-sector circumstances.

There is an additional problem specific to East Pye's proposed duration. Under the current Rules, the general offer-back obligation does not apply to agricultural land acquired on or after 30 October 1992 where the land becomes surplus and available for disposal more than **25 years after acquisition**. East Pye proposes a 60-year operational period. Accordingly, even if the Crichel Down Rules were applicable to this private project company – which should itself be established rather than assumed – the ordinary 60-year operating period would appear to extend far beyond the general 25-year offer-back horizon.

That makes it unsafe for the Application or the Examination to assume that compulsory freehold acquisition is compatible with a straightforward 'return of the land' after decommissioning. A lease provides an obvious legal reversion. At expiry, subject to its terms and any continuing statutory rights, the underlying ownership has remained with the landlord throughout. Compulsory acquisition of the freehold does not.

If East Pye Solar Limited or a successor owns the freehold at the end of the Scheme, the Examination needs to know what obliges that owner to transfer the land to the former freeholder or their successors, on what terms, at what price and in what condition. If there is no such mechanism, then 'restoration to agriculture' and 'return to the landowner' are entirely different propositions.

This creates several material decommissioning risks. Ownership of the land may have passed through a series of project companies or financiers over 60 years. The original owners may have died and their farming businesses may have reorganised. Boundaries, drainage systems and access arrangements may have changed. Some land may contain permanent biodiversity mitigation, woodland or infrastructure. Other areas may have become fragmented from the retained farm holding. The entity responsible for decommissioning may not be the entity which originally acquired the land.

The Applicant therefore needs to identify the intended legal end-state now. If its case is genuinely that the solar fields will be leased for the project period and returned to their owners following decommissioning, the DCO should be structured consistently with that proposition. If permanent freehold acquisition is to remain possible, the Applicant must explain what happens to those freeholds after the authorised use ends and why permanent deprivation of the former owner's reversionary interest is necessary in the first place.

P.6 Other solar NSIPs demonstrate that permanent freehold acquisition is not inherent to large-scale solar

The comparative evidence reinforces the need for an explanation. The SolarQ analysis supplied to BEPS examines 20 ground-mounted solar NSIP proposals. It categorises 17 as involving compulsory freehold acquisition of the solar fields and three—Byers Gill Solar, Helios Renewable Energy and Little Crow Solar—as seeking only compulsory acquisition of rights in the land of the solar fields. Those three schemes account for approximately 1,178 hectares in the analysis.

BEPS does not put that paper forward as legal authority, nor does it assume that every provision of those other DCOs is identical to East Pye Solar. Individual land arrangements and powers require examination on their own terms. The comparative evidence nevertheless establishes an important practical point. **Permanent ownership of every solar field is not an inherent technical requirement of NSIP-scale solar generation.** Large solar projects can and are structured around leasehold occupation, and compulsory acquisition powers for only for rights in the solar fields not freehold acquisition.

That is enough to require a project-specific explanation from East Pye Solar. The relevant question is not whether other solar promoters have also sought freehold powers; many plainly have. The question is why East Pye Solar needs permanent ownership when leasehold arrangements are demonstrably capable of supporting major solar development and when East Pye's own completed Option Agreements themselves appear to contemplate leases. They should also explain why they are seeking compulsory powers to acquire the leaseholds rather than simply rights in the land as a backstop.

The SolarQ evidence should therefore prompt the Applicant to explain, with reference to the actual terms and requirements of this Scheme, why East Pye falls on the freehold side of that distinction. An assertion that freehold acquisition is 'appropriate' cannot substitute for that evidence.

P.7 The Applicant must distinguish project necessity from commercial convenience

There may be obvious commercial attractions in owning land rather than leasing it. Freehold ownership can provide a developer or successor owner with greater flexibility. It may remove the need to administer long-term landlord and tenant relationships. It may simplify refinancing, sale, restructuring, repowering or future project changes. It may also give the project owner greater control over the land after the authorised solar use has ended. Those considerations may explain why permanent ownership is commercially attractive. They do not establish that it is required for the authorised development.

The statutory compulsory-acquisition case concerns the land interests necessary for the Scheme for which development consent is sought. Section 122 does not turn commercial preference into public necessity. The statutory test remains whether the land is required for the relevant development and whether there is a compelling case in the public interest for compulsory acquisition.

This distinction is especially important at East Pye because the Applicant has built flexibility into the DCO application itself. Its Statement of Reasons says that some detailed design cannot yet be confirmed, that future technology may differ from that currently available, and that flexibility is considered essential to successful delivery. That engineering flexibility should not become an unexamined justification for equally broad property powers.

The DCO should confer the land interest necessary to implement the assessed and authorised Scheme. It should not confer permanent ownership merely because permanent ownership would maximise the Applicant's future commercial options.

P.8 The Applicant's own alternatives evidence makes the inconsistency sharper

There is a further inconsistency in the Applicant's approach to compulsory acquisition. Chapter 5 records that the Applicant identified potentially suitable land closer to the final Point of Connection which could have reduced cable length, disruption to residents and businesses, environmental disturbance and cost. Those areas were not treated as reasonable alternatives because the land had not been made available to the Applicant. The Applicant expressly stated that, without willing landowners, compulsory acquisition would have been necessary and that it had sought to avoid that 'as far as practicable'. Landowner willingness therefore played a material role in defining the selected Scheme.

That makes the present freehold case particularly important. The Applicant relied upon willing landowners and voluntary agreements when deciding which land should form the Scheme, yet

it now seeks powers capable of permanently acquiring freeholds within that selected land package notwithstanding completed Option Agreements which appear to contemplate leases.

The Examination should not allow those two stages to blur into one another.

Landowner willingness may explain how the land package was assembled. It does not establish that the Applicant needs permanent ownership of that land. Nor can the proposition that compulsory acquisition elsewhere was undesirable be reconciled without explanation with a request for Article 21 freehold powers over participating solar-field land here.

P.9 The Statement of Reasons does not yet demonstrate why lesser powers are insufficient for Work No. 1

Work No. 1 is the NSIP itself: the ground-mounted solar photovoltaic generating station, including solar modules, mounting structures, electrical infrastructure and associated cabling. The Applicant confirms that compulsory freehold powers are sought over parts of Work No. 1. It simultaneously seeks permanent new rights and restrictions under Article 24 and temporary-possession powers under Articles 31 and 32.

The Statement of Reasons says that freehold has been sought only where those lesser powers are insufficient or inappropriate. It does not, in the material presently identified by BEPS, explain with sufficient specificity why they are insufficient for the ordinary solar-field component of Work No. 1.

Solar modules do not themselves require ownership of the legal estate in the land beneath them. The technical question is whether the Applicant can obtain sufficiently secure possession and control for the authorised operational period, together with the rights needed for construction, access, maintenance, replacement and decommissioning. The Applicant's existing Option Agreements appear already to contemplate leases capable of providing that fundamental possession. The draft DCO separately provides mechanisms for permanent rights and restrictions.

The Applicant should therefore identify the specific function which requires permanent freehold ownership of each Work No. 1 plot. If no such function exists, Article 21 powers over that plot are wider than the Scheme has demonstrated it requires. This is not a minor drafting issue. Work No. 1 comprises the land on which the generating station itself is spread across South Norfolk. The distinction between securing temporary project occupation and permanently extinguishing the landowner's title is potentially substantial.

This is especially important given the response by NGET in its relevant representation: there is no requirement for East Pye Solar to obtain the land for a National Grid Substation through compulsory acquisition, and NGET has yet to confirm where the location of any new substation will be.

P.10 Contractual risk does not, without more, justify acquisition of a greater interest

The Applicant's concern about contractual failure is understandable. A major infrastructure project cannot sensibly depend upon every private agreement remaining immune from dispute or unforeseen events over a lengthy delivery programme.

But the answer must remain proportionate to the risk.

If the risk is that a landowner who has contracted to grant a lease fails to do so, the Applicant should explain why the necessary statutory protection cannot be confined to the interest and rights required to put the Scheme in substantially the same operational position as performance of the agreed land arrangement would have achieved.

It is not self-evident why breach of an agreement to grant a lease should result in the Applicant acquiring a permanently larger interest in the property.

The Statement of Reasons also cites death, divorce and insolvency as examples of events which may disrupt contractual arrangements. Again, those matters may justify having compulsory powers available. They do not answer the separate question of what those powers should permit the Applicant to acquire.

A statutory backstop should secure delivery of the authorised development. It should not confer an unexamined windfall in the form of a greater land interest merely because the voluntary route failed.

The Applicant should therefore disclose, at least in sufficiently clear summary form to permit Examination, the landholding outcome contemplated by its Option Agreements and the materially different outcome permitted by Article 21.

P.11 Compensation does not answer the necessity objection

The Statement of Reasons repeatedly relies upon the fact that compensation is payable where compulsory powers are exercised.

That does not resolve this objection.

Compensation addresses the financial consequences of a compulsory acquisition which is otherwise justified. It does not establish that the particular interest acquired was necessary in the first place.

The question must be asked in the opposite order.

First, what interest is actually necessary to construct, operate, maintain and decommission East Pye? Secondly, is there a compelling case in the public interest for compelling the landowner to surrender that interest? Only then does compensation address the financial consequences of the acquisition.

It would be circular to justify an unnecessarily extensive property power by pointing out that the landowner can subsequently claim compensation for losing the property.

That is particularly important where the distinction is between a finite land interest consistent with a 60-year project and permanent loss of the freehold.

P.12 Other categories of land require the same interest-specific scrutiny

The solar fields present the clearest issue, but the same principle applies across the DCO.The Applicant seeks freehold powers over parts of Work No. 2, the BESS; Work No. 3, project substations; Work No. 4, the National Grid Substation; Work No. 7, security, landscaping and ancillary works; Work No. 10, habitat-management land; and Work No. 11, permissive paths and community-accessible space. Those uses do not all have the same landholding requirements.

A permanent electrical substation may present a different case from a solar field. A habitat-management parcel presents a different case again. A permissive path does not obviously require the same estate as major electrical infrastructure. Ecological mitigation may require long-term control, but long-term control and permanent ownership are not synonymous.

Indeed, the Applicant itself seeks new rights and restrictive covenants for parts of Work Nos. 1, 5, 6, 7, 9 and 10. That demonstrates that the DCO already recognises rights-based solutions as capable of securing important elements of the Scheme.

The Statement of Reasons should therefore not aggregate these materially different uses behind a general assertion that freehold is required. The justification must identify why the particular interest sought is the minimum sufficient interest for the particular purpose.

For Work No. 10 habitat-management land, for example, the Applicant should explain why long-term ecological management cannot be secured through an appropriate lease, covenant, management right or restriction. For Work No. 11, it should explain why provision of permissive paths or community-accessible space requires freehold acquisition where defined public-access and maintenance rights might achieve the stated purpose.

The same principle applies throughout: **control necessary for the Scheme is not automatically ownership necessary for the Scheme.**

P.13 National Grid land and the unresolved connection solution

The compulsory-acquisition case for the proposed National Grid Substation is materially undermined by NGET's own Relevant Representation. The Applicant has included land within the Order Limits for Work No. 4, works in connection with a new National Grid substation, and Work No. 5, works in connection with connection to the existing 400 kV overhead transmission line. It also seeks compulsory-acquisition powers over land and rights associated with those

Works. NGET records that the Applicant's original July 2023 connection agreement required the Applicant to identify a location for the National Grid Substation, provide the necessary land and secure planning or development consent. NGET expressly explains that this was the basis upon which the present DCO application came to include compulsory acquisition of the land and powers required for the substation.

That position has now materially changed. NGET states:

'It is important to note in this context that it is NGETs understanding that the new connection agreement will not include the requirement for the Applicant to secure land or consent for the National Grid Substation.'

That statement goes directly to the necessity of the compulsory powers sought. The factual premise relied upon to justify compulsory acquisition of that land has therefore materially altered. NGET expressly warns that grant of consent for the National Grid Substation would not oblige NGET to use it:

'For the avoidance of doubt, should the Applicant receive consent for the National Grid Substation as part of the Order, this does not trigger or constitute any obligation for NGET to accommodate any connection to the national grid at such a substation.'

NGET states that the wider regulatory and commercial position must still be worked through before the location of the new substation can be confirmed. It states that the final size, design and location of the point-of-connection solution will be influenced by the final Gate 2 offers and that, until those offers have been finalised, 'NGET cannot confirm what that solution will be'.

Those are unusually important statements from the statutory undertaker that would design and construct the National Grid Substation.The position is therefore not merely that detailed engineering remains to be completed. Three more fundamental matters remain unresolved:

- the Applicant may no longer be contractually required to secure the substation land or consent;
- NGET has not confirmed that the substation solution authorised by the DCO will be the solution ultimately adopted; and
- even if the DCO authorises the proposed substation, NGET expressly states that this creates no obligation upon it to accommodate East Pye through that substation.

Chapter 4.5–4.7 addresses the resulting scheme-definition and deliverability consequences in detail. The compulsory-acquisition consequence is narrower but particularly serious.

Section 122 requires a compelling case in the public interest for land to be acquired compulsorily. A power permanently to acquire land cannot properly be justified merely because the land may prove useful under one possible future transmission solution. The Applicant must demonstrate that the particular land interest is required for the development for which consent is sought. At present that causal chain is broken.

The Applicant originally sought the land because its connection agreement required it to provide the land for a particular National Grid solution. NGET now says the replacement agreement is not expected to impose that obligation and that the final connection solution itself

remains unconfirmed. In those circumstances, the Applicant must establish afresh why it requires compulsory powers over the Work No. 4 land at all.

It is not sufficient to argue that obtaining the land would preserve flexibility for NGET. System flexibility and compulsory-acquisition necessity are different concepts. NGET has its own statutory responsibilities and mechanisms for acquiring or securing land required for transmission infrastructure. The Applicant must explain why East Pye Solar Limited itself needs permanently to acquire the freehold of land for infrastructure which NGET may ultimately own, design, construct and operate, particularly when NGET itself says that the new connection agreement is not expected to require East Pye to secure that land. That raises a series of questions which should be answered before compulsory powers are granted.

The Applicant should identify whether it still has any contractual obligation to acquire the National Grid Substation land; who would own that land if Article 21 powers were exercised; whether and on what terms it would subsequently be transferred to NGET; whether NGET actually requires East Pye to acquire the freehold; whether rights rather than freehold would suffice; and what happens to the land and the compulsory powers if NGET adopts a different point-of-connection configuration.

Most importantly, the Applicant should explain why the Secretary of State should authorise compulsory acquisition now when the prospective operator of the infrastructure cannot yet confirm that the authorised solution will be used.

NGET's Relevant Representation does not merely raise a request for drafting protection. It removes an important part of the Applicant's original necessity case. NGET states that the replacement connection agreement is not expected to require East Pye to secure the land or consent for the National Grid Substation and that the final point-of-connection solution cannot yet be confirmed. BEPS therefore submits that compulsory freehold powers for the National Grid Substation land should not be recommended unless the Applicant produces clear evidence, supported by NGET, demonstrating that the particular land and the particular interest sought are genuinely necessary for a confirmed connection solution.

If NGET does not require East Pye to acquire the land, and if NGET has not confirmed that the proposed substation will be the final solution, the Applicant has not presently established why East Pye should be given compulsory powers to acquire it. The proper approach is not to authorise the widest land powers as insurance against whatever transmission solution may later emerge. The connection solution should determine the land requirement; the land power should not be granted first in order to preserve an unresolved connection option.

P.14 National Gas and other statutory undertaker interests

The same principle applies to existing statutory-undertaker land, apparatus and rights elsewhere within the Order Limits. Chapter 4.8 addresses in detail the interaction between the Scheme and National Gas Transmission infrastructure, including the FM05 Yelverton–Stowmarket high-pressure gas transmission pipeline, associated cathodic-protection infrastructure, easement requirements, access tracks, cable crossings, drainage, landscaping and the Applicant's proposed compulsory powers. Those matters need not be repeated here.

Their relevance to the compulsory-acquisition case is straightforward. Compulsory powers should not be granted in a form capable of extinguishing, overriding or materially interfering with operational statutory-undertaker rights and apparatus unless the necessity for that interference has been demonstrated and adequate protective provisions are secured.

That principle is confirmed by NGET's own Relevant Representation. NGET identifies numerous plots over which the Applicant seeks freehold, permanent or temporary rights notwithstanding existing NGET rights and apparatus. It states that its rights of access to inspect, maintain, renew and repair its infrastructure must be maintained at all times and that, where the Applicant seeks to acquire land or rights or interfere with existing or future NGET interests, "appropriate protection" is required.

NGET accordingly requires protective provisions under which the Applicant must obtain NGET's prior written consent before exercising compulsory powers over NGET land, rights or apparatus. It also records that further discussion and agreement with the Applicant remain necessary.

That evidence illustrates the wider problem. The DCO seeks coercive powers now while the detailed terms upon which those powers may safely interact with nationally important infrastructure remain unresolved.

The same concern applies to National Gas Transmission. Where the Scheme crosses or approaches the high-pressure gas main, associated easements and access requirements, the Applicant must demonstrate that the proposed Works, land rights and compulsory powers are compatible with the continuing safe operation, inspection, maintenance and emergency access requirements of that infrastructure.

Protective provisions are therefore not an administrative matter to be tidied up after the principle of the powers has been accepted. They are part of the evidence required to establish that the powers can lawfully and safely be exercised.

Where the statutory undertaker has not agreed the protection required, the ExA should not assume that agreement will inevitably follow. Nor should powers capable of overriding existing rights be granted merely because the Applicant expects commercial negotiations to succeed during or after Examination.

BEPS therefore submits that, before the relevant compulsory powers are recommended, the Applicant should identify every unresolved statutory-undertaker interaction, the plots and Works concerned, the rights potentially affected, the current status of protective provisions and whether the relevant undertaker agrees that the proposed development can proceed on the terms contained in the draft DCO.

Until those protections are settled, unresolved statutory-undertaker interfaces weaken both the deliverability case and the proposition that the compulsory powers sought are presently necessary, proportionate and safe to confer.

P.15 The human-rights analysis must address the intensity of the interference

The Applicant accepts that Article 1 of the First Protocol to the ECHR is engaged and that the draft DCO has the potential to interfere with the property rights of persons whose land or interests are acquired. It concludes that the interference is justified because the Scheme would produce very significant public benefits and because the powers are said to be necessary and proportionate.

That conclusion depends upon the very question BEPS raises.

Proportionality cannot be assessed solely by asking whether some interference with property rights is justified. The nature and extent of the interference matter.

Permanent loss of a freehold is materially different from granting defined rights or surrendering possession for the operational life of a project while retaining the underlying title.

Where the public purpose can be achieved through a materially less intrusive property interest, that is plainly relevant to whether the wider interference has been justified. The Applicant's own compulsory-acquisition guidance recognises the need for the interference with affected rights to be necessary and proportionate.

The human-rights analysis therefore cannot simply assume the necessity of Article 21 and then conclude that Article 21 is proportionate.

It must demonstrate why the lesser interference would not work.

P.16 The compulsory-acquisition objection stands independently of the wider need case

BEPS addresses the Applicant's wider need case in Chapter 1. That chapter explains why generic national renewable-energy policy, Gate 2 status, commercial optionality and possible future attrition do not demonstrate an unmet T7 requirement which East Pye itself is required to fill.

That issue is relevant to the second limb of the compulsory-acquisition case because the strength of the specific public benefit claimed for East Pye necessarily informs whether there is a compelling case in the public interest for taking private land. But the present objection does not depend upon Chapter 1 being accepted.

Even if the Examining Authority were to assume for present purposes that East Pye should be built, a separate question would remain:

Why must the Applicant own these solar fields permanently in order to build it?

The Statement of Reasons does not answer that question by referring to national renewable-energy need. National policy may bear upon the desirability of generating electricity. It does not establish the form of property interest necessary to place panels on a field for 60 years. The distinction should be maintained rigorously.

The Applicant must first establish the minimum land interest required to deliver the Scheme. Only then can the wider public-interest balance be applied to the compulsory taking of that interest.

P.17 The Applicant should be required to state its intentions unequivocally

The present Application leaves an avoidable ambiguity over one of the most serious powers contained in the draft DCO.

The Applicant should therefore be required to state unequivocally whether it actually intends the ordinary solar-field land to be held under long leases pursuant to the completed Option Agreements or whether it intends, or wishes to preserve the ability, to acquire those freeholds permanently.

If leases are intended, the Applicant should identify their duration and explain why the DCO cannot be confined to the lesser statutory rights required to guarantee delivery and remove third-party impediments.

If compulsory freehold acquisition is genuinely contemplated, the Applicant should identify the affected plots and explain, plot by plot, why ownership is required rather than leasehold occupation or lesser rights.

The Applicant should also explain what happens at decommissioning to any solar-field freehold acquired compulsorily. If the stated end-state is restoration to agricultural use, the Examination should understand who will then own the land and why permanent transfer of ownership was necessary to achieve a development whose principal solar use has ended.

Those questions should be answered before compulsory powers are authorised, not after consent when the Applicant decides which powers it wishes to exercise.

P.18 The comparative evidence makes a generic answer inadequate

SolarQ's analysis is particularly useful because it removes any basis for assuming that the answer is self-evident.

Its sample includes projects promoted through different landholding models. It identifies 17 projects characterised as seeking freehold possession and three characterised as leasehold schemes.

That does not mean East Pye must adopt the model used at Byers Gill, Helios or Little Crow.

It does mean the Applicant must explain why it cannot.

The question is especially compelling because East Pye's own documents already point towards a leasehold model. The Applicant is not being asked to adopt an unfamiliar mechanism imported from another project. Its Statement of Reasons itself describes completed Option Agreements under which freeholders are expected to grant leases.

The issue is therefore internal to the Applicant's own case.

Why is a lease sufficient when the landowner performs the Option Agreement, but permanent acquisition of the freehold potentially necessary when the landowner does not?

Unless there is a substantive project reason for that distinction, the difference appears to arise from the breadth of the statutory remedy sought rather than from the physical requirements of the solar farm.

That is precisely the kind of issue the necessity and proportionality tests are intended to expose.

P.19 Overall conclusion

The compulsory-acquisition case should not be approached on the basis that, because East Pye requires land, every land power in the draft DCO follows.

The Applicant seeks a sophisticated hierarchy of powers ranging from temporary possession and permanent rights to outright freehold acquisition. It therefore has both the ability and the obligation to distinguish between different levels of interference.

Its own evidence shows that Option Agreements are already in place for the Solar PV Sites and that those agreements contemplate freeholders granting leases. Its own environmental case describes the principal solar use as having a 60-year operational life followed by decommissioning. Its own Statement of Reasons says that freehold acquisition is sought only where lesser interests would be insufficient. Yet the DCO seeks Article 21 powers over parts of the solar generating land without presently providing a convincing explanation of why leasehold occupation and appropriately framed rights cannot secure that same temporary development.

The independent SolarQ comparison reinforces the point by identifying other large solar NSIPs proceeding on leasehold models.

The issue is therefore not whether East Pye needs land. It plainly does.

The issue is whether it needs **this degree of ownership**.

The Applicant has not yet demonstrated that proposition.

That failure is especially serious because compulsory acquisition is not a planning convenience. Section 122 requires a compelling case in the public interest for the land to be acquired compulsorily. The existence of a public purpose does not dispense with the need to justify the extent of the private interest taken.

BEPS therefore submits that the ExA should not recommend the Article 21 powers over solar-field land in their present form unless and until the Applicant has identified its intended landholding model, disclosed the substantive basis on which its existing Option Agreements require leases, and demonstrated plot by plot why a lesser interest would be insufficient.

Where a long lease and defined rights can secure construction, operation, maintenance and decommissioning for the full life of the Scheme, permanent acquisition of the underlying freehold has not been shown to be necessary.

Where the Applicant says it has no present intention of acquiring the freehold, that is not an answer. It is a reason to question why the power is sought.

Where it does intend to acquire the freehold, it should say so plainly and justify it.

The DCO should confer no greater property power than the authorised development demonstrably requires. On the Applicant's present evidence, that fundamental test has not yet been met.

P.20 Remedy sought

BEPS asks the Examining Authority to require, before the close of Examination, a revised compulsory-acquisition justification which distinguishes land occupation from land ownership and identifies, for every plot subject to Article 21, why permanent freehold acquisition is necessary rather than leasehold occupation, permanent rights, restrictions or temporary possession.

That revised case should state expressly whether the Applicant intends to acquire solar-field freeholds or to operate through the leases contemplated by its Option Agreements; identify the circumstances in which Article 21 would actually be exercised; explain the post-decommissioning ownership position; distinguish the land requirements of Work No. 1 from those of the BESS, substations, habitat land and community land; and reconcile the compulsory powers sought for the National Grid infrastructure with NGET's current position on the final connection solution.

If the Applicant cannot demonstrate why freehold acquisition is required for a particular parcel, the freehold power over that parcel should be removed and replaced, where genuinely necessary, with the minimum lesser rights sufficient to deliver the authorised Scheme.

The Secretary of State should not be asked to grant permanent compulsory ownership merely as insurance against contractual failure, for commercial convenience, or to preserve future optionality.

The power sought must follow the demonstrated need for the land interest. The Applicant cannot reverse that sequence by seeking the widest power first and deciding later how much of it it actually needs.

P.21 Confidentiality and non-objection obligations: landowners must remain free to participate

The Examination should establish whether any East Pye Option Agreement, lease, heads of terms or related land agreement contains confidentiality, non-objection or other provisions capable of restricting a landowner's participation in the DCO process. BEPS does not assert that such provisions exist at East Pye. The point is that, because the Applicant relies upon voluntary land agreements and the apparent absence or resolution of landowner objections as part of its land and compulsory-acquisition case, that freedom should be demonstrated rather than assumed.

The issue is not ordinary commercial confidentiality. There may be legitimate reasons to protect rents, option payments and other commercially sensitive terms. The concern is different: any provision which prevents or discourages a landowner from objecting to the Scheme, making a Relevant or Written Representation, appearing at a hearing, commenting on compulsory acquisition, providing factual evidence about the land, or communicating environmental or land-use concerns to the Planning Inspectorate or statutory bodies.

That question is particularly legitimate because another Island Green Power project, Lime Down Solar Park, attracted public controversy in 2025 over arrangements reported to contain a condition requiring affected landowners not to object and to withdraw existing objections. Island Green Power subsequently acknowledged that the wording should not have been included and stated that affected landowners remained free to make representations. That episode does not establish that comparable provisions exist at East Pye, but it makes the issue one which should be answered expressly.

The point is also material because East Pye Solar has evolved substantially since many land agreements may first have been entered into. The final application includes extensive solar development, BESS, multiple substations, National Grid infrastructure, cabling, access works, habitat land and compulsory-acquisition powers across approximately 1,212 hectares. A landowner who originally agreed an option or prospective lease may now face materially different infrastructure, access, drainage, environmental or compulsory-acquisition consequences. Agreement to an option is not necessarily agreement to the final DCO.

That is especially important where the voluntary bargain may contemplate a lease but the DCO seeks compulsory freehold acquisition. A participating landowner may have

relevant evidence about whether permanent acquisition was ever contemplated, the effect on the farm holding, severance, drainage, private water supplies, soils, access, local ecology or decommissioning. Such evidence is directly relevant to the Examination and must not be inhibited by private contractual terms.

The Applicant's own Statement of Reasons relies upon engagement with affected persons, voluntary agreements and continuing negotiations as part of its compulsory-acquisition case. Those matters can only be given proper evidential weight if participating landowners remain free to express concerns. Silence should not be treated as evidence of support if contractual provisions may have influenced that silence.

BEPS therefore asks the ExA to require the Applicant to confirm whether any East Pye Solar land agreement has at any time contained provisions which prevent or discourage objection, require support or withdrawal of representations, restrict participation in the Examination, make payments conditional upon non-objection, impose financial consequences for objecting, or restrict disclosure of information relevant to the planning or compulsory-acquisition merits of the Scheme.

If no such provisions exist, the Applicant should confirm that unequivocally. If any have existed, it should identify their nature, confirm whether they have been expressly and unconditionally waived, and notify the affected landowners that they are free to participate fully in the Examination without contractual or financial penalty.

The distinction should be explicit:

Agreement to enter into an option or lease is not agreement to every subsequent form of the DCO application, and commercial confidentiality must not prevent an affected landowner from giving relevant evidence about the Scheme or the compulsory powers sought over their land.

Until that position is confirmed, the ExA should not infer support, consent or absence of concern merely from the silence of participating landowners.

Part V – DCO controls: genuinely cross-cutting issues

P.22 Preliminary works and commencement must not precede essential safeguards

The definition of commencement is a cross-cutting control point because it determines when the principal Requirements begin to bite. If environmentally consequential activities can be carried out as "permitted preliminary works" before those Requirements apply, the protection offered by the DCO may be substantially weakened.

PINS has already identified this issue. Its section 51 advice questioned whether the proposed "permitted preliminary works" were properly captured within the authorised

development and advised the Applicant to consider whether the definitions of "commence" and "permitted preliminary works" should be amended so that site preparation capable of causing significant environmental effects is not excluded from commencement. The concern expressly extends to effects involving noise, protected species and archaeology.

The Applicant has now responded by introducing a specific control for permitted preliminary works. Revision 2 of Requirement 13 provides that those works must be carried out in accordance with a separate Permitted Preliminary Works Environmental Management Plan, introduced expressly in response to the Inspectorate's section 51 advice. BEPS welcomes the recognition that preliminary works require specific environmental control. The amendment does not, however, remove the examination issue. The ExA must establish precisely what activities fall within "permitted preliminary works", which Requirements are disapplied before formal commencement, and whether vegetation clearance, intrusive investigations, archaeological works, drainage works, access formation, piling trials or other potentially consequential activities could occur before the full suite of ecological, archaeological, hydrological and construction controls has been discharged.

That concern is well founded in the context of East Pye. Activities capable of being characterised as preparatory can themselves cause irreversible or difficult-to-remedy harm. Vegetation and hedgerow clearance can affect protected species and habitat connectivity. Intrusive ground investigation and trial piling can create groundwater pathways or disturb contamination. Archaeological investigation may itself involve destructive excavation. Access formation, compounds and temporary haul routes can disturb soils, drainage, trees and hedgerows. Utility diversions and drainage works may affect watercourses and third-party infrastructure. The environmental consequences of those activities are addressed in detail in Chapters 8, 9, 11, 15 and 16.

The legal point is narrower. Those safeguards must apply before the harm occurs. It would be circular for the DCO to require ecological, archaeological, groundwater, soil, drainage or traffic controls before "commencement", while defining commencement so narrowly that activities capable of causing those very effects may already have taken place.

The Applicant should therefore provide an exhaustive schedule of every activity excluded from the definition of commencement and identify, for each, the Requirements and other controls that apply before it may begin. No vegetation clearance, hedgerow or tree work, intrusive ground investigation, trial piling, archaeological excavation, access construction, drainage work, compound formation, utility diversion or comparable activity should escape substantive environmental control merely because it is labelled preliminary.

Where the Applicant wishes genuinely low-impact surveys or investigations to remain outside commencement, the exclusion should be tightly defined. Environmentally consequential preparatory works should either constitute commencement or be subject to a separate pre-commencement Requirement imposing the same relevant safeguards that would have applied had full construction begun.

The principle should be simple: the legal label attached to an activity cannot determine whether environmental protection applies. Its actual potential effects must do so.

P.23 Staging, phasing and token commencement

The Scheme extends across numerous geographically separate Sites, Sub-Sites, cable corridors, substations, access routes and grid works. That makes staged implementation inevitable, but the draft DCO must distinguish legitimate construction phasing from a power to define the project incrementally after consent.

The concern arises where Requirements may be discharged for a “stage” or “part” without the stages themselves first being fixed. If the undertaker can define stages after consent, environmental controls may be fragmented in ways not tested in the ES. One Site may proceed under one version of a management plan while another proceeds years later under another. Mitigation relied upon across the Scheme may be delayed until a later phase. Different construction fronts may overlap in combinations not assessed. Surveys undertaken for the application may also become materially out of date before later Sites are built.

Chapter 4 already identifies the possibility of prolonged staging, construction of only some solar Sites, delayed BESS, omission of substations and partial implementation. The DCO consequence is that the phasing structure must itself be controlled.

There is a further risk of token commencement. If a minor activity on one part of the Order Limits is sufficient to “commence” the authorised development as a whole, the Applicant may preserve the benefit of the entire DCO while leaving substantial Sites or Works untouched for many years. That could preserve statutory and compulsory powers over land long after the evidence used to assess particular Works has become stale.

This is particularly serious for ecology, where protected-species use and habitat condition can change materially; for drainage and groundwater, where physical and regulatory baselines may change; and for highways and surrounding development, where the network against which impacts were assessed may no longer be the same.

Revision 2 of Requirement 2 now requires, before commencement, a written scheme setting out the construction phase or phases, together with a timetable and a plan identifying the phasing areas. That is a useful improvement and acknowledges the need for greater control over phasing. It does not, however, resolve the concerns identified above. The Requirement does not specify a maximum interval between phases, an overall construction long-stop, the consequences of a phase being commenced but subsequently abandoned, expiry of unused Works powers, or the mitigation dependencies which must be maintained where construction is substantially staggered. Nor does a submitted timetable itself establish the maximum environmentally assessed phasing scenario.

BEPS therefore submits that that Requirement 2 should be strengthened so that the Scheme-wide phasing plan should identify the constituent stages, the Works included in each, their sequencing, the maximum periods between stages, mitigation dependencies and the point at which land and powers associated with any abandoned stage fall away.

The Order should also provide that commencement of a minor or preliminary element does not preserve indefinitely the right to build materially independent Works. Where a principal Site, BESS, substation or other severable component has not commenced within a defined period, its authorisation and associated land powers should expire unless a justified extension is approved through an appropriate statutory process.

The Applicant should not be entitled to obtain one DCO for a geographically dispersed Scheme and then preserve every element through nominal commencement of only one small part.

P.24 The Requirements must be precise, mandatory and testable

The draft DCO relies heavily upon Requirements and outline control documents. That approach is legitimate only if the obligations are sufficiently precise to be examined, discharged and enforced.

PINS has already identified a material weakness. Its section 51 advice criticised repeated use in the outline management plans of expressions such as “where practicable” and “as far as reasonably practicable”, warning that such unbounded qualifiers may reduce the clarity and precision of measures relied upon in the ES, and may affect their “examinability and testability”. PINS made the same point in relation to the Design Principles and Parameters, advising that unbounded qualifiers should be replaced with quantified and testable commitments.

That concern applies directly to the Applicant’s mitigation case. A measure relied upon to reduce an effect from significant to non-significant cannot safely remain subject to the undertaker’s later assessment of practicability. If the environmental conclusion depends on the measure, the default position should be that the measure is mandatory.

The problem is compounded by the frequent use of the expression “substantially in accordance with” when final plans are to be prepared after consent. Chapter 4 already identifies why this matters: unless the permissible departure is tightly bounded, a final plan may differ from the outline version on which the environmental assessment relied while still being said to satisfy the Requirement. BEPS has therefore already proposed that any amendment mechanism should prevent departure where it would exceed an assessed parameter, produce materially different effects, affect additional land, prejudice third-party rights, undermine mitigation or alter the compulsory-acquisition justification.

The revised Commitments Register does not cure that problem. Revision 2 improves administrative traceability by introducing individual commitment references and columns identifying delivery, responsibility and compliance. However, the Register continues expressly to state that it "is not a secured document"; it functions as a tracker directing commitments to other securing mechanisms. More importantly, substantive commitments continue to contain qualifications such as "where practicable", "as far as practicable", "where possible" and "as far as reasonably practical", including measures concerning vegetation retention, lighting, heritage settings, siting in relation to residential and recreational receptors and continued availability of PRoWs. Revision 2 therefore improves the administration of the commitments but does not answer the Inspectorate's underlying concern about whether mitigation relied upon by the ES is sufficiently precise, testable and enforceable.

The cross-cutting requirement should therefore be that every measure material to environmental acceptability is translated into a precise and enforceable control. Each Requirement should identify the approving body, required submission, mandatory consultees, objective standard, timing, monitoring obligation, remedial trigger and responsible party.

BEPS does not suggest that every management-plan sentence must be converted into an absolute prohibition. Some professional judgment will inevitably remain. But where discretion is retained, the DCO must identify who exercises it, according to what objective criteria and subject to what evidence and approval.

The present approach too often substitutes future judgment for present commitment. That is not adequate where the ES has already assumed the mitigation will work.

P.25 Post-consent approvals must not determine questions of principle

The substantive chapters identify extensive reliance upon later investigations, detailed designs, licences, management plans and approvals. The critical legal distinction is between legitimate implementation detail and a matter that determines whether the development is environmentally acceptable at all.

Post-consent controls are appropriate where the principle of the solution is already established and the later decision merely fixes its detailed implementation. They are not an adequate substitute where the later work must determine whether an acceptable solution exists.

That distinction arises repeatedly at East Pye. The Commitments Register records that intrusive ground investigations, Foundation Works Risk Assessments, UXO follow-up and hydrogeological assessments for trenchless crossings may be undertaken after consent or before construction. Transport arrangements depend materially upon later CTMP and related plans. Operational noise mitigation may involve selection of quieter equipment, relocation, reorientation, acoustic enclosures or barriers at detailed-design stage. BESS safety depends materially upon later BSMP and emergency-response arrangements. Archaeological work remains dependent upon further targeted investigation and mitigation.

The Environment Agency provides a concrete example of why that distinction matters. It has identified the absence of Maximum Design Scenario values for foundation and piling depths at the project substations and Site 1B 400 kV substation, stating that without the maximum vertical extent of disturbance the potential impacts on groundwater cannot be assessed. That is not merely a question of choosing a contractor's method after consent. The missing parameter affects whether the environmental effect can presently be assessed.

The same principle applies throughout. If later work is required to determine whether protected-species harm can be avoided, whether a highway route can physically operate, whether groundwater can be protected, whether operational noise can meet the required level, or whether a BESS emergency system can safely function, the Examination is not being asked merely to approve future detail. It is being asked to assume that a satisfactory solution will later be found.

That reverses the proper sequence. The Applicant should demonstrate the existence of an acceptable solution before consent and use Requirements to secure its implementation afterwards.

Where a matter affects the location, scale, principle, deliverability or environmental acceptability of a Work, it should be resolved during Examination or the relevant Work or flexibility should be removed. Chapter 4 already identifies that consequence for unresolved BESS, National Grid, cable and highway solutions.

The DCO should therefore not become a mechanism for completing the environmental design after consent. It should secure a design whose acceptability has already been demonstrated.

P.26 Requirement discharge, consultation, amendments and deemed approval

Where substantial matters are nevertheless left to discharge of Requirements, the discharge procedure becomes an important part of the environmental protection itself.

The DCO should identify mandatory consultees according to subject matter. Where the Environment Agency, Natural England, Norfolk County Council, the LLFA, National Highways, the fire and rescue service, the local planning authority, heritage officers or statutory undertakers possess relevant regulatory or technical responsibility, consultation should not depend upon whether the discharging authority or undertaker chooses to seek their view.

BEPS acknowledges that Revision 2 improves this position. Schedule 15 now provides that, where an approved document is subsequently amended, any body or authority which was required to be consulted upon the original approval is also a "requirement consultee" for the amendment. That improvement should be retained. It reduces, but does not eliminate, BEPS's concern about later alteration of environmentally important documents.

That is particularly important where those bodies have already identified unresolved issues during examination. A final groundwater, drainage, protected-species, transport or emergency-response plan should not be capable of approval without consultation with the body whose statutory function is directly engaged.

The procedure should also be transparent. Final plans, consultation responses, approvals and later amendments should be publicly available, with clear version control. Interested parties should be able to identify what has replaced the outline document examined and whether the environmental obligations have changed.

The more fundamental deemed-approval concern remains unaffected by that improvement. BEPS also objects to deemed approval for environmentally sensitive Requirements. Administrative silence cannot provide substantive evidence that a technically complex submission is acceptable. A drainage scheme, private-water-supply protection plan, protected-species strategy, BESS safety plan, archaeological mitigation scheme, soil-restoration plan or decommissioning scheme should not take effect merely because a decision-maker has failed to determine it within a specified period. The DCO hearing note identifies this concern expressly.

Any determination period should stop where further information is reasonably required, and deemed approval should not operate where a mandatory consultee has raised an unresolved objection.

Later amendments require equivalent control. A final approved plan should not be capable of incremental weakening through repeated “non-material” changes. An amendment should be permitted only where the approving authority is satisfied, following appropriate consultation and on evidence, that it remains within the assessed envelope, does not weaken mitigation, does not affect additional land or third-party rights and does not produce materially new or different effects.

The relevant principle is again straightforward: the DCO must secure the environmental outcome, not merely a process by which the undertaker may later propose a different one.

Part VI – Whole-life powers and liabilities

P.27 Maintenance, replacement and repowering

The legal definition of “maintain” requires particularly close control because the Applicant’s own development description anticipates major replacement programmes during the operational period.

Chapter 4 records that all solar panels may be replaced once, with a complete panel-replacement phase lasting between 12 and 24 months, an average workforce of approximately 129 and a peak workforce of 240. It also assumes that the BESS may be replaced up to five times and that transformers, with an assumed 30-year life, may be

replaced once. Construction routes would be reused and AIL approvals sought later where required.

Those activities are not ordinary maintenance in any meaningful environmental sense. A 12–24 month replacement of all panels resembles a second scheme-wide construction phase. Repeated BESS replacement may involve extensive HGV movements, cranes, temporary storage, hazardous or damaged batteries, waste handling and potentially different battery chemistry or technology.

PINS' section 51 advice has already raised the related drafting issue by asking whether the definition of "maintain" could authorise development with significant environmental effects that had not been assessed.

The DCO must therefore distinguish three concepts: routine maintenance, major replacement and repowering.

Routine maintenance may reasonably encompass repair and like-for-like replacement of individual failed components. Major replacement should be subject to separate environmental controls reflecting the scale of the operation. Repowering—meaning a material increase or alteration in generating or storage capacity, dimensions, technology or hazard profile—should not be capable of being achieved under the maintenance power at all unless separately assessed and authorised.

Replacement equipment should remain within the assessed maximum parameters and should not result in greater noise, heat output, EMF, fire risk, traffic demand or other environmental effect than the equipment assessed. The Environment Agency has separately identified uncertainty over the operational life and decommissioning of cabling, illustrating that whole-life component assumptions are not fully resolved.

The Order should therefore expressly prevent "maintain" from becoming an unexamined power to rebuild or materially re-engineer East Pye during its 60-year life.

P.28 The 60-year period must not be capable of indefinite extension

The Applicant presents the principal solar development as temporary, with an anticipated operational life of 60 years. The LVIA assumes decommissioning commencing in 2091, based upon that 60-year design life, and a further 12–24 month decommissioning period. That temporal limit must be legally precise.

The DCO should identify the event from which the 60-year period runs. It should not be capable of moving according to the date on which individual Sites, substations or BESS elements are commissioned unless that outcome has been expressly assessed.

Revision 2 now confirms that this is not merely a hypothetical drafting concern. Requirement 21 expressly provides for the 60-year period to run separately by reference to final commissioning of "each part" of Work No. 1.

A dispersed Scheme creates obvious ambiguity. If Site 1 begins operation in one year and Site 10 several years later, does each acquire its own 60-year operating period? If the BESS is constructed substantially later than the solar generation, does it receive a fresh 60 years? If panels are comprehensively replaced after 30 or 40 years, does that affect the end date? If only part of the Scheme is initially commissioned, can later commissioning of another part extend the overall life?

The answer should be no unless expressly justified and environmentally assessed.

Replacement should not reset the clock. Nor should delayed implementation enable successive components to extend industrial use across the Order Limits well beyond the period on which the planning and environmental case was presented.

The DCO should therefore contain a single objectively ascertainable operational end date or a clearly defined formula tied to first or final commissioning, together with an absolute long-stop date beyond which the relevant solar and BESS Works may not operate. Any materially later extension should require a fresh statutory consent process.

A development promoted as temporary should not acquire an effectively indefinite life through staggered commissioning and rolling replacement.

P.29 Cessation, abandonment and partial failure

The DCO also needs to regulate outcomes other than successful operation for exactly 60 years followed by orderly decommissioning.

The application itself permits realistic scenarios in which parts of the Scheme may be delayed, omitted or never fully implemented. The BESS has materially different connection status from the solar component. The National Grid solution remains subject to further determination. Partial build-out is therefore not merely theoretical.

The Order should specify what happens if a Site is constructed but never commissioned; if the BESS compound is built but cannot obtain a usable connection; if a solar Site ceases generating permanently; if infrastructure is abandoned after commencement; or if only part of the authorised development proceeds.

Without a cessation mechanism, land could remain fenced, industrialised or burdened by redundant equipment indefinitely even though the public purpose relied upon to justify the development and compulsory powers is no longer being delivered.

BEPS therefore seeks a defined cessation trigger. Where a material component has ceased beneficial operation for a continuous specified period, and the cessation is not caused by temporary maintenance or another objectively justified event, the undertaker should be required either to recommence operation within an approved period or to decommission and restore that component.

The same principle should apply to failed partial development. Unbuilt Works should not preserve land powers indefinitely, while built but stranded infrastructure should not remain simply because the overall DCO has not reached its 60-year endpoint.

The DCO should address failure, not assume it away.

P.30 Decommissioning security

A decommissioning plan is not the same as financial security for decommissioning.

Examination material now indicates that private landowner agreements contain decommissioning securities intended to protect against default or insolvency and capable of periodic revaluation or top-up. That materially changes the evidential position from that understood when BEPS's original objection was prepared.

It does not, however, establish the existence of a coordinated, Scheme-wide, publicly enforceable and independently costed restoration security. The outstanding question is whether the private securities collectively provide adequate and durable funding for the full liabilities arising from removal, soil and drainage reinstatement, contamination remediation, habitat obligations and aftercare, including following transfer or insolvency of the undertaker.

A future DEMP identifies a process. It does not demonstrate that money will be available to implement that process if the undertaker becomes insolvent or abandons the Scheme.

The liability is substantial. It may encompass removal of panels, BESS equipment, transformers, substations and access infrastructure; treatment of damaged or hazardous batteries; cable decisions; soil reinstatement; pollution remediation; habitat protection and restoration; protected-species measures; drainage reinstatement; waste transport and processing; and long-term remedial monitoring.

The Environment Agency has itself identified uncertainty concerning the lifespan and ultimate treatment of below-ground cabling and recommends that future removal be considered during pre-construction design. That illustrates why future end-of-life liabilities cannot responsibly be treated as a simple reversal of construction.

BEPS therefore submits that the DCO should require an independently costed, ring-fenced and insolvency-protected financial security mechanism. The amount should cover the full reasonably foreseeable cost of decommissioning and restoration, be index-linked, independently reviewed at regular intervals and increased where costs or liabilities rise.

The security should be callable upon default, insolvency or failure to comply with a decommissioning obligation. It should bind successors and transferees and should not be released merely because equipment has been removed. Release should occur only

after the responsible authority has certified that the required restoration and remediation have been completed to the specified standard.

The precise form of security can be determined through the Examination. The essential point cannot: the public and affected landowners should not bear the residual risk that a 60-year industrial development becomes financially incapable of restoring the land it occupied.

P.31 Transfer of the benefit of the Order

The transfer provisions require corresponding protection.

A DCO may outlive the original project company and may involve transfer of particular assets or Works to other bodies, notably NGET. That makes clarity over successor liability essential.

Chapter 4 already identifies the risk at the National Grid interface: construction, ownership, operation, environmental compliance and decommissioning responsibilities must not become divided in a way that leaves no identifiable entity responsible for a breach. The WR specifically warns against a situation in which the Applicant says a matter is controlled by NGET, NGET says it was constructed under the Applicant's DCO and the local authority lacks a clear party against whom to enforce.

The same concern applies more generally if the benefit of the Order may be transferred or split.

A transfer must not separate valuable operating assets from environmental liabilities. It must not leave one entity owning the solar plant, another the BESS, another the land or grid infrastructure, while responsibility for common drainage, ecological mitigation, emergency response or decommissioning becomes uncertain. Nor should transfer enable the financial security required from the original undertaker to disappear.

BEPS therefore submits that any transfer of the benefit of the DCO should automatically carry with it every relevant environmental, mitigation, maintenance, monitoring, emergency-response, restoration and decommissioning obligation. Chapter 4 already identifies that requirement in relation to NGET or another transferee.

Where the transfer is substantial, the transferee should also demonstrate adequate technical competence and financial resources, including continuation or replacement of any decommissioning security on terms no weaker than those previously secured.

No transfer should take effect in a way that leaves responsibility fragmented between entities or makes enforcement more difficult. Where the Order is split between undertakers, the DCO should identify expressly which body bears each continuing obligation and, where necessary, impose joint or continuing responsibility for cross-Scheme matters.

The benefit of the Order may be transferable. The liabilities on which its environmental acceptability depends must be equally durable.

Part VIII – Overall CPO/DCO consequences

P.33 The cumulative problem: the Applicant seeks the widest powers before resolving the Scheme

The defects identified in the substantive chapters are not isolated technical disagreements. Taken together, they reveal a more fundamental problem: the Applicant seeks extensive statutory and compulsory powers before it has demonstrated one settled, deliverable and environmentally controlled implementation case.

Chapter 4 identifies unresolved questions about the identity and severability of the authorised development, including the relationship between solar and BESS, optional or omitted Works, the National Grid connection solution, cable flexibility, partial build-out, replacement and decommissioning. Chapters 1 and 5 address the weight of the claimed project-specific benefit and whether less harmful alternatives were properly excluded. Chapter 2 identifies incomplete baseline evidence and excessive reliance on later surveys, plans and approvals. Chapters 8, 11, 15 and 16 identify unresolved protected-species licensing, transport deliverability, soil restoration and ground-condition controls. The cumulative chapter addresses whether those individual uncertainties interact across the Scheme as a whole.

The Applicant's own documents reinforce that concern. The Statement of Reasons accepts that compulsory acquisition requires a clear idea of how the land will be used, that no more land should be acquired than reasonably required, that reasonable alternatives must have been explored and that there must be reasonable prospects of the necessary funds being available. Yet the application simultaneously preserves substantial design and implementation flexibility, relies upon later consents, licences and agreements, and continues negotiations over land and rights. The Commitments Register is itself expressly not a secured document.

The cumulative consequence is that the Applicant seeks extensive coercive powers before it has demonstrated one fixed, deliverable and environmentally controlled implementation case to which those powers can safely attach.

That sequence is wrong. The Scheme should determine the powers required. The powers should not be granted at maximum breadth and the Scheme resolved afterwards.

P.34 The compelling case for compulsory acquisition has not been established

The Applicant's Statement of Reasons correctly recognises that section 122 requires both that the land is required for the Scheme and that there is a compelling case in the

public interest for compulsory acquisition. It further accepts that the land sought must be no more than reasonably required, that reasonable alternatives must have been explored and that funding must have a reasonable prospect of being available.

The present application does not yet demonstrate those propositions for all of the powers sought.

First, important Works remain uncertain or potentially optional. The BESS does not have the same connection status as the solar component. The National Grid solution remains unresolved. Some Sites, substations and cable infrastructure may be omitted or implemented differently. Where the Work itself is not shown to be necessary in the form authorised, the case for compulsorily acquiring the land required solely for that Work is correspondingly weakened.

Secondly, the Applicant seeks powers wider than the minimum interest may require. Its own Statement of Reasons confirms that Option Agreements are already in place for the solar Sites, BESS, project substations and National Grid Substation, while negotiations for leases and rights continue. A need for secure land control does not automatically establish a need for permanent freehold acquisition. Where a lease, permanent right or temporary possession would achieve the authorised purpose, the greater interference requires a separate justification.

Thirdly, unused powers may survive partial implementation. If the BESS does not proceed, if NGET adopts another connection solution, if cable corridors are refined or if some Sites are omitted, the DCO should not continue to burden land for Works no longer required. Compulsory acquisition cannot properly be justified as insurance against every possible future implementation scenario.

Fourthly, NGET's own Relevant Representation materially weakens the necessity case for the National Grid Substation land. NGET states that it understands the replacement connection agreement will not require East Pye to secure the land or consent for the National Grid Substation, and that consent for the proposed substation would not oblige NGET to use it. It also states that the final point-of-connection solution cannot yet be confirmed. That is difficult to reconcile with permanent compulsory acquisition of land for a solution which the future operator has not confirmed.

Fifthly, the funding position remains contingent. The Applicant's own material indicates an estimated project cost of approximately £1 billion–£1.05 billion, with further funding to be sought after consent, the final financing structure not yet determined and final investment decision occurring after DCO grant. PINS has separately raised concerns about the adequacy of funding assurance for compulsory acquisition. The issue is not that project finance must necessarily be fully committed before consent; it is that coercive land powers should not be treated as routine where the final delivery and financing arrangements remain unresolved.

The Applicant's conclusion that national energy policy itself establishes the compelling case is too broad. Its Statement of Reasons ultimately asserts that policy need and

claimed benefits justify acquisition of land and rights across the Scheme. Section 122 requires a more particularised exercise. The question is not merely whether renewable energy serves a public purpose, but whether this land, this interest and this power are necessary and proportionate for the Scheme actually capable of proceeding.

On the present evidence, that has not been demonstrated for the full extent of the compulsory powers sought.

P.35 The draft DCO does not yet provide an adequate control mechanism

The separate DCO question is whether the Order itself ensures that the Scheme ultimately built, operated, replaced and decommissioned remains the Scheme examined.

At present, it does not provide sufficient confidence.

The draft framework combines broad Works and maintenance powers, staged commencement, substantial detailed-design flexibility, later management plans, later licences and external consents. BEPS's DCO hearing analysis records that important mitigation remains subject to later design and that the Commitments Register is not itself secured.

The ExA cannot rely on statements about what the Applicant presently intends to do. The Order must itself control what the undertaker may lawfully do.

That requires six things.

First, the authorised envelope must be bounded by clear and enforceable parameters.

Secondly, mitigation relied upon in the ES must be secured by binding Requirements or equivalent legal mechanisms, not left only in narrative documents or the Commitments Register.

Thirdly, commencement and phasing must be controlled so that preliminary or token works cannot bypass safeguards or preserve materially independent Works indefinitely.

Fourthly, later replacement and maintenance must not permit unassessed repowering or materially different technology.

Fifthly, decommissioning and restoration obligations must be backed by durable financial and successor arrangements rather than assumptions about the continued solvency of the original project company.

Sixthly, powers and obligations must fall away or transfer coherently where Works are omitted, abandoned or transferred.

The issue is not whether post-consent detail is permissible. It plainly is. The issue is whether post-consent processes are being used to implement an acceptable Scheme or to determine whether an acceptable Scheme exists. The latter is not a drafting detail; it is a failure to resolve the development before granting the powers.

Unless those deficiencies are corrected, the draft DCO remains broader than the environmental and deliverability case presently supports.

P.36 Remedies sought

BEPS asks the Examining Authority to require the Applicant, before the close of Examination, to provide a revised DCO and compulsory-acquisition case which resolves the relationship between the Scheme assessed, the Works authorised and the land powers sought.In particular, the Applicant should be required to:

1. tighten the definitions, design parameters and limits of deviation in the draft DCO;
2. provide a Scheme-to-powers schedule and Work-to-ES audit identifying the environmental assessment and land powers supporting every principal Work;
3. correct and reconcile the Works Plans, Land Plans, Book of Reference and other legal plans;
4. identify which Works are mandatory, optional or severable;
5. demonstrate how the Gate 1 BESS and any solar-only or partial implementation scenario are controlled;
6. provide for expiry or release of powers over Works that are not implemented;
7. justify compulsory acquisition plot by plot and interest by interest;
8. remove freehold powers wherever leasehold, rights or temporary possession would adequately secure the authorised purpose;
9. tighten commencement and phasing provisions to prevent environmentally consequential preliminary works and token commencement;
10. provide a complete mitigation-to-Requirement audit;
11. strengthen Requirement discharge, statutory consultation, amendment and enforcement provisions;
12. distinguish routine maintenance from replacement and prohibit unassessed repowering;
13. include clear cessation and abandonment triggers;
14. secure independently costed, index-linked and insolvency-proof decommissioning and restoration security;
15. ensure all environmental and financial liabilities bind transferees and successors; and
16. confirm that participating landowners remain free to give evidence and make representations without contractual or financial penalty.

These remedies are not requests for additional drafting sophistication. They go directly to whether the statutory powers sought are justified and whether the environmental case relied upon is actually secured. The governing principle should be simple:

If the Applicant cannot demonstrate the necessity of a particular Work, land parcel, property interest or statutory power, that power should not be granted. If the environmentally acceptable operation of the Scheme depends upon a mitigation measure, that measure should be secured by the Order.

The DCO should not authorise first and resolve necessity, design, mitigation and financial responsibility later.

Chapter 1

1.1.1 The central question for the Examination

Has the Applicant demonstrated one environmentally coherent and deliverable scheme which has been designed for this particular landscape, or has it assembled a series of topic-specific assessments and mitigation measures around a predetermined 500 MW project, without demonstrating that those solutions are mutually compatible or acceptable when the environment is considered as a whole?

East Pye is not proposed within an environmentally interchangeable landscape. It would be imposed across 1,212.3 hectares of a still recognisably rural and agricultural part of South Norfolk, extending through ten dispersed Sites, numerous Sub-Sites, approximately 24 km of cable corridor, a BESS, multiple substations, a new National Grid Substation and associated highway and grid works. The Applicant's own baseline records rural villages and hamlets, mature hedgerows and trees, rivers and ordinary watercourses, important agricultural soils, County Wildlife Sites and Roadside Nature Reserves, nationally important wildlife sites, numerous Grade I and Grade II* listed buildings, conservation areas and historic settlement patterns within and immediately adjoining the Scheme.

The Applicant's own LVIA confirms that this is not a landscape of uniformly low sensitivity merely because it lacks a national landscape designation. It identifies High sensitivity receptors including the Tas Rural River Valley, Chet Tributary Farmland, Thurlton Tributary Farmland with Parkland and important recreational routes, with the remaining assessed landscape receptors generally of at least Medium sensitivity. The assessment itself predicts numerous significant adverse landscape and visual effects.

The historic, ecological and agricultural qualities of this landscape are also interconnected. Its value does not reside only in individual listed buildings, individual hedgerows, individual bird territories or isolated watercourses. It lies in the surviving relationship between villages and their agricultural hinterland; churches and historic settlements; lanes, footpaths and field patterns; mature hedgerows, trees and woodland; open farmland used by declining farmland birds; river valleys, ditches and groundwater; and land still managed for food production and wildlife. The Scheme is capable of changing those relationships for generations.

That risk cannot be dismissed simply by describing the solar development as temporary. The operational period is proposed to extend for 60 years. More importantly, the Applicant's own landscape assessment assumes that mature woodland, trees, hedgerows and scrub introduced as mitigation may remain after decommissioning, while the National Grid Substation and associated grid infrastructure would also remain. The environmental question is therefore not simply whether solar panels can eventually be removed. It is whether development on this scale would permanently reshape the structure, ecology, historic character and experience of the receiving landscape in order to accommodate it.

That distinction matters because the Environmental Statement repeatedly approaches the Scheme through individual technical disciplines. Landscape harm is addressed through planting. Ecological harm is addressed through habitat creation and management. Highway

problems are deferred to route refinement and haul-road solutions. Drainage problems are addressed through later drainage design. Noise may require barriers, enclosures, relocation or reorientation of plant. Agricultural effects are answered partly by long-term grassland management. Heritage effects are reduced through separation and screening.

Each solution may appear capable of addressing one problem when viewed through the relevant technical chapter. The central difficulty is that the same solution may create another.

New woodland and hedgerows may screen solar infrastructure but permanently enclose an historically open agricultural landscape. The same planting may alter the setting of heritage assets and reduce the openness and sightlines required by ground-nesting and open-country birds. Moving plant to protect a residential receptor may move it towards an ecological, heritage or drainage constraint. Rerouting haul roads to solve highway objections may require additional hedgerow removal, soil disturbance, watercourse crossings or works close to sensitive receptors. Additional drainage infrastructure may occupy land or affect habitats and archaeology. Retaining mitigation planting after decommissioning may preserve newly created habitat while preventing restoration of the former agricultural and historic landscape.

These are not theoretical concerns. They arise from the Applicant's own assessments.

There is also evidence that important methodological assumptions have been derived from generic experience of solar development rather than demonstrated from the particular characteristics of East Pye. Chapter 7, for example, justifies the extent of its visual study area partly on the basis that ‘previous experience of similar types of development’ indicates that a 2 km study area will normally capture significant effects. Chapter 14 similarly states that, because there is no solar-specific socio-economic methodology, its approach is based upon professional judgement, previous experience and good practice.

There is nothing inherently improper about drawing upon professional experience or established methodology. The problem arises if generic assumptions derived from other schemes become substitutes for examining the characteristics of the receiving environment itself.

The landscape threatened by East Pye must be assessed on its own terms. A standard methodology cannot establish that a particular two-kilometre study area captures the effects of a dispersed 1,212-hectare scheme. A standard planting strategy cannot establish that further enclosure is ecologically appropriate within habitat used by open-country birds, or where Countryside Stewardship fields have intentionally created habitat for ground-nesting birds. A generic assumption that solar development is reversible cannot establish restoration where the Applicant assumes that mature planting and permanent grid infrastructure will remain. Nor can the national need for solar generation establish that this particular 500 MW configuration, spread across this particular landscape, represents an environmentally acceptable way of meeting that need.

The design process should therefore be interrogated in the opposite direction from that presented by much of the Environmental Statement. The starting question should not be:

How can a 500 MW East Pye Solar project be fitted into this landscape and its resulting effects mitigated?

It should be:

What form and scale of development, if any, can this landscape accommodate without unacceptable loss of the environmental functions and characteristics which already exist?

That distinction goes to the heart of good design and the mitigation hierarchy. Where significant constraints are identified, the first response should be avoidance and design change, including reduction or removal of development areas where necessary. Screening, management plans, future detailed design and compensation come later. They cannot retrospectively demonstrate that the underlying choice of location, extent and configuration was environmentally appropriate.

This Written Representation therefore asks the Examining Authority to test the Application against one overarching proposition:

Has the Applicant demonstrated a single physically deliverable version of East Pye in which the access strategy, drainage design, landscape mitigation, ecological requirements, heritage protection, soil management, noise mitigation, grid infrastructure, residential protection and decommissioning end state can all coexist within the authorised envelope without creating effects greater than those assessed?

If the answer depends upon different assumptions in different chapters, future design choices which have not been environmentally reconciled, or mitigation measures which solve one problem by creating another, then the Environmental Statement has not yet demonstrated an environmentally coherent Scheme.

That is particularly serious here because the consequence of getting the assessment wrong is not simply a temporary localised impact. It is the potential long-term or even permanent reshaping of an unusually extensive, historically and ecologically important and interconnected rural landscape to accommodate a predetermined transmission-scale ‘temporary’ development.

BEPS submits that this question should sit at the centre of the Examination. The individual objections which follow are not separate complaints about unrelated environmental topics. They are evidence of the same underlying issue: whether East Pye has genuinely been designed around the constraints and carrying capacity of this particular place, or whether the place is being progressively redesigned to accommodate East Pye.

1.1.2 Good design: the appropriate examination framework

BEPS submits that the East Pye Solar Scheme should be examined expressly against the Planning Inspectorate's published **Advice on Good Design for Nationally Significant Infrastructure Projects**, read with section 4.7 of EN-1 (2025).

The relevance of that guidance is direct. The Applicant itself relies upon the Planning Inspectorate's Good Design Advice and states that its Design Approach Document and Design Principles demonstrate how good design has been delivered through the evolution of the Scheme.

The Examination should therefore test that proposition against the criteria which the Planning Inspectorate itself identifies.

The Advice makes clear that good design is not principally an aesthetic exercise. It requires a **holistic approach** which responds to place and takes account of complex environments. A successful design process must be intentional, transparent, iterative, multidisciplinary and deliverable. It must begin with a clear analysis of the context of the place, use environmental information and consultation to inform design choices, explain why those choices were made, and produce an integrated project-wide outcome.

The Advice further states that EIA should inform the design process and that its influence should be clearly articulated, particularly in site and infrastructure appraisal, site selection and alternatives. Where parameters are retained, the assumptions and design principles underpinning those parameters must be clear.

The August 2026 NPPF provides additional contemporary support for that approach. Policy DP3 requires development to respond to the history, character and features of its site and setting, to integrate with and enhance its surroundings and to contribute to nature, movement, compact form and a strong sense of place. Policy DP4 requires design quality to be considered throughout the evolution, assessment and delivery of development and guards against the quality relied upon at consent being materially diminished during subsequent detailed design. Those principles are particularly relevant to East Pye because substantial elements of the final disposition of infrastructure remain within a post-consent design envelope.

1.1.3 The critical distinction: designing for the place or fitting the project into it

This distinction is particularly important for East Pye. The Applicant's own Chapter 5 states that its project-level design principles seek to achieve the Applicant's required levels of energy generation and storage while responding to the local context. It also states that a smaller generating development was not considered further as an alternative. That sequencing requires close examination.

Good design, as defined by PINS, begins with understanding the place, its constraints and opportunities, and allowing that analysis to inform site selection and design evolution. It is not sufficient to establish the required size and technological form of a project first and then seek to accommodate its consequences through buffers, screening, offsets, management plans and later detailed design.

East Pye is proposed across a particularly sensitive and interconnected rural environment. Its historic villages, churches and farmsteads, open agricultural landscape, mature hedgerows, veteran trees, BMV soils, farmland-bird habitat, protected ecological sites, rivers, drainage

systems, dark skies, rural roads and recreational routes are not independent constraints. Together they constitute the place into which the development is proposed.

The question for good design is therefore not simply whether each constraint has been given a mitigation response. It is whether the combined constraints should have resulted in a different development. That may include a different site configuration, removal of particular parcels, relocation of infrastructure, greater avoidance, a materially smaller footprint or, where environmental capacity is exceeded, rejection of development in that location entirely.

1.1.4 Good design requires an integrated solution

The Planning Inspectorate's requirement for an integrated and holistic approach is especially important because East Pye's proposed mitigation measures frequently operate across more than one environmental discipline. Planting introduced to screen development may permanently alter landscape character, heritage setting and open-country bird habitat. An internal haul road introduced to solve a highway objection may affect soils, watercourses, hedgerows, archaeology, cultural heritage setting, and ecological and agricultural receptors. A drainage solution may affect land take, soil, groundwater and aquatic ecology. Noise mitigation may require relocation, barriers or enclosures with corresponding visual, ecological or heritage effects. Retention of mitigation planting after decommissioning may benefit newly created habitats while preventing restoration of the former agricultural and historic landscape.

These interactions are not peripheral to good design. They are precisely why the Planning Inspectorate requires a holistic, multidisciplinary process and an integrated design concept. The Applicant should therefore demonstrate that there is **one environmentally coherent design**, rather than a collection of individual mitigation solutions developed within separate ES disciplines.

1.1.5 Good design must be demonstrated by design evolution

There is also an important difference between mitigation and design. The Applicant records that environmental surveys and consultation resulted in removal or reduction of solar development in some locations. Those are relevant examples of design evolution and should be given appropriate credit. But the Examination must equally identify constraints which did **not** cause the project to change.

For example, the Applicant records that potentially preferable land closer to the Point of Connection was identified but not progressed because the land was not available to the Applicant. It also records that a smaller-capacity Scheme was not considered further. The final Scheme nevertheless remains spread across ten Sites and numerous Sub-Sites and requires approximately 24 km of interconnecting cable corridor.

The PINS good-design test requires more than demonstrating that environmental constraints were mapped. It requires a clear narrative explaining how analysis of those constraints shaped the choices eventually made. Accordingly, for each principal constraint the Applicant should be asked:

What did this constraint actually cause you to change?

If the answer is only a buffer, screening, later management or compensatory habitat, the ExA should ask why avoidance, relocation or reduction was not selected first. Place is an outcome, not merely a receptor

The PINS Advice places particular emphasis upon **place**. It requires a locally contextual design narrative, stewardship of the local landscape, enhancement of local identity and a clear explanation of the quality of place which the completed development will create.

That is a difficult but important question for East Pye Solar**. The Applicant should therefore be required to describe positively the landscape which will exist if the Scheme is built.**

Not simply where panels will be screened, but:

- What will the character of South Norfolk between these villages be?
- What happens to the historic relationship between settlements and their agricultural hinterland?
- What happens to openness?
- What happens to tranquillity and dark skies?
- What becomes of the agricultural identity of the landscape?
- What landscape will walkers and residents experience after the mitigation planting has matured?
- What ecological assemblage will the more enclosed landscape support?
- And what remains after 60 years when the solar equipment is removed but mature landscape mitigation and National Grid infrastructure may remain?

A proposal cannot demonstrate good design merely by reducing the visibility of its infrastructure. The resulting place itself must be coherent.

1.1.6 The examination test

BEPS therefore submits that the Planning Inspectorate's Good Design Advice provides an appropriate framework for examining the Scheme across chapter boundaries.

The Applicant should be required to demonstrate that:

1. the design started from a sufficiently detailed understanding of the particular environmental, historic, agricultural and community context of East Pye.
2. those constraints genuinely influenced site selection, scale and configuration rather than simply influencing subsequent mitigation.
3. consultation and environmental assessment caused identifiable, consistent and material design changes.
4. the design principles resolve competing environmental requirements rather than addressing them independently.
5. the permitted Rochdale Envelope contains at least one physically deliverable design which satisfies all relevant environmental assumptions simultaneously.
6. future design flexibility is sufficiently controlled to prevent later decisions from transferring harm between receptors.

7. the Scheme produces a coherent long-term place rather than relying predominantly upon screening to conceal an industrial development from the landscape in which it has been placed.
8. the proposed post-decommissioning condition is consistent across landscape, ecology, agriculture, heritage and land-use assessments.

The ultimate good-design question is therefore closely aligned with the central question BEPS asks of the Examination:

Has the Applicant demonstrated one integrated, environmentally coherent and deliverable Scheme genuinely designed in response to the particular character and environmental capacity of this area of South Norfolk, or has it sought to reshape that environment to accommodate a predetermined 500 MW development through a series of potentially incompatible topic-specific mitigation measures?

Since this Written Representation was prepared, the National Planning Policy Framework was replaced on 17 August 2026. The Energy NPSs remain the primary policy framework for this NSIP, but the current NPPF is capable of being an important and relevant consideration. It materially reinforces the issues raised in this chapter. In particular, Policy W3 gives substantial weight to relevant energy-security, economic-development and net-zero benefits and states that applicants should not generally be required to demonstrate the overall need for renewable or low-carbon energy development. BEPS therefore does not invite the Examination to impose a separate requirement upon the Applicant to prove generic national need for solar generation. The relevant issue is the weight properly attributable to the benefits of this particular Scheme, the deliverability of the components from which those benefits are said to arise, and whether its particular scale, configuration and environmental effects are acceptable when the NPSs and other relevant policies are applied.

That question should be examined expressly through the Issue Specific Hearing programme and addressed in the Examining Authority's final assessment of good design. ISH1 has materially strengthened this issue. The Applicant confirmed that the Illustrative Masterplan is not the final layout; the number and location of significant 33 kV switch rooms and conversion units remain to detailed design; ancillary operational buildings may be distributed across the Sites; fencing remains subject to further refinement; and material choices remain open concerning project-substation technology and layout. The ExA consequently required further parameters and illustrative material. The good-design question is therefore no longer hypothetical: the Examination must determine whether the DCO secures the design quality relied upon by the Applicant rather than merely an envelope within which that quality is hoped to emerge later.

1.1.7 The Application was required to be environmentally coherent before Examination

There is a key distinction between examining a design and completing one.

EN-1 (2025) requires applications to be ready for examination on submission. The DCO process is front-loaded: Examination should test a coherent, deliverable scheme, not be used to resolve fundamental design deficiencies. At East Pye Solar, many outstanding issues are not minor details but core elements of the physical solution, including access and haul routes, drainage, crossings, plant layout, noise mitigation, ecological measures, lighting, and the interaction of planting with heritage and habitat requirements.

While some flexibility is legitimate, there is a clear difference between refining an assessed scheme and using Examination to find the first environmentally acceptable scheme. If resolving objections requires materially different infrastructure arrangements, the Applicant must demonstrate that a single, internally consistent and fully assessed configuration already exists across all topics.

The Examination should not become an iterative design process. The key question is whether the Application already contains a complete, deliverable solution in which all mitigation measures are mutually compatible.

1.1.8 Residual harm cannot be identified until avoidance and mitigation are exhausted

EN-1 establishes a strict sequence: avoid, reduce, mitigate, then assess residual effects. Only then can CNP policy be applied. At East Pye Solar, national need does not convert avoidable harm into residual harm, and compensation does not reduce the original impact. Before any effect is treated as residual, the Examination should ask whether it could have been avoided through design change—such as site deletion, relocation, alternative routing, or reduced development in constrained areas.

The August 2026 NPPF reinforces that sequencing in particularly clear terms in relation to the natural environment. Policy N2 requires significant biodiversity harm first to be avoided through locating development on an alternative site with less harmful impacts; only where avoidance is not possible does the sequence move through mitigation and, ultimately, compensation. It also requires agricultural land quality and grade to be taken into account and poorer-quality agricultural land to be used where possible. At East Pye those principles are directly relevant because the Applicant's own design history shows that ecological, heritage and agricultural constraints were capable of producing avoidance in some parcels while materially comparable constraints remain within the retained Scheme.

EN-1 does not entitle an applicant to fix capacity and footprint first and then mitigate around them. The correct sequence is: avoid → reduce → mitigate → residual harm → compensation → planning balance (including CNP where applicable)

not: fix scheme → mitigate around it → reclassify remaining harm as residual → rely on CNP.

1.1.9 Precautionary assumptions are not a substitute for avoidance design

Where the Applicant relies on future micrositing or buffers, a precautionary assumption of species or features may be appropriate for assessment, but it is not sufficient for design.

If avoidance depends on location, the Applicant must demonstrate that the location and functional extent of receptors are known with enough precision to ensure avoidance is actually achievable.

It is not enough to assume, for example, that bats, birds, archaeological features or drainage pathways are present somewhere within a broad area and then rely on later refinement to avoid them. This issue was also identified in Lime Down.

The Applicant cannot rely on uncertainty to justify precaution, and then rely on future precision to justify avoidance. Where avoidance is the strategy, spatial certainty is a prerequisite.

1.1.10 The Examination should follow receptors across chapter boundaries

The ES is structured by topic, but effects are experienced by receptors. A single receptor may experience combined effects from multiple chapters: visual change, noise, lighting, traffic, habitat change, and construction disturbance. Individually acceptable effects may combine into a materially different overall experience.

For example:

- Residents may experience visual, noise, lighting, traffic and amenity impacts together.
- Heritage assets may experience combined setting, visual, traffic and construction effects.
- PRoW users may experience continuous exposure to infrastructure, noise, fencing, planting and traffic.
- Ecological receptors may experience habitat loss, edge effects, disturbance and hydrological change together.
- Watercourses may experience cumulative construction and drainage impacts.

The key point is that receptors experience one scheme, not separate ES chapters.

The Examination should therefore assess the combined effect on each receptor, not just the significance of individual topic-based impacts.

This is not standard inter-project cumulative assessment, but internal accumulation within East Pye itself. Without this approach, there is a risk that each chapter appears acceptable in isolation while the overall effect on receptors is never properly assessed.

1.1.11 Selective land removal does not demonstrate a consistently applied mitigation hierarchy

The Applicant relies upon the removal of solar development from a number of parcels as evidence that environmental assessment and consultation materially influenced the Scheme. BEPS accepts that those removals are preferable to retaining development in the affected locations. The difficulty is that the reasons given for removing development in those places recur elsewhere across East Pye, where development has nevertheless been retained.

The issue is therefore not simply whether some land was removed. It is whether the Applicant has applied a **consistent and intelligible threshold for avoidance across the Scheme**.

Chapter 5 provides a particularly clear example at former Sub-Site 3A. Solar infrastructure was removed entirely because of a combination of limited highway access, proximity to Spring Wood Ancient Replanted Woodland and associated bat roosts, part of Spring Wood Hempnall County Wildlife Site, high unexploded-ordnance risk, evidence of a former deer park and the fact that much of the parcel was Grade 2 BMV agricultural land.

Those are legitimate reasons for avoidance. But several of the same classes of constraint remain elsewhere within the Scheme.

Development remains immediately beside or close to ancient woodland and County Wildlife Sites elsewhere in the Order Limits. Site 7, for example, contains development around an exceptionally dense ecological and historic network, including Pope's Wood, D'Oyly's Grove and Saxlingham Grove, together with numerous nearby listed buildings. The Applicant's own design evolution records only partial removal from Sub-Site 7C notwithstanding listed buildings, adjacent residential properties, a PRoW and the need for ecological connectivity with Pope's Wood CWS.

The heritage comparisons are still more revealing.

At Sub-Site 8B, panels were removed from the northern part because Historic England and others raised concerns about elevated land affecting the setting of the Grade II listed Upgate Green Farmhouse. The Applicant describes that removal as necessary to ensure there would be no infringement upon its setting.

Yet development remains at Sub-Site 4B only approximately 45 metres from the Grade I Church of St Michael, 70 metres from the Grade II* Old Rectory and 10 metres from a Grade II listed barn. Site 5 similarly remains approximately 25 metres from the Grade I Church of St Catherine. Site 7 retains development close to numerous listed buildings, including Wood Farmhouse at approximately 30 metres, Grove Farmhouse at approximately 45 metres and several others within 100 metres.

BEPS does not suggest that distance alone determines heritage harm. Topography, orientation, historical association, visibility and the contribution made by setting must all be considered. The point is different: **if heritage sensitivity was sufficient to justify complete or substantial avoidance in one location, the Applicant must explain transparently why equally or more**

highly designated and closely related heritage receptors elsewhere are capable of being addressed merely through buffers, planting or residual assessment.

The same inconsistency arises with residential amenity. At Site 9, development was progressively removed because of effects upon residential properties on Mill Lane and High Green and the relationship with Brooke Conservation Area. Following statutory consultation, panels were removed entirely from the western part of the Site for those reasons.

Yet the final Order Limits retain development extraordinarily close to residential receptors elsewhere: Chapter 3 records dwellings approximately 25 metres from Sub-Site 4B, adjoining or close to Sites 5 and 6, approximately 25–50 metres from Sub-Site 7C, approximately 30 metres from Sub-Site 7D and approximately 15 metres from Sub-Site 7L. The fact that residential proximity prompted avoidance at Site 9 therefore raises an obvious question about the threshold applied elsewhere.

Agricultural land shows the same pattern. Grade 2 BMV land formed one of the reasons for removal of Sub-Site 3A. A discrete Grade 2 parcel close to Ringers Grove was also removed, and removals at Sub-Site 8B and Site 9 happened additionally to remove BMV land.
Those decisions demonstrate that avoiding BMV land was technically possible when the Applicant considered other constraints sufficiently strong. They do not demonstrate a Scheme-wide preference for poorer-quality agricultural land. Large areas of BMV land remain within the final development simply because, elsewhere, that same agricultural constraint has been treated as capable of mitigation or later restoration.

Aviation provides another example of the need for consistency. At Sub-Site 10B, panels were removed from the southern and eastern parts following discussions with Seething Airfield and the Applicant's aviation specialists concerning the consequences of aircraft engine failure. That demonstrates that aviation operational requirements can properly operate as an **avoidance constraint** capable of changing the solar layout. The Examination should therefore scrutinise with equal care the Applicant's response to the materially different but nevertheless substantive operational-safety concerns raised in relation to Tibenham Airfield and Site 1.

These examples matter because isolated land removals can otherwise create a misleading impression of a constraints-led scheme. A design process does not demonstrate effective application of the mitigation hierarchy merely by identifying a handful of locations where development has been deleted. The relevant question is whether the **principle which caused deletion has been applied consistently wherever the same type of constraint occurs**.

Nor is the answer necessarily that every constrained parcel must be removed. Different locations may legitimately produce different outcomes. But where they do, the Applicant should provide the comparative reasoning.

The Examination should therefore require the Applicant to identify, for each material parcel removal:

- the constraint or combination of constraints which triggered avoidance;
- the threshold or professional judgement by which removal was considered necessary;
- every retained development area where the same type of constraint occurs;

- why avoidance was required in the first location but not the second;
- what alternative mitigation is relied upon in the retained location; and
- why that alternative provides an environmentally equivalent or otherwise acceptable outcome.

Without that exercise, the design-evolution record demonstrates **selective avoidance**, not necessarily a consistently applied mitigation hierarchy.

There is a particular risk that the removed areas function as highly visible examples of design responsiveness while the overall scale and configuration of the 500 MW Scheme remain substantially intact. The Applicant's own Chapter 5 states that the project-level design principles are intended to achieve its required levels of energy generation and storage while responding to local context. It is therefore necessary to determine whether environmental constraints were permitted to determine the extent of development, or whether avoidance was applied only where sufficient generating land remained available elsewhere to preserve the predetermined project objective.

That is the distinction between substantive and tokenistic design evolution.

BEPS submits that the Applicant should receive appropriate credit for genuine avoidance where it has occurred. But those examples also establish an evidential benchmark against which the retained Scheme must be judged. If proximity to a heritage asset, residential receptor, ancient woodland, BMV land, flood risk or aviation constraint justified removing panels in one location, the Applicant must explain why materially comparable or more severe constraints elsewhere did not produce the same first-stage response.

Otherwise, the design-evolution exercise does not demonstrate that the environment shaped East Pye. It demonstrates that selected parts of East Pye were adjusted sufficiently to allow the underlying 500 MW Scheme to remain.

1.2 Regional Need and Public Interest (NPS EN-1 §4.2.3; §4.1.2)

National policy establishes a strong need for low-carbon energy infrastructure. The August 2026 NPPF reinforces that position: Policy W3 states that substantial weight should be given to relevant energy-security, economic-development and net-zero benefits and that applicants should not generally be required to demonstrate the overall need for renewable or low-carbon energy development.

BEPS therefore does not contend that the Applicant must prove a separate generic national need for 500 MW of solar generation. The narrower issue is the weight properly attributable to the benefits claimed for East Pye itself. Gate status, regional pipeline evidence and national renewable-energy objectives do not determine whether every component of this Scheme will be delivered as promoted, whether its dispersed configuration represents an environmentally appropriate means of delivering those benefits, whether its associated BESS will become operational on a compatible timetable, or whether claims concerning congestion, curtailment, balancing and consumer benefit are demonstrated by Scheme-specific evidence.

The T7 evidence is relevant for that purpose. It does not establish a statutory cap on further solar development, but it does demonstrate that Gate 2 status should not be treated as evidence of an otherwise unmet regional requirement. BEPS's evidence records approximately 4,015 MW of renewable generation already within the T7 long-term planning pipeline by January 2026, around 96% of it solar, against the 3,300 MW CP2035 Tx+Dx solar modelling envelope. NESO's FOI response records that its Gate 2 "at/over CP2035" assessment used operational capacity only rather than the wider consented and planning pipeline. The significance of that evidence is therefore one of weight and characterisation of Scheme-specific benefit, not a contention that 3,300 MW operates as a legal ceiling.

In T7 (East Anglia), Ofgem RESP/REPD data show approximately **4,015 MW** of renewable generation already in the long-term planning pipeline (in construction, consented or in planning examination by January 2026), of which around **96% is solar**. This already exceeds the CP2035 T7 (Tx + Dx) regional solar modelling envelope of **3,300 MW**.

However, NESO's FOI response confirms that the Gate 2 'at/over CP2035' assessment was conducted using **operational capacity only (552.84 MW at the Gate 2 window close date)** and did not account for consented or in-planning solar capacity. Gate 2 status therefore does not evidence unmet regional need; it evidences compliance with connections-reform criteria based on a narrow operational baseline, and reflects queue reform sequencing rather than spatial system optimisation.

Further, the 13 February 2026 joint industry statement confirms that **formal Gate 2 transmission offers will not be issued until between mid-May 2026 and January 2027**, following further engineering review. At present, East Pye Solar has been **allocated into the Gate 2 cohort**, but has not received or accepted a revised, engineering-confirmed Gate 2 connection offer. Allocation is not equivalent to a binding or deliverable connection agreement.

Where the planning pipeline already meets or exceeds the CP2035 modelling envelope, and where formal connection offers remain subject to ongoing engineering reassessment, further large-scale transmission solar in T7 for 2031 cannot be justified on the basis of regional capacity necessity. Gate 2 allocation does not demonstrate strategic need or confirmed deliverability.

Moreover, East Pye Solar's associated battery storage has secured only **Gate 1**, not Gate 2. This materially undermines any claim that the scheme provides firm flexibility, congestion relief or system balancing in the region. Allocating Gate 2 to generation without secured Gate 2 status for its associated storage increases constraint risk in a region already saturated in planning terms and offers no guaranteed optimisation benefit.

In addition, the scheme's grid connection is dependent upon a **new 400kV substation**, which is entirely scheme-driven and increases engineering complexity. The February 2026 statement makes clear that sequencing of offers will vary based on engineering complexity and scale of reassessment. In those circumstances, the scheme cannot rely on provisional Gate 2 allocation as proof of strategic regional benefit or confirmed grid deliverability.

The evidence does not merely fail to prove that East Pye is uniquely necessary. It positively undermines the Applicant's attempt to derive project-specific necessity from Gate 2 status or from generic national policy. T7 already has a substantial solar pipeline; that pipeline exceeds the published 3,300 MW regional figure relied upon by BEPS; and NESO's Gate 2 regional assessment used operational capacity rather than the wider consented and planning pipeline. The Applicant has therefore not demonstrated any unmet T7 solar requirement which East Pye is needed to satisfy. BEPS does not contend that the 3,300 MW figure is a statutory cap or that Gate 2 status is irrelevant; the point is that neither establishes a project-specific need for East Pye.

The public-interest case required by NPS EN-1 §4.1.2 and §4.2.3 is therefore not demonstrated.

1.2.1Consumer Cost and System Risk (NPS EN-1 §4.1.2)

The absence of demonstrable regional need has direct consumer cost implications. Where planning-pipeline solar capacity in T7 already exceeds the CP2035 modelling envelope, an additional 500 MW transmission-connected solar project requires particular scrutiny as to congestion, curtailment and constraint exposure, because those factors directly affect the useful system value of the additional generation.

The allocation of Gate 2 to generation capacity without secured Gate 2 flexibility or storage capacity compounds that risk. Under NPS EN-1 §4.1.2, decision-makers must have regard to the need to ensure security of supply at the lowest cost to consumers. A scheme which adds generation into an already saturated regional envelope, without secured balancing capability and without a confirmed engineering-backed connection offer, risks imposing avoidable system costs through curtailment and constraint management. EN-1 recognises that security of supply must be delivered at least cost to consumers.

In such circumstances, the claimed system benefit is not demonstrated and the proportionality of environmental, heritage and agricultural harms must be assessed against a materially weakened need case.

The Applicant provides no Scheme-specific evidence demonstrating that East Pye will reduce either consumer bills or whole-system electricity costs. That claim cannot simply be inferred from the generic proposition that solar generation has low marginal costs. The relevant question is whether this particular 500 MW transmission-connected Scheme remains cost-beneficial once the additional transmission infrastructure, new National Grid substation, network reinforcement, balancing requirements, constraint and curtailment costs, BESS charging and round-trip losses, and associated system costs are taken into account. This is particularly important because the Applicant positively asserts that East Pye 'will not cause grid constraints or experience excessive curtailment' at its connection point. That is a project-specific factual assertion and should be evidenced accordingly. The Applicant should therefore disclose the modelling and assumptions underlying it, including the generation profile, relevant network topology and reinforcement dates, competing Gate 2 generation, constraint boundaries, dispatch assumptions, BESS operating strategy, sensitivity years and projected annual curtailment. In the absence of that evidence, the ExA cannot safely give material weight

to affordability as a Scheme benefit. The wider evidence concerning of consumer benefit require scrutiny, but the decisive evidence must come from the Applicant, NESO, Ofgem and National Grid and must demonstrate that East Pye itself produces a net system and consumer benefit rather than merely adding generation and infrastructure costs to an already heavily developed transmission system.

NGET's own Relevant Representation establishes that the final size, design and location of the point-of-connection infrastructure remain undecided; that the wider regulatory and commercial position must first be resolved; and that consent for the Applicant's proposed National Grid Substation would not oblige NGET to use it. The Applicant therefore cannot presently rely upon the proposed Site 1B substation as evidence that East Pye represents an economic, efficient or cost-effective grid connection. Those are precisely the matters NGET says remain to be determined.

1.2.2 Inconsistency with CP2035 Objectives

CP2035 is intended to deliver a secure, cost-effective and balanced electricity system within defined regional envelopes. In T7, the RESP/REPD data show that the planning pipeline already exceeds the 3,300 MW CP2035 (Tx + Dx) solar capacity limit. NESO's FOI response confirms that the Gate 2 'at/over CP2035' assessment was conducted using operational capacity only, excluding consented and in-planning projects.

As a result, Gate 2 allocation does not demonstrate that East Pye is required to remedy an identified T7 solar shortfall or that this particular 500 MW project is necessary to achieve CP2035 objectives; it demonstrates only compliance with connections-reform methodology.

Where:

- The regional planning pipeline already meets or exceeds the CP2035 modelling envelope;
- Formal Gate 2 offers remain subject to ongoing engineering reassessment;
- The scheme depends upon delivery of a new 400kV National Grid substation; and
- The associated battery storage has not secured Gate 2 status;

- it is legitimate to question whether the project is consistent with the core CP2035 objectives of coordinated, cost-efficient and system-balanced deployment.
- On the present evidence, the scheme risks undermining — rather than advancing — CP2035's aims of efficient system design and least-cost delivery.

On the evidence presently available, the Applicant has failed to demonstrate that East Pye is required to meet any identified T7 solar shortfall, that refusal would frustrate the regional pathway, or that the full 500 MW Scheme is necessary in this location. Gate 2 allocation cannot fill that evidential gap because the regional Gate 2 methodology did not take the wider consented and planning pipeline into account (Appendix H).

1.2.3 Congestion, Curtailment and Strategic Positioning Risk

The National Energy System Operator (NESO) has recently warned that 'misalignment between the national wholesale price and locational balancing needs, along with the scale and predictability of congestion, presents significant risks of strategic positioning against constraints,' and that this risk increases where the network becomes more congested. East Anglia is already a structurally constrained transmission region. The T7 (East Anglia) solar pipeline materially exceeds the Clean Power 2035 capacity limit (c. 4,015 MW in the planning/consented pipeline against a 3,300 MW capacity limit), and NSIP-scale transmission-connected solar projects already account for a disproportionate share of regional capacity.

East Pye Solar proposes a further 500 MW transmission-connected scheme in this oversaturated node, reliant on a new 400kV substation and without confirmed Gate 2 BESS flexibility. In these circumstances, approval would add further transmission-connected solar generation into a region already exposed to substantial network constraints, increasing the importance of demonstrating how East Pye's output will be absorbed, stored or exported without materially increasing congestion, curtailment and balancing costs. That outcome is inconsistent with the Clean Power 2030 spatial principle of deploying 'the right projects in the right place at the right time,' and undermines the proportionality balance required under NPS EN-1. Where additional transmission-scale solar materially exacerbates congestion in a region already exceeding system targets, the harms cannot be justified by generic net-zero need.

the Applicant positively asserts that East Pye 'will not cause grid constraints or experience excessive curtailment' at its connection point (statement of Need APP/7.11 Executive Summary, p. 3). That is a project-specific factual assertion and should be evidenced accordingly. The Applicant should therefore disclose the modelling and assumptions underlying it, including the generation profile, relevant network topology and reinforcement dates, competing Gate 2 generation, constraint boundaries, dispatch assumptions, BESS operating strategy, sensitivity years and projected annual curtailment. In the absence of that evidence, the ExA cannot safely give material weight to affordability as a Scheme benefit.

NGET's own Relevant Representation materially weakens the Applicant's claim that East Pye occupies a settled, efficient and low-risk grid position. NGET expressly states that consent for the proposed National Grid Substation would not oblige it to accommodate the Scheme at that substation, that the "wider regulatory and commercial context" must still be worked through before the location can be confirmed, and that the final size, design and location of the connection solution will depend in part on the outcome of other Gate 2 offers. NGET further states that it cannot yet confirm what the final solution will be and that potentially significant additional transmission infrastructure may be required to facilitate East Pye's connection. This is difficult to reconcile with any suggestion that the present Site 1B solution is already demonstrated to be economically efficient, unconstrained or strategically optimal. At best, the Applicant has secured a route to a future connection; it has not established the final network solution, the infrastructure required to deliver it, or the resulting constraint and curtailment consequences. Those uncertainties should substantially reduce the weight attached to

claimed benefits based on assumed grid efficiency, low curtailment and cost-effective strategic positioning.

A further strategic inconsistency arises from the emerging North Anglia Node A connection point on the proposed Norwich–Tilbury transmission reinforcement. The TEC register identifies multiple substantial generation and storage projects with connection arrangements associated with North Anglia Connection Node A. That appears to contemplate a further major 400 kV connection node in South Norfolk on the new transmission infrastructure.

That emerging network configuration materially strengthens the need to scrutinise East Pye's proposed new National Grid Substation at Site 1B. East Pye is promoted as a 60-year 'temporary' solar development, yet the Applicant seeks consent for substantial National Grid infrastructure connecting into the existing 400 kV transmission line, infrastructure which the Applicant itself now accepts may remain after the solar generating station has been decommissioned. At the same time, National Grid appears to be developing a separate strategic connection node on the proposed new transmission line in broadly the same South Norfolk area for multiple future projects.

BEPS does not suggest that the existence of North Anglia Node A necessarily makes East Pye's proposed connection technically impossible or that National Grid can never require more than one substation. The issue is one of strategic necessity, efficiency and proportionality. If a new multi-user 400 kV connection node is already planned on the future transmission network in South Norfolk, the Applicant and NGET should explain why a second new National Grid substation should also be constructed on the existing network at Great Moulton principally to serve East Pye, particularly where East Pye is presented as temporary but the grid infrastructure may remain permanently.

The Examination should therefore require NGET to explain whether North Anglia Node A was considered as part of the connection options for East Pye; whether East Pye could technically connect to that future node or another element of the Norwich–Tilbury reinforcement; what network, programme or cost considerations led to rejection of that option; whether construction of the Site 1B substation remains necessary once the future North Anglia network configuration is taken into account; and whether the permanent infrastructure proposed at Site 1B represents the most economic and efficient long-term network solution rather than a project-specific connection arrangement driven by the timing of East Pye's existing connection agreement.

This is particularly important because NGET has itself stated that the final size, design and location of East Pye's point-of-connection solution remain subject to the wider regulatory and commercial process and that consent for the proposed Site 1B substation would not oblige NGET to use that solution. In those circumstances, the existence of a further planned multi-user connection node in the same part of South Norfolk reinforces BEPS's submission that the strategic necessity, permanence and proportionality of East Pye's proposed National Grid Substation have not yet been demonstrated.

1.2.4 East Pye is one project within the Applicant's much larger development portfolio

The project-specific need case must also be considered in the context of the Applicant's own development portfolio. East Pye is not the Applicant's only prospective contribution to national solar deployment. Island Green Power is a major utility-scale solar developer which is now owned by Macquarie Asset Management. Macquarie states that Island Green Power has a UK pipeline exceeding 15 GW of utility-scale solar and battery-storage projects. Island Green Power's own current portfolio identifies numerous large solar projects in development, including East Pye, The Droves, Lime Down, Green Hill, Humberhead, Arrow Valley and Light Valley, alongside the already consented Cottam and West Burton projects.That context is directly relevant to the weight which should be attributed to assertions of project-specific necessity.

Most importantly, the Applicant is simultaneously promoting **The Droves Solar Farm**, another proposed 500 MW solar project in Norfolk – its DCO application was accepted by the Planning Inspectorate on 16 December 2025.

The Applicant is therefore seeking consent for two separate 500 MW solar NSIPs in Norfolk in the T7 region at broadly the same time: **East Pye and The Droves**. This materially weakens any suggestion that the national need for renewable generation establishes a particular necessity for East Pye. The Applicant is not presenting East Pye as the sole project through which it can contribute to national solar deployment. It is pursuing a portfolio of very large projects, including another 500 MW project in the same county and wider transmission region, as part of a UK development pipeline measured in many gigawatts.

That is important when the Applicant relies upon concepts such as pipeline attrition and optionality. A large development portfolio necessarily creates commercial and system optionality. Some projects may obtain consent, some may be delayed, some may change and some may never proceed. Maintaining multiple prospective projects may therefore be rational from the perspective of the developer or the connections system. But that does not establish that every individual member of the portfolio is necessary. It also does not justify uncertainty for communities or compulsory purchase powers over their land.

Portfolio optionality is not project-specific necessity.

Nor does possible attrition elsewhere establish that the environmental harm of East Pye must be accepted now. The fact that another project might ultimately fail to proceed explains why a developer may wish to preserve multiple options. It does not demonstrate why East Pye must occupy this particular nationally important ecological and historic landscape.

The existence of The Droves makes that distinction particularly acute. If the same Applicant is separately promoting another 500 MW solar NSIP within Norfolk, the Applicant should explain what specific system requirement requires **both** projects, and what identifiable deficit would arise if East Pye were not consented.

It should also explain how the two projects relate to the same wider regional generation pipeline, transmission constraints and CP2035 modelling context. The relevant question is not simply whether each individual project can point to national renewable-energy policy. It is what additional system benefit East Pye provides once the Applicant's own other projects and the wider T7 pipeline are taken into account.

That analysis is especially important because the environmental cost of East Pye is unusually high. The Scheme would extend across ten dispersed Sites within a landscape supporting nationally important bats, multiple barbastelle maternity colonies, ancient woodland, BMV agricultural soils, sensitive water systems, historic conservation villages, ancient churches, listed buildings and substantial admitted landscape effects. The comparison must therefore be project-specific:

What demonstrable public benefit is obtained by consenting East Pye, in addition to the Applicant's other substantial solar projects and the existing regional pipeline, which is sufficient to justify the particular environmental harm of these ten Sites?

The Applicant has not answered that question merely by demonstrating that East Pye is capable of generating 500 MW or that some attrition elsewhere in the national pipeline may occur.

Indeed, Macquarie's acquisition of Island Green Power reinforces the need to distinguish public benefit from commercial portfolio strategy. Macquarie describes Island Green Power as a platform through which it intends to expand its UK renewable-energy activities, while Island Green Power maintains a UK utility-scale solar and storage pipeline exceeding 15 GW. There is nothing improper in that commercial strategy. But the planning system should not equate the commercial value of maintaining multiple development options with proof that each project is environmentally necessary.

The correct conclusion is therefore:

East Pye Solar must justify itself. It cannot derive project-specific necessity merely from the general national need for renewable generation, from the possibility of attrition elsewhere, or from the commercial value of maintaining a large portfolio of prospective solar projects. Possible attrition elsewhere does not establish necessity for East Pye Solar. Unless the Applicant identifies which capacity is assumed to fall away, on what evidence, and what resulting T7 deficit East Pye is required to fill, attrition remains an assumption rather than a project-specific need case.

That is particularly relevant where the Applicant is simultaneously promoting another 500 MW solar NSIP in Norfolk and has a UK utility-scale solar and storage pipeline exceeding 15 GW. The greater the availability of alternative projects within the Applicant's own portfolio and the wider national pipeline, the more important it is to demonstrate why the exceptional environmental cost of East Pye must be incurred in this particular landscape.

1.3 BESS undeliverability

East Pye Solar's claimed deliverability is materially undermined by the instability and asymmetry of its grid position. The project's transmission-connected solar element is in the Gate 2 queue with an indicative 2031 connection date (but no firm offer), yet its co-located BESS – which industry experts have acknowledged is essential to the commercial viability of large NSIP solar in congested transmission regions – remains only in the Gate 1 queue.

Recent reporting on NESO's revised connections timetable confirms ongoing delays, rerunning of engineering studies, and heightened uncertainty across transmission zones, together with no clear pathway for non-protected BESS projects to secure new capacity under the reformed queue. In that context, East Pye's storage element cannot be treated as secured or deliverable, and without firm storage capacity the scheme faces exposure to curtailment, congestion and revenue volatility in an already oversubscribed region. The project is therefore grid-dependent, storage-dependent and timetable-dependent on a reform process NESO itself describes as uncertain.

This materially weakens the claim that there is a reasonable prospect of implementation or a compelling case in the public interest, and strengthens the need for the Examining Authority to scrutinise deliverability, funding realism and financial security with particular care.

Under NESO's Connections Reform process, Gate 2 capacity has been prioritised for projects demonstrably aligned with Clean Power 2030 and already sufficiently advanced. Gate 2 Phase 1 offers (to 2030) have largely been issued to 'protected' or strategically aligned projects, and Gate 2 Phase 2 offers (covering 2031–35) are scheduled for issuance during 2026–27. However, industry reporting on the Gate 2 to Whole Queue outcomes confirms that battery storage is heavily oversubscribed, with only a subset of projects securing Gate 2 status and very limited headroom remaining within the 2035 planning window. Large volumes of storage schemes were reduced to Gate 1 only, with no defined timetable for a further application window under the enduring regime. In that context, East Pye Solar's BESS — which currently holds only Gate 1 status and is located within an already saturated T7 transmission region — cannot reasonably demonstrate a realistic prospect of securing a Gate 2 offer before 2035, if at all. Without Gate 2 allocation, the BESS lacks confirmed transmission capacity and therefore cannot be treated as deliverable under NPS EN-1 requirements that projects demonstrate a credible grid connection and implementation pathway. The project's reliance on unconfirmed future Gate 2 capacity renders the claimed flexibility, congestion mitigation and system-balancing benefits speculative rather than secured.

The position of the proposed 500 MW BESS is materially different from that of the solar generating element. The solar element has progressed through Gate 2, whereas the BESS remains at Gate 1. The issue is therefore not whether battery storage has generic national value, but whether the particular East Pye BESS has a demonstrated route to connection and whether the integrated solar-plus-storage benefits attributed to the Scheme are reasonably capable of being delivered.

The regional position is highly constrained. NESO's February 2026 EIR response records 784 MW of T7 Gate 2 battery capacity for the first relevant period and 927.6 MW for 2031–35, giving 1,711.6 MW in total, against connections-reform allocations of 200 MW and 200 MW respectively. Existing Gate 2 battery capacity is therefore approximately 4.28 times the combined 400 MW T7 allocation. NESO expressly identifies significant battery oversupply and records a further 4,283.1 MW of T7 Gate 1 battery projects which did not satisfy the relevant Gate 2 strategic-alignment or protection requirements.

NESO's June 2026 methodology expressly states that, where an application relies upon ordinary CP2030 capacity alignment in a technology zone oversupplied both zonally and nationally, NESO may determine that the relevant project technology stage has failed Strategic Alignment before detailed checks or queue formation. That provision does not apply where the project instead benefits from a protection or Project Designation.

This is directly relevant to East Pye because its BESS remains Gate 1 in a materially oversupplied T7 battery zone, while no applicable protection or designation has been identified.

The wider national position is also material. Ofgem's September 2026 evidence indicates that operational and prioritised battery capacity substantially exceeds projected 2035 system requirements. That does not mean that every additional battery project is unnecessary, but it makes the route by which a further Gate 1 project is expected to enter the prioritised queue a material project-specific question.

NESO's protection methodology is particularly important. Projects which progressed through the connections reform process under specified protection clauses may receive Gate 2 despite zonal permitted capacity having been exceeded. East Pye is not in the same position as earlier protected projects merely because its solar element has Gate 2. NESO's methodology expressly allows the protected and unprotected elements of hybrid projects to be treated separately.

For staged or hybrid projects, the methodology expressly provides that if one stage or technology meets the Gate 2 Strategic Alignment Criteria and another does not, only the qualifying stage or technology receives Gate 2. The solar element's Gate 2 status therefore does not itself confer Gate 2 upon the BESS.

East Pye's DCO application was not submitted until 2026. It therefore cannot satisfy the planning-submission date required for Protection Clause 3a, and it was likewise not submitted and validated by the earlier date required for Clause 3b. Protection Clause 2b remains theoretically available only if the BESS obtains one of the qualifying support or procurement arrangements specified by NESO. No evidence presently identified by BEPS demonstrates that East Pye BESS holds such an arrangement.

NESO's published connections-reform position is that there is presently no ordinary permitted capacity for additional batteries in future windows unless a project qualifies through an applicable protection route, more than approximately 55 GW of existing Gate 2 battery capacity exits the pipeline, or future strategic planning materially increases permitted battery capacity. Project designation provides a further exceptional route in qualifying circumstances, but the Applicant has not demonstrated that East Pye satisfies the current designation criteria.

The correct examination question is therefore not whether Gate 2 is legally impossible. It is: **what presently identifiable route does the Applicant rely upon for this particular 500 MW Gate 1 BESS to become connected and operational, and on what timetable?**

That question is material because East Pye is promoted as an integrated solar-plus-storage project. The Examination should distinguish between physical co-location within the same DCO and electrical and temporal co-deliverability. The presence of the BESS within the Order Limits does not establish that it will connect, commission or operate contemporaneously with the solar generation.

The Applicant should therefore identify and assess the reasonable implementation scenarios permitted by the DCO, including solar becoming operational materially before the BESS, delayed or reduced BESS, a differently configured BESS, and solar proceeding for all or a substantial part of its operational life without Work No. 2. For each scenario it should identify which claimed benefits remain, which are deferred or lost, and whether the environmental assessment, electrical design, replacement assumptions and DCO controls remain robust.

The benefits attributed to East Pye should correspondingly be disaggregated. The solar-generation benefit is available if the solar element proceeds, but flexibility and balancing benefits attributed to the BESS depend upon the storage component obtaining a connection and becoming operational. Claimed co-location benefits depend upon both elements operating on compatible timescales. Claimed reductions in curtailment require evidence that the BESS will actually be connected when required and can operate in the manner assumed. Wider system-cost or consumer benefits attributed to storage cannot simply be inferred from the inclusion of a BESS within the DCO.

The weight given to those claimed benefits should therefore reflect the demonstrated deliverability of the BESS rather than its physical inclusion within the application.

1.4 Deliverability Challenges of large-scale standalone solar

Industry evidence from the UK solar sector further underscores the systemic economic and deliverability challenges posed by large-scale standalone solar in a congested market. According to a Solar Power Portal article discussing outcomes from the Solar Finance & Investment Europe summit, ‘Panellists agreed that standalone solar is becoming more challenging. Folgado said returns are tightening as cannibalisation and negative pricing increase. ‘Solar co-located with batteries makes sense,’ he said. ‘Standalone solar is much tougher.’’ This admission from market participants confirms that as transmission-connected solar capacity proliferates and cannibalisation effects intensify, standalone solar projects face materially reduced economic returns and heightened risk of negative pricing. In the context of the Clean Power 2030 pipeline and **gate-based grid access reforms**, such realities further diminish the justification for advancing new standalone solar capacity in this region, particularly where congestion, curtailment, and negative wholesale pricing already undermine revenue certainty and project deliverability.

This market evidence is relied upon only as contextual evidence of the importance of storage, curtailment and revenue cannibalisation to the deliverability of large-scale solar. It is not relied upon as proof that East Pye itself is commercially unviable.

1.5 Negative Pricing

The experience in Spain demonstrates that very large volumes of solar capacity can create system-level problems where deployment runs ahead of grid capacity, storage, flexible demand and locational need. The result is not simply cheaper electricity, but increasing negative-price periods, curtailment, distressed asset values and pressure for further network and storage investment. This is directly relevant to the planning balance for East Pye Solar, because the applicant relies heavily on a generic national need for solar generation, while failing to demonstrate a specific regional or locational need for this scheme, or that its co-located storage will be available in time to make the solar generation genuinely useful to the system.

The Secretary of State should therefore be cautious about treating nameplate solar capacity as equivalent to deliverable public benefit. The relevant benefit is not the theoretical maximum output of the panels, but the extent to which the electricity can be absorbed by the grid, stored, exported, or matched to demand at the time it is generated. Where grid connection, storage, curtailment and regional need are uncertain, the public benefit should be reduced accordingly in the planning balance.

BEPS does not contend that the Spanish market provides a direct forecast for Great Britain. The comparison illustrates the general system consequence of adding large quantities of coincident solar output without equivalent network, storage and demand flexibility. The Scheme-specific issue remains whether East Pye's claimed curtailment, balancing and consumer benefits are supported by evidence for T7 and by a deliverable BESS.

1.6 Compulsory Acquisition and Protected-Species Licensing: Consequences of Unproven Locational Necessity

1.6.1 Compulsory Acquisition – No Compelling Case in the Public Interest

Under **Planning Act 2008 s122(3)**, compulsory acquisition powers may only be granted where there is a **'compelling case in the public interest.'** This is a high statutory threshold. The Secretary of State must be satisfied that:

- There is a compelling case in the public interest for the land to be acquired;
- The interference with private rights is proportionate; and
- The public benefits clearly outweigh the private harm.

NPS EN-1 §4.1.2 and §4.2.3 require a compelling public-interest case linked to national need. Where regional solar capacity in T7 already meets or exceeds the CP2035 modelling envelope (as evidenced by RESP/REPD pipeline data), and where Gate 2 status reflects queue methodology rather than unmet regional need, that compelling case is materially weakened.

Compulsory acquisition would:

- Permanently interfere with agricultural land interests;

- Override landowner rights;
- Sterilise Best and Most Versatile land;
- Impact private water supplies, fibre infrastructure and farming businesses.

The T7 evidence does not by itself determine the section 122 question. Its relevance is to the weight and certainty of the public benefits relied upon by the Applicant. The section 122 test remains whether the particular land or interest is required for the development and whether there is a compelling case in the public interest for its compulsory acquisition. Where material components of the Scheme remain optional, severable or dependent upon unresolved connection arrangements, and where the benefits attributed to those components remain contingent, that uncertainty is relevant to whether the particular compulsory powers sought have been justified.

The compulsory-acquisition case must therefore be made plot by plot and interest by interest against the Scheme actually capable of proceeding. Generic national renewable-energy policy cannot by itself establish why permanent freehold, rather than a lesser right or temporary interest, is necessary over a particular parcel.

1.6.2 European Protected Species licensing – no satisfactory alternative and unresolved favourable-conservation-status test

East Pye Solar engages European Protected Species licensing principally because of its potential effects on bats, including barbastelle, and potentially other species such as great crested newt. White-clawed crayfish are subject to separate statutory protection and conservation duties but should not be described as a European Protected Species for the purposes of this licensing test.

Under Regulation 55 of the Conservation of Habitats and Species Regulations 2017, a licence affecting a European Protected Species may be granted only for one of the purposes specified in Regulation 55(2) and only where the licensing authority is also satisfied that there is **no satisfactory alternative** and that the authorised action **will not be detrimental to the maintenance of the population of the species concerned at a favourable conservation status in its natural range**. Natural England describes the three licensing tests in equivalent terms: the activity must be for an eligible purpose, there must be no satisfactory alternative causing less harm, and the activity must not harm the long-term conservation status of the species.

For development of this kind, the Applicant may seek to rely upon the public-interest purpose within Regulation 55(2). That is distinct from the separate Habitats Regulations Assessment derogation regime for European sites, under which IROPI forms part of the alternative-solutions/IROPI/compensation sequence. The two regimes should not be conflated.

The decisive difficulty for East Pye is therefore not an abstract assertion that renewable energy cannot serve a statutory purpose. It is whether the Applicant can demonstrate, on the evidence of this particular Scheme, both that there is **no satisfactory less-damaging alternative** and that the Scheme will not adversely affect the favourable conservation status of the protected species concerned.

The first of those questions is especially important because the Applicant has not demonstrated that this particular 500 MW development must occupy this particular landscape. Chapter 5 of this Written Representation shows that the broad project scale was fixed before full environmental optimisation; that the land search was substantially shaped by land availability and grid opportunity; that smaller configurations were not meaningfully pursued; and that the Applicant has not demonstrated a South Norfolk-specific or T7-specific necessity for the whole retained Scheme.

That matters directly to the 'no satisfactory alternative' test. The relevant alternatives are not confined to minor micrositing around individual roost trees after the Scheme has already been fixed. They include materially less damaging layouts, removal of development from the most important maternity-colony support landscapes, reduction in scale, alternative routing and, where necessary, alternative locations.

The Applicant's own design history confirms that removal of development is technically possible where it is judged necessary. Development has been deleted or reduced in response to ancient woodland, bat, heritage, BMV, residential and aviation constraints in some locations while materially similar constraints remain elsewhere. That makes it particularly important for the Applicant to demonstrate why avoidance of protected-species habitat elsewhere is not a satisfactory alternative.

The favourable-conservation-status test is still more problematic.

The Applicant's own surveys identify the bat assemblage across the Order Limits as being of **national importance**. Barbastelle was recorded throughout the Scheme, with extensive activity across the development landscape. The Applicant also identifies multiple maternity colonies and accepts that the Order Limits lie within overlapping Core Sustenance Zones.

The Norfolk Barbastelle Study Group has since provided further evidence confirming a maternity colony at Little Wood and indicating probable additional maternity colonies at Brooke Wood and Lower Spring Wood. Critically, the Study Group states that further radiotracking and woodland assessment are required before the full distribution and functional habitat use of the maternity-colony network can be established.

The present problem is therefore evidentially fundamental. The Applicant is asking the decision-maker to proceed before the full maternity-colony baseline, principal commuting routes, foraging areas, alternative roost networks and functional relationships between overlapping colonies have been established.

That uncertainty cannot properly be treated as evidence that favourable conservation status will be maintained.

The relevant receptor is not simply an individual roost tree. The evidence indicates a landscape-scale barbastelle metapopulation dependent upon interconnected woodland, mature hedgerows, tree lines, dark corridors, ponds, streams and agricultural foraging habitat. The Scheme would introduce panel arrays, fencing, lighting, access works, repeated hedgerow crossings, substations, cable corridors, construction disturbance and long-term habitat change across that functional landscape.

Natural England has itself emphasised, in another Norfolk bat case, that the developer must demonstrate both that there is no satisfactory alternative and that the conservation status of the bats will not be negatively affected. Those tests require evidence, not an assumption that later licensing will resolve the problem.

A future EPS licence application therefore cannot be treated as routine post-consent administration. Before development consent is granted, there must be a sufficiently robust evidential basis for concluding that any necessary licence has a realistic prospect of being granted. At East Pye, that requires a substantially clearer understanding of the protected-species population and its functional habitat than is presently available.

The Applicant's reliance upon generic buffers, future management plans, retained hedgerows and later protected-species licensing does not answer either statutory question. Retention of habitat features does not prove that they will remain functionally usable; nor does habitat creation elsewhere demonstrate that disruption of established maternity-colony support habitat will leave the population at favourable conservation status.

The consequence is not that BEPS must prove now that an EPS licence could never be granted. The burden is narrower. The Applicant must demonstrate a sufficiently evidenced and realistic licensing pathway before consent is granted. On the present evidence, it has not done so.

The position is especially serious because the outstanding information is capable of changing the Scheme itself. Further radiotracking may identify principal commuting routes, foraging areas or maternity-colony support habitat requiring additional avoidance or deletion of development. Once the DCO has fixed the development envelope and compulsory powers, later survey cannot provide the same opportunity for genuine avoidance.

The correct conclusion is therefore:

East Pye has not yet demonstrated that there is no satisfactory less-damaging alternative to development affecting the nationally important barbastelle landscape, nor that the Scheme can proceed without detriment to the maintenance of the affected populations at favourable conservation status. Those are statutory licensing questions, not matters that can safely be assumed away through future mitigation. Until the maternity-colony and functional-habitat baseline is sufficiently complete to answer them, the protected-species licensing pathway remains materially uncertain and the Application is premature.

1.6.3. Proportionality and the separate statutory tests

Both compulsory acquisition and EPS licensing involve significant interference with private rights and protected ecological interests. In public law terms, such interference must be proportionate. If:

- The CP2035 regional envelope is already met;
- Gate 2 allocation does not demonstrate unmet need;
- The associated battery storage lacks secured Gate 2 status and may be undeliverable;

- The scheme increases congestion risk in an already saturated region;

then the incremental public benefit of this particular scheme is marginal at best. In those circumstances:

- The proportionality balance shifts;
- those uncertainties materially affect the weight and evidence available when the relevant statutory tests are applied.

Where materially less damaging alternatives have not been adequately considered, or where the component said to justify land acquisition or environmental interference is not shown to be deliverable, those uncertainties bear upon the relevant statutory test.

1.6.4. Conclusion

Compulsory acquisition powers and EPS licences are not routine planning tools; they are exceptional legal mechanisms justified only by demonstrable public necessity.

Where:

- Regional solar capacity consented or ahead of it in Planning already meets or exceeds CP2035 capacity limits;
- Gate 2 allocation does not evidence unmet need;
- Engineering-confirmed connection offers have not yet been issued;
- Associated storage lacks secured Gate 2 status;
- The scheme is promoted for ‘optionality’ and in case of ‘attrition’

the scheme cannot demonstrate a compelling case in the public interest. The Applicant must satisfy the relevant statutory tests on their own terms, using the actual Scheme and the alternatives reasonably available to it. Generic national renewable-energy need does not answer whether a particular land interest is necessary under section 122, nor whether a less damaging satisfactory alternative exists for the purposes of any required EPS licence.

1.7 Availability of Alternative Regions with Unmet Capacity Envelopes

National renewable energy need is not geographically fixed to a single transmission region. Electricity generated at transmission level is distributed across the national network. Accordingly, large-scale transmission-connected solar projects are not inherently constrained to any one region unless there is demonstrable regional capacity necessity.

Publicly available CP2035 modelling identifies regional capacity envelopes for transmission and distribution (Tx + Dx). In T7 (East Anglia), the long-term planning pipeline already exceeds the 3,300 MW modelling envelope when consented, in-construction and in-examination projects are taken into account (as if Jan 2025). By contrast, other transmission regions remain below their respective modelling envelopes.

This establishes two uncontested propositions:

1. Solar deployment is regionally uneven;
2. Additional transmission-connected solar capacity is not uniquely required in T7 in order to meet national objectives.

Where some regions remain below their modelling envelopes, while T7 exceeds its envelope in planning terms, it follows that large-scale solar generation is capable of being delivered elsewhere without adding to cumulative saturation in T7.

This is not an argument that renewable generation is unnecessary. It is an argument that the applicant has not demonstrated why this scale of transmission-connected development must be located in a region where the modelling envelope is already met or exceeded by projects already consented or in planning by January 2026 according to T7 tResp.

In a nationally networked electricity system, the rational and proportionate approach to deployment is to direct additional large-scale infrastructure toward regions where modelling envelopes have not yet been met, particularly where doing so would avoid cumulative environmental, agricultural and heritage harm in already saturated areas. Accordingly, there is no locational necessity inherent in T7 unless regional capacity deficiency is demonstrated.

In the absence of evidence that T7 requires additional large-scale transmission solar to meet national targets, the applicant has not demonstrated why the project could not, and should not, have been brought forward in an alternative transmission region where capacity remains below modelling thresholds. T7 is primarily designed to facilitate the transmission of offshore wind – this is why it has relatively low solar 'capacity limits' (NESO's terminology). Offshore wind will prioritised, causing excess solar to be constrained.

Conclusion

The question is not whether the UK requires renewable energy. It does. The question is whether this particular 500 MW transmission-connected scheme, in an already oversubscribed and highly constrained transmission region, represents a proportionate, cost-efficient and strategically necessary deployment. On the present evidence, it does not.

1.8 Grid Capacity, Gate 2 Allocation and Deliverability Failure

East Pye Solar cannot demonstrate regional necessity or secured grid deliverability. The T7 transmission region already contains approximately 4,015 MW of renewable generation within the planning and long-term pipeline, materially exceeding NESO's CP2035 T7 (Tx + Dx) capacity limit of 3,300 MW. NESO has confirmed that its oversubscription assessment for Gate 2 allocation was based on operational capacity (c.552.84 MW) rather than pipeline capacity. Accordingly, the fact that East Pye has received Gate 2 status for its generation component does not demonstrate alignment with regional need under Clean Power 2030 or CP2035; it reflects a methodological approach that disregarded already consented and pipeline schemes.

Gate 2 allocation is therefore not evidence of necessity. It cannot itself establish an unmet regional solar deficit, project-specific locational necessity, or that East Pye is uniquely required. That distinction is decisive. Gate 2 demonstrates progression through the connections process under the methodology NESO applied. It does not answer the planning question whether a further 500 MW solar NSIP is needed in T7 in excess of the regional capacity limits, whether refusal of East Pye would create any regional shortfall, or why this particular Scheme should be located in this highly constrained landscape.

Industry evidence further confirms that additional standalone transmission-connected solar in saturated regions is economically and systemically problematic. As reported in Solar Power Portal:

'Panellists agreed that standalone solar is becoming more challenging. Folgado said returns are tightening as cannibalisation and negative pricing increase. "Solar co-located with batteries makes sense," he said. "Standalone solar is much tougher."'

This admission from market participants demonstrates that excess transmission-connected solar increases cannibalisation and negative pricing, heightens curtailment risk, and reduces effective system value. In an already oversubscribed region, additional large-scale standalone solar risks exacerbating congestion and constraint payments, transferring costs to consumers while delivering diminishing marginal benefit.

Crucially, East Pye's BESS does not hold Gate 2 status. Under NESO's Connections Reform process, Battery storage has proven heavily oversubscribed, with only a subset of projects securing Gate 2 offers in the 2030–2035 window. Large volumes of BESS schemes have been reduced to Gate 1 only, and no defined timetable exists for additional Gate 2 application windows under the enduring regime. In that context, East Pye's BESS — located within an already saturated T7 transmission region — cannot demonstrate a realistic prospect of securing Gate 2 allocation before 2035, if at all.

Without Gate 2 allocation, the BESS lacks confirmed transmission capacity and cannot be relied upon to mitigate congestion, smooth output, or address cannibalisation effects. The project therefore functions, in practical terms, as a standalone transmission-connected solar scheme in an oversaturated region — precisely the project type identified by industry itself as 'much tougher' under current market conditions.

At a Solar Power Portal webinar in January 2026, analyst Josh Cornes said: 'There are a lot of projects that are unfeasible without both solar and BESS, wind and BESS co-location, and because NESO haven't looked at them as one project, they've looked at them as two different things, they've given Gate 1s to mainly BESS and Gate 2 to the solar side of things, but obviously without the BESS, the solar can't be built … these projects just aren't feasible without both technologies.'

(https://www.solarpowerportal.co.uk/solar-planning/video-what-does-grid-connection-reform-mean-for-uk-solar-and-bess-developers).

Under **NPS EN-1 (2023)**, nationally significant infrastructure must demonstrate a compelling case in the public interest and a credible pathway to delivery. A scheme that:

- Exceeds regional planning capacity limits,
- Increases congestion in a saturated transmission zone,
- Faces tightening economics due to cannibalisation and negative pricing, and
- Relies on speculative future Gate 2 capacity for its storage component

cannot demonstrate secured system need, locational necessity, or deliverability. The claimed 500 MW public benefit is therefore not equivalent to 500 MW of reliably delivered or economically efficient capacity.

In these circumstances, the extensive environmental, heritage, ecological and community harms identified elsewhere in this objection cannot be justified as proportionate to any demonstrable regional system requirement.

The Applicant cannot place generic national renewable need on one side of the balance and the specific environmental harms of East Pye Solar on the other. The relevant benefit is the demonstrated public benefit of East Pye Solar itself. On the present evidence, no specific T7 deficit requiring East Pye has been identified

1.9 Deliverability Risks

In addition to the above deliverability risks, East Pye Solar faces multiple, interconnected others, arising from the exceptionally constrained site it has chosen. Most of the land parcels are impacted by several of these constraints at the same time. These are minimised in the chapter-by-chapter structure of East Pye Solar's own application, but patently evident from the land-parcel specific written representations made by BEPS/affected Parish Councils.

1.9.1 Deliverability Risk: European Protected Species Licensing

East Pye Solar faces a material protected-species licensing risk because the Scheme lies within the functional landscape of a nationally important bat assemblage, including multiple barbastelle maternity colonies and overlapping Core Sustenance Zones. The Applicant's own surveys establish widespread barbastelle activity across the Order Limits, while the Norfolk Barbastelle Study Group considers further radiotracking and woodland survey necessary before the maternity-colony network and its functional habitat use are fully understood.

Where works risk an offence affecting European Protected Species, any necessary licence must satisfy the statutory tests, including no satisfactory alternative and maintenance of the species at favourable conservation status. The issue for the DCO Examination is therefore whether there is a sufficiently robust evidential basis to conclude that any required licence has a realistic prospect of being granted.

At present, that confidence is not established. The Applicant has not yet demonstrated the complete distribution of maternity colonies, the principal commuting and foraging

routes, or the cumulative effects of development across overlapping colony landscapes. Nor has it demonstrated why less damaging alternatives—including deletion, relocation or reduction of development within important supporting habitat—are unavailable.

The licensing issue should therefore not be deferred on the assumption that later survey and mitigation will resolve it. Further survey may identify habitat whose importance requires avoidance or materially different design. That information is relevant now, before the development envelope is authorised.

The correct conclusion is not that an EPS licence can never be granted. It is that, on the present evidence, the Applicant has not demonstrated a sufficiently secure licensing pathway to enable the Scheme's deliverability to be assumed.

1.9.2 Deliverability Risk: Water Environment and WFD Compliance

East Pye Solar raises a material WFD and water-environment risk because substantial parts of the Scheme are hydrologically connected to the River Tas, Hempnall Beck and associated ditch and groundwater systems. The Environment Agency continues to identify unresolved matters concerning groundwater, watercourse crossings, piling, cabling, pollution prevention, fisheries, aquatic ecology and private and public water supplies.

The relevant question is not whether BEPS can prove in advance that WFD deterioration will occur. It is whether the Applicant has provided sufficient evidence to enable the competent authority to determine, with appropriate confidence, that the authorised Scheme will comply with the applicable no-deterioration and waterbody-objective requirements.

That has not yet been demonstrated.

Important components of the hydrogeological case remain dependent on future investigation, including Foundation Works Risk Assessments and potentially HDD-specific hydrogeological assessment. The aquatic baseline has also been affected by dry survey conditions and incomplete species evidence.

The consequence is therefore evidential and regulatory: the Applicant has not yet closed the pathway by which piling, trenching, HDD, drainage change, sediment mobilisation or pollution could affect connected waterbodies. Until it does so, the Examining Authority should not assume that WFD compliance or the claimed negligible residual water effects are secured.

If the outstanding evidence ultimately demonstrates a risk of prohibited deterioration that cannot be avoided or brought within the applicable regulatory framework, that would constrain consent. At present, however, the immediate problem is that the evidence required to reach the necessary conclusion is incomplete.

1.9.3 Deliverability Risk: Private Water Supplies and Aquifer Protection

The Scheme affects Principal Aquifer areas and lies close to clusters of private water supplies. The Environment Agency has repeatedly required greater clarity regarding abstraction locations, groundwater pathways, piling, underground cables, contamination and private and public water supplies.

The Applicant therefore needs to demonstrate that construction and operation will not create unacceptable risks to drinking-water receptors through preferential pathways, contamination mobilisation, altered recharge, transformer oil, BESS-related pollutants or contaminated firewater.

On the present evidence, that demonstration is incomplete. In particular, the available material does not provide a receptor-specific hydrogeological assessment for every potentially affected supply showing abstraction depth, aquifer unit, hydraulic connectivity, flow direction and relevant pollutant pathways.

The correct conclusion is not that any theoretical risk to a private supply makes the Scheme unlawful. It is that the DCO should not proceed on an assumption of negligible effect where the receptor and pathway evidence required to support that conclusion remains incomplete.

Where a private drinking-water supply could be affected, avoidance and protection must be demonstrated before consent or secured through sufficiently precise controls. If an acceptable protective solution cannot be demonstrated for a particular location or activity, that element of the Scheme should be redesigned or removed.

1.9.4 Deliverability Risk: Major Accidents and Disasters – Site 1 Infrastructure Cluster

Site 1 combines a proposed National Grid 400 kV substation, a 400 kV project substation and BESS infrastructure within a sensitive rural and hydrogeological setting. That concentration creates credible accident and pollution pathways involving transformer oil, battery fire, contaminated firewater, emergency access and potential interaction with surrounding receptors.

The Environmental Statement must therefore demonstrate that reasonably foreseeable major-accident scenarios have been adequately assessed and that the design and DCO controls are capable of reducing the resulting environmental effects to an acceptable level.

At present, important engineering parameters and emergency arrangements remain dependent on later design. The Environment Agency has required further detail concerning BESS and substation pollution control, and Norfolk Fire and Rescue has raised matters concerning emergency response.

The issue is not that the presence of BESS or 400 kV infrastructure itself prevents consent. It is that the Applicant cannot rely on a conclusion of negligible or not significant effect until the relevant containment, drainage, access and emergency assumptions are sufficiently defined and secured.

If those matters cannot be resolved within the assessed envelope, the infrastructure cluster would require redesign. Until they are resolved, the claimed residual safety and pollution effects remain mitigation-dependent rather than established.

ExQ1 has now independently required the Applicant to explain why aspects of BESS fire safety remain dependent upon later assessment and design. That reinforces BEPS's existing point that a future safety-management plan cannot substitute for establishing at examination stage that the authorised configuration has an acceptable maximum-case risk profile.

1.9.5 Deliverability Risk: Aviation Safeguarding and Glint/Glare

Site 1 lies within the operational environment of Tibenham Airfield. Norfolk Gliding Club continues to raise substantive concerns regarding glint and glare, thermal effects, engine-failure emergency landing and bird-strike risk, and argues that the Applicant's assessment does not adequately reflect actual gliding and powered-aircraft operations.

These concerns require resolution because aviation safety cannot be reduced to an ordinary visual-amenity issue.

The correct examination question is whether the Applicant has demonstrated, on the final layout and infrastructure parameters, that the Scheme can coexist safely with actual Tibenham operations and that any necessary mitigation is effective and secured.

Where significant design changes have occurred since earlier aviation work—including changes to substation voltage, height and grid infrastructure—the Applicant should demonstrate that the final worst case has been assessed.

The existence of an unresolved aviation objection does not itself prove that consent is legally impossible. It does mean that the Examining Authority should not assume the aviation case is closed while the airfield operator continues to identify credible safety mechanisms that it says have not been adequately assessed.

If those concerns cannot be resolved through evidence or design change, that would become a serious constraint on the acceptability and deliverability of Site 1.

ISH1 materially widened the aviation issue beyond glint and glare. The ExA required the Applicant to identify which aviation effects had been scoped out and why, and to provide a standalone aviation-safety document addressing the wider operational issues raised during the hearing. The examination issue now expressly includes emergency

landing/EFATO considerations, glider launch, obstacles and other operational interactions, not merely reflected sunlight.

1.9.6 Deliverability Risk: Heritage Harm and Setting

East Pye lies within a dense historic landscape containing Grade I, Grade II* and Grade II listed buildings, conservation areas and historic settlement patterns whose significance is in part derived from rural setting, openness and long-established relationships with surrounding farmland.

The statutory heritage duties require the decision-maker to give considerable importance and weight to the preservation of listed buildings and their settings. The planning balance must therefore address the actual degree of harm identified, not treat Chapter 20's 'not significant' EIA label as determinative.

Historic England accepts that the Scheme changes the settings of designated assets and that residual harm may remain after mitigation. It also identifies cumulative interaction with Tasway and incomplete archaeological evaluation as requiring further consideration.

The current draft should not speculate that substantial harm is likely unless the evidence supports that conclusion for a particular asset. The stronger argument is that even less-than-substantial harm must be given the statutory weight required, and that screening cannot necessarily restore the historic openness or landscape relationships which contribute to significance.

The heritage issue therefore becomes consent-limiting where, after proper weighting of the harm, the public benefits of this particular Scheme do not justify it. That conclusion must be reached asset by asset and cumulatively, not assumed from a generic EIA significance category.

The independent HIA identifies harm from the principal built development to 36 designated assets and harm to 41 designated assets overall once associated road and abnormal-load works are included.

1.9.7 Deliverability Risk: Construction Access and Abnormal Indivisible Loads

The transport case is different because some questions are genuinely binary.

Large 400 kV transformers and other abnormal loads must physically reach their destination. National Highways and Norfolk County Council continue to require further evidence and changes concerning strategic junctions, local routes, cumulative traffic, traffic controls and AIL arrangements.

The Applicant must therefore demonstrate an end-to-end route that is physically feasible, legally available, structurally suitable and compatible with the environmental constraints along it.

If no such route exists, the relevant infrastructure cannot be constructed as authorised. That is not simply an EIA significance judgment.

However, the present evidential position should still be stated carefully. The current evidence demonstrates that the routeing case remains unresolved; it does not yet prove that no feasible route can ever exist.

The appropriate conclusion is therefore that the Scheme's constructability has not yet been demonstrated. If the solution requires materially different highway works, third-party land, vegetation removal or environmental effects outside the assessed envelope, those changes cannot simply be deferred to a future CTMP.

ISH1 also confirmed that the access strategy for Sites 7–10 remains unresolved and that NCC favours additional internal haul-route solutions to avoid unsuitable rural roads. Those routes themselves create land, landscape, ecology, drainage, soil and PRoW effects which must be assessed rather than treated as environmentally neutral mitigation.

1.9.8 Deliverability Risk: Soils, Heavy Clay and Irreversibility

The Applicant's own assessment accepts a significant risk of irreversible loss or downgrading of BMV agricultural land. Natural England also requires fuller ALC coverage, avoidance of peat and measures to keep permanent infrastructure off BMV land where possible.

The soil issue is therefore not properly described as a legal gateway to delivery. It is a significant environmental and planning-balance issue whose weight increases where reversibility is uncertain.

The Applicant relies heavily on the proposition that the Scheme is temporary and that land can ultimately be restored. That assumption must be tested against heavy clay soils, compaction, cable trenching, access and haul routes, repeated replacement activity and altered agricultural drainage.

Where irreversible degradation would occur, the effect must be treated as such. It cannot be downgraded merely because the structures above ground are removable.

The Applicant should therefore demonstrate the extent to which the land can actually be restored to its previous agricultural capability and identify where that cannot be assured. Any permanent or irreversible loss must then be weighed expressly in the planning balance.

1.9.9 Deliverability Risk: Replacement and Lifecycle Assessment

The 60-year Scheme includes foreseeable replacement of panels, batteries and other electrical equipment. The Applicant's own material therefore anticipates substantial future works which may resemble construction in traffic, soil disturbance, ecological disturbance and waste generation.

The issue is not that every future replacement detail must be known now. The EIA must nevertheless assess the likely significant effects of the project over its whole life using a reasonable worst case.

Where future replacement could materially exceed the assessed effects, or where its impacts depend on routes, compounds, habitat conditions or equipment not presently controlled by the DCO, the whole-life assessment remains incomplete.

The appropriate consequence is that the Applicant should define and assess the reasonable replacement envelope now and secure appropriate controls. If it cannot demonstrate that foreseeable replacement remains within the assessed environmental envelope, the residual-effect conclusions should not assume that it does.

1.9.10 Deliverability Risk: Decommissioning and Financial Security

The absence of ring-fenced decommissioning security does not, by itself, establish that the Scheme is legally incapable of consent. It does, however, materially weaken the Applicant's reliance on eventual restoration as mitigation for a 60-year development.

Norfolk Wildlife Trust specifically asks how decommissioning obligations will survive changes in ownership, who will pay and what happens if the current developer no longer owns or controls the Scheme at the end of its life.

Those questions matter because several environmental conclusions depend upon removal, restoration and long-term management actually occurring.

Examination material now indicates that private landowner agreements contain decommissioning securities intended to protect against default or insolvency and capable of periodic revaluation or top-up. That changes but does not resolve BEPS's objection. The outstanding issue is whether those private, landowner-specific securities amount to a coordinated, independently costed, index-linked and publicly enforceable whole-Scheme restoration mechanism, including soil, drainage, contamination and aftercare liabilities, and whether they remain effective following transfer or insolvency of the undertaker.

1.9.11 Cumulative Infrastructure Nexus – Site 1

Site 1 concentrates numerous constraints: major 400 kV infrastructure, BESS, aviation activity, groundwater sensitivity, private water supplies, railway proximity, transport requirements and heritage receptors. The significance of that concentration is

cumulative. Each matter may be capable of resolution individually, but the Applicant must demonstrate that the solutions can coexist in one final design.

The risk is therefore not that one unresolved issue automatically makes the Scheme legally impossible. It is that mitigation for one constraint may worsen another, and the present Application has not yet demonstrated one integrated configuration satisfying all of them simultaneously.

Site 1 should accordingly be treated as a project-level test of environmental coherence and deliverability. If the Applicant cannot demonstrate one design in which aviation, access, drainage, groundwater protection, fire safety, grid requirements and environmental mitigation all operate together within the assessed envelope, the Site should not be assumed to be deliverable.

NGET's Relevant Representation materially qualifies the Applicant's presentation of the Site 1B National Grid substation as a settled connection solution. NGET explains that the original July 2023 connection agreement required East Pye Solar to identify land for the National Grid substation and secure the necessary consent, which is why the DCO application includes the relevant land and compulsory-acquisition powers. NGET now states, however, that its understanding is that the replacement connection agreement will not require the Applicant to secure either the land or consent for the National Grid substation. It further makes clear that granting consent for the proposed substation would not oblige NGET to use it, and that the final size, design and location of the point-of-connection solution cannot yet be confirmed because they depend upon the wider regulatory and commercial process and the outcome of Gate 2 offers. The present position is therefore that East Pye has a connection pathway, but the particular Site 1B transmission solution for which permanent infrastructure and land powers are sought is not yet confirmed by NGET as the solution it will ultimately implement. That uncertainty is material to scheme definition, environmental assessment, deliverability and the justification for compulsory acquisition of the relevant land.

The ExA has additionally required the Applicant to explain the National Grid substation's capacity to accommodate other projects, the certainty and timing of its delivery as East Pye's point of connection and how that timing would be secured, together with any cumulative or downstream consequences of future third-party use. The proposed substation therefore cannot yet be treated simply as a fixed East Pye component whose wider network consequences are exhausted by the present ES.

Great British Grid and the changing connection context

The Government's announcement of Great British Grid on 29 September 2026 materially changes the wider policy context in which East Pye's connection infrastructure should be examined. Great British Grid is intended to invest in electricity-network infrastructure, increase competition, accelerate connections, facilitate wider use of self-build connections and support competitive delivery of transmission assets. It does not replace NESO's system-planning role, Ofgem's regulatory role or the existing

network operators, and it does not itself resolve East Pye's Gate or connection position.

Its significance for East Pye is therefore not that a different connection solution can presently be assumed, but that the future delivery and ownership of transmission infrastructure is becoming more competitive and strategically coordinated. In circumstances where NGET has not confirmed that the Site 1B solution authorised by the DCO will be the final solution adopted, the Applicant should explain whether that proposal remains the most efficient and proportionate long-term network solution in the emerging transmission framework, whether alternative delivery or connection arrangements are now material, and whether the proposed permanent infrastructure is intended solely for East Pye or may perform a wider future network function.

Great British Grid does not remove the present uncertainty. It strengthens the case for resolving, before consent, what infrastructure is actually required and why.

Why should the DCO authorise this particular permanent 400 kV solution now when the connection solution is not confirmed and national policy is actively changing how future transmission infrastructure is planned, financed and delivered?

1.10 Cumulative Risk, Mitigation Limits and Planning Balance

The number and interaction of unresolved matters at East Pye are themselves material to the planning balance.

They include protected-species licensing, water and groundwater protection, private supplies, aviation, major-accident controls, transport and AIL feasibility, soils, heritage, grid uncertainty, replacement and decommissioning.

These should not all be described as separate 'legal gateways'. Their legal and planning consequences differ. Some concern whether statutory tests can ultimately be satisfied; some concern whether environmental effects have been adequately assessed; some concern physical constructability; others concern the weight to be given to residual harm.

The common point is narrower and stronger: the Applicant has not yet demonstrated that all of these matters can be resolved simultaneously within one authorised and environmentally assessed Scheme.

That distinction is important. A project is not made acceptable simply because each unresolved issue might theoretically be capable of later mitigation. The decision-maker must have sufficient confidence now that the authorised development is capable of implementation without departing materially from the assumptions on which the EIA and planning balance depend.

Where resolution would require substantial site deletion, materially different access, new infrastructure, altered drainage, changed grid works or mitigation outside the

assessed envelope, the problem is no longer one of detailed post-consent refinement. It is evidence that the Scheme as submitted has not yet been demonstrated to be environmentally coherent or deliverable.

The cumulative effect of these uncertainties should therefore reduce the weight attached to the Applicant's assertions of secured deliverability and increase the weight given to avoidance, redesign and, if the core conflicts cannot be resolved, refusal.

1.11 Failures of East Pye Solar's Chapter 1

Chapter 1 describes separate competent experts; it does not demonstrate an integrated EIA

Chapter 1 relies upon Regulation 14(4) of the EIA Regulations and identifies the competent experts responsible for each environmental chapter. BEPS does not question the principle that specialist disciplines should be prepared by appropriately qualified professionals. The difficulty is that competent preparation of individual chapters does not establish competent integration of those chapters.

The Applicant's own Table 1.2 demonstrates that the ES was prepared by several different organisations and specialist teams. Landscape, ecology, water, transport, noise and socio-economics were principally prepared by Stantec; cultural heritage by GHC Heritage; soils and agricultural land by Kernon Countryside Consultants; climate change by Bureau Veritas; and EMF and parts of Chapter 18 by Pager Power and others. That multidisciplinary structure is normal for an NSIP, but it creates an obvious need for systematic interdisciplinary reconciliation.

The Planning Inspectorate's guidance makes the requirement clear. Its cumulative-effects advice distinguishes effects with other developments from the interrelationships between environmental aspects of the proposed NSIP itself. It states that the ES should identify where multiple impacts combine upon sensitive receptors and assess those combined effects. More significantly for East Pye, it expressly states that mitigation proposed for one environmental topic must take account of other sensitive receptors, giving the example that planting intended to mitigate landscape and visual effects must also consider its ecological consequences.

The Inspectorate's EIA advice similarly states that interdependencies between environmental aspects must be assessed so that the environmental impacts of the development are considered as a whole, and that mitigation measures should not be developed in isolation because they may relate to more than one environmental aspect.

This goes directly to the problem identified throughout BEPS's Written Representation.

The question is therefore not whether the individual authors listed in Table 1.2 possess appropriate professional qualifications. It is whether there was an effective interdisciplinary process by which their assumptions, mitigation proposals and conclusions were tested against one another. Chapter 1 identifies no such process.

For East Pye Solar that omission is material. The same planting affects landscape, ecology and heritage. The same haul route affects transport, soils, water, ecology, landscape and residents. The same drainage system affects flood risk, groundwater, aquatic ecology and soil. The same plant relocation may affect noise, landscape, heritage, drainage and residential amenity. The same decommissioning assumption determines conclusions in landscape, soils, agriculture, ecology and heritage.

The Applicant should therefore demonstrate how the competent experts identified in Table 1.2 coordinated their assessments, how conflicting environmental objectives were resolved and how changes originating in one discipline were communicated to and reassessed by every other affected discipline.

A list of competent experts is evidence of specialist authorship. It is not evidence that the resulting Scheme has been assessed as one functioning environmental system.

1.12 Identified mitigation is not the same as secured mitigation

Chapter 1 states that the EIA identifies residual effects remaining after implementation of ‘secured embedded and additional mitigation measures’. **That description is too categorical.**

Across the Environmental Statement, important mitigation remains dependent upon outline documents, detailed plans to be prepared after consent, subsequent approvals, final equipment selection, micrositing, licences, monitoring arrangements and other future decisions.

For example, the transport assessment relies upon final Construction and Operational Transport Management Plans; operational noise conclusions rely upon future measures and final design capable of achieving specified noise outcomes; the landscape assessment relies upon future establishment and long-term management of planting; detailed ecological management remains dependent upon later implementation plans and, where required, licensing; and drainage, access and other matters continue to be refined.

The Applicant's own Commitments Register is particularly relevant because it states that the register itself is not a secured document but records commitments intended to be secured elsewhere.

There is an important legal and evidential distinction between:

- a mitigation measure which has been suggested;
- a commitment which the Applicant intends to implement;
- an outline management principle;
- a future approval mechanism;
- and a measure whose necessary environmental outcome is actually secured by the DCO.

Residual-effect conclusions should only assume mitigation to the extent that its delivery, location, performance and necessary environmental outcome are sufficiently certain.

That matters especially where the significance conclusion depends upon the mitigation. Chapter 12, for example, reaches residual operational noise conclusions after assuming additional mitigation even though the chapter describes those measures as ‘example additional mitigation’ and leaves aspects of the final solution to detailed design. The question is not whether some future acoustic treatment might be capable of reducing noise. It is whether the DCO secures the outcome upon which the residual-effect conclusion depends.

The same distinction applies across the ES. Accordingly, the Examination should not accept Chapter 1's general statement that residual effects are those remaining after ‘secured’ mitigation without testing, measure by measure:

- what precisely is required;
- where it must occur;
- what performance standard must be achieved;
- when it must be delivered;
- how long it must be maintained;
- who approves it;
- what monitoring verifies success;
- what happens if it fails; and
- which enforceable DCO provision secures that outcome.

Until that exercise is undertaken, some of the ES's residual-effect conclusions are better characterised as **mitigation-dependent predictions** rather than secured environmental outcomes.

1.13 Chapter 1 overstates the adequacy and continuity of the consultation-stage environmental information

Chapter 1 states that the PEIR enabled consultees to understand the likely significant environmental effects of the Scheme and develop an informed view. It then characterises the subsequent targeted-consultation changes as ‘localised’ and ‘minor’ and states that they did not give rise to materially new or different likely significant environmental effects. Those propositions are disputed and should not be treated as established facts.

Norfolk County Council, the Environment Agency, Highways, the LLFA, BEPS and ,ultiple other consultees raised concerns about the adequacy of the environmental baseline information available to consultees during the statutory consultation and targeted consultation stages. A significant proportion of the environmental surveys underpinning the Environmental Statement were not available at the time of statutory consultation, and many key survey datasets were either absent, incomplete, or not yet undertaken.

Following statutory consultation, the Scheme changed in several material respects. South Norfolk Council records the confirmation of the Site 1B National Grid Substation, abandonment of the alternative location, an increase in the Site 1B Project Substation from 132 kV to 400 kV, additional panels at Site 7D, additional land for grid and highway works, revised AIL arrangements and a changed construction traffic strategy. These were not merely drafting

alterations. They changed the location, scale or environmental relationship of major components of the Scheme.

Surveys were not issued or meaningfully updated even at the targeted consultation stage, neither was the PEIR updated. As a result, consultees were not in a position to review the full evidential basis for the environmental assessments when forming their views on the evolving Scheme. In practical terms, the Environmental Statement represents the first point at which the majority of these survey results have been made available in a consolidated and complete form, meaning that key aspects of the environmental baseline and impact assessment have not previously been subject to informed consultation.

The material issue is not whether the changes created an entirely new category of environmental effect. A change can materially alter the magnitude, location, receptor or interaction of an existing effect without creating a new environmental topic. Accordingly, Chapter 1's assertion that the changes produced no materially new or different likely significant effects requires evidential demonstration, not repetition. The Applicant should show, for each material post-PEIR change, the original assessed parameter, the revised parameter, the receptors affected, the original and revised effects, any altered mitigation and the basis upon which the significance conclusion was said to remain unchanged.

Without that reconciliation, Chapter 1's consultation narrative presents as settled the very environmental conclusion which remains in dispute.

1.14 The introductory description obscures the 500 MW design premise

Chapter 1 describes the Scheme simply as having generating capacity ‘exceeding 100 MW’. That may identify the statutory threshold relevant to NSIP status, but it does not adequately explain the design premise which produced East Pye.

Chapter 5 is considerably more revealing. It states that the Applicant began from the need to accommodate the 500 MW Grid Connection Agreement and, using the land requirements assumed for solar generation, searched for approximately 1,100 hectares of land capable of accommodating the panels and associated infrastructure. That distinction matters.

East Pye is not simply an unspecified generating station above the NSIP threshold. It is a project whose site search, land requirement, dispersed configuration and alternatives assessment were materially shaped by the Applicant's decision to pursue approximately 500 MW of transmission-connected solar generation. That premise should be explicit at the outset because it is central to the environmental case.

The Examination must distinguish between the statutory proposition that large-scale renewable generation is nationally needed and the project-specific proposition that **500 MW had to be accommodated within this particular search exercise**.

The latter is an Applicant design objective. It is not itself an environmental constraint or statutory requirement. That distinction is particularly important when considering whether

environmental constraints were permitted to reduce the extent of development, whether smaller configurations were genuinely considered, and whether the retained Scheme represents the environmental capacity of the place or the land area required to preserve the Applicant's chosen output.

1.15 Chapter 19 cannot cure interactions missed in the underlying assessments

Chapter 1 describes Chapter 19 as providing a summary of the cumulative and in-combination assessments presented within the individual technical chapters. That structure cannot cure a failure to identify cross-topic effects at source.

If, for example, landscape planting has been assessed only as visual mitigation without its consequences for open-country birds or heritage setting being identified in Chapters 8 and 10, Chapter 19 cannot retrospectively make those assessments complete. The same applies where transport mitigation creates new ecological or hydrological effects, or where significant landscape effects have not been carried through into tourism or residential amenity conclusions. A summary chapter can only combine effects which the underlying assessments have first recognised and evaluated.

The relevant test is therefore not whether Chapter 19 contains a cumulative-effects table, but whether the individual technical assessments have correctly identified the interactions between the Scheme's effects and mitigation measures so that their combined consequences can meaningfully be assessed.

An interaction omitted at source does not become assessed merely because the ES contains a later cumulative-effects chapter.

Chapter 2: EIA Methodology

2.1 Introduction: why methodology is a substantive issue

Chapter 2 is not merely introductory. It determines the reliability of every later Environmental Statement conclusion by establishing how receptors are identified and valued, how the baseline and future baseline are defined, how magnitude and sensitivity are combined, which effects are treated as significant, how duration and reversibility are classified, and how cumulative effects, embedded mitigation and professional judgment are addressed. A weakness in that framework is therefore capable of propagating through every technical chapter.

BEPS's central concern is that the EIA methodology does not demonstrate a sufficiently site-specific, ecosystem-led or precautionary assessment of East Pye Solar. It applies generic assessment structures to a dispersed scheme situated within an unusually sensitive and interconnected ecological, hydrological, historic and rural landscape. Those methodological weaknesses materially reduce confidence in repeated conclusions that effects will be minor, negligible or not significant.

The deficiencies arise at several levels. Chapter 2 contains internal uncertainty over duration, receptor sensitivity and effect classification. The methodology is not applied consistently between technical chapters. Material baseline information is incomplete, disputed or inaccurately described. At the same time, the assessment relies extensively on future management plans, surveys, investigations, licences and detailed design decisions that may determine whether effects arise and how significant they will be.

These concerns are not confined to BEPS. Norfolk County Council's Lead Local Flood Authority identifies inconsistencies in the treatment of construction, operation and decommissioning periods, the absence of clear future baselines, unclear sensitivity definitions and inconsistencies between the magnitude and significance tables. The Environment Agency identifies incomplete baseline evidence, missing maximum design parameters, inconsistent effect matrices, unresolved groundwater pathways and extensive reliance on later risk assessments and management plans. South Norfolk Council identifies baseline uncertainty, insufficient worst-case assessment and excessive design flexibility across ecology, noise, heritage and landscape. National Highways similarly identifies missing junction-level evidence, insufficiently granular cumulative assessment and construction controls that remain to be strengthened.

The issue is therefore not whether the ES contains a conventional methodology chapter. It is whether the methodology provides a reliable basis for assessing this particular Scheme, in this particular receiving environment, throughout its construction, operation, replacement and decommissioning life.

2.2 Applicable EIA principles and the applicant's own stated framework

A lawful and reliable EIA must identify, describe and assess the likely significant effects of a sufficiently defined development. Where flexibility is retained, the assessment must address the realistic worst-case outcome rather than a series of favourable or incompatible assumptions. Mitigation relied upon to reduce significance must be sufficiently certain, effective and secured. Cumulative and interrelated effects must be assessed, and the methods, assumptions, limitations and material professional judgments must be transparent. None of those requirements can be satisfied unless the baseline information is sufficiently complete, current and spatially appropriate to support the conclusions reached.

Since this Written Representation was prepared, the National Planning Policy Framework was replaced on 17 August 2026. The Energy NPSs remain the primary policy framework for this NSIP, but the current NPPF is materially relevant to the adequacy of the evidential basis on which environmental conclusions are reached. Its policies repeatedly require, or proceed on the basis, that the decision-maker has sufficient information to understand the receiving environment and the effects of development before relying upon mitigation or later detailed design. In particular, Policy N2 requires sufficient information to demonstrate compliance with the natural-environment policies and requires significant biodiversity harm first to be avoided through location on an alternative site with less harmful impacts; Policy P2 expects adequate site-assessment information concerning ground conditions and contamination; Policy F5 and the associated flood-risk and drainage policies require a sound evidential basis for locating and designing development in relation to flood risk; Policy HE5 requires the decision-maker to be satisfied that the assessment accurately reflects effects upon heritage significance; and Policy P3 requires cumulative pollution effects on health, living conditions and the natural environment to be considered. These policies reinforce BEPS's central methodological point: a conclusion of acceptability cannot safely precede the information necessary to establish the receptor, pathway, effect and mitigation on which that conclusion depends.

APP/6.3.2.3 sets out the legislation, policy and guidance which the applicant says govern ES Chapters 6 to 18. It records requirements concerning ecological networks and the mitigation hierarchy, Water Framework Directive compliance, flood risk and water resources, heritage significance and setting, landscape character, soil protection, climate resilience, whole-life greenhouse gas assessment, waste and major accidents. That appendix is a schedule of applicable standards; it is not evidence that the substantive chapters have met them.

The ES must therefore be tested against both the applicable legal and policy framework and the Applicant's own stated standards. It is insufficient merely to cite CIEEM guidance, Water Framework Directive requirements, Historic England guidance or the National Policy Statements if the underlying baseline is incomplete, the receptor hierarchy is inconsistent, the reasonable worst-case design is not defined, or the mitigation relied upon remains subject to later determination.

2.3 Failure to provide a site-specific, ecosystem-led methodology

The methodology is not demonstrably calibrated to the environmental character of the East Pye area. It relies on standardised sensitivity and magnitude matrices, conventional solar-development survey scopes and familiar mitigation measures such as buffers, hedgerow retention, grassland creation, trenchless crossing and later management plans. Those tools may be appropriate in principle, but the ES does not show that they have been adapted sufficiently to the particular environmental network affected by this Scheme.

The South Norfolk Claylands contain an unusually dense and interconnected set of receptors. These include confirmed and predicted maternity colonies of the European Protected Species barbastelle bat; overlapping Core Sustenance Zones; ancient woodland and priority woodland networks; chalk aquifer and surface-water connectivity; downstream chalk-stream habitat supporting or potentially supporting white-clawed crayfish; ponds, fen, grazing marsh, meadow, woodland, orchard and roadside habitats; rare and priority botanical assemblages; and farmland managed to support ground-nesting birds.

The applicant's own spatial plans reinforce this point. APP/2.9 shows the Order Limits and cable corridors in the context of County Wildlife Sites, Roadside Nature Reserves and Priority Habitat Inventory features including woodland, grazing marsh, lowland meadow, fen, ponds, reedbeds and orchards. APP/2.10 shows the wider relationship with statutory designations, ancient woodland, Sites of Special Scientific Interest and European sites. The receiving environment is therefore not a collection of isolated arable fields. It is a connected ecological and hydrological landscape.

A methodology designed principally around field-level assessment is not sufficient for a Scheme whose effects operate through woodland networks, aquifers, streams, hedgerows, flight corridors and multiple development parcels. The assessment needed to begin with those functional systems and then test the Scheme against them, rather than treating ecological connectivity mainly as an aggregation of individual parcel effects.

2.4 Failure to apply a landscape-scale ecological framework

Ecological effects must be assessed at the spatial scale at which the receptor functions. Barbastelle maternity colonies do not depend on a single woodland or hedgerow. They depend on networks of roosting woodland, overlapping Core

Sustenance Zones, dark commuting routes and dispersed feeding habitat. Chalk-stream receptors are connected to groundwater and may therefore be affected by piling, trenching, drilling or contamination sources located away from the immediate watercourse. Farmland parcels, ponds, woodland edges, hedgerows and green lanes likewise operate as parts of habitat mosaics rather than as self-contained receptors.

The ES nevertheless repeatedly structures its assessment around Sites, sub-sites, fields and individual designated features. That approach risks understating cumulative fragmentation, weakening of flight lines, displacement from feeding habitat, lighting effects across several corridors, hydrological pathways, repeated disturbance and the combined loss of functional habitat. The relevant ecological question is not simply how many hectares are physically removed from each field. It is whether the Scheme, considered as a whole, alters the functionality, connectivity and resilience of the ecological network upon which protected and priority species depend.

South Norfolk Council's RR materially supports that concern. It records ten bat species, describes the site as nationally important for its bat assemblage, and identifies twelve barbastelle maternity colonies whose Core Sustenance Zones overlap the Order Limits. It also raises the likelihood of further colonies in adjoining ancient woodland which has not been surveyed by the Norfolk and Norwich Bat Group, and requests species-specific assessment rather than reliance on broad bat groupings.

Norfolk County Council similarly records maternity roosts in woodland around the Scheme and considers the area potentially of national importance. It identifies possible direct effects on habitats used by those colonies during construction and potentially decommissioning. These are not marginal receptor-specific disagreements. They indicate that the ecological assessment may have been conducted at too narrow a spatial scale.

The same concern applies to water-linked ecology. The Environment Agency identifies omitted groundwater-dependent terrestrial ecosystems, potential preferential groundwater pathways, thermal effects from cables and risks arising from deep foundations and trenchless drilling. Those issues cannot be assessed adequately through separate parcel, watercourse and habitat evaluations without an integrated landscape-scale framework.

2.4.1 The central methodological problem: cross-topic inconsistencies and interactions

A recurring defect in the Environmental Statement is that environmental topics are assessed in separate chapters without adequate reconciliation of the assumptions, mitigation measures and conclusions between them. The division of an ES into specialist chapters is administratively necessary. It does not mean that landscape,

ecology, soils, water, heritage, transport, recreation, tourism and residential amenity exist independently of one another.

The EIA Regulations require assessment of the interaction between population and human health, biodiversity, land, soil, water, air and climate, material assets, cultural heritage and landscape. EN-1 (2025) expressly repeats that requirement and requires consideration of direct, indirect, secondary, cumulative, long-term, permanent and temporary effects. More importantly, paragraph 4.3.19 requires the decision-maker to consider how the accumulation and interrelationship of effects may affect the environment, economy or community **as a whole**, even where individual effects appear acceptable when considered separately with mitigation.

That requirement is particularly important for East Pye. This is not a compact development occupying one homogeneous site. The Order Limits extend across 1,212.3 ha, comprising ten dispersed Sites and numerous Sub-Sites, a BESS, multiple project substations, a new National Grid Substation, grid connection infrastructure, approximately 24 km of cable corridor and separate highway works. The same rural landscape, watercourses, soils, habitats, roads, heritage settings, recreational routes and communities are therefore affected repeatedly by different components of the same Scheme.

BEPS does not suggest that the existence of separate ES chapters is itself defective. The objection is that conclusions reached within them are not consistently propagated across the Environmental Statement. Measures treated as mitigation or benefit in one chapter may cause harm in another; assumptions about restoration in one chapter conflict with the future landscape assumed elsewhere; significant effects established by one discipline are discounted by a dependent assessment; and changes required to solve one unresolved problem may create effects which have never been assessed by the other disciplines.Chapter boundaries are an administrative convenience. They are not environmental boundaries.

ISH1 materially confirmed that this concern is not confined to BEPS's interpretation of the ES. The Examination identified numerous aspects of the Scheme whose final configuration remains unresolved across disciplines, including AIS/GIS technology for the project substations, the number and location of conversion units and switch rooms, ancillary operational buildings, fencing, lighting, construction compounds, haul routes and the final disposition of major infrastructure. The ExA also required the Applicant to correct inconsistencies between the Indicative Masterplan and Works Plans where land is variously shown as retained agricultural land, mitigation land, biodiversity land and cabling works. Those matters are methodologically important because the same physical space is being relied upon differently by different parts of the environmental case. A receptor-led and spatially reconciled EIA cannot assume mutually inconsistent land uses or design outcomes and then conclude independently within each topic that effects are acceptable.

2.4.2 Landscape mitigation may itself cause ecological and heritage harm

The clearest example is the Applicant's extensive reliance on new hedgerow, tree, woodland and scrub planting.

Chapter 7 treats that planting primarily as embedded landscape mitigation. Hedgerows are to be managed towards a target height of approximately 3 m to screen views from nearby PRoWs and visual receptors, while trees and woodland are expressly described as primary mechanisms for filtering and screening views. The same planting is also credited with providing habitat and strengthening ecological connectivity.

That is not an integrated assessment of the consequences of the planting.

As Chapter 8 of this Written Representation demonstrates, substantial parts of the existing landscape already perform important ecological functions precisely because they are open. The Applicant's own breeding-bird evidence records a major farmland-bird assemblage, including numerous skylark territories within permanent development areas. Ground-nesting and open-country birds require sufficiently large open areas, low disturbance and sightlines which allow detection of predators. Converting open farmland into smaller compartments enclosed by taller hedges, woodland belts, fencing and other vertical structures may therefore benefit some woodland, scrub or boundary species while reducing habitat suitability for skylark, lapwing and other open-country species.

That ecological trade-off cannot be converted into an unqualified biodiversity benefit merely because additional woody habitat scores positively elsewhere. The relevant question is whether the existing **function** of the habitat is retained for the species which currently depend upon it.

There is a parallel heritage issue. Chapter 10 itself acknowledges that the transition from agriculture to solar, together with new hedgerow and tree planting, alters historic landscape character from construction through to decommissioning. It nevertheless concludes that the planting will enhance existing field boundaries and that the overall historic landscape effect is negligible.

That conclusion requires more than an assertion that native planting is desirable. A new screening belt may conceal solar infrastructure while simultaneously enclosing an historically open view, changing the relationship between a church and its agricultural hinterland, altering a historic field pattern or changing the experience of an historic lane or conservation area.

The same hedge cannot simply be counted as landscape mitigation, heritage mitigation and ecological enhancement without assessing what it encloses, what open habitat it removes, what historic relationship it changes and what long-term landscape it creates.

Mitigation must itself be assessed as an environmental intervention.

2.4.3 The Environmental Statement contains incompatible concepts of reversibility and restoration

The same problem appears in the treatment of decommissioning.

Chapter 10 characterises the change from agricultural use to energy generation as temporary and reversible. Chapter 15 similarly anticipates that long-term grassland management may provide temporary soil benefits which may reduce or disappear if arable agriculture resumes after decommissioning.

Chapter 7 describes a materially different end state.

It assumes that the National Grid Substation and Grid Connection Scheme elements will remain and that established landscape mitigation planting, including woodland, trees and hedgerows, will also remain in situ. Elsewhere it states that broadleaf woodland, linear tree belts, scrub and hedgerows would be retained while only areas of grassland are assumed to revert to their former agricultural use.
Those are not equivalent baselines.

If substantial mature planting and permanent grid infrastructure remain, the post-decommissioning landscape will not be the pre-development agricultural landscape. Its landscape character, ecological structure, field enclosure, heritage relationships and potentially its agricultural functionality will have been altered for the long term.

The Applicant therefore needs one coherent end-state assumption, applied consistently across landscape, ecology, heritage, soils, agriculture, drainage and decommissioning. It cannot rely upon return to agriculture when assessing reversibility in one chapter while relying upon permanent retention of the very landscape changes created to screen the Scheme in another.

2.4.4 Significant landscape effects are not carried through into the socio-economic assessment

A further example is the relationship between Chapters 7 and 14.

Chapter 7 identifies numerous significant adverse landscape and visual effects. These include Major and Major-to-Substantial adverse effects upon high and medium sensitivity receptors and PRoWs around Sites 7, 8 and 9. It also identifies effects upon tranquillity, remoteness and the experience of the rural landscape.

Chapter 14 nevertheless assigns the tourism industry a Low magnitude impact and a Minor Adverse, not significant, effect during construction, operation and decommissioning. That conclusion is reached notwithstanding Chapter 14's own identification of local campsites, accommodation businesses and visitor attractions, and evidence of approximately 2.76 million tourism day visits and £84 million of associated expenditure in South Norfolk.

The cumulative assessment demonstrates the same compartmentalisation. Chapter 14 accepts that East Pye together with 22 other energy schemes may adversely affect visual amenity and thereby tourism, but reasons that only tourism activities in the 'immediate proximity' of individual sites are likely to be affected and consequently concludes only a Minor Adverse cumulative effect.

That reasoning does not adequately address a Scheme whose own Order Limits extend repeatedly across a wide part of rural South Norfolk. A walker, cyclist, visitor or rural accommodation customer does not experience the landscape through the boundaries of individual LVIA assessment parcels.

Nor does assessment of the tourism industry at South Norfolk district level answer whether particular businesses whose attraction depends upon tranquillity, countryside views, walking, cycling or rural character may experience materially greater effects.

An EIA cannot identify widespread significant landscape and recreational effects in one chapter and allow a dependent socio-economic assessment to proceed without explaining why those effects produce only a Low magnitude change to the economic receptors which depend upon that landscape.

2.4.5 Lighting illustrates the failure to reconcile a common impact pathway

Lighting presents another cross-topic issue.

The Planning Inspectorate expressly required assessment of night-time lighting effects on landscape and visual receptors and ecological receptors including bats, specifically identifying intermittent sources such as motion-activated security lighting.

Chapter 7 records that motion-sensing security lighting will be provided at the Project Substations, National Grid Substation and BESS Site but relies principally upon the Lighting Strategy to conclude that significant lighting effects are unlikely. The Chapter also states among its assumptions and limitations that lighting effects are not assessed within the LVIA itself.

The issue is not confined to landscape. The same lighting may affect dark rural character, residential amenity, the setting of heritage assets and the behaviour and functional connectivity of light-sensitive bats. Chapter 8 identifies the particular importance of maintaining dark commuting and foraging routes within a landscape supporting barbastelle maternity colonies.

A Lighting Strategy is a mitigation document. It is not a substitute for demonstrating, across all relevant topics, what the residual effects of the lighting will be. The Applicant should identify where the PINS-requested assessment of the common lighting pathway has actually been undertaken and reconcile its conclusions across landscape, ecology, heritage and residential receptors.

2.4.6 Water, soils, groundwater and aquatic ecology are one connected system

The compartmentalisation is equally problematic below ground.

The Scheme crosses a landscape containing the River Tas, Hempnall Beck, tributaries, ordinary watercourses, field drainage systems, aquifers and private water supplies. Chapters 8, 9, 15 and 16 divide responsibility respectively between ecology, the water environment, soils/agricultural land and ground conditions. The actual pathways do not divide in that way.

Soil disturbance and compaction can alter runoff. Runoff enters ditches and tributaries. Watercourse crossings affect flow and sediment transport. HDD or other trenchless construction interacts with groundwater and watercourses. Mobilised contamination can reach groundwater or surface water. Those waters support aquatic habitats and protected species and, in some locations, private water supplies.

Chapter 16 itself records disagreement concerning the appropriate treatment of groundwater travel times around private water supplies and ultimately concludes that credible contaminant linkages have not been identified. Evidence submitted in relation to the River Tas and white-clawed crayfish raises a parallel question about whether aquatic receptors and downstream pathways were adequately represented in the ecological baseline.

These matters cannot safely be resolved by each chapter assuming that the relevant pathway is dealt with somewhere else. The assessment must follow the pathway from source, through soil and groundwater or surface water, to the ultimate human and ecological receptor.

2.4.7 Changes to the transport solution may invalidate assumptions elsewhere

The same principle applies to the unresolved construction access strategy.

As Chapter 11 of this Written Representation explains, substantial elements of the final haul-road, access and construction route strategy remain disputed by the relevant highway authorities. Any material alteration to those routes is not merely a transport matter.

A new or relocated haul route may require additional land, hedgerow removal, tree works, watercourse crossings, drainage structures, soil stripping, proximity to dwellings, interaction with PRoWs, disturbance of protected species, works near heritage assets or crossing of utility infrastructure. It may also alter noise, air quality and traffic effects.

Management of a fixed and environmentally assessed route can properly be mitigation. Selection or material redesign of the route after consent is scheme design.

Accordingly, if the transport solution changes during Examination, the Applicant must demonstrate that every consequential landscape, ecological, hydrological, heritage,

soil, noise and safety effect remains within the assessed envelope. It is not sufficient for Chapter 11 alone to be amended while the dependent environmental chapters remain unchanged.

2.4.8 Agricultural management demonstrates a further unresolved trade-off

Chapter 15 anticipates a change over most of the Order Limits from arable cultivation to long-term grassland and relies upon that change in predicting beneficial effects upon soil organic carbon, erosion and soil health.

That assessment cannot be separated from the ecological and landscape management actually proposed.

As Chapters 8 and 15 of this Written Representation explain, the ecological consequences depend on whether land is grazed, mechanically cut, treated with herbicide, maintained as open grassland, planted with trees or hedges, or retained as open arable habitat for farmland birds. Those choices affect soil structure and carbon, botanical diversity, invertebrates, ground-nesting birds, runoff, chemical inputs and agricultural functionality.

There is therefore no single generic category of ‘grassland’ which can simultaneously be assumed to deliver soil benefit, biodiversity gain and agricultural continuity. The management regime must be fixed with sufficient precision for its consequences across all relevant environmental topics to be assessed.

2.4.9 Consequence for the reliability of the Environmental Statement

These examples reveal a wider methodological problem.

East Pye is assessed as though mitigation can be credited separately within each discipline. In reality, a change that reduces one effect may create or intensify another. Screening planting may reduce visibility while damaging openness. A buffer may protect a woodland while moving infrastructure onto BMV land. A haul-route change may solve a highway objection while creating a new ecological or hydrological impact. Long-term grassland may alter soil condition while removing existing arable-bird habitat. Retention of mature planting after decommissioning may preserve ecological habitat while preventing restoration of the historic and agricultural baseline.

The problem is therefore not simply cumulative impact from other developments. It is the **intra-project interaction of East Pye's own effects and mitigation measures**.

BEPS submits that these inconsistencies raise a material question as to whether the interaction requirement in Regulation 5(2)(e) and EN-1 section 4.3 has been adequately discharged. They also affect the weight which can safely be attached to individual residual-effect conclusions where those conclusions depend upon assumptions contradicted elsewhere in the application.

Before the close of Examination, the Applicant should therefore be required to provide a cross-topic reconciliation of the Environmental Statement. That should identify each material design or mitigation measure; the chapters which rely upon it; the beneficial and adverse consequences it produces for other receptors; and any resulting change to significance conclusions.

In particular, the Applicant should establish a single coherent description of the Scheme and receiving environment at construction, Year 1, Year 15, the end of the 60-year operational period and following decommissioning. Landscape, ecological, agricultural, heritage and socio-economic conclusions should all be tested against that same future environment.

Where a material assumption, route, management regime, mitigation measure or end state changes, every dependent assessment should be revisited.

The environment affected by East Pye is one functioning system. The decision-maker must therefore be given an assessment of the Scheme's effects upon that system as a whole, not merely a collection of individually tolerable conclusions reached within separate technical chapters.

2.4.10 Design changes and mitigation displacement across environmental topics

A further weakness is the assumption that unresolved design matters can be addressed within the technical chapter in which the problem first arises. In a scheme of this scale, mitigation is rarely confined to one environmental topic. Moving infrastructure, altering access, introducing barriers, changing drainage or enlarging buffers may reduce one effect while creating or intensifying another.

The transport case illustrates the problem. Norfolk County Council, as highway authority, does not support the submitted construction strategy for Sites 7–10 and instead requires a materially different approach involving access from appropriate standard roads and substantially greater use of internal haul routes and Cable Route Corridors. For Sites 7–9 it expects access through CRC8 with internal haul routes or CRC connections; for Sites 10A–10D it seeks a shared Harvey Lane access with internal routes. It expressly concludes that the present strategy does not adequately address significant highway constraints and cannot presently be supported.

Those changes are not exclusively transport mitigation. An internal haul route is physical development. Depending on its final alignment it may require soil stripping, temporary or permanent surfacing, drainage, watercourse crossings, hedgerow gaps, tree works and additional land. It may affect archaeological remains, protected species, BMV agricultural land, PRoWs, nearby dwellings and landscape character. The Order Limits already contain an approximately 24 km Cable Route Corridor running through a landscape crossed by the Hempnall Beck, River Tas and numerous ordinary watercourses and field drains. A transport solution dependent upon greater use of those corridors must therefore be tested against the assessments of ecology, soils,

water, heritage, landscape, noise and ground conditions, not simply inserted into a later Construction Traffic Management Plan.

The Applicant's own LVIA demonstrates the degree of residual flexibility. It identifies clashes between indicative access routes and ancient or veteran-tree buffer zones but assumes that these can be resolved at detailed design because the access routes may be relocated within Work No. 4. That may ultimately prove possible, but relocation is not environmentally neutral. Avoiding one tree may move an access route towards another hedgerow, habitat, watercourse, archaeological feature, dwelling or area of higher-quality soil. The environmental consequence depends upon where the route moves.

The same issue arises in drainage. The LLFA identifies significant outstanding matters in the submitted drainage case, including calculations which do not reflect the drainage layouts, inconsistent runoff coefficients and, critically, the absence of confirmed drainage designs, discharge locations and treatment trains for discrete drainage areas. It concludes that further work is required before the viability and water-quality performance of the drainage system can be demonstrated. It separately challenges assumptions concerning ordinary watercourses and surface-water flow paths and requires either hydraulic modelling or a precautionary approach avoiding the identified flood extent.

Again, the eventual solution may have consequences beyond Chapter 9. Additional attenuation, swales, drainage channels, treatment features or revised discharge locations may require additional land and excavation, alter soil handling, interact with habitats and watercourses, affect archaeological deposits and change the landscape design. If avoidance of a surface-water flow path requires infrastructure to move, the environmental consequences of the new location must also be assessed.

Operational noise provides a third example. South Norfolk Council's specialist review records that the Applicant may need low-noise equipment, acoustic enclosures, relocation or reorientation of plant or noise barriers, with the final solution left to detailed design. The Council also identifies shortcomings in the present acoustic assessment, including insufficient justification for the treatment of tonal and other acoustic characteristics and unresolved low-frequency noise issues.

Those measures again have cross-topic consequences. A noise barrier may increase the visual mass of infrastructure. Reorienting or relocating plant may alter effects on neighbouring dwellings, heritage assets, ecological buffers, drainage infrastructure or BMV land. Acoustic enclosures can change equipment dimensions and potentially the assessed design envelope. Moving equipment away from one receptor does not demonstrate mitigation unless the receiving location has also been environmentally assessed.

The same principle applies to ecological and landscape mitigation. Chapter 7 relies upon new hedgerows, trees and woodland as primary mechanisms for screening the Scheme and simultaneously credits them with ecological connectivity and habitat

benefits. Yet South Norfolk Council itself warns that reliance on tree planting can remove important views and create enclosure within the existing open landscape. As explained above, greater enclosure may also reduce the functional value of open farmland for ground-nesting and open-country birds. A measure which mitigates visual effects may therefore create heritage, landscape or ecological harm.

This is mitigation displacement. The Environmental Statement repeatedly assumes that the solution to an adverse effect can be developed within the relevant topic without demonstrating that the resulting intervention remains environmentally acceptable when considered across the Scheme as a whole.

BEPS does not contend that every detailed design decision must be fixed before consent. A parameter-based DCO necessarily permits some later refinement. The critical distinction is between refinement within an environmentally assessed envelope and a later design choice which determines the existence, location or significance of an environmental effect. Where resolving an outstanding problem requires infrastructure to be moved, a route to be changed, a drainage system to be redesigned, additional engineering works to be introduced or mitigation to occupy different land, the Applicant must demonstrate that the resulting configuration remains within the assessed worst case for **every affected environmental topic**.

A mitigation measure cannot be accepted merely because it solves the problem which caused it to be introduced.

2.4.11 Consequence: the residual-effect conclusions require cross-topic reconciliation

The consequence is material. The individual residual-effect conclusions in the ES cannot safely be treated as self-contained findings where they depend upon design assumptions or mitigation measures which remain unresolved, conflict with assumptions elsewhere, or create effects falling within another environmental discipline.

This is not a criticism that every uncertainty invalidates an EIA. Nor does BEPS suggest that all later detailed design is impermissible. The problem is cumulative and structural. Across the application:

- the highway authority rejects material elements of the submitted access strategy and seeks different haul-routing arrangements;
- the LLFA identifies unresolved drainage design, discharge, modelling and water-quality matters requiring further work;
- operational noise mitigation may depend upon plant selection, relocation, reorientation, acoustic enclosure or barriers at detailed design;
- landscape mitigation relies upon substantial new vegetation which itself changes landscape character, heritage setting and potentially ecological habitat function;

- access alignments remain sufficiently flexible to be relocated at detailed design in response to tree constraints;
- the post-decommissioning assumptions differ between environmental topics, with mature mitigation planting and National Grid infrastructure remaining while other chapters rely upon the concept of restoration or return to agricultural use; and
- significant landscape and recreational effects are not consistently carried through into dependent socio-economic conclusions.

These are not isolated drafting discrepancies. They concern the environmental configuration which has actually been assessed.

The significance conclusions in an EIA are the end product of a chain: **baseline → development parameters → impact pathway → mitigation → residual effect**. If a material element in that chain changes, the residual conclusion must be checked again. It is not sufficient to change the mitigation and retain the conclusion.

This is particularly important under the Rochdale Envelope. Flexibility is permissible only where the environmental assessment has considered the realistic worst case that the consent would allow. It cannot operate as a mechanism by which material environmental choices are postponed while the ES assumes that whichever choice is subsequently made will remain less harmful than the assessed scheme. That proposition must be demonstrated.

East Pye's dispersed form makes that discipline essential. The Scheme contains ten Sites and numerous Sub-Sites, multiple substations, BESS infrastructure, a National Grid Substation, grid works, approximately 24 km of cable corridor and separate highway interventions across a sensitive rural environment. A change made to resolve one constraint can readily intersect another.

The ExA should therefore require a formal cross-topic reconciliation before relying upon the ES residual-effect conclusions. At minimum, the Applicant should identify each material outstanding design or mitigation matter and state:

1. what assumption was used in each relevant ES chapter;
2. what range of final design outcomes remains authorised;
3. which environmental receptors could be affected by the final choice;
4. whether the worst case of each permitted outcome has already been assessed across all relevant topics;
5. what mitigation is relied upon and where it is secured;
6. whether that mitigation itself creates or displaces another environmental effect; and
7. whether any significance conclusion changes as a result.

Particular reconciliation is required for the final construction access and haul-route strategy; drainage and surface-water design; noise mitigation and final plant arrangement; landscape and ecological planting; watercourse and cable crossings;

soil-management requirements; lighting; substations and grid infrastructure; and the post-decommissioning end state.

Where the Applicant cannot demonstrate that a final solution lies within the assessed cross-topic envelope, the answer is not simply to defer the matter to a management plan. The relevant design must either be resolved and environmentally assessed during Examination, constrained by the DCO to the assessed outcome, or removed from the authorised development.

Until that exercise is undertaken, the repeated conclusion that individual effects will be Minor, Negligible or Not Significant gives a misleading impression of certainty. The question for the ExA is not whether each technical chapter can identify a possible mitigation measure in isolation. It is whether **one physically deliverable version of East Pye exists which simultaneously satisfies the assumptions, mitigation commitments and residual-effect conclusions across the Environmental Statement as a whole**.

On the present evidence, that has not yet been demonstrated.

2.5 Incomplete, uneven and untimely baseline data

A significance matrix cannot cure an incomplete baseline. Where the distribution, status, sensitivity or functional relationship of receptors is uncertain, the resulting magnitude and significance conclusions are necessarily provisional. This is particularly serious where the ES then relies upon those conclusions to justify a finding of no significant effect or to defer further surveys and mitigation until after consent.

The baseline difficulties identified across the application include incomplete or disputed evidence concerning bat maternity networks, white-clawed crayfish, botany, groundwater-dependent habitats, water quality, Source Protection Zones, private and public water supplies, historic hedgerows, veteran trees, archaeology, noise sources and strategic-road junctions.

The methodological concern is not that every baseline question must be free from all uncertainty. It is that material uncertainty must be identified, reflected in the significance judgment and resolved precautionarily where the consequences could be serious or irreversible. It should not be treated as a matter which can automatically be corrected through later surveys, contractor method statements or post-consent approval.

ExQ1 has now independently tested the same issue across multiple disciplines. The ExA asks why important matters concerning drainage and infiltration testing, soil characterisation, ground investigation, health mitigation, BESS fire assessment, transport measures and design remain dependent upon later work while present conclusions of acceptability have already been reached. The significance of those questions is methodological rather than topic-specific. They engage the same distinction identified throughout this chapter: whether later work merely refines an

already demonstrated acceptable solution, or whether it will determine whether such a solution exists at all.

That distinction should be applied consistently across the Scheme. Where later information may require relocation of infrastructure, a different foundation system, a different drainage strategy, greater ecological avoidance, altered access, additional stand-off, revised mitigation or deletion of a Work, the missing information goes to the acceptability of the authorised envelope rather than to routine implementation detail.

2.5.1 White-clawed crayfish and aquatic ecology

Statutory consultation proceeded without a complete downstream assessment of white-clawed crayfish across the connected chalk-stream system. The applicant's conclusion that the species is unlikely to be present appears to rely substantially on habitat appraisal and the absence of field signs, rather than on a complete presence-or-absence survey of all potentially affected connected habitat.

South Norfolk Council notes that the Aquatic Habitat Assessment found no field signs but questions reliance on that observation where a breeding population is known in the River Tas catchment. It considers that the conclusion appears to be based on habitat suitability rather than a definitive species survey. Norfolk County Council likewise states that absence of signs during a walkover cannot confirm absence and calls for robust biosecurity, pollution-prevention and sediment-management controls because of the species' vulnerability and the wider catchment context.

The methodological issue is not confined to whether crayfish occur within the Order Limits. The relevant question is whether construction and decommissioning activities may affect downstream connected habitat through sediment release, pollution, drilling-fluid breakout, altered groundwater or surface-water pathways, disease transmission, temporary crossings or disturbance of watercourse beds and banks.

That concern is reinforced by the Environment Agency's findings. APP/7.1 permits temporary construction access ramps over watercourses where haul routes cannot avoid them, while the final crossing methods and crossing schedule remain subject to detailed design. The Environment Agency requests firmer watercourse buffers, confirmation of trenchless methods at Main Rivers, improved drilling-fluid breakout procedures, fuller water-quality monitoring and clearer pollution controls for temporary works.

Accordingly, the absence of confirmed crayfish records at individual crossing points does not justify a conclusion that effects on the species or its supporting habitat are negligible. The assessment must follow the connected water system, identify downstream pathways and apply precautionary biosecurity, sediment and pollution controls wherever works could affect suitable habitat.

2.5.2 Bat survey coverage and maternity-colony function

The bat baseline must be sufficient to assess the Scheme at colony and landscape scale. South Norfolk Council records ten bat species, describes the assemblage as nationally important and identifies multiple barbastelle maternity colonies whose Core Sustenance Zones overlap the Order Limits. Norfolk County Council likewise identifies maternity roosts in surrounding woodland and considers the area potentially of national importance.

The December 2025 report by Jane Harris materially strengthens that concern. It explains that the South Norfolk Claylands support a barbastelle metapopulation dependent on scattered woodland, high hedges, pollarded trees, open fields and landscape connectivity. Using a 6 km Core Sustenance Zone, it identified six maternity colonies whose CSZs lie within or abut the Scheme area, including two colonies beside the proposed cable route and one expected to be surrounded by solar arrays. It also records that several woodlands, particularly at the eastern end of the Scheme, had not previously been surveyed.

The 2025 fieldwork assessed five woodland areas close to the Scheme. All contained suitable barbastelle roost features. Radiotracking confirmed a previously unknown maternity colony in Little Wood near Shotesham, with a pre-parturition emergence count of up to 36 bats and an estimated post-parturition colony of approximately 55, described as large in the Norfolk context. Acoustic results also predicted maternity colonies in Brooke Wood and Lower Spring Wood, while Spring Wood, Hempnall Green was confirmed as being used for roosting and feeding but requires further work to establish its status.

The report also establishes that relatively small belts of mature broadleaved trees within otherwise coniferous plantations may support maternity colonies and should not be dismissed without detailed assessment. It identifies ageing ash affected by dieback as an increasingly important source of split and lifting bark suitable for barbastelle roosts. This is particularly relevant to South Norfolk woodlands and means that woodland size, plantation classification or apparent commercial character cannot safely be used as proxies for low roost potential.

The Applicant should therefore identify the age and seasonal coverage of all bat data, whether every relevant adjoining woodland has been surveyed, whether effects were assessed colony by colony, and how overlapping CSZs, dark commuting routes, woodland edges, hedgerows, panel proximity, access tracks, lighting and construction disturbance were considered cumulatively. The assessment must include roosts outside the Order Limits where the Scheme may remove, fragment or disturb supporting habitat.

The Harris report expressly requires further radiotracking at Brooke Wood, Lower Spring Wood and Spring Wood, Hempnall Green, and assessment of additional candidate woodlands including Hempnall Little Wood, Winters Grove, Ringers Grove, Tindall Wood, Sexton Wood, Hedenham Wood, Park Plantation and smaller scattered woods

across the Scheme area. Its conclusion is clear: the effects of East Pye Solar cannot be properly assessed without a fuller understanding of barbastelle distribution and habitat use throughout the Scheme landscape.

That evidential gap also affects European Protected Species licensing. The tests of no satisfactory alternative and maintenance of favourable conservation status cannot be addressed reliably unless the maternity-colony network, roost resource, commuting routes and foraging habitat are sufficiently understood before consent.

2.5.3 Botanical baseline

BEPS's consultation-stage objection was that the PEIR did not demonstrate systematic botanical recording across all land affected or potentially affected by the Scheme. That concern is serious because the area is not botanically ordinary. The January 2026 letter from two experienced local botanists identifies multiple threatened and locally important species along roads, verges, tracks and field edges liable to be affected by access works, road widening and construction traffic. These include sulphur clover, listed as Endangered in Great Britain and Vulnerable in England; dyer's greenweed and pepper saxifrage, both listed as Endangered in Great Britain; and crosswort, listed as Near Threatened in England. The letter states that South Norfolk supports about 20% of the national sulphur clover population and that up to five of Norfolk's eight extant dyer's greenweed sites may lie within the affected area.

The concern is not limited to individual species. The letter describes irreplaceable assemblages surviving on ancient verges, drove roads, parish boundaries and former commons, including the nationally significant combination of dyer's greenweed, sulphur clover and spiny restharrow around Lodge Road, Hundred Lane, Carpenter's Walk and Prangle Lane. These communities may occupy strips only 30–50 cm wide and are therefore acutely vulnerable to road widening, vehicle overrun and verge damage. Their long continuity, associated fungi and local seedbanks mean that they cannot credibly be recreated elsewhere through generic seeding or BNG compensation.

A complete botanical baseline was therefore required before access routes, cable corridors and site entrances were fixed. The letter calls for full-area walkover surveys by a botanist of at least FISC level 5, with one survey in June for grassland vegetation and another after harvest but before sowing for arable flora, followed by redesign to avoid valuable areas and further consultation on any materially revised scheme.

The Applicant should now identify precisely what Phase 1, UKHab and targeted botanical surveys were completed, when, by whom, to what geographic extent and with what limitations. It must also explain how the results altered the layout, access strategy, cable route, BNG baseline and mitigation. Unless that is demonstrated, the ecological baseline may be understated, avoidance areas may have been missed and claimed BNG may rest on an unreliable valuation of existing habitat.

ISH1 has now resulted in a specific action requiring the Applicant to engage with local botanical evidence concerning rare species records and the effects of road widening

and access works, reinforcing BEPS's submission that the botanical baseline was not complete when significance conclusions were reached.

2.5.4 Other baseline omissions identified by consultees

The ecological concerns form part of a wider pattern. The Environment Agency identifies omitted or inadequately described groundwater-dependent terrestrial ecosystems, inaccurate Source Protection Zone information, missing water-quality data, insufficient ground investigation and incomplete assessment of private and public water supplies.

South Norfolk Council identifies uncertainty concerning historic hedgerows, veteran trees, great crested newt data, adjoining bat roosts, operational noise sources and contaminated land. National Highways identifies missing junction-level modelling and collision information for the strategic road network. Norfolk County Council identifies insufficient archaeological trenching in geophysically 'blank' areas and missing information on internal array cabling, preventing reliable assessment of combined below-ground effects.

These examples demonstrate that the problem is methodological rather than confined to one discipline: significance conclusions have repeatedly been reached despite material baseline uncertainty.

2.5.5 Consultation consequences of incomplete baseline information

Where material survey seasons or receptor assessments were incomplete during statutory consultation, consultees could not fully assess the likely significant effects or the effectiveness of the proposed mitigation. The Applicant must therefore explain what information became available later, how it altered the environmental assessment or Scheme design, and how affected consultees and communities were given a fair opportunity to respond.

Not every later survey necessarily required a fresh statutory consultation. The relevant question is whether later information materially changed the understanding of the baseline, likely effects, mitigation or development envelope. Where it did, the Applicant must demonstrate that consultation remained intelligent and informed.

2.6 Generic significance matrices are not calibrated to site-specific ecological sensitivity

The ES relies on standard sensitivity, magnitude and significance matrices, but does not adequately demonstrate that those matrices were adapted to the functional requirements of the receptors present. Barbastelle maternity colonies require dark and connected commuting and feeding networks; chalk streams and groundwater-dependent habitats may be affected by sediment, heat, drilling and altered flow pathways; white-clawed crayfish may be vulnerable to limited pollution or biosecurity

failures; and rare botanical assemblages or Countryside Stewardship habitat may have substantial functional value despite limited spatial extent.

Norfolk County Council's LLFA identifies internal uncertainty in Chapter 2. 'High' sensitivity combines national and international receptors, while 'Medium' includes receptors described as being of high importance. The relationship between value, importance, susceptibility and sensitivity is therefore unclear.

The Environment Agency also identifies materially different scale-of-effect matrices in Chapters 9 and 16 for comparable groundwater receptors. It considers that the Chapter 9 matrix may underestimate effects and prevent meaningful comparison between disciplines.

The matrix is not a neutral tool. Where receptor value is compressed, magnitude categories are broad and professional judgment is insufficiently explained, a small change in classification may determine whether a serious effect is labelled significant or not significant.

2.7 Generic mitigation assumptions do not demonstrate ecological functionality

The existence of a mitigation measure does not establish that it will function for the receptor concerned. Buffer strips, retained hedgerows, grassland beneath panels, replacement planting, sensitive lighting, trenchless crossings, pre-construction surveys and ecological supervision cannot automatically be treated as sufficient embedded mitigation.

The Applicant must demonstrate the receptor protected, the ecological function retained, the required width and condition, the securing mechanism, the period before the measure becomes effective, the monitoring regime, the response to failure and its continued effectiveness during replacement and decommissioning.

For barbastelle, retained hedgerows and generic buffers do not by themselves demonstrate maintenance of dark, unfragmented commuting and foraging habitat. For chalk streams and crayfish, general pollution-prevention wording does not resolve drilling-fluid breakout, sediment, temporary crossings, groundwater pathways or biosecurity risk. Ground-nesting bird habitat supported through Countryside Stewardship cannot simply be displaced or recreated without evidence of equivalent location, management, area and functional use.

APP/7.1 and APP/7.2 reinforce this concern because they defer important ecological controls to later walkovers, protected-species surveys, licensing, EcoCoW advice, lighting strategies and detailed management plans. Those documents may implement mitigation, but they should not be used to postpone determining whether the mitigation is feasible and sufficient.

2.8 Cumulative and functional-connectivity underassessment

Cumulative ecological assessment is not limited to adding hectares of habitat loss. It must assess the integrity and function of the ecological network affected by the components of this Scheme and by other developments.

2.8.1 Barbastelle Core Sustenance Zones

The assessment should map every confirmed and reasonably predicted maternity colony, overlapping Core Sustenance Zones, woodland and hedgerow links, dark corridors, panel proximity, access tracks, lighting nodes and construction disturbance. South Norfolk Council's evidence of twelve overlapping maternity-colony Core Sustenance Zones demonstrates why a broad bat-assemblage assessment is insufficient. Effects should be assessed by colony where the evidence permits and then cumulatively across the maternity network.

2.8.2 Hydrological connectivity

The assessment must connect BESS and substation locations, deep foundations, piling, cable trenches, HDD crossings, groundwater pathways, Source Protection Zones, groundwater-dependent habitats, chalk streams, aquatic ecology and water supplies.

The Environment Agency identifies risks from deep foundations, preferential pathways, cable heat, inaccurate Source Protection Zone descriptions and omitted groundwater-dependent ecosystems. It requires hydrogeological and foundation works risk assessments informed by intrusive investigation. These matters cannot be assessed reliably as separate ground, water and ecology effects where they share the same pathways and receptors.

2.8.3 Combined effects of the Scheme

The internal cumulative assessment should address the combined effects of solar arrays, BESS, substations, pylons, cable corridors, temporary compounds, access works, fencing, lighting, drainage and replacement cycles. The Scheme should not be divided into separate work packages where the same habitat network is exposed to repeated, overlapping or simultaneous disturbance.

The August 2026 NPPF now reinforces several of those receptor-network concepts expressly. Policy N2 requires ecological networks extending beyond the development site to be strengthened; Policy TR8 treats public rights of way as a network and recognises the importance of direct and circular recreational routes; Policy P3 requires cumulative pollution effects to be considered; and Policy TR6 requires reasonable future transport scenarios and cumulative effects to be assessed. ExQ1 similarly questions the Applicant's treatment of individual PRoWs in isolation and asks for consideration of sequential experience along circular routes. The principle is wider than

recreation: bats, residents, watercourses, heritage assets and settlements likewise experience connected and repeated effects rather than isolated technical-chapter events.

2.8.4 External cumulative schemes

The cumulative assessment must reflect the exceptional concentration of energy and infrastructure development in South Norfolk. Relevant schemes include other solar NSIPs and BESS projects, Norwich to Tilbury, offshore-wind cable and converter infrastructure, National Grid works, strategic highway schemes and major local development. These projects may overlap in programme, geography, haul routes, ecological networks and affected communities.

South Norfolk Council identifies cumulative risks to landscape, heritage, ecology, businesses and communities, including overlapping construction programmes, abnormal-load movements, road widening and associated loss of trees and hedgerows. Norfolk County Council likewise objects to the clustered loss of agricultural land and the cumulative effects of solar and transmission infrastructure across Norfolk, particularly in South Norfolk.

The assessment cannot lawfully stop at a list of projects or a comparison of individual land-take figures. It must assess whether combined construction traffic, habitat fragmentation, noise, lighting, hydrological disturbance and landscape industrialisation affect the same receptors at the same time. Where overlapping programmes remain uncertain, that uncertainty must be assessed rather than used to exclude effects.

2.9 Temporal methodology and ecological timescales

Chapter 2 applies generic duration categories that are not reliably adapted to ecological timescales. A two-year effect cannot automatically be treated as short-term merely because it is temporary in project terms. Nor can a 60-year loss of habitat function sensibly be described as temporary simply because eventual decommissioning is proposed.

The Environment Agency specifically rejects the ecology chapter’s classification of effects lasting up to two years as short-term for fish. It states that effects lasting more than six months should be assessed as permanent for relevant WFD purposes because two spawning or juvenile cohorts may be affected. This demonstrates why duration must be receptor-specific.

The same problem arises for maternity-colony function, mature hedgerows, woodland edges, soil communities and chalk-stream habitats. Their ecological function may take decades to recover, if it recovers at all. The methodology must also assess repeated BESS replacement, wholesale panel replacement and transformer replacement, including the disturbance of habitats that may have matured during operation. APP/7.2 confirms repeated BESS replacement and a major panel-replacement cycle during the 60-year life of the Scheme.

2.10 Future baseline and climate-dependent ecological change

The future baseline is insufficient if it assumes the receiving environment remains static while the Applicant's mitigation planting matures successfully. Over a 60-year operational period, ecological and hydrological conditions will change.

The assessment should address drought, groundwater decline, more intense rainfall, sediment and runoff risk, changing water temperatures, altered bat and bird distributions, habitat succession, planting mortality, invasive species and the future condition of surrounding habitats. Those changes may affect both receptor sensitivity and mitigation performance.

This is particularly important where the Scheme relies on long-term planting, drainage maintenance, watercourse protection and stable groundwater conditions. APP/7.2 shows that operational acceptability depends heavily on vegetation establishment and continued maintenance over decades. The Applicant cannot claim the future benefits of mature planting while failing to assess the future deterioration, displacement or increased vulnerability of the wider ecological network.

2.11 Professional judgment and unexplained ecological conclusions

Professional judgment is not objectionable in itself, but it must be transparent, evidence-based and precautionary where uncertainty is material. The ES repeatedly reaches conclusions of negligible, minor or not significant effect without always exposing the reasoning necessary to test them.

Examples include the conclusions that solar development will not materially affect barbastelle colony function; aquatic invertebrates, fish and crayfish will not be significantly harmed; cable heat will remain confined to the immediate cable vicinity; freshwater fish are of limited importance; private water supplies are of only moderate sensitivity; habitat fragmentation is minor; and generic buffers will be effective.

Several consultees dispute those judgments. The Environment Agency challenges the valuation of fish, the treatment of cable heat, groundwater pathways and water-supply sensitivity. South Norfolk Council disputes the sufficiency of the bat, noise and heritage judgments.

For each material conclusion, the Applicant should identify the evidence relied upon, the expert making the judgment, the assumptions adopted, the uncertainty recognised, the reason for the selected significance category and why a precautionary conclusion was not preferred. Without that audit trail, professional judgment becomes an unreviewable route to downgrading effects.

2.12 Rochdale envelope and changing ecological effects

The ecological assessment must correspond to the same maximum design configuration assessed elsewhere. Ecological effects may vary materially according to whether the Scheme uses 4.5 metre tracker panels or lower fixed panels, panel spacing and movement, proximity to woodland and watercourses, lighting design, BESS and substation footprint, foundation depth, cable burial depth, HDD depth, launch-pit location, access alignment and vegetation clearance.

APP/7.18 preserves substantial flexibility across those parameters. The Applicant must therefore demonstrate which maximum configuration was assessed in Chapter 8 and whether it is consistent with the maxima used in the landscape, water, noise and heritage chapters.

The Environment Agency's finding that maximum foundation depths are absent for some substations is particularly serious because ecological conclusions concerning groundwater-dependent habitats cannot be reliable if the vertical extent of disturbance is unknown. A flexible envelope is permissible only where the realistic worst case has been assessed and secured.

ISH1 has made the Rochdale-envelope issue more concrete. The Applicant confirmed that the Illustrative Masterplan is not the final layout and that important components remain subject to post-consent choice. The ExA consequently sought further information concerning overplanting, panel ratings, hectares per MW, panel type and location, minimum panel separations, conversion-unit and switchroom numbers and locations, fencing, lighting, substation technology and whether the authorised envelope could permit a materially greater installed capacity than that presented. These are not merely aesthetic matters. They affect landscape, heritage, ecology, noise, drainage, transport, ground conditions, aviation and cumulative effects. The EIA must therefore demonstrate that every materially different configuration permitted by the DCO remains within a discipline-specific and whole-Scheme reasonable worst case.

2.13 Outline controls and excessive deferral

The application relies heavily on future documents to resolve matters that may determine whether significant effects arise. APP/7.1 defers pre-construction walkovers, further protected-species surveys, licensing, detailed water management, crossing schedules, hydrogeological assessment and construction methods. APP/7.2 defers sensitive lighting, future ecological management, EcoCoW controls for replacement works, possible later badger licensing and detailed operational mitigation.

Post-consent information is not objectionable merely because it is produced later. The critical distinction is whether it refines implementation of an already assessed and acceptable solution, or whether it supplies information required to determine whether such a solution exists. East Pye repeatedly approaches that boundary.

Several of the outstanding matters are not questions of detailed design but questions of environmental knowledge. The Applicant still lacks, or has only recently begun to obtain or supplement, important information concerning botany, aquatic ecology, bat functional habitat, aviation safety, high pressure gas pipeline safety, private water supplies and hydrogeology. Those matters are capable of determining where development can safely occur, what avoidance is required, what mitigation is feasible and whether the authorised development can remain within the effects assessed. They therefore go to the environmental acceptability of the authorised envelope itself, not merely to its later implementation.

The distinction is fundamental. Later work may legitimately refine an already demonstrated acceptable solution. It should not be used to discover, after consent, whether an acceptable solution exists.

The correct test is simple: does the later document merely implement an already assessed and fixed outcome, or will it determine whether an effect occurs, how large it is or whether mitigation is feasible? If the latter, the environmental issue has not been resolved at examination stage.

Future surveys may update method statements, but they cannot lawfully substitute for an adequate baseline. Detailed design may refine mitigation, but it cannot be allowed to determine later whether protected-species habitat, groundwater pathways or watercourse crossings are acceptable. The present level of deferral materially weakens the reliability of the ES conclusions.

ExQ1 now provides direct examples. The ExA asks how an adequate ground, groundwater and contamination baseline can be demonstrated without application-stage intrusive investigation; how drainage design can be finalised where infiltration testing and hydraulic detail remain outstanding; how health and fire conclusions can be relied upon where future assessment is still required; and which transport and design measures remain dependent upon later approval. Those questions support BEPS's submission that some matters currently described as 'detailed design' are in substance pre-consent questions of feasibility and environmental acceptability.

2.14 Consequences for consultation, HRA and EPS licensing

2.14.1 Consultation

Where material ecological information was absent or incomplete during statutory consultation, consultees could not properly test the significance of effects or the adequacy of mitigation. That concern arises particularly in relation to barbastelle maternity colonies, botanical interest, white-clawed crayfish and hydrological connectivity. The later Harris report identified a new maternity colony at Little Wood, predicted further colonies at Brooke Wood and Lower Spring Wood, and concluded that the Scheme's effects could not be properly assessed without fuller knowledge of barbastelle distribution and habitat use. The botanical objection likewise identified

threatened species and irreplaceable verge assemblages not demonstrated to have been systematically surveyed at PEIR stage.

The Applicant must therefore show what material evidence emerged after consultation, how it changed the assessment or design, and whether affected consultees and communities had a fair opportunity to respond. The issue is not that every later survey required a fresh consultation. It is whether the later evidence materially altered the environmental case.

2.14.2 Habitats Regulations Assessment

The EIA defects do not automatically render the HRA unlawful. They do, however, undermine its evidential foundation where conclusions depend on ecological connectivity, groundwater pathways or cumulative effects that remain incompletely understood.

APP/2.10 shows the Scheme in the wider context of European sites, SSSIs and ancient woodland. The Environment Agency has identified omitted groundwater-dependent terrestrial ecosystems, unresolved hydrogeological pathways and risks from piling, trenchless drilling and cable heat. If those pathways could connect the Scheme to European sites or supporting habitats, screening and in-combination conclusions cannot safely rest on generic mitigation or later risk assessments.

2.14.3 European Protected Species licensing

The relevant EPS licensing tests are a permitted statutory purpose, no satisfactory alternative, and maintenance of the species at favourable conservation status. IROPI is not the applicable EPS licensing test.

Those tests cannot be considered reliably while the barbastelle maternity network remains incompletely defined. The Harris report confirmed a new maternity colony, predicted further colonies and identified additional woodlands requiring investigation. South Norfolk Council also records multiple overlapping Core Sustenance Zones and raises the likelihood of further colonies in unsurveyed woodland.

Without a sufficiently complete understanding of roosts, commuting corridors, foraging habitat and cumulative effects, the Applicant cannot demonstrate that alternatives have been properly considered or that favourable conservation status can be maintained. Licensing cannot be treated as a routine post-consent formality.

2.14.4 Planning balance

These methodological uncertainties materially reduce the weight that can be placed on the Applicant’s repeated conclusions that effects are negligible, minor or fully mitigated. They also weaken the proportionality and residual-harm assessment under EN-1 and EN-3.

Where the baseline is incomplete, the design remains flexible and mitigation is deferred, the decision-maker should not assume the most favourable outcome. Uncertainty concerning serious or irreversible harm must weigh against consent unless resolved during examination.

The August 2026 NPPF W3 does not reduce the need for robust environmental information. Substantial weight to renewable-energy benefits does not convert an uncertain environmental effect into a known one. The planning balance can only be completed against effects which have been adequately identified and assessed.

2.15 Wider cross-topic manifestations of the same defect

The methodological problem is not confined to ecology. The Environment Agency identifies inconsistent significance matrices between Chapters 9 and 16, missing maximum foundation depths, incomplete groundwater evidence and inaccurate Source Protection Zone descriptions. National Highways identifies missing junction-level modelling, collision assessment and sufficiently granular cumulative traffic analysis.

South Norfolk Council says the noise assessment does not demonstrate the true rural worst case, omits or inadequately explains key source data and relies on unconfirmed mitigation. It also questions the effectiveness of landscape planting and the completeness of hedgerow and veteran-tree evidence. Norfolk County Council identifies insufficient archaeological trenching in apparently blank areas, missing internal array-cabling information and inconsistencies in the temporal methodology and future baseline.

The same pattern recurs throughout: incomplete baseline evidence, broad professional judgment, missing maximum parameters, generic mitigation and post-consent deferral are used to support findings of no significant effect.

The hearing record provides several further examples of the same methodological defect. The Site 7 haul-road crossing of the high-pressure gas pipeline remained technically unexplained at ISH1. The Applicant was required to provide a standalone aviation-safety document addressing matters beyond glint and glare. The ExA required further explanation of the National Grid substation's capacity for other projects, the certainty and timing of its delivery and the cumulative or downstream consequences of future third-party use. It also required the Applicant to explain how adverse effects on some individuals are translated into a conclusion of no significant population-level health effect, and whether concern or anxiety arising from perceived risks has been assessed separately. These are not isolated requests for clarification; they show that the Scheme's environmental conclusions continue to depend upon interactions and assumptions which have not yet been fully reconciled.

2.16 Methodological consequences and overall finding

First, the methodology is not demonstrably tailored to the ecological and hydrological characteristics of the East Pye landscape. It treats a connected system of woodland, hedgerows, aquifers, streams, verges and farmland mosaics through largely generic and parcel-based assessment structures.

Second, the baseline remains incomplete or disputed in material respects, including barbastelle maternity networks, white-clawed crayfish, botanical interest, groundwater-dependent habitats, water quality, Source Protection Zones and other receptors.

Third, generic matrices and mitigation templates have not been shown to reflect the functional requirements of the receptors affected. Fourth, cumulative, hydrological and ecological connectivity have not been integrated adequately. Fifth, important matters remain deferred to later surveys, management plans, licences and design decisions.

In those circumstances, the ES cannot reliably determine the realistic scale and significance of effects across the full Scheme. The weakness is not confined to one ecology appendix. It affects consultation, cumulative assessment, protected-species licensing, water and groundwater assessment, the mitigation case and the weight to be given to residual-harm conclusions in the planning balance.

The methodological consequence is therefore now clearer than when this Written Representation was first prepared. The problem is not simply that some chapters contain gaps or that some mitigation remains to be detailed. The Examination has itself identified repeated instances in which the information needed to understand the receptor, define the authorised development, identify the reasonable worst case or test the effectiveness of mitigation remains outstanding while the ES has already reached conclusions of no significant effect.

The EIA can only support development consent if the Examining Authority can identify a coherent evidential chain for each material issue: baseline receptor → source/pathway → magnitude and significance → avoidance and mitigation → residual effect → secured DCO control.

Where the receptor remains incompletely defined, the pathway is uncertain, the design is still materially flexible or the mitigation is not yet demonstrated and secured, the residual-effect conclusion is necessarily provisional rather than established.

The ExA should therefore distinguish explicitly between matters which may legitimately be refined after consent and matters which must be resolved during Examination because they determine whether the Scheme is environmentally acceptable at all. Where the latter cannot be resolved within the assessed DCO envelope, the relevant flexibility or Work should be reduced, relocated or removed rather than deferred.

2.17 Examination questions

The Applicant should be required to provide:

1. A scheme-wide ecological-network plan showing statutory and non-statutory sites, ancient woodland, priority habitats, watercourses, ponds, known and predicted maternity colonies and overlapping Core Sustenance Zones.
2. A complete survey schedule identifying dates, seasons, coverage, limitations and unsurveyed areas.
3. Full details of Phase 1, UKHab and targeted botanical work across Sites, cable corridors, accesses and temporary works areas, and how that evidence informed design and BNG.
4. A colony-specific barbastelle assessment, including cumulative effects within overlapping Core Sustenance Zones and impacts on roosts outside the Order Limits.
5. The full evidential basis for concluding that white-clawed crayfish and other aquatic receptors will not experience significant effects.
6. An integrated assessment of groundwater, cable heat, trenching, HDD, piling, pollution pathways and terrestrial and aquatic ecology.
7. A schedule of every ecological conclusion dependent on future surveys, licensing or detailed design.
8. An explanation of how generic duration categories were adapted for fish, bats, breeding birds, ancient woodland and other receptors.
9. A reconciliation of the sensitivity and significance methodologies in Chapters 2, 8, 9 and 16.
10. An assessment showing how ecological effects change under the maximum tracker-panel, BESS, substation, pylon, piling, trenching and HDD envelope.

2.18 Remedies sought

The Applicant should be required to complete and disclose all necessary seasonally appropriate surveys, including a complete botanical baseline, updated maternity-colony assessment, adequate crayfish and aquatic ecology evidence, corrected statutory-site, GWDTE and Source Protection Zone information, and transparent survey limitations.

The ES should then be revised to provide a landscape-scale ecological assessment, colony-specific barbastelle analysis, integrated groundwater, surface-water and ecology assessment, receptor-specific duration criteria, cumulative functional-connectivity assessment and reconciled significance matrices.

The Scheme should be redesigned to remove or substantially reduce development within the most sensitive ecological networks, secure wider fixed buffers and dark corridors, avoid development immediately adjoining maternity-colony woodland, fix watercourse-crossing principles and impose tighter controls on lighting, piling, HDD and cable routing.

There should be a consolidated schedule identifying every material item of post-consent information and classifying it either as implementation detail or as information

capable of altering the acceptability, location or design of a Work; a cross-topic spatial reconciliation showing where mitigation, biodiversity land, retained agricultural land, cabling, access and other Works overlap or compete for the same land; a whole-Scheme reasonable-worst-case schedule identifying, for each flexible component, the configuration assessed in each environmental discipline and the DCO control which prevents a worse outcome.

The DCO should not rely on ‘where practicable’ wording for essential mitigation. It should prohibit material departure from assessed parameters, require consultation with Natural England, the Environment Agency and relevant local authorities, impose objective approval criteria and monitoring triggers, and prevent commencement where essential surveys, licences or risk assessments remain outstanding.

Unless these deficiencies are corrected during examination, the Examining Authority cannot safely rely on conclusions that ecological, hydrological and cumulative effects are minor, negligible or not significant. The primary remedy is refusal of the Scheme as presently defined. Alternatively, no favourable recommendation should be made unless the necessary evidence, revised assessments, avoidance measures and binding controls have been provided, consulted upon where necessary, examined and secured.

Chapter 3: The Order Limits

3.1 Overarching Objection to the Applicant's Treatment of Site and Surroundings

BEPS objects to the Applicant's treatment of site and surroundings on the basis that it does not provide a sufficiently complete, integrated or legally reliable account of the receiving environment against which the likely significant effects of the Scheme must be identified and assessed.

For a development of this scale, extent, duration and complexity, the description of site and surroundings is not a merely introductory exercise. It forms part of the environmental baseline on which the wider assessment depends. If that baseline is incomplete, artificially segmented or methodologically misconceived, the subsequent assessment is liable to misstate the sensitivity of the receiving environment, understate likely significant effects, and distort the planning balance.

The Scheme is not a limited intervention in a simple or homogeneous landscape. It is a dispersed, infrastructure-intensive proposal extending across a broad tract of South Norfolk countryside and involving generating areas, substations, battery storage, grid connection works, cable routes, access arrangements and associated development. The receiving environment is correspondingly complex and must be assessed as such.

Since this Written Representation was prepared, the National Planning Policy Framework was replaced on 17 August 2026. The Energy NPSs remain the primary policy framework for this NSIP, but the current NPPF materially reinforces the importance of correctly characterising the receiving environment. Policy N2 requires development proposals to consider the environmental qualities of the land proposed for development, including habitats, landscape character and the countryside; to take account of the quality and grade of agricultural land; to connect to and strengthen ecological networks extending beyond the site; and to conserve established natural features where possible. Policy DP3 similarly requires development to respond to the history, character and features of its site and setting so that it integrates with and enhances its surroundings. Those policies are difficult to apply reliably if the receiving environment is first divided into artificial development parcels and its landscape, ecological, agricultural, hydrological and historic functions are considered separately rather than as characteristics of one place.

3.2 Fragmentation of the Receiving Environment

The first and most fundamental defect in the Applicant's approach is fragmentation. The Scheme is treated as a series of separate sites, parcels, corridors and infrastructure components, rather than as a single development introduced into one coherent environmental and cultural landscape.

That is a methodological error, not a mere matter of presentation. The affected area is not properly understood by dividing it into operational compartments. The environmental reality is one of continuity and connection: fields are linked to lanes; lanes to settlements; settlements to heritage assets; heritage assets to their wider setting; woodlands to foraging habitat; habitat to hydrology; hydrology to aquifers, drains, ditches and private water supplies; and all of those elements to the ordinary use and experience of the countryside by residents, landowners and the public.

A parcelised description therefore risks obscuring the true scale and nature of the Scheme's interaction with its surroundings. It encourages an artificially narrow understanding of impact and tends to suppress the fact that the Scheme would operate across one living landscape rather than within a series of environmentally discrete compartments.

3.3 Failure to Describe Interrelationships

The second defect is the failure to describe adequately the interrelationships that define the site and its surroundings. In this part of South Norfolk, the relevant constraints and sensitivities are not discrete topics capable of being understood in isolation. They are overlapping aspects of one place.

The affected area is characterised by a settled agricultural landscape of heavy clay soils, productive farmland, historic villages and dispersed farmsteads, narrow rural roads, public rights of way, mature hedgerow patterns, designated and undesignated heritage assets, protected and ancient woodland, protected species habitat, stewardship-managed land, sensitive water environments, aquifer-linked systems, private water supplies and active aviation interests.

The significance of the landscape lies not merely in the presence of those individual receptors, but in their relationship to one another. Hydrology cannot lawfully be reduced to drainage features alone, because field drains, ditches, culverts, groundwater pathways, abstraction points and downstream receptors form connected systems. Heritage cannot lawfully be reduced to a list of designated assets, because significance depends in part on openness, tranquillity, long views, dark skies, settlement form and the continuing legibility of historic landscape patterns. Ecology cannot lawfully be reduced to habitat parcels, because species movement, foraging function, disturbance, lighting and hydrological dependency operate across the wider landscape. Agricultural land cannot lawfully be reduced to acreage alone, because soil structure, compaction risk, drainage, stewardship and reversibility are interdependent.

A lawful account of site and surroundings must therefore do more than identify the location of receptors or describe the land within a red-line boundary. It must explain how the landscape functions as an interconnected whole and how the Scheme's component parts would interact with that whole.

3.4 Understatement of Environmental Sensitivity

A further consequence of the Applicant's fragmented approach is that it tends to understate the sensitivity of the receiving environment. The land affected is not generic countryside. It is a historically settled, environmentally constrained and agriculturally productive landscape with multiple overlapping protections, vulnerabilities and functional relationships.

Its sensitivity derives not only from designated assets or mapped constraints viewed individually, but from the cumulative coexistence of heritage significance, ecological dependency, hydrological vulnerability, agricultural productivity, rural amenity, settlement character and infrastructure pressure. A description that isolates those matters from one another will almost inevitably dilute the apparent seriousness of the whole.

That is particularly material where the Scheme includes substantial industrial elements, including large-scale substations, battery storage and grid connection infrastructure, whose effects are not confined to the fields in which they sit. Such infrastructure alters the character, risk profile and lived experience of the wider area. A proper account of site and surroundings must reflect that transformation.

3.5 Failure to Treat the Area as a Living Historic and Environmental Landscape

The Applicant's approach also fails to treat the affected area as a living landscape. This is not an empty spatial envelope available for abstract allocation to infrastructure. It is countryside shaped by long-settled agricultural use, historic routeways, stewardship, ecological processes, inherited patterns of landholding, and the long-term relationship between villages, farmsteads, churches, lanes, fields and woodlands.

That matters because the assessment of likely significant effects must engage with the actual place likely to be affected, not a simplified development platform. A site-and-surroundings chapter that omits the lived, functional and historical character of the landscape risks misdescribing the baseline itself.

In this case, the landscape must be described as a living historic and environmental system in which agricultural management, habitat use, settlement pattern, rights of way, tranquillity, heritage setting, groundwater conditions and rural infrastructure all contribute to the significance and sensitivity of the area. Any treatment that fails to do so is materially deficient.

3.6 Consequences for the EIA as a Whole

These defects are not confined to a single chapter. They go directly to the adequacy of the environmental assessment as a whole. The site-and-surroundings chapter provides the baseline framework for subsequent topic assessments. If that framework is partial, compartmentalised or misleading, the defect is carried forward into later judgments on significance, mitigation and residual effect.

A fragmented baseline is liable to distort the assessment of landscape and visual effects by treating change as localised rather than systemic. It is liable to distort heritage assessment by

severing assets from their wider agricultural and spatial context. It is liable to distort ecology by underplaying functional habitat linkages and landscape-scale effects. It is liable to distort water assessment by failing to capture pathway connectivity. It is liable to distort soils and agricultural land by ignoring the interaction of soil type, drainage, management and reversibility. It is liable to distort transport, amenity and human health assessment by overlooking how burdens accumulate across settlements, lanes and community spaces.

It is equally liable to distort cumulative assessment. The cumulative burden of the Scheme cannot be properly understood if the baseline itself has already been artificially broken apart into separate technical components. In that respect, the inadequacy of the site-and-surroundings chapter is not incidental: it is capable of infecting the assessment of cumulative and in-combination effects across the Scheme as a whole.

3.7 Historic Settlement Pattern, Heritage Context and Rural Character

The Applicant's treatment of site and surroundings fails to reflect the fact that the Scheme is located within a historically settled and heritage-rich rural landscape whose character is inseparable from its pattern of villages, hamlets, farmsteads, churches, lanes, field systems and long-established agricultural use.

This is not a landscape in which heritage significance is confined to a small number of designated assets considered individually. Rather, the significance of the area derives to a substantial extent from the historic settlement pattern itself: the relationship between dispersed settlements and open farmland; between parish churches and their surrounding countryside; between historic farmsteads and the land historically associated with them; and between the surviving grain of lanes, boundaries and fields and the wider legibility of the historic landscape.

Rural character in this part of South Norfolk is therefore not simply visual in the narrow sense. It is spatial, historical and experiential. It arises from the continued readability of a settled agrarian landscape in which built form remains closely related to topography, field pattern, agricultural use and long views across open countryside. The contribution made by that setting is not incidental. It is often fundamental both to the significance of heritage assets and to the character of the area more generally.

In such a landscape, the distinction between 'heritage' and 'surroundings' cannot lawfully be treated as sharp or self-contained. The surroundings are part of the heritage context. The agricultural land between settlements is not empty space, but part of the setting in which historic assets are experienced and understood. The open character of the land, the continuity of historic routeways, the absence of large-scale industrial structures, the persistence of dark skies, and the ordinary relationship between settlement edges and surrounding fields all contribute to the significance of the place.

The Scheme would introduce industrial-scale solar infrastructure, substations, battery storage, security fencing, lighting, access works, cable works and associated engineered development into that historic rural context. The effect is not confined to direct physical change within

development footprints. It extends to the wider transformation of the setting in which historic settlements and assets are experienced. That includes effects on openness, rural composition, visual coherence, tranquillity, sequential views, and the legibility of the historic landscape as an agricultural system rather than an energy-industrial corridor.

The relevant heritage context must therefore be understood at landscape scale. A site-and-surroundings chapter is deficient if it treats historic villages, churches, farmsteads, listed buildings, conservation areas and undesignated historic features as isolated receptors detached from the countryside that gives them meaning. It is equally deficient if it treats the land between them as development space of limited significance simply because it is not itself designated. In a landscape of this kind, intervening farmland frequently performs a crucial heritage function by preserving separation, openness, historic approaches, key views and the agricultural setting of rural settlements and assets.

BEPS's position is that the Scheme area must be understood as part of a wider historic landscape of substantial sensitivity, in which numerous designated and undesignated heritage receptors are embedded within, and derive significance from, their rural surroundings. The historic environment here is not limited to individual buildings or sites, but includes settlement form, landscape pattern, routeways, field enclosure, visual relationships and the long continuity of agricultural land use.

That proposition is now supported by BEPS's final independent Heritage Impact Assessment. Following site visits to the potentially affected listed buildings and Conservation Areas, that assessment identifies less-than-substantial harm from the principal built development to 36 designated heritage assets and adverse effects upon 41 designated heritage assets overall once associated road and abnormal-load works are included. The affected assets include two Grade I and three Grade II* listed buildings. The importance of that evidence for Chapter 3 is not simply numerical. The HIA identifies recurring attributes of setting which the Applicant's more parcelised baseline tends to understate: openness and enclosure, topography, historic and functional relationships, group value, historic agricultural use, tranquillity, remoteness, seasonal visibility and the experience of moving through the landscape.

The HIA therefore reinforces the central proposition of this chapter. The farmland separating churches, farmsteads, villages and historic routeways is not environmentally or historically neutral simply because it is undesignated. In many locations it makes a positive contribution to significance through openness, agricultural continuity, views, approaches and historic relationships. Screening development from view may therefore reduce visibility while simultaneously changing the very openness or spatial relationship which contributes to heritage significance.

That point is especially important because the cumulative experience of the area depends on repeated and overlapping encounters with this historic rural character. The significance of one village or church cannot be fully understood without regard to its relationship with neighbouring settlements, surrounding farmland, connecting lanes and wider views. Likewise, the effect of the Scheme cannot properly be assessed by examining each heritage asset in isolation while ignoring the broader transformation of the rural matrix within which those assets sit.

A lawful and reliable description of site and surroundings must therefore identify expressly the historic settlement pattern, the density of heritage receptors, the contribution made by open agricultural land to setting and significance, and the importance of rural character as a heritage value in its own right. Any treatment that fails to do so materially understates the sensitivity of the receiving environment.

Accordingly, BEPS objects to any account of site and surroundings that presents this area as merely a collection of development parcels adjacent to selected heritage receptors. The correct baseline is a coherent historic rural landscape in which settlements, heritage assets and countryside form an interdependent whole. Unless that baseline is properly described, the subsequent assessment of heritage, landscape, amenity and cumulative effects will be fundamentally weakened.

3.7.1 Agricultural Land, Heavy Clay Soils, BMV Land and the Working Countryside

The Applicant's treatment of site and surroundings is also deficient because it fails to describe the Scheme area properly as a working agricultural landscape, rather than merely a spatial envelope within which energy infrastructure may be accommodated. In this part of South Norfolk, agricultural land is not a neutral backdrop. It is the principal land use, the basis of the area's historic and present character, and a core element of the environmental baseline against which the likely significant effects of the Scheme must be assessed.

The affected area comprises actively managed farmland forming part of a wider productive rural system. Its agricultural significance is not limited to the fact of cultivation. It includes land quality, soil function, drainage behaviour, field structure, farm viability, stewardship value and the continuing role of agriculture in sustaining the character and economy of the countryside. Any lawful description of site and surroundings must therefore identify the land not simply as open space, but as an operational agricultural resource with environmental, economic and landscape significance.

That requirement is especially important here because a substantial proportion of the proposed solar parcels lies on Best and Most Versatile ('BMV') agricultural land. The Applicant itself recognises that BMV land comprises Grades 1, 2 and 3a, and that national policy requires applicants to seek to minimise impacts on such land and, where agricultural land is necessary, to prefer poorer quality land where possible. The detailed surveys identify approximately 397.4 ha of Grade 2 and 431.7 ha of Grade 3a land, amounting to approximately 829.1 ha of surveyed Best and Most Versatile agricultural land. That represents approximately 78.7% of the surveyed land addressed in BEPS's later agricultural analysis, while part of the Cable Route Corridor remains unsurveyed. BMV land is therefore not an incidental feature of the Order Limits but one of the defining characteristics of the receiving environment.

The significance of that figure is heightened by the fact that this is not simply a question of abstract land classification. In South Norfolk, agricultural quality, soil condition and landscape character are closely connected. Productive farmland forms the physical and economic fabric of the countryside. Where land is both visually integral to the rural landscape and agriculturally

valuable, development upon it gives rise to a compounded form of harm: to land use, to rural character, to local farming systems and to the long-term integrity of the agricultural resource.

The Applicant's approach is also inadequate because it does not treat soils as a central characteristic of the place. This is a landscape of heavy clay soils, with all the consequences that follow from that condition: susceptibility to compaction, smearing, rutting, structural degradation, impeded drainage, difficult restoration and long-term uncertainty as to reversibility following intensive engineering activity. Those are not secondary technical matters to be addressed later in management documents. They are part of the description of the site itself. A lawful account of site and surroundings must recognise that the agricultural land affected is not only extensive and in significant part BMV, but also physically vulnerable.

That vulnerability is fundamental to the character of the working countryside in this area. Heavy clay soils shape patterns of cultivation, field management, drainage infrastructure and agricultural resilience. They also influence ecological conditions, surface-water behaviour, accessibility, and the practical consequences of construction traffic, piling, trenching, cable installation, substation works and repeated operational access. The interaction between soil type, agricultural quality and hydrological behaviour means that soils cannot lawfully be treated as a narrow topic chapter issue divorced from the general description of site and surroundings.

Nor is it sufficient to suggest that the continued presence of some agricultural activity would preserve the essential agricultural character of the land. The relevant baseline question is not whether fragments of ancillary grazing might persist around or beneath infrastructure, but whether the land would continue to function as productive, high-quality agricultural land forming part of a coherent working countryside. In BEPS's view, industrial-scale solar development across predominantly BMV farmland, particularly on heavy clay soils vulnerable to structural damage, cannot be described as leaving the agricultural character of the site materially unchanged.

The working countryside in this area also includes land subject to agri-environment and stewardship functions, including land managed for ecological purposes alongside food production. That reinforces the point that agricultural land here performs multiple roles simultaneously. It is productive land, ecological land, landscape land and heritage setting. A site-and-surroundings chapter that reduces it to available acreage or generic field parcels materially understates its significance.

The proper baseline must therefore recognise at least four connected propositions. First, the Scheme is proposed within a living agricultural landscape, not on surplus or degraded land. Second, a substantial proportion of the solar parcels are, on BEPS's analysis, located on BMV land. Third, the area is characterised by heavy clay soils whose physical vulnerability bears directly on agricultural function, drainage and reversibility. Fourth, the agricultural land affected contributes not only to food production, but to the wider rural character, environmental function and historic continuity of the South Norfolk countryside.

Accordingly, BEPS objects to any account of site and surroundings that does not expressly describe the affected area as a productive and sensitive agricultural landscape, including the

prevalence of BMV land and the importance of heavy clay soils to the functioning of the countryside. Unless that baseline is properly stated, the subsequent assessment of soils, agricultural land, landscape character, ecology, hydrology, reversibility and cumulative effects will be materially weakened from the outset.

The August 2026 NPPF now makes the relevance of that baseline still clearer. Policy N2 requires the quality of agricultural land, including BMV status **and its grade**, to be taken into account and states that, where significant development of agricultural land is necessary, areas of poorer-quality land should be used where possible. The agricultural baseline therefore needs to distinguish not merely between "agricultural" and "non-agricultural" land but between the different grades and physical characteristics of the land which the Scheme would occupy.

3.8 Water Environment, Drainage Connectivity and Private Water Supplies

The Applicant's treatment of site and surroundings is further deficient because it does not describe the affected area as a hydrologically connected environment in which fields, drains, ditches, culverts, groundwater pathways, aquifers, abstractions and downstream receptors operate as parts of one system. In this landscape, water environment constraints are not incidental or localised. They are fundamental to the character, functioning and sensitivity of the site and its surroundings.

The Scheme is not proposed on land that can lawfully be understood as hydrologically self-contained. The surrounding countryside is shaped by a network of surface and subsurface connections: field drains, drainage ditches, ordinary watercourses, culverts, groundwater movement, aquifer-linked pathways and catchment relationships. These features do not stop at field boundaries or red-line boundaries. They connect agricultural land, settlements, ecological receptors, private water supplies and downstream water environments into a single hydrological system.

That point is particularly important in a scheme involving extensive ground disturbance, cable trenching, substation works, battery storage, access construction, permanent foundations, drainage interventions and long-term operational infrastructure. The effects of such works cannot be understood solely by reference to the immediate footprint of individual components. The relevant question is how those components interact with the wider water environment, both on the surface and below ground.

In this part of South Norfolk, the water environment is also inseparable from the agricultural and environmental character of the landscape. Drainage infrastructure exists not merely as an engineering feature, but as part of the long-term management of heavy agricultural soils, cultivation patterns and water movement across the countryside. Groundwater conditions influence agricultural viability, habitat function, building conservation, private water supply security and the sensitivity of downstream receptors. A lawful description of site and surroundings must therefore recognise hydrological connectivity as a defining characteristic of the place.

The same is true of private water supplies. In a dispersed rural landscape such as this, private wells, boreholes and other abstractions are not exceptional or irrelevant receptors. They are part of the ordinary infrastructure of habitation and land use. Their existence materially increases the sensitivity of the receiving environment because it means that contamination risk, drawdown, pathway creation, altered drainage behaviour and accidental release events may affect not only abstract environmental receptors but real households, farms and businesses dependent on local groundwater.

A site-and-surroundings chapter is therefore inadequate if it fails to identify expressly the presence, significance and vulnerability of private water supplies across the Scheme area and its zone of influence. The baseline must include not only mapped watercourses and flood zones, but the wider pattern of hydrological dependency in the landscape: aquifer sensitivity, groundwater connectivity, drainage routes, abstraction points, receptor locations and the potential for interaction between them.

This is particularly material where the Scheme includes substantial electrical infrastructure, including substations and battery storage, because those elements introduce contamination and major accident pathways that are qualitatively different from ordinary agricultural use. Oil, firewater, construction pollutants, disturbed contaminated ground, sediment mobilisation and other hazardous releases must be understood not simply as on-site matters, but as risks operating through a connected hydrological system. If the receiving environment is described in fragmented or over-localised terms, those pathways are liable to be understated from the outset.

Nor is it sufficient to treat water environment issues as confined to flood risk in the narrow sense. Flooding is only one aspect of hydrological sensitivity. The relevant baseline also includes groundwater vulnerability, recharge and flow pathways, chalk-stream catchment sensitivity, water quality, drainage interdependence, water supply security and the relationship between land disturbance and downstream ecological receptors. A chapter on site and surroundings that reduces water to mapped flood constraints alone does not describe the real environmental conditions of the area.

The proper baseline must therefore recognise that the Scheme is proposed within a living hydrological landscape. The fields, drainage systems, aquifers, abstractions, settlements and ecological receptors potentially affected are interdependent. Water movement across this countryside is not incidental to the site; it is one of the principal ways in which effects may travel across it.

Accordingly, BEPS objects to any account of site and surroundings that does not expressly describe the affected area as a hydrologically connected and groundwater-sensitive environment, including the importance of drainage connectivity and the presence and vulnerability of private water supplies. Unless that baseline is properly stated, the subsequent assessment of water environment effects, major accident risk, human health, ecology, agricultural impact and cumulative effects will be materially weakened.

3.9 Ecology, Woodland Networks and Functional Habitat Connectivity

The Applicant's treatment of site and surroundings is also deficient because it does not describe the affected area as a functioning ecological landscape in which woodlands, hedgerows, field margins, watercourses, pasture, arable land and managed habitats operate together as interconnected components of a wider ecological system. In this part of South Norfolk, ecological value does not reside solely within isolated designated sites or discrete habitat parcels. It arises to a substantial degree from the connectivity of the landscape as a whole.

The Scheme is proposed within a countryside characterised by interlocking woodland networks, mature hedgerow systems, agricultural land used by protected and priority species, drainage features, and areas of land subject to ecological management and stewardship. The significance of these features lies not merely in their individual presence, but in the functional relationships between them: movement, foraging, commuting, breeding, shelter, hydrological dependency and seasonal use across the wider landscape.

That ecological reality cannot lawfully be captured by describing habitat on a parcel-by-parcel basis alone. Species do not observe development boundaries. Functional habitat extends across fields, routeways, hedgerows, woodland edges, grass margins, wet features and connecting corridors. A site-and-surroundings chapter that treats ecological receptors as fixed and localised risks fundamentally understating the sensitivity of the receiving environment and the extent to which effects may arise through fragmentation, severance, displacement, disturbance or loss of ecological coherence.

This point is especially important in a landscape where protected species are known or strongly likely to depend on the continuity of the countryside rather than on isolated habitat islands. Woodland blocks are not ecologically self-contained. Their value depends in part on the condition and accessibility of the surrounding land, including dark corridors, foraging areas, flight lines, edge habitat and the wider permeability of the agricultural matrix. Likewise, agricultural fields cannot be treated as ecologically negligible merely because they are farmed. In this area, farmland itself forms part of the habitat resource and movement network for protected and priority species.

The same is true of land managed under stewardship or other ecological enhancement regimes. Such land is not surplus space awaiting alternative use. It is part of an existing ecological system that has been deliberately managed to support species and habitat function over time. Its importance lies not only in species presence at a given moment, but in its contribution to the wider structure, resilience and continuity of the landscape. Any lawful description of site and surroundings must therefore identify existing ecological management and habitat functionality as baseline characteristics of the place.

The Applicant's approach is further deficient because it risks separating designated sites, protected woodlands and notable habitats from the wider countryside that sustains them. In reality, the sensitivity of woodland, including ancient and designated woodland, often depends not only on the condition of the woodland itself but on the integrity of surrounding land uses,

hydrology, lighting conditions, disturbance levels and habitat connectivity. A chapter on site and surroundings that does not explain those dependencies materially understates ecological sensitivity.

Nor can ecology lawfully be confined to a narrow inventory of habitats. The relevant baseline must include functional habitat connectivity, species use of farmed land, the role of hedgerows and margins as connective infrastructure, the significance of dark and quiet rural conditions, and the interaction between ecological function and other environmental characteristics such as hydrology, soil condition and agricultural management. In a landscape of this type, ecology is inseparable from the wider rural system.

That is particularly material for a Scheme of this scale and distribution. The environmental consequences do not arise only from direct habitat removal. They may also arise from the cumulative insertion of fencing, substations, battery storage, lighting, access routes, cable works, operational activity and long-term landscape change across multiple locations. Such infrastructure may alter movement patterns, reduce permeability, degrade dark corridors, fragment foraging land, intensify edge effects and weaken the coherence of habitat networks across the wider countryside.

The proper baseline must therefore recognise that the site and surroundings form an ecologically connected landscape in which woodland networks, agricultural land, stewardship land, hedgerows, water features and species movement corridors are interdependent. The sensitivity of the receiving environment lies not only in designated sites or isolated receptors, but in the functional integrity of the wider system.

Accordingly, BEPS objects to any account of site and surroundings that does not expressly describe the affected area as a connected ecological landscape, including the importance of woodland networks, functional habitat connectivity, species use of the wider countryside and the ecological role of managed farmland and margins. Unless that baseline is properly stated, the subsequent assessment of ecological effects, protected species impacts, mitigation, habitat compensation and cumulative effects will be materially weakened.

3.10 Public Rights of Way, Rural Amenity and the Experience of the Countryside

The Applicant's treatment of site and surroundings is further deficient because it does not adequately describe the affected area as a lived and experienced countryside used not only for farming and habitation, but for movement, recreation, quiet enjoyment and ordinary day-to-day contact with the rural environment. In this landscape, public rights of way, lanes, open views, tranquillity and the experience of passing through a coherent agricultural countryside form part of the environmental baseline and must be treated as such.

The Scheme is proposed within a rural area crossed and bordered by public rights of way, minor roads, lanes and other routes by which residents and visitors experience the countryside. These are not merely lines on a map or transport links of limited relevance. They are part of the historic

and functional structure of the landscape and part of the means by which its openness, continuity, quietness and rural character are encountered and understood.

The significance of public rights of way in this context is not confined to whether a route remains technically open. The relevant question is how the character, amenity and experience of those routes would change if the surrounding countryside were transformed by extensive solar infrastructure, substations, battery storage, security fencing, lighting, access tracks, compounds, cabling and associated activity. A route may remain legally available while being materially altered in character, attractiveness, perceived safety and amenity value.

That point is especially important in a dispersed rural landscape where the experience of the countryside depends on continuity between paths, lanes, fields, hedgerows, settlements and views. Rights of way do not operate in isolation from their surroundings. Their value lies in movement through an open and legible landscape, in the ability to experience historic settlement form and agricultural setting, and in the sense of relative tranquillity and escape from industrial development. A site-and-surroundings chapter that records rights of way merely as physical receptors or route constraints fails to capture their true significance.

Rural amenity in this area likewise cannot lawfully be reduced to visual impact in a narrow sense. It includes openness, tranquillity, dark skies, the absence of industrial activity, the relationship between villages and surrounding fields, the character of minor roads and lanes, and the cumulative experience of a countryside that remains recognisably agricultural rather than infrastructural. Those qualities are part of the ordinary enjoyment of the area by residents, walkers, riders, road users and others, and they contribute directly to the environmental sensitivity of the site and surroundings.

The Applicant's approach is therefore deficient insofar as it fails to describe the countryside as an inhabited and experienced place. The affected environment is not simply a technical platform for development. It is used and understood by people through daily movement, recreation, access to neighbouring settlements, appreciation of views, and long familiarity with a settled rural landscape. A lawful baseline must identify that experiential dimension expressly.

This is particularly material for a Scheme of this scale and distribution. The cumulative insertion of industrial elements across multiple parcels may alter the experience of the countryside well beyond the immediate footprint of infrastructure. Fencing, inverter stations, substations, battery storage, access movements, surveillance equipment, engineered tracks and the narrowing of routes into visually and perceptually enclosed corridors may collectively change the character of how the landscape is used and perceived. Such effects are real environmental effects and must be grounded in an accurate description of site and surroundings.

The proper baseline must therefore recognise that public rights of way and rural amenity are integral components of the receiving environment. The countryside here is not merely seen; it is traversed, inhabited and experienced. Its value lies partly in the continuity of that experience across fields, lanes, settlements and views. Any account that ignores or underplays that point materially understates the sensitivity of the landscape.

Accordingly, BEPS objects to any account of site and surroundings that does not expressly describe the affected area as a countryside experienced through public rights of way, rural routes, tranquillity, openness and everyday amenity. Unless that baseline is properly stated, the subsequent assessment of landscape, visual impact, amenity, accessibility, human health and cumulative effects will be materially weakened.

3.11 Cumulative Infrastructure Pressure and the Transformation of Rural Character

The Applicant's treatment of site and surroundings is also deficient because it does not describe the affected area in its true cumulative context. The Scheme is not proposed in a static or unpressured landscape. It is proposed within a part of South Norfolk already subject to substantial and increasing pressure from energy infrastructure, grid reinforcement, associated works and wider development change. That cumulative context is not a separate add-on to the baseline. It forms part of the site and surroundings themselves.

A lawful description of site and surroundings must therefore identify not only the present character of the countryside, but the extent to which that character is already being altered, or is at material risk of alteration, by overlapping infrastructure pressures. In this case, the relevant receiving environment is not simply an agricultural landscape in the abstract, but an agricultural landscape facing progressive industrialisation through the concentration of solar generation, substations, battery storage, cable corridors, overhead line works, construction traffic and related energy development.

That issue is particularly acute because parts of the Scheme, and in particular the principal grid connection area, function as a cumulative nexus rather than as isolated development locations. The significance of those areas cannot be understood by considering each component individually. The combined presence of large-scale substations, battery storage, cable connections, overhead line interface works and associated access and operational infrastructure creates a cumulative form of transformation that is qualitatively different from the effect of any single element viewed in isolation.

The same is true at landscape scale. The effect of the Scheme is not limited to the direct presence of infrastructure within particular parcels. It arises also from the wider shift in character produced when multiple parts of a settled rural landscape are progressively reconfigured around energy generation and transmission uses. That process changes how the countryside functions, how it is perceived, how settlements relate to their surroundings, and how the area is experienced by residents, landowners and users of the public realm.

A site-and-surroundings chapter is therefore inadequate if it presents the affected area as though it were a largely unchanging baseline into which one proposal is simply inserted. The baseline must include the cumulative burden already present or reasonably foreseeable: energy infrastructure concentration, grid-related development, associated land-take, pressure on roads and lanes, increased industrialisation of views, and the progressive erosion of the distinction between working countryside and utility corridor.

This is not merely a matter of visual accumulation. Cumulative infrastructure pressure affects multiple dimensions of the receiving environment at once. It alters landscape character, heritage setting, ecological coherence, agricultural continuity, hydrological risk, traffic conditions, amenity, perceptions of tranquillity and the overall integrity of the rural system. Where those pressures converge within one area, the sensitivity of the receiving environment is heightened rather than diminished.

The Applicant's approach is further deficient if it treats cumulative effects as a later-stage technical exercise detached from the initial description of site and surroundings. That is the wrong way round. In a landscape already under material pressure, cumulative context is part of the baseline from the outset. If it is omitted or downplayed at the descriptive stage, all later assessments risk understating the true magnitude of change produced by the Scheme.

In BEPS's view, the proper baseline must recognise that this part of South Norfolk is not simply rural in character, but rural under cumulative pressure. The environmental question is therefore not whether one further scheme can be visually or technically fitted into available land parcels. It is whether the cumulative concentration of energy and associated infrastructure is fundamentally transforming the character, function and resilience of the countryside as a whole.

That question is particularly important in a landscape whose value lies in continuity: continuity of agricultural use, settlement pattern, heritage setting, ecological function, hydrological integrity, quiet enjoyment and the ordinary relationship between villages and their surrounding land. Cumulative infrastructure pressure threatens that continuity even where individual elements are dispersed. The relevant transformation is systemic, not merely local.

Accordingly, BEPS objects to any account of site and surroundings that does not expressly describe the affected area in its full cumulative context, including existing and foreseeable infrastructure pressure and the resulting transformation of rural character. Unless that baseline is properly stated, the subsequent assessment of cumulative effects, landscape character, heritage setting, ecology, hydrology, amenity and overall environmental significance will be materially weakened.

3.12 Site-by-Site Fragmentation and the False Neutrality of Parcel Descriptions

The Applicant's site-by-site description of the Scheme is itself objectionable in method. Chapter 3 states that the Site is described 'in its entirety' and also by reference to individual Sites 1 to 10, with separate treatment of the BESS Site, the National Grid Substation Site and the Cable Route Corridor.

That structure creates a false impression of neutrality and containment. By presenting each parcel as an individual 'site' with its own brief description, distances and nearby receptors, the chapter tends to normalise each location as an ordinary piece of farmland capable of accommodating infrastructure subject only to localised effects. In reality, the parcels do not

function as separate environmental units. They form part of one dispersed but integrated industrial scheme operating across a single rural landscape.

The legal and assessment problem is that parcel descriptions of this kind invite a reductionist reading of the baseline. They encourage the decision-maker to ask whether each field, taken in isolation, appears sufficiently distant from particular receptors or sufficiently open to contain development. That is the wrong question. The correct question is how each parcel functions within the wider environmental, agricultural, hydrological, ecological, heritage and settlement system, and how the Scheme's multiple parcels operate cumulatively across that system.

The result is a form of false neutrality. Agricultural fields are described as though they were environmentally spare units, when in fact each parcel may carry site-specific constraints and also contribute to wider landscape integrity, ecological connectivity, agricultural productivity, hydrological function, heritage setting, settlement separation or cumulative industrialisation. A description that strips away those wider functions is not neutral; it is selective.

BEPS therefore objects to the parcelised structure of the chapter insofar as it obscures the true nature of the receiving environment and suppresses the fact that parcel-specific constraints cannot be understood apart from the landscape-scale system of which they form part. This objection is without prejudice to more detailed parcel-by-parcel objections to be provided separately.

The proper method is to treat the individual parcel descriptions as subordinate to, not a substitute for, an integrated account of the whole landscape. Unless that is done, the chapter risks understating both parcel-specific harm and scheme-wide cumulative transformation.

3.13 Site 1, the Grid Hub and the Cumulative Industrial Nexus

The Applicant's treatment of Site 1 is materially inadequate because it does not recognise that this area is not simply one more solar parcel. Chapter 3 identifies Site 1 as including sub-Sites 1A and 1B, describes it as agricultural fields, and notes that it lies to the south-east of Great Moulton, north of the National Grid Substation Site and BESS Site, with nearby residential receptors including individual dwellings within short distances.

That description gravely understates the significance of Site 1. In reality, Site 1 forms part of the Scheme's principal grid and energy hub. It must be understood together with the adjacent BESS Site, the National Grid Substation Site, associated grid connection works, access requirements and the wider concentration of major electrical infrastructure in the Great Moulton area. Considered properly, this is not an ordinary field parcel but a cumulative industrial nexus.

The environmental importance of Site 1 lies precisely in the interaction of multiple constraints in one location: proximity to Great Moulton and nearby dwellings; the concentration of large-scale electrical infrastructure; likely major accident and contamination pathways; groundwater and private water supply sensitivity; hydrological connectivity; agricultural land loss; aviation and safeguarding issues; and cumulative transformation of rural character. A site description

that treats the land merely as agricultural fields with nearby receptors fails to describe the true receiving environment.

Site 1 must therefore be assessed not in isolation but as part of an integrated hub of substations, storage, connection infrastructure and associated disturbance. The issue is not simply whether sub-Site 1A or 1B can physically contain development. It is whether the concentration of this infrastructure in one location fundamentally alters the character, risk profile and environmental functioning of the surrounding countryside and nearby settlement edge.

BEPS objects to any account of Site 1 that does not recognise it as a location of exceptional cumulative sensitivity and consequence. The baseline for this area must include the combined presence or proposed presence of the National Grid Substation Option 2 Site, the BESS Site, the separate National Grid Substation Site, grid connection infrastructure, nearby homes, private receptors and the wider hydrological and ecological setting.

The Examination has since confirmed that the final infrastructure position at this location remains materially unsettled. The ExA has required the Applicant to explain the National Grid substation's capacity to accommodate other projects, the certainty and timing of its delivery as East Pye's point of connection and how that timing would be secured, together with any cumulative or downstream consequences of future third-party use. The Applicant was also required to provide further illustrative material for the National Grid substation and overhead-line works and to clarify the parameters applying to project and National Grid substations.

ISH1 also materially widened the aviation issue at Site 1. The Examination is no longer confined to glint and glare: emergency landing and EFATO considerations, glider launch failure, obstacles, turbulence and the interaction of substations, pylons and BESS with the operational airfield environment are now expressly live issues. The receiving environment around Site 1 must therefore include the functioning aviation environment as well as the physical fields and settlements on the ground.

Those developments reinforce the description of Site 1 as a constraint cluster rather than an ordinary agricultural parcel. Its baseline includes major electrical infrastructure, unresolved future network use, aviation operations, groundwater and private-water receptors, nearby homes, agricultural land, landscape and heritage sensitivity and strategic transport and rail infrastructure. Those relationships must be understood together before the environmental capacity of the location can be assessed.

Unless Site 1 is described as a cumulative industrial nexus rather than a simple parcel of agricultural land, the subsequent assessment of landscape, amenity, human health, major accident risk, hydrology, agricultural land, ecology and cumulative effects will be materially weakened.

3.14 BESS Site, National Grid Substation Site and Grid Connection Infrastructure

Chapter 3 separately identifies a BESS Site and a National Grid Substation Site, including grid connection infrastructure. That separation in form should not be permitted to obscure the

reality that these are among the most industrial and consequential elements of the entire Scheme.

The BESS Site, National Grid Substation Site and related connection works are not ancillary in any ordinary sense. They are central components of the Scheme's industrial operation. Their environmental significance is qualitatively different from that of solar arrays because they introduce substantial built form, electrical plant, operational infrastructure, noise, lighting, security measures, engineering compounds, access demands and elevated major accident and contamination risks.

A lawful description of site and surroundings must therefore treat these elements as major industrial interventions in a rural setting, not merely as technical features sitting alongside the solar fields. Their effects are liable to extend beyond their footprints through changes to rural character, visual composition, amenity, perceived safety, hazard profile, hydrological risk and cumulative infrastructure concentration.

The same applies to grid connection infrastructure. Cable sealing end compounds, overhead line interface works, replacement or repositioned pylons, access arrangements and related engineering should not be presented as peripheral or neutral connecting features. They are part of the means by which industrialisation is extended across the countryside and may have significant interactions with heritage setting, hydrology, agricultural operations, ecology, aviation, public rights of way and rural amenity.

BEPS therefore objects to any treatment of the BESS Site, National Grid Substation Site and grid connection infrastructure that presents them as isolated technical components rather than as core industrial elements whose siting, concentration and interaction with the surrounding environment are central to the adequacy of the baseline.

The proper baseline must identify these locations as major infrastructure nodes within a sensitive rural landscape. Unless that is done, the chapter materially understates the industrial character of the Scheme and weakens subsequent assessment of major accident risk, human health, hydrology, landscape, heritage, amenity and cumulative impact.

3.15 Cable Route Corridor, Uncertainty and Concealed Effects

Chapter 3 states that the Sites are connected by a Cable Route Corridor within which the cable route would be located, and the wider PEIR makes clear that the corridor is being presented at this stage as a broad area expected to be refined later.

BEPS objects to that approach because it imports substantial uncertainty into the description of site and surroundings while at the same time normalising the corridor as though it were a settled feature of limited environmental consequence. It is neither. A wide and unresolved corridor can conceal significant uncertainty as to route alignment, construction impacts, crossing points, engineering requirements and receptor interaction.

The Cable Route Corridor is not merely a line between sites. It is a zone of potential disturbance extending across farmland, roads, verges, hedgerows, drainage systems, watercourses, habitat

networks, settlements, utilities and other sensitive receptors. Its environmental significance lies not only in the final route chosen, but in the breadth of the corridor itself and the fact that the actual route remains materially unsettled while consultation and baseline description are being undertaken.

That uncertainty is especially material in this landscape because cable works may interact with heavy clay soils, field drainage, ditches, culverts, groundwater pathways, private water supplies, agricultural management, fibre infrastructure, road margins, rights of way and ecological connectivity. These are not peripheral matters capable of being left to refinement without consequence. They go directly to the adequacy of the baseline.

A site-and-surroundings chapter is therefore deficient if it identifies the CRC only in broad spatial terms without describing the range of sensitive features and pathway risks potentially affected across its length. The unresolved width of the corridor increases, rather than reduces, the need for a careful and candid account of the surrounding environment.

The baseline mapping also now requires correction for material physical change which has occurred in the landscape. In particular, parts of the application mapping do not show the completed Long Stratton Bypass and its associated mitigation landscape. BEPS has identified that Cable Route Corridor CRC4 intersects newly established bypass biodiversity mitigation, including planted woodland and wildlife ponds, land which is consequently not represented accurately on older base mapping and has not been characterised as part of the Applicant's original ecological baseline. A cable corridor cannot be assessed reliably against a pre-development map where the receiving environment has since acquired new habitat and drainage features which the authorised works may affect.

BEPS accordingly objects to any treatment of the CRC that conceals uncertainty behind a schematic corridor description. Unless and until the corridor's interaction with hydrology, soils, ecology, utilities, access routes, settlements and agricultural operations is properly described, the baseline remains materially incomplete.

3.16 Settlement Proximity, Residential Receptors and Village-Edge Harm

The Applicant's site descriptions repeatedly identify nearby villages and dwellings by distance. Site 1, for example, is described by reference to Great Moulton and to individual residential dwellings lying relatively close to the sub-sites.

BEPS objects to that treatment insofar as it reduces residential and settlement receptors to proximity markers rather than recognising village-edge and dwelling-edge relationships as part of the environmental baseline itself. The issue is not simply how many metres separate infrastructure from the nearest house. It is how a historically settled rural landscape functions where villages, isolated dwellings, lanes, fields and surrounding open countryside are closely interrelated.

In South Norfolk, settlement character depends heavily on the relationship between built edges and surrounding agricultural land. The countryside around villages is not empty buffer space. It contributes to openness, visual relief, tranquillity, setting, access to the countryside and the

ordinary experience of living in a rural settlement. Where industrial-scale energy infrastructure approaches settlement edges, the resulting harm may arise through cumulative alteration of character and amenity, not merely through direct physical encroachment.

The same applies to isolated rural dwellings and farmsteads. Their environmental sensitivity is not captured by simple stand-off distances. It includes their dependence on dark skies, quiet surroundings, open views, workable access, agricultural context and the absence of nearby industrial plant, fencing, surveillance equipment, substations, battery compounds and related activity.

A lawful description of site and surroundings must therefore identify not only the location of residential receptors but the character of the settlement edge and the role of surrounding land in sustaining residential amenity and rural identity. A chapter that merely lists villages and closest dwellings by distance materially understates the sensitivity of the receiving environment.

BEPS accordingly objects to any account of settlement proximity that treats villages and dwellings as isolated receptors detached from the wider countryside that gives them meaning and amenity value. The baseline must reflect village-edge harm, settlement encroachment and the cumulative erosion of rural residential character.

3.17 Surrounding Infrastructure, Airfields, Rail and Baseline Change

The Applicant's treatment of site and surroundings is also deficient because it does not sufficiently identify the wider infrastructure relationships that shape the sensitivity of the affected area. In this case, the surrounding environment includes not only farmland and settlements, but active airfields, transport corridors, strategic infrastructure interfaces and an evolving baseline altered by recent and foreseeable development change.

Those surrounding relationships are not merely later technical topics. They are characteristics of the receiving environment which bear upon the suitability and sensitivity of the affected land. The aviation context is now particularly clear following ISH1 and ExQ1: the ExA has required a standalone aviation-safety document and an explanation of the aviation effects considered beyond glint and glare. Tibenham therefore needs to be described as an operational aviation receptor with emergency-landing, glider-launch and obstacle relationships to Site 1, rather than merely as an airfield from which panels may be visible.

A site-and-surroundings chapter is therefore inadequate if it presents the land as though it existed independently of those surrounding infrastructure relationships. The true baseline includes the operational and environmental constraints arising from nearby airfields, rail lines, roads and connection infrastructure, together with the way those elements already shape the functioning and sensitivity of the countryside.

The baseline must also reflect material change in the surrounding environment. In this case, recent and foreseeable changes to traffic patterns, settlement growth, infrastructure concentration and related development pressure are part of the real receiving environment

against which the Scheme falls to be assessed. A static account of site and surroundings risks becoming misleading where the surrounding baseline is itself changing.

That point is particularly important because baseline change may intensify existing pressures rather than relieve them. Altered road patterns, nearby housing growth, increased grid concentration and other infrastructure changes may interact with the Scheme to produce a more constrained and more cumulative environment than a simple site description would suggest.

BEPS accordingly objects to any treatment of site and surroundings that fails to identify surrounding infrastructure constraints, aviation and rail relationships, and material baseline change as integral components of the receiving environment. Unless those matters are built into the baseline at the outset, later assessment of transport, aviation, amenity, cumulative effects and overall deliverability will be materially weakened.

3.18 Baseline Deficiency

For the reasons set out above, BEPS objects to the Applicant's treatment of site and surroundings as materially deficient in method and substance. The chapter does not describe the receiving environment as it truly exists: a coherent, historically settled, agriculturally productive, hydrologically connected, ecologically functioning and increasingly pressured South Norfolk rural landscape.

Instead, the Applicant's approach fragments that landscape into parcels, corridors and infrastructure components, understates the interrelationship of receptors and constraints, and fails to identify the full cumulative context in which the Scheme would be introduced. In doing so, it risks presenting the land as more divisible, more containable and less sensitive than it is in reality.

That is not a minor descriptive flaw. It goes to the adequacy of the environmental baseline itself. A misdescribed baseline is liable to infect the subsequent assessment of landscape and visual effects, heritage setting, ecology, hydrology, agricultural land, amenity, human health, major accident risk, cumulative effects and overall environmental significance.

BEPS's position is therefore that the site and surroundings must be reassessed and described as a single interconnected environmental and cultural system, including the full significance of the working countryside, the prevalence of BMV land, heavy clay soil vulnerability, drainage and groundwater connectivity, private water supplies, historic settlement pattern, heritage context, functional habitat networks, public rights of way, residential and village-edge sensitivity, cumulative infrastructure pressure, and the exceptional consequence of the Site 1 grid hub area.

Unless and until that is done, the Applicant's account of site and surroundings cannot be treated as a reliable foundation for the wider EIA, and all subsequent topic assessments that depend on that baseline must be approached with corresponding caution.

3.19 Description of the Site and Surroundings / The Receiving Environment as it Truly Exists

The authorised Scheme now extends across Order Limits of approximately 1,212.3 hectares and comprises ten dispersed principal Sites and Sub-Sites, the BESS, project substations, the proposed National Grid Substation and grid-connection works, extensive cable corridors, access and highway works, construction areas and mitigation land. The relevant baseline is therefore the land actually contained within or functionally affected by the submitted DCO, not the materially wider and differently configured pre-application search area from which earlier site descriptions were derived.

This is not a simple or generic development location. It is a coherent rural environment whose significance lies in the interrelationship of its parts. The receiving environment is a living agricultural landscape of villages, hamlets, farmsteads, parish churches, narrow lanes, rights of way, hedgerows, tree belts, drainage features and long-worked fields. It is experienced not as separate numbered sites but as one connected countryside in which agricultural use, historic settlement pattern, ecological function, hydrological pathways and everyday rural amenity overlap spatially and functionally. Fields are not empty development platforms. They are part of the setting of villages and listed buildings, part of the working agricultural economy, part of habitat networks, part of drainage systems and part of the ordinary experience of moving through and living in the countryside.

The surrounding landscape is strongly defined by its agricultural character. It is an actively farmed countryside rather than degraded or transitional land. On EPS's analysis, approximately 83% of the solar parcels are on Best and Most Versatile agricultural land. That is a defining characteristic of the receiving environment. It means the Scheme is proposed predominantly on productive farmland of high agricultural value, not on poorer-quality or previously developed land. In this area, that agricultural value is inseparable from landscape character: the open, cultivated fields contribute not only to food production but also to rural identity, to the setting of settlements and heritage assets, and to the legibility of the countryside as a working agricultural system.

The physical condition of that farmland is equally important. This is a heavy clay landscape. The soils are therefore likely to be vulnerable to compaction, smearing, rutting, impeded drainage and long-term structural damage from repeated heavy construction activity, trenching, access works, substation construction and associated engineering. Those soil conditions are not merely technical matters for a later topic chapter. They are part of the site itself. They shape how the land is farmed, how water moves across it, how resilient it is to disturbance, and how far any claim of reversibility can realistically be sustained.

The historic environment is embedded throughout this countryside. Its significance does not depend only upon isolated designated assets. It derives substantially from the wider settlement pattern: dispersed villages and farmsteads, parish churches experienced across open farmland, historic routeways, mature boundaries and the continuing legibility of an agrarian landscape. BEPS's final independent HIA now identifies less-than-substantial harm from the

principal built development to 36 designated heritage assets and adverse effects upon 41 designated heritage assets overall once associated highway and abnormal-load works are included, including two Grade I and three Grade II* listed buildings. The importance of that finding is not simply the number of assets affected. It demonstrates how frequently open agricultural setting, historic approaches, tranquillity, group relationships and long-established landscape structure contribute to significance across the Order Limits. The true receiving environment is therefore not “agricultural fields with nearby heritage receptors”, but a heritage-rich rural landscape in which the countryside itself repeatedly contributes to significance.

The water environment is equally integral to the character and functioning of the site and surroundings. This is not hydrologically self-contained land. It is crossed and connected by field drains, ditches, ordinary watercourses, culverts and groundwater pathways. The wider landscape includes aquifer-sensitive areas, private abstractions and downstream receptors – the river Waveney and Tas chalk streams – whose condition depends on the continued integrity of these systems. In a rural landscape such as this, private water supplies are part of the ordinary infrastructure of life and farming, not exceptional anomalies. The receiving environment must therefore be understood as a connected hydrological system in which disturbance in one location may travel via drainage and groundwater pathways to affect homes, farms, ecology and water quality elsewhere.

That point is particularly important because the Scheme is not limited to solar arrays. It includes battery storage, major substations, cable trenching, joint bays, fibre chambers, access works and grid connection infrastructure. The wider EIA confirms that the cable route will cross roads and tracks, rights of way, underground utilities and chalk-stream connected watercourses; that open-cut trenching will primarily be used; that trenchless crossings such as HDD may be required; that joint bays, fibre chambers, access land, temporary compounds and laydown areas will be required within the corridor; and that local hedgerow removal may be needed for access and visibility splays. This confirms that the receiving environment is not simply the solar fields themselves, but also a web of roads, verges, drainage features, water crossings, field boundaries, utilities and access points distributed through the countryside.

Ecologically, the site and surroundings form a functioning landscape rather than a set of isolated habitat fragments. Ancient woodland blocks, hedgerows, tree belts, field margins, agricultural land and wet features together provide habitat structure, movement corridors, foraging areas and ecological continuity. In this part of South Norfolk, ecological value does not reside only within designated sites. It also arises from the permeability and integrity of the wider countryside. Farmed land itself is part of this ecological matrix, especially where it is under stewardship or provides feeding, movement or breeding function for protected and priority species. Woodland is not ecologically self-contained; its significance depends in part on the surrounding land remaining connected, dark, quiet and hydrologically stable. The true receiving environment is therefore a connected ecological landscape, not simply a set of fields near designated sites.

The countryside is also an inhabited and experienced place. It is crossed and bordered by public rights of way, restricted byways, footpaths, minor roads and lanes by which residents and visitors move through and understand the landscape. These routes are not incidental

constraints. They are part of the historic grain of the countryside and part of the way openness, tranquillity and rural continuity are experienced. The value of such routes lies not merely in technical access remaining available, but in the quality of the surroundings through which they pass: open agricultural land, relative quiet, long views, separation from industrial development and continuity between villages and countryside.

The relationship between settlements and surrounding land is likewise central. Villages and scattered rural dwellings and farmsteads across the area, do not sit apart from the fields around them. Their amenity, identity and character depend heavily on their immediate agricultural setting, on dark skies, on open views, on manageable access and on the absence of nearby industrial-scale infrastructure. The true receiving environment therefore includes village-edge and dwelling-edge sensitivity, not merely notional distance measurements.

The area must also be understood in its cumulative context. This is not a static rural landscape into which a single project is inserted. It is a countryside already under growing pressure from energy infrastructure, grid reinforcement, associated development and changing transport and settlement patterns. That cumulative pressure is especially acute around Great Moulton, where Site 1, the BESS Site, the National Grid Substation Site and related grid connection works form a single zone of exceptional consequence. The true receiving environment around Site 1 is therefore not an ordinary group of fields. It is a prospective grid and energy hub within a sensitive rural setting, close to homes, rights of way, agricultural land and heritage receptors, and likely to be one of the principal locations at which cumulative industrialisation would be experienced.

Taken together, the site and surroundings are therefore best understood as one coherent South Norfolk rural system: historically settled, agriculturally productive, heavily reliant on high-quality farmland, physically shaped by heavy clay soils and field drainage, hydrologically connected, ecologically functional, crossed by public routes, closely related to village edges and heritage assets, and increasingly vulnerable to cumulative industrial transformation. That is the receiving environment as it truly exists. It is not a collection of neutral development parcels linked by a technical corridor. It is a living countryside whose environmental value arises from continuity, interdependence and long-settled rural character.

3.X.4 BEPS will assess the Applicant's final treatment of site and surroundings against three core requirements. First, it must describe the affected landscape as an integrated environmental and cultural whole, rather than reducing it to a series of separate development parcels, corridors and infrastructure components. Second, it must identify the principal constraints, sensitivities and interrelationships that define this part of South Norfolk, including the interaction between agricultural land quality, heavy clay soils, hydrology, private water supplies, heritage setting, ecological function, settlement character, rights of way and cumulative infrastructure pressure. Third, it must provide a baseline that is sufficiently complete, specific and robust to enable the lawful identification and assessment of likely significant effects across the environmental topics. A chapter that fails those requirements is not merely incomplete in descriptive terms; it is liable to undermine the adequacy of the wider assessment that depends upon it.

3.X.5 BEPS's position is that the burden rests squarely on the Applicant to present an accurate, coherent and decision-useful account of the receiving environment. It is not for consultees, affected communities, local authorities or the decision-maker to piece together the true character, sensitivity and functioning of the site and surroundings from fragmented references dispersed across separate technical chapters, figures, appendices or later submissions. The chapter on site and surroundings must itself perform that function clearly and reliably. If it does not, the resulting Environmental Statement will proceed from a defective baseline, with corresponding consequences for the lawfulness and reliability of the subsequent assessment.

3.20 The Applicant's Baseline Is Contradicted by Its Own Statutory and Specialist Consultees

The inadequacy identified above is no longer merely BEPS's interpretation of Chapter 3. The Relevant Representations of Norfolk Wildlife Trust, Natural England and Historic England independently demonstrate that the Order Limits contain, adjoin or functionally interact with ecological, agricultural, hydrological and heritage features which Chapter 3 understates, fragments or fails to recognise as defining characteristics of the receiving environment.

Those representations carry particular weight. Natural England is the statutory nature conservation adviser and identifies unresolved issues concerning protected species, incomplete Agricultural Land Classification survey coverage, possible peat, permanent infrastructure on Best and Most Versatile agricultural land and the adequacy of future soil-management controls. It also confirms that the Order Limits are hydrologically linked to six Sites of Special Scientific Interest and two ancient woodlands.

Historic England is the Government's statutory adviser on the historic environment. Although it considers parts of the Applicant's assessment and mitigation approach appropriate, it confirms that the Scheme is likely to cause significant setting effects and policy harm to designated heritage assets, that residual harm is likely to remain, that archaeological evaluation is incomplete in parts of the Order Limits, and that cumulative effects with Tasway Energy Park and associated BESS development require further examination.

Norfolk Wildlife Trust brings detailed local ecological knowledge and has engaged directly with the Applicant and its ecological consultants throughout the pre-application process. Its representation identifies a landscape of ancient woodland, species-rich hedgerows, ecologically important road verges, rare flora, farmland birds and nationally important bat activity, and concludes that further information and design refinement are required before the Scheme can be regarded as ecologically acceptable.

BEPS does not suggest that all three bodies oppose every aspect of the Scheme. Natural England and Historic England take qualified positions and identify matters capable of resolution if evidence is supplied and mitigation is properly secured. The important point is that even those consultees identify unresolved questions of baseline

completeness, ecological and hydrological connectivity, archaeological uncertainty, mitigation efficacy and cumulative harm. Their evidence directly contradicts any suggestion that Chapter 3 provides a complete or environmentally neutral account of the Order Limits.

Subsequent examination developments reinforce that conclusion. ExQ1 asks Natural England specifically whether the Applicant has established an adequate bat baseline, including in relation to barbastelle and woodland adjoining the Order Limits; asks further questions concerning incomplete soils, drainage and ground-condition evidence; and requires a heritage schedule capable of reconciling the competing conclusions on affected assets. ISH1 has also generated specific actions concerning local botanical evidence, unresolved infrastructure layouts, transport routes and the environmental consequences of the final design. The adequacy of the receiving-environment baseline is therefore itself now an active examination issue rather than a matter which can be treated as settled.

3.21 The Scheme Is Located in a Landscape 'Dense with Nature', Not Generic Agricultural Land

Chapter 3 describes the landscape within and around the Sites as comprising 'predominantly agricultural fields and rural villages and hamlets', and later refers to fields bordered by hedgerows, trees and woodland blocks. That description is superficially accurate but environmentally misleading. It identifies physical land-cover categories while failing to explain how those features function together as a connected ecological system.

Norfolk Wildlife Trust provides a materially different and more environmentally informed description. It identifies pockets of ancient woodland, miles of species-rich hedgerows, semi-natural road verges, Roadside Nature Reserves, significant barbastelle maternity populations, rare farmland birds including corn bunting, turtle dove and yellowhammer, and rare threatened flora dispersed across the landscape. Its conclusion is direct: this is 'not a landscape of large flat fields, sparse with nature'; it is 'dense with nature – understated but infusing the landscape.'

Chapter 3's Terminology Conceals Ecological Function

Describing land as 'agricultural' does not establish that it is ecologically unimportant or of low sensitivity. In this landscape, agricultural fields form part of the functional habitat matrix supporting bats, farmland birds, protected species and wider ecological connectivity. Their value lies not only in the habitat present within individual fields, but in their relationship with hedgerows, woodland edges, watercourses, ditches, field margins and dark commuting routes.

Chapter 3 lists hedgerows, woodland blocks and nearby designated sites, but does not explain those functional relationships. It therefore encourages the reader to treat fields as development land, hedgerows as boundary features and woodlands as isolated constraints. That is not the ecological reality described by Norfolk Wildlife Trust. The

relevant receptor is the functioning landscape network, not the individual feature viewed in isolation.

This distinction is material. Bats commute and forage across multiple parcels. Farmland birds depend on extensive open and edge habitats. Rare botanical species survive along verges and margins. Woodland value depends partly on surrounding habitat, hydrology and darkness. A baseline that records the physical presence of these features but omits their functional interdependence materially understates the sensitivity of the Order Limits.

Ecological Value Is Dispersed Rather Than Confined to Designated Sites

Chapter 3 states that no international, European, national or local statutory nature conservation site lies within the Order Limits. That statement must not be allowed to imply that the land within the Order Limits is ecologically ordinary or unconstrained.

Norfolk Wildlife Trust's evidence demonstrates that ecological value is widely dispersed across the countryside. Rare flora, farmland birds and bat activity are not confined to protected sites. The Scheme's ecological sensitivity arises partly from the undesignated land connecting woodlands, hedgerows, watercourses, roosting locations and designated habitats.

The absence of a statutory designation within a particular solar parcel therefore does not mean that the parcel lacks ecological importance. Undesignated agricultural land may provide essential foraging habitat, movement routes, buffering, hydrological support or connectivity between higher-value features. Those functions may be impaired by fencing, lighting, trenching, access works, vegetation removal, construction disturbance and the cumulative occupation of multiple parcels.

Chapter 3's designation-led presentation consequently understates the true baseline. It records the location of protected sites but does not adequately describe the wider countryside on which the ecological integrity of those sites and species depends.

The Applicant Has Attempted to Reshape the Landscape to Fit the Scheme

Norfolk Wildlife Trust considers that the ecological character and landscape form of this part of South Norfolk are poorly suited to the proposed development. Its criticism is fundamental: the Scheme should have been reshaped to suit the landscape, whereas the current design attempts to reshape the landscape to fit the Scheme. It also describes the development as stretching across a 'huge swathe of land' and having a very significant impact footprint relative to its generating output.

Chapter 3's parcel-based approach facilitates that design error. By dividing the countryside into numbered sites, sub-sites and corridors, the Applicant presents ecological constraints as local matters to be buffered, crossed, restored or managed after the development envelope has already been selected.

The mitigation hierarchy requires the opposite approach. Once the receiving environment is correctly understood as ecologically dense, connected and constrained, the first response should be avoidance and fundamental redesign. The proper question is not how infrastructure can be inserted throughout the landscape and its effects subsequently managed, but why development remains proposed across the most sensitive and functionally important parts of that landscape at all.

Reliance on future buffers, habitat restoration, management plans and monitoring does not cure a defective siting strategy. It confirms that the Scheme has been designed across a landscape whose ecological character should have constrained the extent and location of the Order Limits from the outset.

3.22 The Order Limits Directly Contain and Adjoin Ecologically Sensitive Sites

Chapter 3 largely presents non-statutory ecological sites by reference to their distance from individual Sites and Sub-Sites. Norfolk Wildlife Trust's representation demonstrates that this approach is inadequate. It states that the Order Limits include parts of Lower Spring Wood County Wildlife Site and Fritton Grange Meadows County Wildlife Site, and include or adjoin several Roadside Nature Reserves, including Bussey's Loke, Market Lane and Parker's Lane.

These are not remote receptors capable of being dealt with through a simple proximity table. They are sites through which, beneath which, or immediately beside which authorised works may occur. Their ecological condition may be affected by the location of HDD compounds, access works, lighting, vehicle movements, construction activity, hydrological disturbance and the adequacy of protective buffers.

Chapter 3 Understates Direct Interaction with Non-Statutory Designated Sites

The distinction between a receptor lying 'within', 'adjacent to' or merely 'near' the Order Limits is environmentally decisive. A list of distances does not establish whether the authorised development, temporary working areas, HDD entry and exit compounds, access works, lighting, storage areas or construction traffic would enter a designated site, affect its buffer, alter its hydrology or impair the features for which it was selected.

Norfolk Wildlife Trust confirms that the precise locations of HDD entry and exit points will not be determined until detailed design. It therefore considers that the ecological effects on the affected County Wildlife Sites cannot yet be fully assessed and that the sufficiency of the proposed buffers has not been demonstrated. It specifically identifies risks from drilling compounds, vehicle movements, noise, lighting and hydrological effects, notwithstanding the proposed use of trenchless construction.

That uncertainty exposes a central defect in Chapter 3. The Order Limits are presented as a defined environmental envelope, but environmentally consequential works within that envelope remain unfixed. The chapter therefore gives the appearance of spatial

certainty while deferring the actual location and effects of works capable of harming sensitive habitats.

Norfolk Wildlife Trust seeks identification of HDD entry and exit points before the close of Examination, larger precautionary buffers, exclusion of compounds, lighting and storage from those buffers, and detailed hydrogeological assessment where HDD may affect fen habitat. Those requests demonstrate that the present description and assessment do not yet establish that the Order Limits can accommodate the works without unacceptable ecological effects.

Site 3 Is Not an Ordinary Solar Parcel

Chapter 3 describes Site 3 as approximately 57.8 hectares of land south of Lundy Green and notes only that it contains farm tracks and hedgerows delineating fields. That description materially understates the site's ecological context.

Norfolk Wildlife Trust states that it previously recommended deletion of Site 3 because of potential effects on a County Wildlife Site, ancient woodland and bats. Although it acknowledges that design changes have been made, it remains concerned about works in this area and continues to recommend that Site 3 should ideally be removed from the Scheme.

That is a landscape-level avoidance recommendation from the county's principal wildlife trust. It cannot be reconciled with a baseline that presents Site 3 principally as an agricultural parcel containing hedgerows and tracks.

The decisive planning fact is that Site 3 lies within an ecological context considered sufficiently constrained by woodland, County Wildlife Site and bat interests that avoidance through deletion remains the preferred response. That conclusion should have shaped the Order Limits before submission. It should not be treated as a matter to be managed later through local mitigation.

BEPS therefore submits that Site 3 is a clear example of the consequences of the Applicant's parcelised baseline. By describing the land physically rather than functionally, Chapter 3 conceals the very constraints that should have determined whether the parcel formed part of the Scheme at all.

The Scheme Boundary Has Been Drawn Around Unresolved Works

The precise locations of HDD entry and exit points, associated compounds and supporting infrastructure remain deferred to detailed design. Norfolk Wildlife Trust states that, without that information, the ecological effects on the affected County Wildlife Sites cannot be fully assessed and the adequacy of the proposed buffers cannot be determined.

That is a fundamental baseline defect. The Order Limits are presented as a defined environmental envelope, yet some of the works most capable of causing ecological and

hydrological harm remain unfixed within it. Their eventual locations will determine proximity to designated habitat, woodland, fen, hedgerows, watercourses and dark corridors, together with the effects of lighting, noise, access and vehicle movements.

The baseline therefore describes a fixed boundary around unfixed works. That does not demonstrate that the authorised development can be accommodated safely within the Order Limits. It merely transfers the decisive siting choices, and their environmental consequences, to the post-consent stage.

3.23 Roadside Verges Are Part of the Ecological Baseline, Not Expendable Highway Margins

Chapter 3 includes highway works within the authorised development but describes the affected roads principally as access infrastructure. It does not identify the connected roadside-verge network as an ecological receptor in its own right, notwithstanding the prevalence of Roadside Nature Reserves and species-rich verges across the Scheme area.

That omission is material. The construction strategy depends on rural roads, site accesses, passing places, visibility splays and routes for HGVs and abnormal loads. The environmental baseline must therefore include the habitats directly exposed to those works and movements.

The Baseline Omits Non-Designated Species-Rich Verges

Norfolk Wildlife Trust states that the application does not contain a comprehensive assessment of construction effects on roadside-verge habitats across the transport network. It identifies South Norfolk's verges as important for rare botany and explains that many rare plants persist there precisely because the verges have escaped agricultural improvement.

Those habitats are exposed to road widening, passing-place construction, visibility-splay clearance, HGV over-running, abnormal-load movements and repeated soil compaction. Even where direct removal is not proposed, construction traffic may degrade the vegetation and soil conditions on which rare species depend.

Chapter 3's treatment of these areas as highway margins therefore conceals their ecological significance. Before those routes can be relied upon, the Applicant must identify the affected verge habitats and demonstrate that important botanical assemblages will be avoided.

ISH1 has since resulted in a specific action requiring the Applicant to engage with the local botanical evidence concerning rare plant records and the effects of proposed road works. That action materially reinforces the point made here: highway land and roadside verges cannot be assumed to be low-value construction margins before their botanical interest has been properly established.

‘Temporary’ Highway Works May Cause Permanent Ecological Damage

The description of works as temporary says nothing about the permanence of their effects. Norfolk Wildlife Trust warns that temporary works may cause disproportionate ecological damage through vegetation clearance, disturbance, over-running and compaction.

Established verge flora cannot necessarily be recreated by reinstating the highway boundary after construction. Soil compaction, altered drainage and loss of mature vegetation may permanently change habitat condition.

The baseline cannot therefore classify such works by duration alone. Temporary possession or temporary engineering may cause irreversible ecological loss. Unless the affected verges are surveyed before consent and avoidance measures are secured, the significance of that risk remains unknown.

3.24 The Applicant Has Failed to Describe a Nationally Important Bat Landscape

Norfolk Wildlife Trust identifies bats as one of the most significant ecological issues raised by the application. The Applicant’s own ES records eleven bat species and concludes that the Order Limits and surrounding landscape support a ‘nationally important assemblage of foraging and commuting bats’. That assemblage includes barbastelle, identified by the Applicant as the rarest bat in the United Kingdom.

Chapter 3 does not convey the consequence of that evidence. It describes hedgerows, woodland blocks and watercourses as separate physical features, rather than as the connected landscape infrastructure on which the bat assemblage depends.

The Bat Receptor Is the Landscape, Not the Individual Hedge

The Applicant’s surveys show bat use across multiple development parcels. The relevant receptor is therefore not an individual hedge or woodland edge considered in isolation. It is the connected landscape-scale network of roosts, foraging areas, woodland edges, watercourses, tree lines, hedgerows and dark commuting routes.

Chapter 3’s division of the Order Limits into separate Sites, Sub-Sites and corridors is ecologically artificial. Bats do not follow the Applicant’s parcel boundaries. Severance, disturbance or lighting in one part of the network may reduce permeability and alter habitat use elsewhere.

A baseline which records retained habitat features but fails to describe their collective function cannot support a reliable assessment of effects on a nationally important assemblage.

Ten-Metre Hedgerow Gaps Cannot Be Assumed Harmless

The Applicant concludes that temporary hedgerow gaps of up to 10 metres would not significantly affect bat movement. Norfolk Wildlife Trust expressly questions whether that conclusion is sufficiently evidenced, particularly for barbastelle, and warns that relatively small breaks in linear features may alter commuting behaviour and landscape permeability.

This is a direct consequence of treating hedgerows as physical boundaries rather than functional ecological corridors. The relevant question is not merely how many metres of hedge would be removed. It is whether the break, together with lighting, noise, construction activity and surrounding land-use change, would continue to permit the established movement of bats.

The Applicant has not demonstrated that all proposed gaps are ecologically immaterial. An unsupported assumption of continued permeability cannot substitute for route-specific evidence.

Retention Is Not the Same as Maintenance of Function

The Applicant relies heavily on retaining existing hedgerows and habitat corridors. Retention on a plan does not establish continued ecological functionality.

Norfolk Wildlife Trust identifies risks from lighting, vehicle movements, construction disturbance, insufficient buffers and degradation of habitat quality. It seeks closer scrutiny of lighting controls, important commuting routes and the enforceability of mitigation commitments.

A hedge may remain physically present but cease to perform its existing ecological function if it is illuminated, severed, narrowed, repeatedly disturbed or enclosed by industrial development. The baseline must therefore identify functional corridors and the conditions necessary to maintain them, rather than treating physical retention as determinative.

New Planting Cannot Replace Established Functional Habitat

Norfolk Wildlife Trust also warns that habitat creation cannot automatically replace mature hedgerows and established commuting routes, which may take decades to achieve equivalent ecological function. It expresses particular concern that biodiversity-gain calculations do not fully account for temporal losses during habitat establishment.

The mitigation hierarchy requires the Applicant first to identify and avoid damage to existing function. It is neither rational nor precautionary to assume that quantified future planting can compensate immediately for the degradation of mature bat corridors supporting a nationally important assemblage.

Where equivalent function cannot be delivered at the time of loss, avoidance is required. Biodiversity units and future management commitments do not remove the intervening ecological deficit.

The Examination has subsequently put the adequacy of that baseline directly to Natural England. ExQ1 asks whether the Applicant has established an adequate bat baseline, expressly including barbastelle and woodland adjacent to the Order Limits. That question is significant because the issue is not merely whether bats have been recorded; the Applicant's own evidence already establishes a nationally important assemblage. The remaining question is whether the survey evidence is sufficient to identify the functional maternity-colony landscape, woodland relationships, commuting routes and foraging areas which need to be protected before the authorised layout is fixed.

3.25 Lowland Fen, Hydrological Dependency and Concealed Pathway Risk

The ecological baseline cannot be separated from hydrology. Norfolk Wildlife Trust identifies approximately 0.72 hectares of irreplaceable lowland fen within the study area, including habitat associated with Fritton Grange Meadows CWS and the Hempnall Beck corridor. It states that insufficient evidence has been provided to demonstrate that HDD beneath the fen would not affect groundwater conditions or the hydrological processes on which the habitat depends.

Natural England separately confirms that the Order Limits are hydrologically connected through watercourses or groundwater flow to nationally designated sites and ancient woodland. Chapter 3 lists watercourses, aquifers and flood zones, but does not disclose the ecological consequences of those connections.

The Order Limits Are Hydrologically Connected to Nationally Important Receptors

Natural England identifies hydrological links between the Order Limits and Fritton Common SSSI, Pulham Market Big Wood SSSI, Shotesham–Woodton Hornbeam Woods SSSI, Shotesham Common SSSI, Hedenham Wood SSSI and Tindall Wood Ditchingham SSSI. It also identifies links to Saxlingham Grove Ancient Woodland and Popes Wood and Doylys Grove Ancient Woodland.

These are high-sensitivity receptors. The surface-water and groundwater pathways connecting them to the Order Limits mean that disturbance or pollution need not occur within a protected-site boundary to cause harm.

Chapter 3's description of rivers, ordinary watercourses and aquifers therefore omits the decisive environmental fact: the Order Limits form part of a connected hydrological system capable of transmitting effects to a network of nationally designated and irreplaceable habitats.

The Applicant's Conclusions Depend on Mitigation Being Fully Secured

Natural England accepts that significant adverse effects on the identified SSSIs may be ruled out only on the basis that the mitigation in the outline CEMP is implemented and secured. It specifically requires controls over surface-water runoff, water quality and water quantity for the construction phase.

That is not a finding that the receiving environment is insensitive. It confirms the opposite: the receptors are highly sensitive and hydrologically connected, but effects may be controlled if the specified mitigation is effective, timely and legally enforceable.

Any failure to secure, maintain or implement those controls would undermine the basis of Natural England's qualified agreement. The Applicant cannot rely on that agreement while treating the underlying hydrological sensitivity as immaterial.

Lowland Fen Cannot Be Treated as an Isolated Mapped Habitat

Lowland fen is irreplaceable habitat dependent on groundwater level, water chemistry and the continued operation of hydrological processes extending beyond its mapped boundary. Passing a cable beneath the habitat does not necessarily avoid those processes.

HDD entry and exit compounds, drilling, dewatering, vibration, compaction, accidental frac-out and altered groundwater conditions may affect the system that sustains the fen even where no direct excavation occurs within the habitat itself. Norfolk Wildlife Trust therefore seeks additional hydrogeological evidence and monitoring commitments.

Until those pathways have been assessed at the actual crossing location, the Applicant has not demonstrated avoidance. It has merely substituted an assumed underground route for evidence that the hydrological function of the habitat will remain intact.

3.26 Protected-Species Uncertainty Remains Embedded Within the Order Limits

Natural England classifies protected species as an amber issue. The Outline Protected Species Mitigation Strategy indicates that licences may be required for water vole or otter, great crested newts, roosting bats and badger-sett closures. Natural England seeks confirmation whether licence applications have been made and strongly advises early action to prevent delay.

Those potential licensing requirements demonstrate that protected-species constraints are embedded across the Order Limits. They are not remote or speculative matters.

Chapter 3 Does Not Disclose the Extent of Potential Licensing Constraint

Chapter 3 describes fields, hedgerows, woodland and watercourses without explaining that works within those features may require statutory species licences. That omission prevents the reader from understanding the extent to which the Order Limits remain constrained by protected-species law and unresolved mitigation requirements.

The issue is particularly acute for a dispersed and phased project. Different works may affect different species, habitats and licence regimes at different times. A high-level reference to later ecological documentation does not provide a decision-useful account of those constraints within the Order Limits.

Licensing Uncertainty Is Also a Deliverability Issue

The absence of a licence at application stage does not automatically make the DCO unlawful. It does, however, require the Applicant to demonstrate with sufficient certainty that the necessary avoidance, mitigation and compensation are deliverable and that no obvious impediment exists to the grant of any required licence.

That demonstration has not yet been completed. Natural England continues to seek clarity regarding the need for licences affecting several species.

Until the licensing position is resolved, the Order Limits contain material ecological and legal uncertainty. The Examining Authority cannot simply assume that all affected works will later satisfy the relevant licensing tests.

Future Licensing Cannot Repair an Incomplete EIA Baseline

Protected-species licensing is not a substitute for environmental impact assessment. The ES must first identify the affected species, the habitat functions on which they depend, the likely effects of the authorised development and the avoidance or mitigation necessary to address them.

The Applicant cannot defer that assessment on the basis that detailed surveys or licence applications will follow consent. A future licence may regulate an identified offence; it cannot cure an ES that failed to establish the ecological baseline and assess the likely significant effects with sufficient certainty.

3.27 The Agricultural Baseline Remains Incomplete Across the Order Limits

Natural England identifies incomplete ALC coverage, possible peat, permanent infrastructure on BMV land and insufficient detail in the Soil Resource and Management Plan as amber issues.

Those are not confined to Chapter 15. They demonstrate that Chapter 3 does not provide a complete account of the land resource within the Order Limits, particularly across the Cable Route Corridor and temporary works areas.

The Cable Route Corridor Has Not Been Fully Surveyed for Agricultural Land Quality

Chapter 3 confirms that the Cable Route Corridor extends for approximately 24 kilometres and covers about 158.9 hectares. Natural England states that detailed ALC surveys should cover the whole Order Limits, including the cable corridors, but that the submitted information does not demonstrate that those surveys have been completed.

The Applicant therefore seeks powers over a substantial linear landholding without having established the agricultural quality and soil resources throughout it. That prevents informed route refinement and prevents the decision-maker from knowing the full extent of BMV land exposed to trenching, compounds, tracks and soil handling.

The Chapter 3 baseline is consequently incomplete across a significant part of the authorised development.

'Temporary' Cable Works May Permanently Degrade Land Quality

Natural England warns that underground cable installation, temporary access tracks and construction compounds may cause permanent soil damage, ALC degradation and long-term or permanent loss of BMV land if works are undertaken inappropriately.

That risk is heightened by the scale of the cable network and the breadth of the working corridor. Trenching, stockpiling, trafficking and reinstatement may alter soil structure, drainage and productive capacity long after the temporary works have ended.

The legal duration of possession does not determine the duration of the environmental effect. Temporary works may cause permanent agricultural degradation. The baseline and assessment must address that possibility directly.

Peat Has Not Been Adequately Resolved

Natural England seeks clarification regarding the possible presence of deep, permeable sandy and peaty soils affected by groundwater and advises that peat within the Order Limits should be avoided.

That uncertainty is material to soil conservation, hydrology, carbon storage, construction method and restoration. It cannot properly be deferred to later soil management.

Until the presence and extent of peat are conclusively established, the Applicant cannot demonstrate that the baseline is complete or that infrastructure and cable routes have avoided the most sensitive soils.

Permanent Infrastructure on BMV Land Has Not Been Avoided

Natural England records that approximately 6 hectares of BMV land would be permanently lost to infrastructure and advises that the siting of that infrastructure should be reconsidered to avoid BMV land. It also notes that BMV land is a high-

sensitivity receptor and that even relatively limited permanent loss may be significant, particularly cumulatively.

The statutory adviser's response is avoidance, not merely restoration or management. The Applicant has not demonstrated why the permanent grid infrastructure must occupy BMV land or why a less harmful configuration is unavailable.

A commitment to manage or restore other soils does not justify permanent development on high-quality agricultural land where avoidance has not been exhausted.

3.28 Ancient Woodland, Veteran Trees and the Inadequacy of Inconsistent Buffers

Natural England treats ancient woodland and ancient or veteran trees as a green issue only on the basis of specified mitigation. It requires the proposed 30-metre buffer to be recorded consistently in the LEMP, CEMP and DEMP and seeks strict controls including arboricultural survey, root-protection measures, no-dig methods, soil-compaction prevention and arboricultural oversight.

Norfolk Wildlife Trust separately seeks safeguards for ancient woodland, veteran trees, historic hedgerows and all temporary hedgerow removals.

Natural England's Acceptance Is Conditional

Natural England's green classification does not establish an absence of risk. It reflects reliance on a 30-metre buffer and a detailed suite of controls being secured and applied consistently through construction, operation and decommissioning.

Any inconsistency between the controlling documents would weaken that protection and undermine the basis of Natural England's position. The buffer cannot remain an informal commitment or appear in only one management plan.

The Order Limits therefore remain acceptable in this respect only if the required protection is legally secured for the full duration of the Scheme.

The Baseline Must Include Woodland Setting and Supporting Habitat

Ancient woodland cannot be described solely by reference to its mapped boundary. Its ecological condition may depend on adjoining soils, groundwater, surface-water movement, root zones, woodland-edge habitat, darkness and connectivity with the wider countryside.

Development may therefore affect woodland without entering it directly. Lighting, drainage alteration, soil compaction, pollution, severance and loss of surrounding habitat may degrade its condition and supporting function.

A baseline limited to mapped woodland polygons and stand-off distances fails to identify those dependencies. The surrounding functional habitat must form part of the receptor.

Hedgerow Replacement Is Not Functional Equivalence

The ES identifies partial removal of 32 hedgerows, removal of five trees and temporary hedgerow removal for cables and access. Norfolk Wildlife Trust seeks confirmation that no ancient or species-rich hedgerow will be removed and requires detailed restoration and monitoring for all temporary losses.

Replacement planting cannot immediately recreate the age, structure, species composition, soil relationships or ecological connectivity of an established historic hedgerow. Nor does reinstatement remove the intervening period of severance.

The Applicant must therefore avoid the most sensitive hedgerows rather than assuming that later planting will provide functional equivalence. Where loss would interrupt established ecological networks, replacement is not a sufficient answer.

3.29 Historic England Confirms That This Is a Heritage-Sensitive Rural Landscape

Historic England considers that the Applicant has provided an appropriate assessment of the location, type and significance of designated and non-designated heritage assets and broadly supports the siting approach for the Site 1 BESS, Project Substation and National Grid Substation. That qualified support must be acknowledged.

It does not, however, support the conclusion that the historic environment is unconstrained or that harm has been removed. Its Relevant Representation confirms significant setting effects, residual harm, incomplete archaeological evaluation and cumulative concern.

The Rural Landscape Is Defined by Churches, Listed Buildings, Conservation Areas and Medieval Settlement

Historic England describes the Scheme area as an extensive, predominantly agricultural part of South Norfolk containing important rural churches, listed buildings and small conservation areas focused on medieval settlement.

That description confirms that the cultural baseline is not a random distribution of isolated assets. It is an agricultural and settlement landscape in which churches, buildings, villages and conservation areas express a continuing rural and medieval pattern.

The open farmland between those assets is not neutral intervening space. It contributes to settlement form, rural approaches, visual relationships and the agricultural settings in which the assets are experienced and understood.

Significant Heritage Effects and Residual Harm Are Accepted

Historic England recognises that the Scheme will change the settings of designated heritage assets and that, in some cases, those changes will result in significant effects amounting to policy harm. It further confirms that residual effects are likely to remain after mitigation.

Chapter 3 does not prepare the reader for that conclusion. Its reliance on lists and distances understates the role of the wider countryside in the significance of the affected assets.

The statutory adviser's position confirms that the surrounding fields and views form part of the setting through which harm arises. Planting may reduce visibility, but it cannot necessarily preserve openness, historic relationships or the legibility of the rural landscape.

The Scale of Affected Designated Heritage Assets Is Substantial

Historic England identifies particular concerns regarding one Scheduled Monument, two Grade I listed buildings, two Grade II* listed buildings, 42 Grade II listed buildings and four Conservation Areas.

This does not mean that every asset will experience the same effect or level of harm. It does demonstrate that the Order Limits extend through an unusually dense and sensitive historic environment requiring both asset-specific and landscape-scale scrutiny.

The scale of that receptor population is inconsistent with any characterisation of the surrounding countryside as a collection of ordinary agricultural parcels.

Unknown Archaeology Remains Capable of Changing the Assessment

Historic England confirms that parts of the Order Limits have not been fully subject to archaeological evaluation and that previously unknown sites potentially equivalent in value to designated heritage assets may still be identified. It requires further evaluation, reassessment of effects and proportionate mitigation through the DCO.

The Applicant describes the Order Limits as though their historic-environment baseline were settled. Historic England confirms that it is not.

Until evaluation is complete, the presence, significance and susceptibility of archaeological remains remain unresolved across parts of the authorised area. Those findings may require avoidance or redesign, not merely excavation after consent.

The Cable Route Corridor Is a Particular Heritage Concern

Historic England expressly identifies the methodology and mitigation for the Cable Route Corridor as a likely area of concern on which it intends to comment further.

That concern is material because the Applicant seeks extensive compulsory powers across a lengthy corridor whose detailed alignment remains flexible. The archaeological and setting consequences of the final route have therefore not been fully resolved before the powers are granted.

The Applicant should not be permitted to treat archaeological mitigation as a substitute for route selection informed by a completed baseline. The corridor must first be refined to avoid harm wherever practicable.

The independent HIA identifies a materially wider pattern of harm

The independent HIA submitted by David Edelston (see Appendix G) materially develops the receiving-environment evidence It identifies less-than-substantial harm from the principal built development to 36 designated heritage assets and adverse effects upon 41 designated heritage assets overall once associated highway and abnormal-load works are included. Those include two Grade I and three Grade II* listed buildings.

The difference is methodological as well as numerical. The HIA identifies recurring heritage attributes which are difficult to capture through a parcel-and-distance description: openness and enclosure, topography, group value, historic and functional relationships, long-established agricultural use, tranquillity, remoteness, seasonal conditions and sequential experience while travelling through the landscape. It also identifies circumstances in which screening may itself harm significance by enclosing historically open settings or severing views and relationships.

The final HIA therefore strengthens Chapter 3's central proposition. The receiving historic environment is not a collection of designated buildings around otherwise neutral development land. It is a connected rural landscape in which open fields, lanes, settlement approaches and historic relationships repeatedly form part of the significance of designated assets.

3.30 Cumulative Effects Are Already a Concern to Ecological and Heritage Consultees

Historic England identifies cumulative effects with Tasway Energy Park and associated BESS projects as a potential concern requiring further consideration. Norfolk Wildlife Trust warns of cumulative farmland-habitat loss, fragmentation of ecological networks, degradation of bat commuting landscapes, pressure on protected species and reduced landscape permeability.

Those concerns confirm that the environmental baseline cannot be limited to the existing physical condition of individual East Pye parcels.

Cumulative Context Is Part of the Baseline

Where specialist consultees identify cumulative ecological and heritage risks, the receiving environment cannot be described as a static countryside affected by East Pye alone.

The baseline must recognise the existing and foreseeable concentration of solar, BESS, grid and associated infrastructure and the progressive pressure those developments place on rural character, habitat networks, heritage settings and agricultural continuity.

Deferring that context to a later cumulative-effects table understates its importance. The increasing infrastructure pressure is itself part of the environment into which East Pye would be introduced.

Cumulative Harm Operates Through Common Landscape Systems

The cumulative effect does not arise merely because several projects appear on the same list. It arises because they act upon the same receptors and systems: the same historic rural landscape, the same ecological networks, the same bat populations, the same farmland resource, the same roads and the same settlement settings.

The environmental system has no regard to project boundaries. Successive habitat losses may impair the same ecological network. Separate substations and battery compounds may industrialise the same rural setting. Different construction programmes may burden the same lanes and communities.

The assessment must therefore examine combined change to common receptors, not simply add together project-specific significance conclusions.

Parcel-by-Parcel Assessment Cannot Capture Landscape-Scale Accumulation

A methodology which first divides East Pye into Sites, Sub-Sites and corridors and then treats other projects as separate external additions risks missing systemic transformation.

Individually moderate or localised effects may combine to alter the character and function of the wider countryside. Habitat permeability may decline through repeated severance; heritage settings may be progressively eroded; and agricultural land may become fragmented by multiple energy uses.

The cumulative question is not whether each parcel or project remains tolerable in isolation. It is whether their combined effect would fundamentally transform the connected landscape.

3.31 The Consultees' Qualified Positions Cannot Be Converted into a Finding of Environmental Acceptability

The Applicant may seek to rely on Natural England's statement that it is broadly satisfied and Historic England's view that the heritage assessment is generally appropriate. Those statements must be read in context.

Neither representation amounts to an unqualified endorsement of the Scheme or confirmation that Chapter 3 provides a complete baseline.

Natural England's 'Green' Conclusions Are Conditional

Natural England's agreement regarding European sites, SSSIs and ancient woodland depends on specified mitigation being implemented and legally secured. It requires water-quality and runoff controls, consistent 30-metre buffers, lifetime management measures and detailed DCO provisions.

Its protected-species and soils positions remain amber. Outstanding matters include licence requirements, incomplete ALC surveys, possible peat, permanent infrastructure on BMV land and deferred detail in the Soil Resource and Management Plan.

Natural England's position therefore confirms conditional resolution of some pathways and continuing uncertainty on others. It does not establish general environmental acceptability.

Historic England's Positive Comments Do Not Remove Acknowledged Harm

Historic England considers the heritage assessment generally appropriate and broadly supports aspects of the Site 1 siting. At the same time, it anticipates significant setting effects, policy harm and residual effects; identifies incomplete archaeological evaluation; raises concern regarding the Cable Route Corridor; and flags cumulative effects with Tasway and associated BESS projects.

Those conclusions cannot be reduced to a statement that Historic England is satisfied. Its position is qualified, asset-specific and dependent upon further scrutiny and enforceable mitigation.

Most importantly, Historic England accepts that mitigation will not remove all harm. That residual harm must be identified and weighed, not obscured by selective reliance on areas of agreement.

Norfolk Wildlife Trust Continues to Require Substantial Redesign and Scrutiny

Norfolk Wildlife Trust considers the landscape poorly suited to the form of development proposed and criticises the Applicant for attempting to reshape the landscape to fit the Scheme. It recommends deletion of Site 3, disputes assumptions regarding bat

connectivity, seeks additional botanical and hydrogeological work, and identifies unresolved risks to designated sites, lowland fen, road verges, farmland birds and protected species.

Its overall conclusion is that further information and design refinement are required before the Project can be considered acceptable in ecological and environmental terms.

The Applicant must not aggregate limited or conditional areas of agreement into a general claim that the receiving environment has been adequately described or that the Scheme is environmentally acceptable. The consultees' positions are topic-specific, conditional and materially qualified. Read fairly, they confirm that the baseline remains incomplete, important effects remain unresolved and substantial design and securing work is still required.

3.32 The Consequences for Scheme Design and the Mitigation Hierarchy

The deficiencies in Chapter 3 are not merely descriptive. They go directly to whether the Scheme has been designed in accordance with the mitigation hierarchy. Once the Order Limits are correctly understood as an interconnected landscape of designated and undesignated habitats, nationally important bat activity, hydrologically linked protected sites, BMV land, possible peat, sensitive heritage settings and unresolved archaeology, the first question is not how the resulting harm might be managed. It is why so much development remains proposed in these locations at all.

The August 2026 NPPF now gives that argument a particularly clear contemporary policy basis. Policy N2 requires significant biodiversity harm first to be avoided through locating development on an alternative site with less harmful impacts before moving through mitigation and, only as a last resort, compensation. The same policy requires agricultural quality and grade to be taken into account and poorer-quality land to be used where possible. It also requires ecological networks extending beyond the site to be strengthened. Those provisions do not establish that every environmental constraint requires deletion of development, but they reinforce the need to demonstrate that avoidance has genuinely been applied before relying upon buffers, habitat creation and later management.

The Baseline Requires Avoidance to Be Tested First

Avoidance has not been applied consistently. Norfolk Wildlife Trust continues to recommend deletion of Site 3 because of its relationship with a County Wildlife Site, ancient woodland and bats. It also seeks larger buffers around County Wildlife Sites and Roadside Nature Reserves, protection of sensitive verges and dark commuting corridors, and prior identification of HDD compounds and entry and exit points.

Natural England advises that permanent infrastructure should be reconsidered to avoid BMV land, that any peat within the Order Limits should be identified and avoided, and that the whole cable corridor should be surveyed so that route refinement can avoid or minimise impacts on BMV soils. It also requires consistent protection of ancient woodland and veteran trees through secured 30-metre buffers.

Historic England identifies likely significant setting effects, residual heritage harm, incomplete archaeological evaluation and particular concern regarding the Cable Route Corridor. Those findings require route refinement, relocation and protection of sensitive settings, not merely later archaeological recording or landscape planting.

Taken together, the evidence requires the Applicant to demonstrate why avoidance has not been preferred at the most constrained locations. That includes responding substantively to Norfolk Wildlife Trust's recommendation concerning Site 3; reconsidering permanent infrastructure on BMV land and any confirmed peat; avoiding sensitive hedgerows, verges and habitat corridors where practicable; protecting dark ecological corridors; refining the Cable Route Corridor against the completed ecological, soil, hydrological and archaeological baseline; and considering removal or relocation of development where the final heritage assessment identifies harm which screening cannot satisfactorily address. The issue is not that each of those constraints automatically dictates deletion, but whether the Applicant has shown that avoidance was considered consistently before mitigation was relied upon.

That reverses the mitigation hierarchy. Avoidance should shape the Scheme before submission. It should not be displaced by an assumption that development may remain in sensitive locations provided that buffers, licences and management plans are produced later.

Mitigation Cannot Cure an Overextended Scheme

The Application relies on an extensive apparatus of future mitigation: detailed CEMPs and LEMPs, protected-species licences, soil-management plans, drainage strategies, lighting controls, HDD method statements, archaeological evaluation, habitat restoration, monitoring, adaptive management and remedial measures.

That volume of future control is not evidence that the Scheme is well sited. It is evidence that the Order Limits encompass too many sensitive and functionally important areas.

Norfolk Wildlife Trust says that further information and design refinement are required before the Scheme can be regarded as ecologically acceptable. Natural England retains amber concerns regarding protected species, incomplete soil surveys, peat, BMV land and deferred soil controls. Historic England anticipates residual heritage harm and confirms that archaeological uncertainty remains.

Mitigation may reduce effects, but it cannot retrospectively establish that the original site-selection exercise was sound. Nor can future habitat creation immediately replace

mature hedgerows, established bat corridors, functioning woodland relationships, rare verge flora, irreplaceable fen habitat, productive BMV soils or the historic agricultural settings of designated assets.

The increasing dependence on post-consent detail therefore exposes, rather than resolves, the underlying problem: the Scheme has been spread too widely across a landscape that should have constrained its extent from the outset.

The Order Limits Should Be Reduced, Not Merely Regulated

The appropriate response is material contraction of the Order Limits, removal of the most constrained sites and corridors, and relocation of permanent infrastructure away from BMV land, peat, irreplaceable habitat, key ecological networks and sensitive heritage settings.

The Applicant should not be permitted to retain a maximum development envelope across sensitive land merely because later plans may determine where works ultimately occur. The environmentally responsible boundary is not the widest area within which impacts might subsequently be managed. It is the smallest area demonstrably necessary after avoidance has been exhausted.

Unless the Applicant materially reduces and redesigns the Scheme, the proposed controls would regulate an environmentally overextended project rather than remedy its fundamental siting defects.

3.33 Overall Conclusion: Chapter 3 Conceals the Constraints That Should Have Shaped the Scheme

Chapter 3 describes 1,212.3 hectares of Order Limits, ten dispersed Sites, multiple substations, a BESS, highway works and approximately 24 kilometres of Cable Route Corridor through parcel areas, coordinates, distances and feature lists. It does not explain the environmental significance of that landscape as an interconnected whole.

Norfolk Wildlife Trust describes a materially different baseline: a landscape ‘dense with nature’, containing nationally important bat activity, ancient woodland relationships, species-rich hedgerows, rare flora, farmland birds, County Wildlife Sites, Roadside Nature Reserves and ecologically sensitive verges. It considers the development footprint inefficient, disputes important assumptions about ecological connectivity and continues to recommend removal of Site 3.

Natural England confirms unresolved protected-species, ALC, peat, BMV and soil-management matters. It also identifies hydrological links between the Order Limits and six SSSIs and two ancient woodlands, with its conclusions dependent on mitigation being effective and legally secured.

Historic England confirms that significant setting effects and policy harm are likely in Historic England confirms that changes to setting are capable of producing policy

harm, that residual heritage harm may remain after mitigation, that archaeological evaluation remains incomplete and that cumulative effects require further scrutiny. BEPS's subsequent independent HIA materially strengthens that evidence by identifying less-than-substantial harm from the principal built development to 36 designated assets and adverse effects upon 41 designated heritage assets overall, including two Grade I and three Grade II* buildings. The resulting heritage baseline is therefore materially more constrained than the Applicant's Chapter 3 description suggests.

The current NPPF reinforces the same conclusion at landscape scale. Policy N2 requires the environmental qualities of the selected land, agricultural quality and ecological networks extending beyond the site to be considered, while DP3 requires development to respond to the history, character and features of the site and its setting. Those policies depend upon the very integrated understanding of place which Chapter 3 presently fails to provide.

The defect in Chapter 3 is therefore not that it omits a few additional receptors. It describes the land in a way that suppresses the decisive planning fact: the Scheme has been laid across an exceptionally constrained, connected and sensitive rural landscape. The unresolved problems identified by the statutory and specialist consultees are not incidental matters of mitigation detail. They arise directly from that fundamental siting choice.

3.34 Remedies Sought

BEPS requests that the Examining Authority require the Applicant to provide a revised, integrated receiving-environment plan identifying all County Wildlife Sites, Roadside Nature Reserves, ancient woodland, veteran trees, species-rich verges, principal bat corridors, known roost areas, lowland fen, watercourses, hydrological links, private abstractions, ALC grades, peat, designated heritage assets, Conservation Areas and areas of archaeological uncertainty. That plan should use a current mapping base and identify material changes to the receiving environment since the earlier surveys, including the completed Long Stratton Bypass and its associated drainage, woodland and biodiversity mitigation.

The Applicant should be required to delete or substantially redesign Site 3 and respond directly to Norfolk Wildlife Trust's continuing recommendation that it be removed. Final HDD entry and exit points, compounds and lighting areas should be fixed before the close of Examination, supported by hydrogeological assessment wherever works may affect lowland fen, County Wildlife Sites, ancient woodland or groundwater-dependent habitat.

Complete botanical surveys should be undertaken for all potentially affected road verges, including non-designated verges, AIL routes, highway-work areas, passing places, visibility splays and locations vulnerable to over-running or compaction. A landscape-scale bat-connectivity plan should identify roosts, principal commuting

routes, foraging areas, dark corridors, temporary and permanent severance points, lighting zones and secured buffers.

Complete ALC and soil-resource surveys should cover the whole Order Limits, including every cable corridor, highway-work area, compound and temporary access area. The Applicant should identify all peat soils and relocate permanent infrastructure away from BMV land and peat.

The receiving-environment evidence should also incorporate the final heritage baseline identified through the Examination, including the assets and setting relationships identified in BEPS's final HIA, together with the outstanding archaeological evaluation. Where further evaluation or final infrastructure design materially alters the understanding of significance or setting, the consequences should be fed back into avoidance and layout rather than treated solely as a post-consent mitigation matter.

The Order Limits should then be materially reduced to reflect genuine avoidance of the most sensitive ecological, agricultural, hydrological and heritage constraints. The DCO must secure Natural England's 30-metre buffers, lifetime drainage inspection and maintenance, protected-species safeguards, detailed soil controls, monitoring, enforceable remedial triggers and long-term ecological management. A revised cumulative assessment should address East Pye, Tasway and other relevant solar, BESS, grid and infrastructure projects through the common ecological, heritage, agricultural, hydrological and landscape receptors they affect.

If the Applicant cannot provide that information, complete the outstanding baseline work and materially reduce the Scheme's interaction with the identified constraints, the proper remedy is not further post-consent management. If those deficiencies cannot be resolved during the Examination within the environmental envelope already assessed, the appropriate consequence is refusal rather than reliance upon further post-consent investigation to determine whether the authorised development can be accommodated acceptably.

Summary: Why the Application Should Be Refused

The application should be refused because the Order Limits have been drawn across an exceptionally extensive, interconnected and sensitive rural landscape without the Applicant first demonstrating that the development can be accommodated without unacceptable environmental harm. Chapter 3 describes 1,212.3 hectares of land, ten dispersed Sites, multiple substations, a BESS, highway works and approximately 24 kilometres of cable corridor principally through parcel areas, distances and feature lists. It does not provide an integrated or reliable account of how the landscape functions environmentally, agriculturally, hydrologically, historically or ecologically.

The deficiency is confirmed by the specialist consultees. Norfolk Wildlife Trust describes the area as a landscape 'dense with nature', containing ancient woodland, species-rich hedgerows, rare roadside flora, farmland birds and nationally important bat activity. It disputes key assumptions concerning habitat connectivity, identifies

unresolved effects on County Wildlife Sites and Roadside Nature Reserves, and continues to recommend deletion of Site 3 because of its relationship with woodland, bats and designated ecological interests.

Natural England identifies unresolved protected-species issues, incomplete Agricultural Land Classification surveys across the cable corridor, possible peat, permanent infrastructure on Best and Most Versatile agricultural land and insufficiently detailed soil-management controls. It also confirms that the Order Limits are hydrologically linked to six Sites of Special Scientific Interest and two ancient woodlands. Its areas of agreement are expressly dependent on mitigation being effective, consistently applied and legally secured.

Historic England confirms that the Scheme is likely to cause significant setting effects and policy harm to designated heritage assets, that residual harm is likely to remain after mitigation, that archaeological evaluation is incomplete in parts of the Order Limits and that cumulative effects with Tasway Energy Park and associated BESS development require further examination. Its concerns encompass one Scheduled Monument, two Grade I listed buildings, two Grade II* listed buildings, 42 Grade II listed buildings and four Conservation Areas.

These are not minor matters capable of being cured through post-consent detail. They arise from the fundamental siting and scale of the Scheme. The application depends on future surveys, detailed design, protected-species licences, HDD locations, management plans, soil controls, archaeological evaluation, monitoring, restoration and adaptive mitigation. That extensive dependence on later controls is not evidence of a well-sited project. It demonstrates that the Order Limits encompass too many sensitive and functionally important areas and that the Applicant has not completed the work necessary to show that the development is environmentally deliverable.

The mitigation hierarchy has therefore been applied in reverse. The Applicant has retained an expansive development envelope and sought to regulate its effects after the event, rather than avoiding the most constrained land at the design stage. Site 3 has not been removed; permanent infrastructure remains proposed on BMV land; peat has not been conclusively identified and avoided; the cable corridor remains insufficiently surveyed and refined; ecologically important verges and dark corridors remain exposed; and significant heritage harm and archaeological uncertainty remain unresolved.

The proper response is not another layer of future management. It is material contraction and redesign of the Scheme, including removal of the most constrained sites and corridors and relocation of permanent infrastructure away from BMV land, peat, irreplaceable habitat, key ecological networks and sensitive heritage settings. The Applicant has not undertaken that exercise and has not demonstrated that a materially reduced and less harmful Scheme would be incapable of meeting its stated purpose.

Development consent should therefore be refused. The Applicant has neither adequately described the receiving environment nor shown that the authorised development can be constructed, operated and decommissioned within it without

unacceptable and insufficiently assessed harm. The outstanding ecological, agricultural, hydrological and heritage problems are not incidental defects in mitigation. They are the foreseeable consequence of placing an overextended industrial scheme across a landscape whose constraints should have prevented this Order Limits boundary from being advanced in the first place.

Chapter 4: The Scheme

4.1 The statutory importance of an accurate scheme description

The starting point for the Examination must be a clear and legally reliable identification of the development for which consent is sought. The Examining Authority and, ultimately, the Secretary of State must be able to understand what each numbered work would authorise; the maximum physical and operational parameters of that work; which elements would be permanent and which temporary; the realistic worst-case form of the development; the relationship between components delivered by different bodies; the extent to which individual elements may be constructed separately; and the controls that would prevent the undertaker from subsequently implementing development materially different from that assessed in the Environmental Statement.

This is not a demand for every item of plant, cable connection, fixing or engineering detail to be selected before consent. Major infrastructure applications may legitimately retain detailed-design flexibility where the nature of the development is settled, its maximum parameters are defined, the environmentally worst realistic case has been assessed and the Development Consent Order contains effective controls ensuring that the final design remains within that assessed envelope. The lawful use of design flexibility therefore depends upon the envelope itself being intelligible, complete and enforceable.

A materially different problem arises where the uncertainty concerns not merely the later selection of equipment, but the identity, location, scale, ownership, necessity or delivery of an essential element of the project. A broad design envelope cannot cure uncertainty about whether a major substation will be constructed at the proposed location; whether it will be used by the relevant network operator; whether a battery storage facility will form part of the connected project; whether significant infrastructure will be delivered by the Applicant or by National Grid Electricity Transmission plc; or whether different parts of the authorised development may be omitted or implemented independently. Those are not ordinary matters of detailed design. They concern the development that the DCO would actually authorise.

The need for precision is particularly important in this application because the Scheme is not a single homogeneous generating station. It comprises dispersed solar sites, alternative panel technologies, a Battery Energy Storage System, multiple project substations, a proposed National Grid substation, overhead-line and pylon works, extensive underground cable corridors, numerous temporary and permanent accesses, construction compounds, drainage infrastructure and replacement activities over an asserted 60-year operational period. Some elements would be delivered and operated by the Applicant; others are intended to become part of the national transmission system. Some may be temporary; others may remain permanently after the solar generating station has ceased operating. The DCO must therefore define both the individual works and the operational relationship between them.

The importance of this issue is recognised expressly by South Norfolk Council. The Council states that the DCO must contain ‘robust, precise and enforceable provisions’ and warns that excessive flexibility, lack of precision and insufficient control could undermine the ability of the decision-maker to conclude that the development complies with the relevant National Policy Statements and the statutory framework under section 104 of the Planning Act 2008. It identifies points of principle where the draft Order introduces uncertainty and where inadequate drafting could exacerbate the significant harms already identified in the application.

The same concern appears in the detailed evidence of Norfolk County Council as Lead Local Flood Authority. The LLFA identifies limited descriptions for a number of Work Nos. and observes that infrastructure such as trenching, swales, drainage systems, utility connections, accesses, security measures and improvements to private tracks is grouped generically as ‘associated development’, rather than clearly allocated to the relevant authorised works. It concludes that the combination of limited works descriptions and a high-level generic description of supporting infrastructure produces an unclear description of the proposed development.

The LLFA also identifies internal inconsistency in the use of the term ‘associated development’. In one part of the Scheme Description it appears to refer to supporting infrastructure such as drainage, services and access. Elsewhere, the same expression appears to encompass major project components including the BESS compound, 132 kV substations, 400 kV substations and the National Grid substation. The LLFA further records that the Applicant relies on flexibility in the ‘arrangement’ of substations, conversion units, panels and the BESS, but does not explain whether ‘arrangement’ refers to location, layout, design type or some combination of those matters. These are not semantic objections. The meaning given to those terms determines the scope of development that may be authorised and the extent of post-consent change that may occur without further environmental assessment.

Norfolk County Council additionally identifies inconsistencies between the works descriptions in Environmental Statement Chapter 4 and the corresponding references on the Works Plans. It observes that some Work Nos. are not adequately described and that the supporting drainage and infrastructure required by major components cannot be identified from the Scheme Description with sufficient certainty. The consequence is that neither consultees nor the decision-maker can reliably determine which physical works are included within each numbered work, where those works may be carried out, or whether their maximum environmental consequences have been assessed.

The Environment Agency raises the same issue from the perspective of environmental protection and enforceability. It objects to the repeated use of the phrase ‘substantially in accordance with’ in the Requirements, stating that the expression introduces unnecessary uncertainty and may undermine the enforceability of controls and the environmental commitments on which consultees have relied. The Agency seeks removal of the word ‘substantially’ so that approved plans and mitigation are not weakened by an undefined tolerance for departure.

The Environment Agency also identifies missing maximum design parameters for significant below-ground works. In particular, it states that no maximum design scenario is provided for the depth of foundations or piling associated with the 132 kV and 400 kV project substations. Without a defined maximum vertical extent of ground disturbance, the Agency cannot assess the interaction with groundwater or the risk of creating pollution pathways. This illustrates why a general commitment to resolve engineering details after consent is not sufficient. Where the omitted parameter governs the maximum environmental effect, it must be established and assessed before the DCO is granted.

The statutory-authority evidence therefore demonstrates a common concern. South Norfolk Council identifies excessive flexibility and insufficiently precise DCO controls. Norfolk County Council identifies unclear and inconsistent descriptions of the works and associated development. The Environment Agency identifies incomplete maximum parameters and Requirements whose wording may permit departure from the documents relied upon in the assessment. These concerns arise independently from authorities exercising different statutory functions, but converge upon the same central issue: the development authorised by the Order must be identifiable and its maximum consequences must be controlled.

The Rochdale Envelope principle does not provide a general licence to defer essential characteristics of the project. It permits reasonable flexibility within an identifiable and assessed envelope. It does not answer uncertainty as to whether a major work is required, whether it will be delivered by the Applicant or another undertaker, whether its proposed location is accepted by the future operator, or whether the DCO could authorise a materially different combination of project components. Nor can reliance on future detailed design remedy a failure to assess the maximum depth, footprint, height, number, technology or operational scenario where those parameters determine the scale and significance of environmental effects.

The requirements of accuracy and certainty also extend beyond the Environmental Statement. The description of the Scheme bears directly upon:

- whether consultation was undertaken on the development now sought;
- whether the environmental worst case was assessed;
- whether mitigation corresponds to the works ultimately authorised;
- whether compulsory acquisition is necessary and proportionate;
- whether statutory undertakers' apparatus and rights are properly protected;
- whether the Scheme is technically and commercially deliverable;
- whether independently delivered components can operate together;
- and whether the Requirements are sufficiently precise to be enforced.

The central question is therefore not whether every bolt, cable and item of plant must be selected at application stage. It is whether the DCO defines a development whose maximum physical, operational and environmental consequences have been identified, assessed and made enforceable. For the reasons developed in the following sections, BEPS considers that the application has not yet achieved that standard.

Since this Written Representation was prepared, the National Planning Policy Framework was replaced on 17 August 2026. The Energy NPSs remain the primary policy framework for this NSIP, but the current NPPF materially reinforces the importance of controlling the development which is actually authorised. Policy DP3 requires development to respond to the history, character and features of its site and setting and to integrate with its surroundings, while Policy DP4 requires design quality to be considered throughout project evolution, assessment and delivery and guards against approved design quality being materially diminished during later detailed design. Those principles are particularly relevant where, as here, substantial elements of final layout, equipment technology and ancillary infrastructure remain to be determined after consent. The DCO must therefore secure the design quality and environmental assumptions relied upon at Examination rather than merely authorise an envelope within which an acceptable design may subsequently be sought.

4.1.1 The Applicant's reliance on the Rochdale Envelope

The Applicant expressly relies upon the Rochdale Envelope. ES Chapter 4 states that the physical description of the Scheme informs every technical assessment in ES Chapters 6 to 18. It recognises that aspects of the design remain unfixed, including the arrangement of the solar panels, conversion units, BESS, project substations, National Grid substation and Grid Connection Infrastructure. The Applicant says that the application and EIA are therefore based on maximum and, where relevant, minimum parameters selected to represent the realistic worst case for each environmental receptor.

The Applicant further states that Table 4.1 identifies the parameters assessed in the ES and that the Design Principles, Parameters and Commitments document provides the principles and maximum parameters for detailed design. Its case is that the draft DCO will require the detailed design to accord with that document, ensuring that the resulting environmental effects are 'the same as or no worse than' those assessed in the Environmental Statement.

That express case establishes the standard against which the application must be examined. It is not sufficient for a parameter merely to appear somewhere within the application. The decision-maker must be satisfied that:

1. every parameter capable of materially affecting an environmental receptor has been identified;
2. the stated maximum is internally consistent across the application documents;
3. each technical chapter has actually assessed the relevant maximum or other realistic worst case;
4. the Works Plans and draft DCO authorise no wider development;
5. and the Requirements make compliance with the assessed envelope legally enforceable.

A Rochdale Envelope does not dilute the obligation to describe the development. It permits limited design flexibility within a defined and assessed boundary. Its legitimacy depends upon the envelope being sufficiently complete, intelligible and controlled to

ensure that the development ultimately constructed cannot produce materially different or greater effects.

4.1.2 Legitimate detailed-design flexibility

BEPS does not suggest that every bolt, cable termination, equipment supplier or minor engineering detail must be selected before consent. Legitimate detailed-design flexibility may include, for example:

- selection between manufacturers whose equipment remains within fixed dimensions and environmental performance standards;
- adjustment of equipment positions within a clearly defined compound;
- refinement of drainage details within a secured maximum impermeable area and discharge regime;
- and selection of a foundation technique within assessed maximum dimensions and depths.

Such flexibility is capable of being lawful where the essential character of the work is settled, the range of possible outcomes is defined, the environmentally worst realistic outcome has been assessed and the DCO prevents departure from that envelope.

The application does provide some maximum parameters of this kind. For example, Table 4.1 specifies maximum panel heights, mounting depths, substation compound areas, cable-trench dimensions, pylon heights and certain building dimensions. Those stated parameters can, in principle, form part of a lawful design envelope, provided they are consistently assessed and secured.

4.1.3 Uncertainty concerning the essential nature of the development

A materially different problem arises where the uncertainty does not concern later equipment selection but the identity, location, scale, ownership, necessity or delivery of an essential work.

That includes uncertainty about:

- whether a proposed National Grid substation will form the final point-of-connection solution;
- whether NGET will construct or use that substation;
- whether the solar and BESS components will be delivered as one integrated project;
- whether the BESS can be omitted, delayed or materially reduced;
- whether major works may be constructed independently;
- whether infrastructure authorised for one connection solution could remain unused if a different solution is selected;
- and whether compulsory powers are sought for works that may not be required.

ISH1 has since confirmed that the retained uncertainty extends further than was apparent when this Written Representation was drafted. The Applicant confirmed that the Illustrative Masterplan is indicative rather than determinative; that important

choices remain open concerning AIS or GIS technology for the project substations; that the precise number and location of 33 kV switch rooms and conversion units remain to detailed design; that ancillary operational buildings may be distributed across the Sites; and that material aspects of fencing, lighting, construction compounds and layout remain capable of later refinement. The ExA consequently required additional parameters, illustrative material and explanations of how those components would be controlled.

Those matters strengthen the distinction drawn in this section. The issue is not whether a manufacturer or exact equipment model remains to be selected, but whether the spatial accumulation, number, technology and distribution of material infrastructure have been sufficiently defined for their combined environmental effects to be assessed and secured. Those are not ordinary matters of detailed design. They determine the nature of the project that the DCO would authorise.

The distinction is fundamental. Selection between two transformer models within a fixed compound may be a detailed-design matter. Selection after consent of a different substation location, a different point of connection, a materially different operational configuration, or a solar-only development in place of the assessed solar-and-storage project is not.

A broad envelope cannot cure uncertainty where the unresolved matter is the identity of the development itself. Nor can post-consent approval properly be used to determine whether an essential work is required, where it will be constructed, who will deliver it or whether the project can operate without it.

4.1.4 The breadth of the authorised works

The need for precision is reinforced by the breadth of Schedule 1 as described in ES Chapter 4. The authorised development is divided into overlapping Work Areas, including:

- Work No. 1: the solar generating station and associated electrical equipment;
- Work No. 2: the BESS compound, access and temporary construction compounds;
- Work Nos. 3A and 3B: up to three 400 kV and up to three 132 kV project substations;
- Work Nos. 4A to 4C: the National Grid substation, associated landscaping, drainage, biodiversity works, temporary compound and access;
- Work Nos. 5A to 5D: new, modified, diverted and removed overhead-line and pylon works;
- Work No. 6: cables up to 132 kV and 400 kV, including tunnelling and supporting infrastructure;
- Work No. 7: fencing, security, access, earthworks, drainage, acoustic barriers, connections and laydown areas;
- Work No. 8: temporary construction and decommissioning laydown areas;
- Work No. 9: access and highway works;
- Work No. 10: habitat-management areas;
- and Work No. 11: permissive paths.

The Work Areas may overlap. In addition, paragraph 4.2.17 describes a very broad category of associated development connected with Works Nos. 1 to 11, including bunds, embankments, trenching, swales, drainage, utilities, accesses, private-track works, site preparation, earthworks, excavations, tunnelling, boring, drilling and other mitigation works.

This drafting makes it especially important that the plans, parameters and Requirements identify where such works may occur, their maximum extent and the principal work to which they relate. Otherwise, generic associated-development powers may extend the physical development beyond the particular works and effects described in the Environmental Statement.

4.1.5 South Norfolk Council's concern about excessive flexibility

South Norfolk Council expressly identifies this issue. It states that the DCO must contain robust, precise and enforceable provisions and warns that excessive flexibility, lack of precision or inadequate controls could undermine the ability of the decision-maker to conclude that the development accords with the relevant National Policy Statements and the section 104 framework.

The Council explains that points of principle arise where the current drafting introduces uncertainty or insufficient control, particularly where those defects may exacerbate the substantial landscape, heritage, ecological and amenity harms already identified.

This is not an objection to design evolution in principle. It is an objection to flexibility that is not bounded by precise maximum parameters or enforceable approval mechanisms.

South Norfolk Council also identifies a specific uncertainty in Requirement 5. It notes that the detailed-design Requirement does not include Works Nos. 4A and 4B relating to the proposed National Grid substation and asks whether those works would be undertaken separately by National Grid or approved through a separate planning application.

That is a direct illustration of the distinction between detailed design and uncertainty about an essential work. If the principal detailed-design Requirement does not apply to the National Grid substation, the application must identify:

- who will approve its detailed design;
- under what statutory mechanism;
- by reference to which environmental parameters;
- and how the decision-maker can be assured that the resulting infrastructure will remain within the assessed envelope.

4.1.6 Norfolk County Council's concern about unclear works descriptions

Norfolk County Council's Lead Local Flood Authority reaches a similar conclusion from its review of the Scheme Description.

The LLFA identifies limited information in the descriptions of a number of Work Areas, including Works Nos. 8, 10 and 11. It observes that supporting infrastructure such as trenching, swales, drainage systems, services, utilities, access, security measures and improvements to private tracks is grouped within a generic associated-development description rather than clearly allocated to individual Work Nos. The LLFA concludes that this combination of limited works descriptions and generic supporting infrastructure produces an unclear description of the proposed development.

The LLFA also identifies two different uses of the expression 'associated development'. In one place it refers to supporting infrastructure such as drainage, utilities and access. Elsewhere it is used to describe major components including the BESS compound, 132 kV substations, 400 kV substations and National Grid substation. It further records that the Applicant seeks flexibility in the 'arrangement' of those components but does not make clear whether 'arrangement' concerns location, layout, technology, configuration or design type.

That ambiguity matters because the environmental consequences of moving equipment within a compound may be limited, whereas changing the location or configuration of an entire substation may materially alter:

- landscape and visual effects;
- heritage setting;
- noise exposure;
- flood risk;
- groundwater effects;
- construction traffic;
- aviation safeguarding;
- and the land required.

The LLFA also records inconsistencies between the works descriptions in ES Chapter 4 and the references on the Works Plans. The Applicant must therefore reconcile the narrative description, Table 4.1, Works Plans, Land Plans, Design Principles, draft DCO and Commitments Register in a single authoritative schedule.

Norfolk County Council's concern about unclear works descriptions and inconsistent mapping

The reliability of the Scheme Description also depends upon the accuracy and consistency of the plans used to define the authorised development. The Works Plans are not merely illustrative background material. They identify the geographical extent and relationship of the numbered works and are therefore central to understanding what the DCO would authorise. Where those plans use outdated base mapping or are

inconsistent with other application drawings, it becomes more difficult for consultees and the decision-maker to identify the development, its interaction with existing infrastructure and the land over which powers are sought.

Norfolk County Council's targeted-consultation response provides a specific example. In relation to additional land areas 8 and 9, the County Council's Lead Local Flood Authority states that the Applicant was using outdated base mapping because the plans did not show or consider the operational Long Stratton Bypass. The LLFA concluded that this demonstrated that the relevant assessment had not been undertaken using the latest available information and required further work.

That defect is particularly significant because the Long Stratton Bypass was no longer a merely proposed development. It was operational by the time of the County Council's November 2025 response. A Works Plan or supporting assessment that continues to depict the previous highway arrangement does not provide an accurate representation of the environment within which the authorised works would be constructed.

The absence of the bypass potentially affects more than cartographic presentation. It may affect:

- the identification of existing roads and junctions;
- the relationship between Work No. 9 highway works and the current highway network;
- construction and AIL routeing assumptions;
- drainage catchments and impermeable highway areas;
- access to individual sites and compounds;
- cumulative traffic assessment;
- vegetation and land-take assumptions;
- and the accuracy of environmental baseline mapping.

The outdated Works Plan must also be considered alongside the wider evidence of inconsistent mapping across the application. Norfolk County Council's LLFA identifies inconsistencies between ES Chapter 4 and the Works Plans. Other parts of the application use different depictions of the Scheme, infrastructure proposals and surrounding development. Major developments are at times represented only by point symbols rather than their true geographical extent, while proposed and operational infrastructure is not shown consistently between plans.

The result is that there is no single, reliable geographical representation against which the full extent of the authorised development can readily be checked. That undermines the Applicant's reliance on Chapter 4 and the Works Plans as the definitive basis for the environmental assessment.

The Applicant should therefore be required to provide:

1. corrected Works Plans using an up-to-date Ordnance Survey or equivalent base;
2. plans showing the operational Long Stratton Bypass accurately;
3. a schedule identifying every application plan that has been superseded or corrected;
4. a reconciliation plan showing all numbered works, existing infrastructure and relevant committed development on one consistent base;

5. confirmation that all environmental assessments used the corrected geography;
6. and revised assessments where the outdated mapping affected routeing, drainage, land take, access or receptor identification.

The issue is not remedied merely by acknowledging that the base map is old. The Examining Authority must be satisfied that the development assessed geographically corresponds with the development shown on the certified Works Plans and capable of being authorised by the DCO.

The Examination has now identified a further internal-plan problem. The ExA required the Applicant to correct inconsistencies between the Indicative Masterplan and the Works Plans, including areas variously depicted as retained agricultural land, mitigation land, biodiversity land and cabling works. That is directly relevant to Scheme definition because those are not interchangeable land uses. The same area cannot simultaneously be relied upon as retained agricultural land, biodiversity mitigation and construction or cable land without the environmental consequences of each permitted use being reconciled.

4.1.7 The Environment Agency's concern about incomplete and uncertain controls

The Environment Agency raises the same issue from the perspective of environmental protection and enforcement.

It objects to the repeated use of the phrase 'substantially in accordance with' in the Requirements. The Agency states that this wording undermines enforceability and creates unnecessary uncertainty because it may allow departure from documents and mitigation commitments upon which the Agency and other consultees relied. It therefore seeks removal of the word 'substantially'.

The concern is particularly material to decommissioning. ES Chapter 4 states that the future Decommissioning Strategy would be prepared 'substantially in accordance with' the Outline Decommissioning Environmental Management Plan. Yet the specific decommissioning method remains uncertain, the National Grid substation and Grid Connection Infrastructure would remain, below-ground infrastructure may be cut off at 1.2 metres, and cables, ducts and joint bays may be left in place.

An undefined tolerance for departing from the outline document would therefore apply to a phase in which the application already retains substantial uncertainty about what will be removed and what will remain.

The Environment Agency also identifies incomplete maximum design information concerning foundations, piling, cabling, drainage and groundwater interaction. Although Table 4.1 supplies maximum depths for several categories of works, including piles up to 12 metres for substations and BESS equipment, the Agency considers that the maximum design scenario is not sufficiently complete or clear across all relevant structures and locations to assess groundwater effects reliably.

This should be resolved by a structure-by-structure and location-by-location maximum foundation schedule, rather than by reliance on generic post-consent risk assessment.

4.1.8 Consequences for the Examination

The same audit must be undertaken geographically. The Applicant should demonstrate that the final Works Plans, Land Plans, Access and Rights of Way Plans, environmental figures and construction-route plans all use a consistent and current baseline. The known omission of the operational Long Stratton Bypass from the Works Plan is evidence that this exercise has not yet been completed.

A DCO should not be made by reference to certified plans that inaccurately depict material existing infrastructure. If the Works Plans are corrected during Examination, the Applicant must explain whether the amendment changes:

- the limits of deviation;
- the relationship between numbered works;
- the land and rights sought;
- highway and drainage effects;
- construction access;
- or the environmental assessment.

Where a correction is substantive rather than purely cartographic, affected parties must be given a fair opportunity to understand and comment on the revised proposal.

An inaccurate or incomplete Scheme Description affects more than the presentation of the application. It bears directly upon:

- whether the development now sought was the development consulted upon;
- whether the realistic worst case has been assessed;
- whether mitigation corresponds to the works ultimately authorised;
- whether independently delivered components can operate together;
- whether the Scheme is technically and commercially deliverable;
- whether compulsory acquisition is necessary and proportionate;
- whether statutory undertakers' rights and apparatus can be protected;
- whether cumulative effects have been assessed against a reliable programme and configuration;
- and whether the Requirements can be enforced.

The Applicant's own approach makes this especially important. It says that the parameters in Chapter 4 inform all technical assessments and that the detailed design will produce effects no worse than those reported. If any technical chapter has assessed an earlier, smaller or different configuration, the Applicant's claimed control mechanism fails.

The Examination must therefore audit the technical assessments against the final Chapter 4 envelope, including:

- tracker panels up to 4.5 metres;
- fixed panels up to 3.5 metres;
- panel piles up to 4 metres;
- project-substation piling up to 12 metres;
- the Site 1B project substation up to 15 metres;
- the National Grid substation occupying up to six hectares;
- up to four new pylons reaching 61 metres;
- cable trenches up to seven metres wide and two metres deep;
- trenchless works reaching 12 metres;
- complete replacement of all panels over a further period of up to 24 months;
- up to five BESS replacement cycles;
- and permanent retention of the National Grid substation and Grid Connection Infrastructure.

The central question is not whether every bolt, cable and item of plant must be fixed at application stage. It is whether the DCO defines a development whose maximum physical, operational and environmental consequences have been identified, assessed and made enforceable. For the reasons developed below, BEPS considers that the application has not yet demonstrated that the authorised development, the assessed development and the development ultimately capable of being delivered are one and the same.

4.2 Authoritative description of the development applied for

The application describes East Pye Solar as a large, dispersed solar photovoltaic generating station with associated battery storage, project substations, a new National Grid substation, underground cable infrastructure, overhead-line works, access and construction infrastructure. South Norfolk Council summarises the application as a proposed 500 MW solar farm with a Battery Energy Storage System, up to three 132 kV substations, up to three 400 kV substations and a new National Grid substation. Norfolk County Council records that the Order Limits extend across approximately 1,212 hectares of agricultural land and that the Scheme is anticipated to have an operational life of 60 years.

That summary, however, does not itself define the full development authorised by the DCO. The Scheme includes alternative technologies, dispersed work areas, substantial temporary infrastructure, repeated replacement activity and elements intended to remain after decommissioning. It is therefore necessary to describe each principal component and to identify where the application retains flexibility or leaves material parameters unresolved.

4.2.1 Solar photovoltaic generating station

The generating element comprises solar photovoltaic development distributed across multiple sites and sub-sites within the Order Limits. Norfolk County Council records

that the application retains both single-axis tracker panels and fixed panels as options and has not narrowed the design to one technology.

The distinction is environmentally material. South Norfolk Council records that tracker panels may reach a maximum height of approximately 4.5 metres and identifies their movement, changing orientation and greater visual prominence as materially different from lower fixed panels. The Council seeks controls requiring panels of no more than approximately 3 metres in sensitive locations, including within the settings of heritage assets.

The authorised solar development therefore appears capable of comprising:

- fixed photovoltaic panels;
- single-axis tracking panels;
- mounting structures secured by driven posts, screw piles, concrete feet or other non-ground-penetrative techniques;
- electrical conversion equipment;
- inverter or conversion units;
- switch rooms;
- internal cabling;
- perimeter fencing;
- security infrastructure;
- CCTV and monitoring equipment;
- internal access tracks;
- drainage works;
- and associated landscaping and ecological mitigation.

The Scheme Description must identify, for each technology, the maximum:

- panel height;
- panel length and width;
- tilt and rotational range;
- row spacing;
- minimum ground clearance;
- mounting depth;
- foundation footprint;
- extent of hardstanding;
- and number and dimensions of associated conversion units.

The available authority evidence indicates that not all of those parameters are presently fixed. Norfolk County Council's LLFA notes, for example, that the application permits concrete feet or other non-ground-penetrative mounting techniques but does not clearly identify all circumstances in which those techniques may be used or their maximum dimensions. The LLFA consequently cannot determine the resulting increase in impermeable area or the drainage infrastructure required.

The application must also explain whether fixed and tracking panels may be mixed freely across all solar sites, whether any site-specific technology restrictions apply, and whether the environmental assessment consistently adopts the more harmful option

for each receptor. A nominally common ‘solar panel’ envelope cannot be treated as environmentally neutral where panel height, movement, mounting method, reflectivity, vegetation clearance, runoff behaviour and visual effects differ materially.

ISH1 has since exposed an additional uncertainty concerning the scale of Work No. 1 itself. The ExA required the Applicant to explain the proposed overplanting ratio and panel ratings, provide hectares-per-MW comparisons with other consented or proposed solar schemes, explain why panel type and final locations remain unfixed, identify minimum separation distances and address whether the absence of an express maximum generating-capacity limit could permit a materially greater installed capacity within the same physical envelope.

This matters because a physical-envelope approach is only sufficient if all environmentally relevant consequences remain bounded independently of electrical output. If technological change permits materially greater generating capacity within the same fields, the Applicant must demonstrate that the resulting number or rating of inverters, transformers, conversion units, switchgear, cooling requirements, noise, heat, EMF, replacement activity and grid infrastructure cannot exceed the assumptions assessed in the ES.

The ExA also required the Applicant to explain why East Pye relies upon a minimum residential separation of 50 metres where the Applicant’s related Droves Solar Farm uses 250 metres. That comparison does not establish that 250 metres is automatically required at East Pye, but it does require the Applicant to explain the environmental and design basis for the materially different minimum adopted here.

4.2.2 Battery Energy Storage System

The Scheme includes a Battery Energy Storage System forming part of the associated development. The BESS is described as occupying a dedicated compound and comprising battery enclosures, power-conversion and electrical equipment, transformers, cooling systems, auxiliary plant, security fencing, access, drainage and fire-safety infrastructure.

The application must define, or expressly acknowledge that it does not define:

- the electrical storage capacity;
- discharge duration;
- maximum compound area;
- maximum number of battery enclosures;
- maximum enclosure dimensions and height;
- battery chemistry or technology envelope;
- number and rating of transformers;
- cooling and ventilation plant;
- auxiliary generation;
- acoustic mitigation;
- fencing and wall heights;
- fire separation distances;

- internal access and emergency routes;
- surface-water drainage;
- firewater containment;
- and the maximum volume of potentially contaminated water requiring storage.

Norfolk County Council's LLFA records that the Applicant had not identified the number or size of the battery storage enclosures and that the BESS might be founded on a reinforced concrete slab or concrete piling. It observes that the equipment, compound, hardstanding and access tracks would create a material impermeable area, but the Scheme Description does not adequately identify the corresponding drainage and attenuation requirements.

The Environment Agency similarly identifies insufficient detail regarding the drainage and pollution-control design of the BESS. It seeks clear confirmation that the entire drainage system would be impermeable, that contaminated firewater could be isolated and contained, that automatic and manual closure systems would be provided, and that the design would accommodate decontamination and potential removal of contaminated drainage aggregate.

The Environment Agency also notes that the BESS could be replaced up to five times during the operational period but considers that the application provides inadequate detail regarding the removal, temporary storage and disposal of damaged or end-of-life batteries. The BESS description must therefore encompass not only its first installation but the maximum foreseeable replacement activity authorised over the 60-year project life.

The Scheme Description must now also distinguish physical authorisation from connection deliverability. The BESS remains at Gate 1 whereas the solar element has progressed to Gate 2. The existence of Work No. 2 within the DCO therefore does not establish that it will connect, commission or operate on the same timetable as the solar generating station.

The description of Work No. 2 should consequently state whether the BESS is mandatory, severable or optional; whether the solar generating station can operate without it; whether it may be commissioned substantially later; and whether its capacity, duration, technology or operating regime may change if connection is delayed. Those implementation scenarios are part of the development capable of being authorised and cannot be left merely as commercial possibilities outside the environmental assessment.

4.2.3 Project substations

The application includes multiple project substations required to collect, transform and transmit electricity from the dispersed solar sites and the BESS. South Norfolk Council

describes the Scheme as including up to three 132 kV substations and up to three 400 kV substations.

The substations may include:

- power transformers;
- switchgear;
- busbars;
- control and protection equipment;
- control buildings;
- switch rooms;
- telecommunications equipment;
- welfare facilities;
- security fencing;
- lighting;
- internal roads;
- hardstanding;
- drainage;
- oil containment;
- firewater containment;
- and permanent access.

The application must state the maximum number of substations that may be built, their maximum footprints and heights, whether they may be single or double configurations, the maximum number and capacity of transformers, the maximum oil inventory, and the maximum extent of buildings, hardstanding and drainage infrastructure.

Norfolk County Council's LLFA records that the application does not clearly establish where all 132 kV equipment will be placed or whether substations will be single or double installations. It identifies the same uncertainty in relation to the 400 kV substations and concludes that the corresponding impermeable areas and surface-water runoff cannot be quantified from the Scheme Description.

The Environment Agency identifies a further gap: no maximum design scenario is provided for the depth of foundations or piling associated with the 132 kV and 400 kV substations. It considers that the potential interaction with groundwater cannot be assessed without that parameter.

The application also underwent a material design change from a 132 kV project substation to a 400 kV installation at Site 1B. Norfolk County Council records that the change increased the proposed maximum height from approximately 7 metres to approximately 13 metres and appeared to involve a significantly larger footprint. That changed component must be treated as part of the authoritative Scheme Description, rather than as a minor detailed-design variation.

ISH1 has subsequently confirmed that the Applicant continues to retain both AIS and GIS options for project substations, principally because procurement and final equipment selection remain unresolved. The ExA required the Applicant to identify the reasonable worst case associated with those alternatives. That is important because

AIS and GIS do not necessarily produce the same footprint, massing, building requirement, visual effect, construction requirement, SF6-related characteristics or maintenance environment.

The Examination also established that the precise number and location of 33 kV switchrooms and conversion units remain unfixed and that these components may occur throughout Work No. 1 areas. The resulting environmental issue is therefore not merely the maximum dimension of one unit, but the number, spacing and cumulative visual, landscape, noise, drainage and access effect of all units which the DCO could permit.

4.2.4 National Grid substation and associated grid works

The Scheme includes a proposed new National Grid substation at Site 1B and associated works to connect it to the existing 400 kV overhead transmission network. The draft Order identifies National Grid substation works under Work Nos. 4A and 4B, together with associated overhead-line and pylon works.

The National Grid element appears to include:

- a new transmission substation;
- diversion of the existing dual-circuit 400 kV overhead line;
- new or replacement pylons;
- overhead conductors;
- connection or sealing-end infrastructure;
- control and protection equipment;
- access roads;
- fencing and security;
- hardstanding;
- drainage;
- lighting;
- and land required for construction and permanent operation.

Norfolk County Council records that the assumed footprint of the National Grid substation increased from approximately three hectares at consultation to up to six hectares in the application. It states that the location remained indicative and that no final design had been provided.

The targeted-consultation evidence also records the potential need for a new 400 kV pylon of up to approximately 61 metres, compared with existing pylons of approximately 53 metres. The application must identify the maximum number, height, location and type of new or replacement pylons and the extent of any permanent overhead-line diversion. The National Grid substation is separately subject to a maximum busbar height of 15 metres.

The Scheme Description must further distinguish:

- works constructed by the Applicant;

- works constructed by NGET;
- land acquired by the Applicant;
- land transferred to or retained by NGET;
- assets owned and operated by NGET;
- and works for which detailed approval would occur outside the Applicant's principal design-control Requirement.

South Norfolk Council notes that the detailed-design Requirement does not appear to include Works Nos. 4A and 4B and asks whether those works would be undertaken separately by National Grid or approved through another planning route. That uncertainty must be resolved in the authoritative description of the development.

4.2.5 Cable Route Corridors

The Scheme includes extensive underground cable corridors connecting the solar sites, substations, BESS and National Grid connection infrastructure. Those works may comprise:

- high-voltage and lower-voltage cables;
- internal array cabling;
- cable trenches;
- ducts;
- joint bays;
- link boxes;
- trenchless crossings;
- horizontal directional drilling;
- launch and reception pits;
- temporary haul roads;
- temporary compounds;
- soil-storage areas;
- drainage and dewatering;
- reinstatement;
- and permanent marker or access infrastructure.

The application must identify:

- the maximum corridor width;
- maximum construction working width;
- number and voltage of cables;
- maximum trench depth and width;
- number and dimensions of joint bays;
- maximum HDD depth and length;
- launch and reception pit dimensions;
- locations of watercourse and infrastructure crossings;
- and the extent of land required temporarily and permanently.

Norfolk County Council identifies an absence of detail concerning the cabling associated with the photovoltaic arrays and states that the cumulative below-ground effects of piling and cabling cannot therefore be determined with confidence.

The Environment Agency identifies further uncertainty concerning the operational lifespan of below-ground cabling, possible thermal effects, the risk of cable trenches acting as preferential groundwater pathways and the design of trenchless crossings. Those matters are part of the development authorised, not merely future construction methodology.

4.2.6 Accesses, haul roads and construction infrastructure

The Scheme requires substantial temporary and permanent construction infrastructure distributed across the Order Limits. That infrastructure includes:

- construction compounds;
- laydown areas;
- temporary and permanent access points;
- internal haul roads;
- cable-route haul roads;
- road-crossing points;
- temporary hardstanding;
- worker welfare facilities;
- temporary water and power supply;
- wheel-wash facilities;
- fuel, oil and chemical storage;
- soil and spoil-storage areas;
- temporary drainage;
- temporary lighting;
- security fencing;
- highway visibility splays;
- abnormal indivisible load works;
- temporary removal of street furniture;
- vegetation clearance;
- and local highway alteration.

Norfolk County Council's LLFA records that approximately ten temporary construction compounds are shown only at a scale that does not reveal their size or layout. It cannot determine whether those compounds and associated hardstanding have been allowed for in the surface-water drainage design.

The targeted-consultation material also added land for visibility splays, AIL movements, temporary highway works and vegetation removal. Norfolk County Council identified a number of those areas as lacking sufficient information to establish whether new impermeable surfaces, drainage works or access tracks would be required.

The construction description must therefore identify the maximum number and area of compounds, the maximum length and width of haul roads, the land required for AIL works and the maximum area of vegetation removal. General reliance on later Construction Traffic Management Plans and Construction Environmental Management Plans cannot substitute for identification of the physical development and land powers sought in the DCO.

4.2.7 Operational period, replacement and repowering

The application assumes an operational period of 60 years. Norfolk County Council records that the Environmental Statement assumes:

- solar panels may have an operational life of approximately 40 years and may be replaced once;
- the BESS could be replaced up to five times;
- and transformers may require replacement during the Scheme's operational life.

These activities must form part of the authoritative project description because they may involve:

- removal and delivery of large quantities of equipment;
- re-establishment of compounds;
- heavy goods vehicles and abnormal loads;
- lifting operations;
- noise and vibration;
- soil disturbance;
- temporary drainage;
- hazardous and non-hazardous waste;
- battery storage and transport;
- and temporary interference with ecological mitigation.

The application must state whether complete replacement of each component is expressly authorised, whether any maximum replacement frequency or simultaneous work area applies, and whether replacement is treated as operational maintenance or as a renewed construction phase.

The Environment Agency's concern regarding repeated BESS replacement illustrates the significance of the omission. It seeks details of how removed batteries would be handled, stored and taken off site, particularly where damaged or leaking batteries may pose a pollution risk. South Norfolk Council similarly seeks controls ensuring that replacement equipment does not worsen the operational noise environment.

4.2.8 Decommissioning and retained infrastructure

At the end of the 60-year operating period, the application proposes removal of the solar panels, BESS and much of the associated infrastructure. The Scheme Description must, however, distinguish clearly between:

- infrastructure that must be removed;
- infrastructure that may be left in place;
- infrastructure that will be transferred to another operator;
- and development that is intended to remain permanently.

Norfolk County Council's LLFA records that the National Grid substation, pylons and overhead-line works appear intended to remain after the solar development is

decommissioned. It also records that cable ducting and joint bays may remain in situ and that below-ground foundations may only be removed to a specified depth. The LLFA considers that infrastructure not intended to be removed should be treated and assessed as permanent development.

The Environment Agency identifies inconsistencies in the application documents concerning whether the National Grid substation and grid connection infrastructure would be subject to decommissioning. The DCO must therefore contain an unambiguous schedule identifying every work that will be removed, every work that may remain, the body responsible for retained infrastructure and the environmental controls that will continue to apply.

4.2.9 Consolidated description and identified uncertainties

The development applied for may be summarised as follows:

Scheme component	Development apparently authorised	Principal maximum or operational parameters	Material uncertainty requiring resolution
Solar generating station	Dispersed ground-mounted photovoltaic arrays across multiple sites and sub-sites	Up to approximately 500 MW; fixed and/or single-axis tracking panels; trackers up to approximately 4.5 m	Final technology by site; row arrangement; foundation methods and depths; total equipment numbers; minimum clearance and impermeable footprint
Mounting and conversion infrastructure	Driven or screw-mounted posts, concrete feet, conversion units, inverter equipment and switch rooms	Multiple foundation and equipment alternatives	Maximum foundation dimensions and depths; drainage consequences; distribution and number of units
BESS	Battery enclosures, transformers, cooling plant, auxiliary systems, fencing, access and firewater infrastructure	Dedicated compound; repeated replacement contemplated	Capacity and duration; technology; enclosure number, size and height; maximum compound layout; drainage and firewater capacity
132 kV project substations	Transformers, switchgear, buildings, access and drainage	Up to three stated by South Norfolk Council	Single or double configurations; equipment numbers; footprints;

			heights; oil inventory; foundation depth
400 kV project substations	Transformers, switchgear, buildings, access and drainage	Up to three stated by South Norfolk Council; Site 1B installation increased from approximately 7 m to 13 m	Final configuration; equipment and transformer numbers; maximum footprint; foundation depth; full reassessment of 132-to-400 kV change
National Grid substation	New transmission substation at Site 1B under Work Nos. 4A and 4B	Assumed footprint up to approximately 6 ha	Final location, size and design; NGET acceptance; Applicant/NGET division of responsibility; detailed approval mechanism
Overhead-line and pylon works	Diversion and connection to existing 400 kV line	New or replacement pylons potentially up to approximately 61 m	Final number, design and alignment; ownership; construction responsibility; permanent retention
Cable Route Corridors	Underground cables, trenches, ducts, joint bays and trenchless crossings	Broad corridors across the Scheme	Cable numbers and voltage; maximum working widths; trench and HDD dimensions; crossing locations; cable lifespan
Construction compounds	Temporary compounds, laydown, welfare, materials and plant	Approximately ten compounds referred to by NCC LLFA	Maximum area, layout, hardstanding, drainage and duration
Access and haul roads	Temporary and permanent accesses, internal roads and cable haul routes	Extensive network across dispersed sites	Final routes; widths; impermeable area; highway crossings; restoration
AIL and highway works	Visibility splays, road alteration, vegetation and street-furniture removal	Added land identified at targeted consultation	End-to-end routes; physical highway works; land requirements; drainage and reinstatement

Operational replacement	Replacement of panels, BESS and transformers	Panels potentially replaced once; BESS up to five times; transformers during project life	Maximum simultaneous replacement; compounds; traffic; waste; battery handling; environmental controls
Decommissioning	Removal and restoration at end of 60 years	Solar and BESS removal generally proposed	Infrastructure left in situ; retained cables, ducts, foundations, pylons and National Grid works; long-term responsibility

This is the development that must be reconciled against the numbered works, Works Plans, Land Plans, Environmental Statement, Requirements and Commitments Register. Where the application leaves a parameter undefined, the Applicant must either provide and assess a maximum value or accept a binding DCO control restricting the development to the envelope actually assessed.

Until that reconciliation is completed, the description of East Pye Solar remains partly a description of a project concept and partly a collection of alternative future designs. The function of the DCO, however, is to authorise identifiable development. The remainder of this chapter examines whether the uncertainties summarised above concern permissible detailed design or the essential nature and deliverability of the Scheme itself.

4.3 Material design evolution after statutory consultation

The Scheme submitted for development consent is not the same design that was presented during the Phase Two statutory consultation undertaken between 18 June and 6 August 2025. Following that consultation, the Applicant made a series of changes affecting the location, scale and configuration of major electrical infrastructure, the extent of solar development, the Order Limits, abnormal-load works and the construction traffic strategy.

Design evolution is not objectionable in itself. Consultation is intended to inform and improve a proposal. The material question is whether changes made after statutory consultation were accompanied by sufficient updated environmental information to allow consultees and the decision-maker to understand their effects, compare them with the PEIR scheme and determine whether the final application remained within the environmental envelope previously presented.

In this case, the Applicant proceeded by way of a targeted non-statutory consultation between 22 October and 26 November 2025. South Norfolk Council records that the information supplied consisted principally of a 20-page change note and that the PEIR was not revised or updated. Norfolk County Council likewise concluded that the

changes did not resolve the substantive strategic and technical concerns it had raised during the statutory consultation.

The changes were not confined to minor micro-siting or drafting corrections. They included selection of the final application location for the proposed National Grid substation, abandonment of an alternative connection site, replacement of a 132 kV project substation with a substantially larger 400 kV installation, taller electrical infrastructure, additional solar development, extensions to the Order Limits and revised construction and AIL arrangements.

4.3.1 Selection of the Site 1B National Grid substation

The PEIR presented two potential locations for the new National Grid substation and point of connection near Great Moulton.

The first option was south of Hundred Lane, close to the BESS and other project electrical infrastructure. The second was within Sub-Site 1B, immediately to the north-east and crossed by the existing 400 kV overhead line. The Applicant's ES Chapter 5 confirms that both options were refined and presented at statutory consultation.

The targeted consultation then confirmed that the Applicant would pursue the Site 1B option and abandon the alternative to the south. South Norfolk Council records this as one of the principal post-consultation changes. Norfolk County Council confirms that the southern option had been favoured by the County Council because it was farther from Great Moulton and would consolidate the BESS, project substation and transmission infrastructure in one area, reducing wider visual effects and construction disturbance. The Applicant instead selected the Site 1B location closer to the village.

The Applicant's final alternatives chapter explains that the southern option was affected by overlap with a consented solar development and was also considered less favourable because of flood-risk and public-right-of-way constraints. Those matters may explain why the Applicant preferred Site 1B, but they do not remove the obligation to reassess the consequences of moving the National Grid substation closer to Great Moulton and its heritage, landscape, residential and aviation receptors.

Norfolk County Council identifies the consequences directly. It records that the selected substation and associated new pylons would be closer to Great Moulton and raises concerns about:

- visual effects on residents and the setting of the village;
- health and safety in the event of a substation fire;
- and physical and mental health effects on residents that had not been investigated adequately.

The change also altered the geographical relationship between the National Grid substation, the existing 400 kV line, the BESS, the project substations, access routes, drainage infrastructure and nearby designated heritage assets. It was therefore capable

of changing the distribution and significance of effects even if the broad categories of effect remained the same.

4.3.2 Abandonment of the southern substation alternative

The abandonment of the southern alternative had consequences beyond the loss of one option from the plans.

The southern site would have consolidated major energy infrastructure near the BESS and project substation. By selecting Site 1B, the Applicant separated the National Grid substation from some of the other principal electrical components and introduced additional overhead-line diversion and pylon works nearer Great Moulton.

The final ES describes the selected solution as a new National Grid substation of up to approximately six hectares, with electrical structures reaching approximately 15 metres and up to four new pylons reaching 61 metres. The environmental comparison therefore needed to address the full final envelope, not simply the fact that one consultation option had been removed.

This was especially important because NGET's subsequent Relevant Representation indicates that the Site 1B substation is not yet a confirmed final network solution. The Applicant therefore selected and assessed a specific location after statutory consultation, while the future network operator has not confirmed that it will be required to use that location or configuration. That issue is addressed in detail below, but it reinforces the importance of a transparent and complete reassessment of the selected design.

4.3.3 Upgrade and relocation of the project substation from 132 kV to 400 kV

The targeted consultation also confirmed that the project substation within Site 1B would be relocated and upgraded from 132 kV to 400 kV. South Norfolk Council records this expressly as a change in both location and size.

Norfolk County Council understood the change to increase the maximum height from approximately 7 metres to approximately 13 metres and to involve a materially larger footprint. It considered that the taller and larger structure would be more visible from Great Moulton and the surrounding countryside and requested clarification of the final footprint.

South Norfolk Council's heritage officer similarly observed that the targeted-consultation material referred to an increase from 7 metres to 13 metres but did not explain whether 13 metres represented a small isolated element or the height of a substantial part of the substation's massing. The Council considered the structure likely to be visible and intrusive in the settings of surrounding heritage assets, including assets within Great Moulton and Moulton Farmhouse, and stated that the heritage impact had not yet been assessed.

The final application widened the envelope further. ES Chapter 4 permits the Site 1B 400 kV project substation to reach approximately 15 metres to the busbars. The progression was therefore:

- approximately 7 metres for the 132 kV design;
- approximately 13 metres in the targeted-consultation material;
- and approximately 15 metres in the final application envelope.

That progression must be traced through every relevant assessment. The Applicant should identify whether the final landscape, heritage, aviation, lighting and noise assessments used the 15-metre structure or an earlier 13-metre assumption.

The voltage change was also capable of altering:

- transformer number and dimensions;
- switchgear and busbar configuration;
- foundation depth;
- transformer oil inventory;
- fire and pollution risk;
- operational noise;
- lighting;
- hardstanding;
- drainage;
- AIL requirements;
- and construction methodology.

It was therefore not sufficient to treat the change merely as a revised label or technical refinement.

4.3.4 Taller new 400 kV pylons

The targeted consultation confirmed that the selected Site 1B connection solution would require changes to the existing 400 kV overhead line and new pylons.

Norfolk County Council records that the proposed new tower could reach approximately 61 metres, compared with the existing towers along the route, which were understood to be approximately 53 metres. It considered that the change raised further landscape and visual concerns and reiterated its earlier preference for avoiding additional pylons.

The final ES authorises up to four new pylons reaching 61 metres, together with overhead-line diversion and temporary pylon works.

The increase was capable of altering:

- long-distance landscape views;
- the setting of Great Moulton and nearby heritage assets;
- aviation safeguarding and visibility;
- construction access and crane requirements;

- foundation works;
- ecological effects;
- and cumulative effects with existing and proposed transmission infrastructure.

The final assessment should therefore demonstrate that the full number, location and 61-metre maximum height were assessed, rather than relying on the scale of the existing pylons or an earlier indicative design.

4.3.5 Additional solar panels at Site 7D

The targeted consultation added solar panels within part of Site 7D.

South Norfolk Council records the additional panels as a specific post-consultation change. Norfolk County Council describes an extension of approximately 4.85 hectares and states that, although limited when viewed alone, it adds to an already extensive solar development and must be included in cumulative landscape and visual assessment.

The County Council's LLFA also records that Site 7D lies at the head of a catchment associated with a natural flood-management scheme at Saxlingham. It considered the catchment sensitive and required clear evidence that the additional panels would not increase flood risk.

South Norfolk Council's heritage officer considered that additional panels could be visible from the upper storeys of designated heritage assets within Saxlingham Green Conservation Area and noted that no details of possible mitigation had been supplied.

The change was therefore capable of affecting:

- landscape character and visual receptors;
- the setting of Saxlingham Green Conservation Area and listed buildings;
- surface-water runoff and downstream flood risk;
- soil and agricultural land;
- ecology and BNG calculations;
- construction access;
- and the cumulative extent of solar industrialisation.

The relevant question was not simply whether 4.85 hectares represented a small percentage of the overall Scheme. It was whether adding panels at that particular location changed effects on sensitive receptors.

4.3.6 Additional land for overhead-line and grid connection works

The targeted consultation added land adjacent to and north-east of Site 1 and to the south-west of Site 1 for works connecting the proposed National Grid substation to the existing overhead transmission line.

Those additions were associated with major grid works rather than incidental landscaping. They potentially enabled:

- pylon construction and replacement;
- overhead-line diversion;
- crane and plant access;
- temporary compounds;
- conductor-stringing areas;
- foundations;
- vegetation removal;
- and permanent operational access.

Norfolk County Council considered that even relatively small additional parcels should be assessed fully where they might accommodate above-ground infrastructure or intensify construction effects.

The added land also reinforces the need for a clear boundary between the Applicant's works and NGET's works. The final application must identify which added parcels are required permanently, which are temporary, what works may occur on each, and whether the associated compulsory powers remain necessary in light of NGET's subsequent position on the connection solution.

4.3.7 Additional land for AILs, visibility splays and highway alterations

The Applicant also expanded the Scheme boundary at numerous locations to accommodate:

- updated visibility splays;
- AIL movements;
- temporary highway alterations;
- temporary removal of street furniture;
- vegetation removal;
- and revised access arrangements.

These changes responded to the practical difficulty of transporting large transformers and other electrical equipment through the rural highway network. They were not environmentally neutral.

South Norfolk Council's landscape officer objected in principle to the removal of mature trees merely to meet temporary construction needs and identified particular concern where added areas lay within or adjacent to the conservation areas of Saxlingham Green, Saxlingham Nethergate and Long Stratton. The Council also noted that the consultation material did not always distinguish temporary vegetation clearance from permanent operational access.

Its heritage officer identified a long section of proposed highway alteration through Saxlingham Nethergate and Saxlingham Green Conservation Areas. The officer observed that grass verges, vegetation and street furniture contribute to the character

and appearance of those areas and that the proposed works were therefore capable of affecting the designated heritage assets.

Norfolk County Council's LLFA found that several added areas lacked sufficient information to determine whether new impermeable surfaces or drainage works would be required. It also identified outdated mapping at areas 8 and 9 because the operational Long Stratton Bypass was not shown or considered.

The post-consultation highway changes were therefore capable of affecting:

- rural lane character;
- conservation areas;
- trees and hedgerows;
- roadside habitats;
- surface-water runoff;
- land take;
- highway safety;
- construction noise and vibration;
- and the accuracy of the baseline mapping.

4.3.8 Changes to construction traffic and AIL routes

The targeted-consultation material also revised the construction traffic strategy. South Norfolk Council records that the changes were said to reflect stakeholder feedback, design evolution, local road constraints and an intention to internalise more construction traffic within the Scheme.

However, the relevant highway authorities did not regard the strategy as settled.

Norfolk County Council's highway authority considered the proposed access strategy unacceptable and stated that construction traffic should generally enter from B-class roads and use internal haul routes. It rejected or questioned a number of routes and access points and required further highway-boundary information, crossing designs and safety audits.

National Highways subsequently stated that the strategic AIL routes had not been determined and that an acceptable routeing strategy should be established in principle before the DCO was decided.

This evidence demonstrates that the route changes were not merely refinements within a settled transport envelope. The final means of delivering the Scheme's major transformers, substations, battery equipment and grid components remained unresolved.

4.3.9 The Applicant's decision not to revise the PEIR

The central procedural and evidential issue is the Applicant's treatment of the changes.

South Norfolk Council records the Applicant's position that the additional areas and activities had been reviewed as part of the environmental assessment and did not change the likely significant effects reported in the PEIR. On that basis, the Applicant made no revisions or updates to the PEIR in support of the targeted consultation.

The Council rejected that approach. It considered that updated information should have been supplied once the Applicant had:

- selected the Site 1B National Grid substation;
- abandoned the southern option;
- and confirmed the upgrade of the Site 1B project substation from 132 kV to 400 kV.

The Council also stated that the 20-page change note provided limited information and that its earlier statutory-consultation concerns remained unaddressed.

Norfolk County Council reached the same overall conclusion. It stated that the targeted changes did not address the substantive matters raised during the PEIR consultation and that the revised substation location and scale created additional concerns requiring further investigation and mitigation.

4.3.10 A general assertion of unchanged significance was insufficient

The Applicant's conclusion that the changes did not alter likely significant effects is itself an environmental conclusion. It required a transparent evidential basis.

A development change may introduce no new category of effect but still change:

- the receptor affected;
- the magnitude of the effect;
- the geographical extent;
- the duration;
- the interaction with other effects;
- or whether the effect crosses the threshold of significance.

For example:

- moving the National Grid substation may not create a new category called 'landscape effect', but it may materially increase the effect on Great Moulton;
- increasing a substation from 7 metres to 13 metres, and ultimately 15 metres, may change heritage and visual effects even though substations were already part of the Scheme;
- adding panels to Site 7D may alter flood risk or conservation-area views even though the total project area changes only modestly;
- and altering AIL routes may affect different conservation areas, bridges, hedgerows and residential receptors.

The appropriate response was therefore a change-specific assessment showing:

1. the PEIR design assumption;

2. the revised design;
3. the affected receptors;
4. the original effect;
5. the revised effect;
6. any changed mitigation;
7. and the reason why the significance conclusion remained unchanged or changed.

No equivalent topic-by-topic comparison was supplied with the targeted consultation.

4.3.11 Landscape and visual consequences

The selected Site 1B National Grid substation, taller project substation, 61-metre pylons, additional Site 7D panels and expanded highway works were all capable of increasing landscape and visual effects.

The principal concerns included:

- closer proximity of major electrical infrastructure to Great Moulton;
- a larger and taller project substation;
- additional vertical infrastructure;
- additional panel coverage;
- removal of roadside vegetation;
- widening or alteration of rural lanes;
- and cumulative interaction with other energy infrastructure.

Norfolk County Council repeatedly sought further details of design, scale and mitigation and encouraged the Applicant to consider an alternative National Grid substation location farther from Great Moulton. South Norfolk Council likewise considered that the changes required updated landscape and visual information.

4.3.12 Heritage consequences

The changes were capable of affecting the settings of heritage assets at Great Moulton, Saxlingham Green, Saxlingham Nethergate and elsewhere.

South Norfolk Council identified:

- closer proximity of the Site 1B substation to designated heritage assets at Great Moulton;
- potential intrusion from the taller 400 kV project substation;
- possible views of the additional Site 7D panels from designated assets;
- and highway alterations affecting the character and appearance of conservation areas.

The Council expressly stated that the effect of the enlarged substation had not yet been assessed by its heritage consultants. That alone demonstrates why an unsupported conclusion of unchanged significance was inadequate.

4.3.13 Noise and residential amenity

South Norfolk Council's Environmental Management Officer considered that confirmation of the BESS and substation locations required the noise assessment to be updated. The officer also required further air-quality and contaminated-land information and warned that the BESS and substation could materially affect amenity and potentially constitute a statutory nuisance unless effective mitigation were secured.

The selected substation location and larger electrical equipment could change:

- the distance to noise-sensitive receptors;
- the number and type of transformers;
- cooling and ventilation requirements;
- tonal characteristics;
- night-time background comparisons;
- and the feasibility of acoustic mitigation.

Those matters required updated modelling based on the final equipment and locations.

4.3.14 Fire, emergency response and public health

Norfolk County Council's Fire and Rescue Service raised concerns about the proximity of the Site 1B National Grid substation and upgraded project substation to residents at Great Moulton. It identified issues relating to:

- emergency vehicle access;
- cordon control;
- and protection of residents from smoke plumes.

The County Council's public-health evidence also considered that the revised location and scale increased the potential for disturbance and adverse physical and mental-health effects. It sought a dedicated assessment, particularly for vulnerable people and those sensitive to noise and environmental change.

Those concerns could not be answered by stating generally that substations had already formed part of the PEIR scheme. Their final proximity, scale and configuration were the relevant variables.

4.3.15 Drainage and flood-risk consequences

The larger substations and added highway works potentially increased impermeable area and displaced existing surface-water storage.

Norfolk County Council's LLFA stated that both the National Grid substation and the 400 kV project substation would require surface-water management because of their substantial impermeable areas. It found insufficient information to determine whether

adequate space had been reserved for attenuation and noted existing areas of surface-water flood risk.

The LLFA also identified:

- flood-risk sensitivity at Site 7D;
- potential runoff from road widening and internal access tracks;
- and insufficient information for several additional land parcels.

The changes therefore required updated drainage plans and calculations, not merely confirmation that drainage would be dealt with later.

4.3.16 Aviation safeguarding consequences

The taller substation and pylon infrastructure, additional panels and revised Site 1 configuration were also capable of altering effects on Tibenham Aerodrome.

Norfolk Gliding Club and the General Aviation Awareness Council state that the Applicant did not undertake meaningful early engagement with the aerodrome operator and had not provided an adequate site-specific operational assessment or mitigation. Site 1 lies on or close to the extended runway centreline and within land said to be relevant to emergency aviation operations.

The final design changes therefore required consideration of:

- the maximum panel extent;
- panel height and movement;
- reflective effects;
- pylon height;
- substation structures;
- emergency landing availability;
- and cumulative effects with other solar and BESS developments.

The aviation consequences are addressed fully in Chapter 18, but they also demonstrate why design changes at Site 1 could not be treated as environmentally neutral.

4.3.17 Archaeological and ecological consequences

Norfolk County Council's Historic Environment Team considered that the proposed changes increased potential impacts on below-ground archaeology. It also recorded that remains of regional significance had already been identified and that substantial archaeological mitigation would be required.

The Natural Environment Team required the additional areas and vegetation removal to be incorporated into the environmental assessment and BNG metric. It also sought assessment of effects on roadside nature reserves and cumulative assessment with the nearby Tasway scheme and BESS proposals.

The changes could therefore alter both the quantity of habitat affected and the reliability of the proposed biodiversity calculations.

4.3.18 Cumulative effects

The design evolution occurred within an area already subject to multiple proposed and consented energy and infrastructure schemes.

South Norfolk Council identified potential cumulative effects with:

- Tasway Energy Park;
- Norwich to Tilbury;
- consented and proposed TCPA energy schemes;
- highway infrastructure;
- and offshore-wind connection works.

It considered that overlapping construction periods could increase landscape, heritage, ecological, community and economic effects.

Norfolk County Council similarly remains concerned about cumulative effects with Tasway, Norwich to Tilbury, Hornsea Three and other solar schemes.

A changed substation, taller pylons, added panels and revised construction routes could alter the Scheme's interaction with those projects. The cumulative assessment therefore needed to be checked against the final design and updated programme.

4.3.19 Conclusion

The post-statutory-consultation changes were material to the physical description and environmental consequences of the Scheme. They included:

- selection of the Site 1B National Grid substation;
- abandonment of the southern alternative;
- relocation and upgrading of the Site 1B project substation from 132 kV to 400 kV;
- an increase from approximately 7 metres to 13 metres at targeted consultation and ultimately 15 metres in the final ES;
- up to four new pylons reaching approximately 61 metres;
- additional solar panels at Site 7D;
- additional land for grid connection works;
- additional land for AILs, visibility splays and vegetation removal;
- and changes to the construction traffic strategy.

Those changes were capable of altering landscape, heritage, noise, fire, public-health, drainage, aviation, traffic, ecology, archaeology, residential-amenity and cumulative effects.

The Applicant's general assertion that the changes did not alter likely significant effects was not a substitute for topic-specific reassessment. The targeted consultation should

have been supported by a transparent comparison showing the effects of the PEIR design against those of the revised design.

The adequacy and legal consequences of the targeted consultation are addressed in the procedural chapter. For present purposes, the important Scheme Description point is that the final application contains materially changed infrastructure whose environmental consequences must be demonstrated by reference to the final submitted envelope, not assumed to be unchanged from the PEIR.

The Applicant should be required to provide a consolidated design-evolution schedule identifying, for every material change:

- the PEIR parameter;
- the targeted-consultation parameter;
- the final application parameter;
- the affected environmental chapters;
- whether those chapters were updated;
- the mitigation added or changed;
- and the Requirement securing the final design.

Unless that audit is completed, the Examining Authority cannot safely conclude that the final development described in ES Chapter 4 has been assessed consistently across the Environmental Statement.

4.4 Solar and BESS are not aligned as one confirmed connection project

The Applicant presents East Pye Solar as an integrated solar-and-storage project. The Scheme Description includes both the solar photovoltaic generating station and a substantial Battery Energy Storage System, while the alternatives and need case rely upon the benefits of co-locating generation and storage. The BESS is described as enabling electricity generated by the solar arrays to be stored and released at times of higher demand, while also providing balancing and resilience services to the transmission system. ES Chapter 4 further states that the BESS may charge either from the solar generating station or directly from the grid. (nsip-documents.planninginspectorate.gov.uk)

The project is therefore promoted as more than a solar farm accompanied by optional ancillary equipment. Storage is relied upon as part of the Scheme's operational rationale and as a means of addressing intermittency, shifting output and supporting the electricity system. ES Chapter 5 describes co-located solar PV and BESS as the Applicant's preferred generating solution and refers to the BESS as supporting grid resilience and stability. (nsip-documents.planninginspectorate.gov.uk)

However, the connection status of the two principal components is not aligned. NGET's Relevant Representation records that the solar generating component has secured Gate 2 status, while the BESS remains at Gate 1. The application therefore combines,

within one DCO, a solar generating station whose connection position has progressed through the Gate 2 process and a storage component whose connection position has not.

That distinction is material because Gate 2 and Gate 1 do not represent the same degree of connection certainty. The solar and BESS components cannot simply be treated as sharing a common confirmed delivery status merely because they are contained within the same application, occupy adjoining land and are described as one project.

4.4.1 Physical co-location does not establish co-deliverability

East Pye is promoted as an integrated solar-plus-storage Scheme. The solar generating station and 500 MW BESS are physically co-located within one DCO and the Applicant attributes system flexibility, balancing, storage and other benefits to that combination.

The connection position is, however, divided. The solar element has progressed to Gate 2, whereas the BESS remains at Gate 1. The fact that both Works appear within the same Order Limits does not establish that they will become operational together, share the same connection timetable or deliver the benefits attributed to an integrated generation-and-storage project.

The Examination should therefore distinguish between **physical co-location** and **electrical and temporal co-deliverability**. The planning and environmental case must be tested against what the DCO permits if the solar element becomes operational substantially before the BESS, if the BESS is reduced or delayed, or if Work No. 2 never progresses to connection.

4.4.2 The BESS has no demonstrated Gate 2 route on the evidence presently available.

The BESS remains at Gate 1. No presently demonstrated project-specific route has been identified by which the East Pye BESS satisfies the June 2026 Gate 2 Strategic Alignment Criteria.

East Pye's 2026 DCO submission date means that it does not satisfy the earlier planning-submission dates associated with the principal planning-based protection routes available to projects which progressed through connections reform.

The Applicant should therefore state expressly which NESO strategic-alignment or protection criterion it relies upon for Work No. 2; whether any qualifying support or procurement arrangement is already held; whether NESO or NGET has provided any project-specific indication that the BESS is expected to obtain Gate 2; and what connection date is assumed in the environmental and benefits case.

4.4.3 The draft DCO must be tested for severability

The critical legal question is what combinations of development the draft DCO would permit.

The Applicant should be required to identify whether the Order allows:

- the solar generating station to be constructed and operated without the BESS;
- the BESS to be delayed for a substantial or indefinite period;
- only part of the BESS compound to be constructed;
- a materially reduced storage capacity;
- the BESS compound and foundations to be constructed before a connection is secured;
- battery equipment to be installed but not energised;
- the BESS to be omitted permanently;
- or the BESS to operate later under a materially different technology and capacity.

The answer cannot be inferred merely from the fact that Work No. 2 appears in Schedule 1. The Applicant must identify the commencement, phasing and dependency provisions that make construction of the BESS mandatory, optional or severable.

If Work No. 1 can be commenced and brought into operation independently of Work No. 2, the DCO is capable of authorising a solar-only scheme. If the BESS may be delayed indefinitely, the same practical result follows for an unknown part of the 60-year operating period. If only a reduced part of the BESS must be built, the benefits and effects of the assessed project may differ materially from those relied upon in the application.

4.4.4 Solar-only development

A solar-only implementation scenario is plainly realistic if the solar component has Gate 2 status and the BESS remains at Gate 1.

The Applicant must therefore explain whether the Environmental Statement and need case assess:

- solar construction without BESS construction;
- operation of the solar farm without storage;
- altered export patterns;
- reduced balancing and time-shifting benefits;
- changed use of the project substations and cables;
- changed construction traffic and land take;
- reduced fire and drainage effects at the BESS site;
- and the consequences for mitigation designed on the assumption that the BESS would be delivered.

An assessment of the full project does not automatically assess the solar-only subset. Some effects may be lower, but others may be different rather than simply reduced. The

operational profile, claimed system benefits, connection arrangements, construction sequence and justification for particular works may all change.

The Secretary of State should not be invited to place weight upon storage benefits unless delivery of the storage component is secured or the solar-only scenario is assessed transparently.

4.4.5 Delayed BESS construction

The DCO may also permit the BESS to be constructed later than the solar component.

A delayed BESS could produce:

- a separate major construction phase;
- repeated mobilisation of compounds and haul routes;
- later HGV and AIL movements;
- renewed noise and disturbance;
- further soil and ecological impacts;
- and a prolonged period during which the project operates without the storage benefits relied upon in the application.

The Applicant should identify:

- the latest permitted commencement date for Work No. 2;
- whether Work No. 2 may commence after the solar farm is operational;
- whether temporary construction compounds may be re-established;
- whether traffic limits apply separately to delayed BESS construction;
- and whether mitigation and baseline surveys must be updated before that later phase.

If no longstop applies, the Order may authorise a solar farm now and leave the BESS as an unimplemented option for a substantial part of the project life.

4.4.5A Claimed co-location benefits must be tested against timing

The benefits attributed to East Pye should be disaggregated rather than assumed to arise from one integrated project. The solar-generation benefit is available if the solar element proceeds, but BESS flexibility and balancing benefits depend upon the storage component obtaining a connection and becoming operational. Claimed co-location benefits require both elements to operate on compatible timescales. Any claimed reduction in curtailment likewise requires evidence that the BESS will actually be connected when needed and is capable of operating in the manner assumed.

The Applicant should therefore assess at least the following reasonable implementation cases:

- solar and BESS commissioning contemporaneously;
- solar operating materially before the BESS;
- materially delayed BESS;

- reduced-capacity or differently configured BESS; and
- solar operating for all or a substantial part of its life without Work No. 2.

For each case the Applicant should identify which benefits remain, which are deferred or disappear, whether the electrical architecture changes and whether the EIA remains within the assessed envelope.

4.4.6 Partial or reduced BESS

The application does not clearly define the minimum storage capacity that must be delivered.

The Applicant should therefore explain whether it could construct:

- only part of the BESS compound;
- fewer enclosures than assumed in the environmental assessment;
- a lower MW capacity;
- a shorter-duration system;
- fewer transformers and inverters;
- or only sufficient equipment to preserve the appearance of compliance with Work No. 2.

A materially reduced BESS could affect:

- the scale of claimed grid-support benefits;
- the extent to which solar output can be time-shifted;
- the operational justification for grid charging;
- construction and replacement traffic;
- drainage and firewater requirements;
- noise;
- and the economic relationship between the solar and storage components.

The Applicant should state whether any minimum BESS capacity is secured and, if not, why the decision-maker should treat the project as a 500 MW-class solar-and-storage scheme rather than a solar scheme accompanied by an undefined optional storage facility.

4.4.7 Different battery technology at initial construction or replacement

The Scheme retains flexibility over battery technology and anticipates that the BESS may be replaced up to five times over the 60-year operating period. (nsip-documents.planninginspectorate.gov.uk)

That creates two related uncertainties.

First, the initial BESS may use a chemistry or enclosure type not specifically identified in the application. Secondly, later replacement cycles may introduce materially different technology.

A different battery system may alter:

- energy density;
- thermal-runaway behaviour;
- firewater demand;
- toxic emissions;
- spacing requirements;
- cooling plant;
- operational noise;
- transformer and inverter requirements;
- equipment weight;
- drainage;
- waste classification;
- and emergency-response procedures.

The Applicant should therefore identify the technology envelope actually assessed and the limits applying to replacement equipment.

A general requirement that replacement equipment should have effects 'no worse than' those assessed is insufficient unless the DCO also identifies the measurable standards against which that judgment will be made. Those standards should include, at minimum:

- maximum stored energy;
- fire propagation characteristics;
- maximum sound-power level;
- maximum heat rejection;
- pollutant inventory;
- maximum enclosure dimensions;
- firewater requirement;
- and maximum traffic and AIL demand.

4.4.8 Construction of BESS infrastructure without a confirmed connection

The DCO may permit the Applicant to construct the BESS compound, foundations, drainage, fencing, access and project-substation infrastructure before the BESS has a confirmed Gate 2 connection position.

That creates the possibility of substantial infrastructure being built but never used for its intended purpose.

The Applicant should explain:

- whether commencement of Work No. 2 is conditional upon an accepted Gate 2 offer or equivalent connection entitlement;
- whether construction may proceed while the BESS remains Gate 1;
- whether the project substation can be oversized for a BESS that is never connected;
- whether land may be compulsorily acquired for unconfirmed BESS works;
- and what restoration obligations would apply if the connection is not obtained.

The need for this control is strengthened by the Applicant's own description of the BESS as capable of charging directly from the grid. The BESS is therefore not merely passive equipment ancillary to the solar arrays. It requires a defined import and export entitlement and an operational relationship with the transmission system.

4.4.9 Environmental consequences of the connection mismatch

The difference in connection status affects several parts of the Environmental Statement.

Construction and phasing

If the BESS is delayed, the assessed 24-month construction programme may not represent the full construction period. A later BESS phase may create a second programme of:

- piling;
- concrete works;
- equipment deliveries;
- cable installation;
- commissioning;
- and traffic.

Transport and AILs

BESS transformers, containers and auxiliary plant may require substantial HGV and AIL movements. If delivery occurs later, the route, highway condition, cumulative-project context and receptor baseline may differ from those assessed.

Noise

The operational noise assessment depends on the number, type and location of:

- battery cooling units;
- inverters;
- transformers;
- and auxiliary plant.

A reduced, delayed or technologically different BESS may not correspond with the assessed source inventory.

Fire and major accidents

Firewater containment, emergency access and plume assumptions depend on:

- chemistry;
- enclosure number;
- stored energy;

- spacing;
- and fire-suppression design.

Those parameters cannot be treated as immaterial to connection status because a later Gate 2 offer may relate to a materially different capacity or technology.

Drainage and water environment

The BESS compound, hardstanding, foundations and firewater systems are a substantial part of the drainage design. Partial or delayed implementation raises questions about whether temporary or permanent drainage would be constructed in advance and whether it would remain unused.

Landscape and land use

If the BESS is omitted but the compound, substation or access remains, the development may produce environmental harm without delivering the storage benefits relied upon to justify it.

Need and benefits

If the project operates as solar-only development, the claimed benefits associated with:

- time-shifting generation;
- reducing curtailment;
- grid balancing;
- system resilience;
- and dispatchability

may be reduced or absent.

4.4.10 The planning balance must not assume benefits which are not demonstrated as deliverable

The Applicant's alternatives and Scheme Description documents treat co-located storage as a positive and integral feature. The decision-maker may therefore be invited to give weight to the ability of the BESS to store renewable generation, release it at times of demand and support the grid.

Those benefits should be treated with caution unless the Applicant demonstrates:

1. that the BESS has a deliverable connection route;
2. that the DCO secures its construction;
3. that a minimum storage capacity and duration are fixed;
4. that it will be available within a defined period;
5. and that the assessed BESS is the BESS capable of obtaining connection.

Otherwise, there is a mismatch between the project whose benefits are advanced and the development the Order may actually deliver.

The Secretary of State should not assess the benefits of a fully integrated solar-and-storage project while granting an Order capable of delivering a materially different solar-only scheme without expressly examining that scenario.

4.4.11 Required works-severability schedule

The Applicant should provide a works-severability schedule setting out, for every principal Work No.:

Matter	Required information
Independent commencement	Whether the Work may commence without the other principal components
Independent operation	Whether the Work may operate independently
Dependency	Which other Work Nos. are legally and technically required
Connection status	Gate status and connection entitlement
Longstop	Latest date by which the Work must be commenced or completed
Minimum implementation	Minimum capacity or physical extent required
Omission	Whether the Work may be omitted permanently
Consequences	Effect of omission on need, benefits, mitigation and compulsory acquisition

The schedule should address Work No. 1, Work No. 2, Work Nos. 3A and 3B, Work No. 4 and Work No. 6 in particular.

Associated-development relationship

Materially asynchronous implementation also bears upon the Applicant's case that the BESS constitutes associated development to the solar NSIP. The fact that Work No. 2 is physically close to the generating station does not by itself answer the functional question. If the solar generating station can be constructed and operated for a material period without the BESS, the Applicant should explain the operational relationship which nevertheless justifies consenting the whole 500 MW BESS as associated development to this NSIP.

BEPS does not contend that asynchronous commissioning necessarily prevents the BESS from constituting associated development. The point is that the functional

relationship relied upon should be demonstrated rather than assumed from common ownership, proximity or shared infrastructure.

4.4.12 Required connection-status schedule

The Applicant should also provide a connection-status schedule identifying:

- the Gate status of the solar component;
- the Gate status of the BESS;
- the capacity assigned to each;
- the relevant connection agreement or offer;
- whether import and export are both authorised;
- the connection date;
- conditions precedent;
- works required from the Applicant;
- works required from NGET;
- and the consequences if the BESS does not progress to Gate 2.

This should be supported by the relevant connection documents, subject only to justified redaction of commercially sensitive material.

4.4.13 Required technical and legal confirmation

The Applicant should confirm expressly:

1. whether the solar farm may lawfully operate without the BESS;
2. whether the BESS may lawfully charge from the grid under the present connection arrangements;
3. whether the BESS may export independently of contemporaneous solar generation;
4. whether the present connection rights include the BESS capacity assumed in the application;
5. whether Work No. 2 may commence while the BESS remains Gate 1;
6. whether the BESS is subject to a separate future connection application;
7. and whether any material change to BESS capacity or technology would require further consent.

The Applicant should also identify which claimed benefits remain if:

- the BESS is not constructed;
- the BESS is delayed;
- the BESS is materially reduced;
- or the BESS receives no connection entitlement.

4.4.14 Required DCO controls

Unless the Applicant demonstrates that the solar and BESS components form one confirmed and deliverable connection project, the DCO should include controls providing that:

- Work No. 2 may not commence until the BESS has a confirmed connection entitlement;
- the maximum and minimum MW and MWh capacity are fixed;
- the permitted battery technology envelope is defined;
- grid charging and independent operation are expressly controlled;
- delayed BESS construction is subject to updated environmental surveys and management plans;
- replacement technology must remain within measurable fire, noise, pollution and traffic limits;
- land and compulsory powers relating solely to the BESS may not be exercised unless its delivery is confirmed;
- and solar-only implementation is either prohibited or expressly assessed and controlled.

4.4.15 Conclusion

The application presents East Pye Solar as an integrated solar-and-storage project and relies upon the operational and system benefits of co-located BESS. Yet NGET's Relevant Representation indicates that the solar component has Gate 2 status while the BESS remains Gate 1. The two principal components therefore do not presently share the same connection certainty.

The draft DCO must be examined to determine whether it permits:

- solar without BESS;
- delayed BESS;
- partial BESS;
- materially reduced storage;
- construction of unconnected BESS infrastructure;
- replacement by materially different technology;
- or permanent non-delivery of the storage component.

Each is a realistic implementation scenario requiring explicit assessment.

An environmental assessment of the full solar-and-storage Scheme does not automatically assess a solar-only development or a project in which storage is delayed for years. Nor should the need case receive the benefits of storage unless delivery of a defined storage component is secured.

The Applicant should therefore provide a complete works-severability schedule, a connection-status schedule, confirmation of the legal and technical operating relationship between the solar farm and BESS, and a transparent account of which benefits survive if the BESS is not delivered.

The decision-maker should not assess the benefits of a fully integrated solar-and-storage project while granting an Order capable of delivering a materially different solar-only scheme without expressly examining and controlling that outcome.

4.5 The proposed National Grid substation is not a confirmed connection solution

The proposed National Grid substation at Site 1B is one of the largest, most permanent and most consequential components of East Pye Solar. The application seeks development consent and compulsory powers for a specific transmission connection solution comprising a new National Grid substation, extensive associated works, modification and diversion of the existing 400 kV overhead transmission line and up to four new pylons.

The Scheme Description treats that infrastructure as integral to East Pye. The fourteen Cable Route Corridors are designed to converge upon Site 1B; Work No. 4 authorises works in connection with the National Grid substation; and Work No. 5 authorises the associated transmission-line works. The alternatives assessment similarly proceeds on the basis that a new substation adjacent to the existing Bramford–Norwich 400 kV line is required.

That apparent certainty is not reflected in NGET's own Relevant Representation.

NGET does not merely reserve detailed engineering choices. Its evidence indicates that the final size, design and location of the point-of-connection solution remain subject to the wider connections-reform process, other Gate 2 projects, technical network requirements and unresolved commercial arrangements. Most significantly, NGET states that obtaining DCO consent for the proposed Site 1B substation would not oblige NGET to accommodate East Pye Solar through that substation.

The application therefore seeks consent, land and compulsory powers for a substantial and potentially permanent item of transmission infrastructure before the prospective network owner and operator has confirmed that the authorised solution will be required or used.

4.5.1 The infrastructure for which consent is sought

The scale of the proposed works is material to that uncertainty.

The application authorises a National Grid substation compound of up to approximately six hectares, with access, drainage, landscaping, biodiversity works and temporary construction areas. Foundations may extend to approximately 12 metres below ground, electrical structures and busbars may reach approximately 15 metres in height, and the associated overhead-line works may require up to four new pylons reaching approximately 61 metres.

Works Nos. 4 and 5 also permit modification, realignment, dismantling and reconstruction of existing transmission infrastructure.

These are not incidental connection works. They are major transmission assets with their own permanent land take, landscape and visual effects, drainage requirements, foundations, access, construction traffic, aviation implications, ecological effects and compulsory-acquisition consequences. The Applicant also accepts that the National Grid substation and Grid Connection Infrastructure may remain after the 60-year solar generating station has been decommissioned.

The distinction between temporary generating infrastructure and potentially permanent transmission infrastructure therefore requires particular scrutiny. A permanent network asset should not be authorised simply because it is presently convenient to the connection strategy of a temporary generating project. Its enduring necessity must itself be demonstrated.

4.5.2 NGET has not confirmed that Site 1B is the final solution

The Applicant's environmental and alternatives cases proceed from the premise that Site 1B is the selected connection solution. NGET's evidence materially qualifies that premise.

NGET states that the final solution remains dependent upon wider regulatory, commercial and network considerations and may be affected by other projects seeking connection in the same part of the transmission system. Those considerations may alter the size, number of bays, electrical configuration, layout, location and associated transmission works ultimately required.

The distinction is therefore not between an indicative and a detailed version of the same substation. It is between the specific Site 1B solution assessed in this application and the transmission solution which NGET may ultimately determine is appropriate.

That distinction is reinforced by the anticipated replacement connection agreement. The Applicant's site-selection case appears to have proceeded on the basis that its existing connection arrangements required it to identify the substation site, provide the necessary land and secure consent. NGET now indicates that the replacement agreement is not expected to require the Applicant to secure the land or consent for the National Grid substation.

That is a material change in the premise upon which Site 1B was selected and upon which compulsory powers are sought.

The Applicant should therefore explain precisely what obligations remain under the existing agreement, what will change under the replacement agreement, who will become responsible for securing the transmission land and consent, and why Works Nos. 4 and 5 remain necessary components of this DCO if that original contractual obligation is removed.

Most importantly, NGET states that DCO consent for the proposed substation:

“does not trigger or constitute any obligation for NGET to accommodate any connection to the national grid at such a substation.”

That statement has direct consequences for the Examination. Consent would provide legal authority for the infrastructure but would not secure NGET’s commitment to construct, adopt, operate or use it.

The ExA should therefore distinguish clearly between an authorised connection option and a confirmed connection solution.

4.5.3 Strategic network planning and North Anglia Node A

The strategic efficiency of constructing a new project-specific National Grid substation on the existing 400 kV transmission line also requires examination in the context of the emerging transmission network in South Norfolk.

The proposed Norwich–Tilbury reinforcement includes North Anglia Node A, and multiple generation and storage projects are identified in the transmission connection pipeline as connecting at that future node. North Anglia Node A therefore appears to be developing as a strategic multi-user connection point associated with the new transmission network.

That emerging network architecture raises an obvious question about the long-term role of Site 1B.

East Pye is promoted as a 60-year solar generating project, whereas the National Grid infrastructure authorised by the DCO may remain permanently. At broadly the same time, National Grid is progressing a separate strategic transmission reinforcement through South Norfolk incorporating a further 400 kV connection node intended to accommodate multiple projects.

BEPS does not suggest that the existence of North Anglia Node A proves that Site 1B is technically unnecessary. Different substations may serve different electrical functions and connection dates. The point is that the strategic alternative now exists and must be addressed.

The Applicant and NGET should therefore explain whether connection through North Anglia Node A, or another part of the future Norwich–Tilbury network, was considered for East Pye; whether such an option is technically possible; what programme, network-security or cost factors rule it out; and why constructing a further permanent National Grid substation on the existing transmission line remains the most economic and efficient long-term network solution.

That question assumes greater importance because NGET has not yet confirmed Site 1B as the final point of connection. The ExA should not be invited to authorise permanent project-specific transmission infrastructure without understanding its

relationship to the strategic network that is simultaneously being developed in the same part of South Norfolk.

4.5.4 Consequences for Scheme definition and deliverability

The uncertainty over the connection solution affects the identity of the authorised development.

On the Applicant's case, Works Nos. 4 and 5 appear essential. All fourteen Cable Route Corridors are directed towards Site 1B and the generating station requires a transmission connection. Yet NGET's position suggests that Site 1B may represent one possible solution rather than the finally determined one.

The Applicant should therefore state unequivocally whether Works Nos. 4 and 5 are mandatory components of East Pye or severable connection options.

If they are essential, there must be sufficient confidence before consent that they can and will be delivered.

If they are optional, the Applicant must identify the alternative means by which the generating station could operate, demonstrate that those alternatives have been environmentally assessed and explain how the DCO prevents partial implementation from producing a materially different project.

The same issue arises in relation to sequencing. The DCO should not permit extensive solar, cable or transmission works to proceed on the assumption of a connection solution which NGET subsequently changes.

The Applicant should therefore explain whether the solar generating sites may be substantially constructed before the final point of connection is confirmed; whether Cable Route Corridors may be installed before NGET has committed to Site 1B; whether overhead-line works may begin before the transmission solution has been approved; and what happens if the connection solution changes after those works have been undertaken.

Without appropriate hold points, the DCO could permit substantial stranded infrastructure: cables, foundations, access roads, pylon works or even the substation itself could be constructed without ultimately forming part of the operational network solution.

That is not merely a commercial risk. It creates potential environmental harm without the public benefit relied upon to justify that harm.

ISH1 has since sharpened these issues through specific action points. The ExA required the Applicant to explain:

- the proposed National Grid substation's capacity and whether it may accommodate other projects;
- the certainty and timing of its delivery as East Pye's point of connection and how that timing would be secured;
- whether future third-party use may create additional cumulative or downstream consequences;
- and to provide an indicative drawing of the substation.

Those questions materially reinforce BEPS's existing objection. The National Grid substation cannot presently be treated simply as a fixed East Pye component whose need, scale, timing and wider network consequences are already exhausted by the ES. The final role of the infrastructure within the wider network is itself now an examination issue.

4.5.5 The assessed envelope cannot accommodate an unknown transmission solution

The Applicant must also demonstrate that the transmission infrastructure ultimately required by NGET will remain within the environmental envelope examined.

The ES presently assesses a defined connection geography: the Site 1B substation, the Cable Route Corridors converging upon it and the associated overhead-line modifications. The maximum parameters include the six-hectare substation area, structures of approximately 15 metres, deep foundations, an eight-metre access track and up to four new pylons reaching approximately 61 metres.

The Applicant should first demonstrate that those maxima were used consistently across landscape, heritage, aviation, transport, ecology, drainage, groundwater, noise and construction assessments. This is particularly important because earlier consultation material referred to a materially smaller substation footprint.

More fundamentally, however, that assessment does not appear to encompass a materially different NGET solution.

If the connections-reform process or other Gate 2 projects require a larger substation, additional bays, further pylons, a different line-entry arrangement or a different geographical location, the resulting effects may differ materially. Those changes could alter landscape and heritage effects, aviation risk, flood and drainage requirements, construction traffic, abnormal-load routes, ecology, land take and compulsory-acquisition requirements.

The Applicant should therefore identify the legal and environmental consequence if the final NGET solution falls outside Works Nos. 4 and 5 or exceeds the assessed parameters. It cannot be assumed that such a change would constitute ordinary detailed design.

Nor should reasonably foreseeable future transmission infrastructure be fragmented from the environmental assessment. If further network works are likely to be required in order for East Pye to operate, the Applicant should identify those works, their likely consent route and programme, and demonstrate that their cumulative effects have been considered.

If the substation is capable of functioning as infrastructure for other projects, the Applicant should distinguish the effects attributable to East Pye from the environmental and land consequences of creating infrastructure with a wider future network role. Conversely, if it is solely required for East Pye, the Applicant and NGET should explain how its delivery is sufficiently certain to support the connection and compulsory-acquisition case.

4.5.6 Compulsory acquisition cannot precede confirmed necessity

The uncertainty over Site 1B is particularly important because the Applicant seeks compulsory powers over land required for the proposed National Grid substation, its access, construction areas, landscaping, drainage, cable interfaces and overhead-line works.

Section 122 requires a compelling case in the public interest for compulsory acquisition. That necessarily requires the Applicant to demonstrate that the land and interest sought are genuinely required for the development authorised.

NGET's evidence weakens that case in three respects.

First, the final location and configuration of the connection solution have not been confirmed.

Secondly, the replacement connection agreement is not expected to require East Pye to secure the substation land or consent.

Thirdly, NGET expressly states that the existence of DCO consent would not oblige it to use the Site 1B substation.

The Applicant must therefore establish afresh why East Pye Solar Limited requires compulsory powers over this particular land.

It should explain whether NGET actually requires East Pye to acquire the land; whether NGET would instead obtain its own interests; whether rights rather than freehold ownership would suffice; whether East Pye would acquire land only to transfer it to NGET; and what happens to the land and powers if Site 1B is not ultimately selected.

Preserving a possible future transmission option is not equivalent to demonstrating that compulsory acquisition is presently necessary.

The DCO should therefore prevent the exercise of compulsory powers for Site 1B until NGET has confirmed in writing that the relevant land and infrastructure are required for the final connection solution. Any land or rights rendered unnecessary by a different solution should cease to be subject to the corresponding powers.

4.5.7 Responsibility, ownership and enforceability

The division of responsibility between the Applicant and NGET also remains insufficiently clear.

The DCO seeks consent for works which NGET may ultimately design, construct, own and operate. The Examination therefore needs to understand who is responsible at each stage for the land, civil engineering, electrical equipment, pylon and overhead-line works, drainage, environmental management, testing, commissioning, operation, maintenance and eventual permanent retention or decommissioning.

This matters because a Requirement imposed upon the Applicant is of limited value if the relevant asset is subsequently transferred to NGET without equivalent continuing obligations.

The position should therefore be recorded in a joint responsibility and ownership matrix identifying, for each material component of Works Nos. 4 and 5:

the design authority; landowner or rights-holder; construction party; operator; body responsible for environmental compliance; body responsible for drainage, access, landscaping and biodiversity measures; emergency responsibility; and long-term responsibility following East Pye's decommissioning.

The DCO should ensure that every relevant environmental obligation transfers with the infrastructure or otherwise continues to bind the body controlling it.

This is particularly important because the transmission infrastructure may remain after the generating station has ceased operating. The application must therefore distinguish clearly between East Pye's restoration obligations and the continuing environmental obligations associated with infrastructure retained permanently by NGET.

4.5.8 Information required during Examination

The remaining uncertainty can be addressed efficiently if the Applicant and NGET provide a consolidated evidential response rather than further isolated statements.

BEPS submits that the ExA should require sufficient information to establish:

- the material terms of the existing connection agreement and proposed replacement agreement insofar as they concern land, consent and delivery responsibility;

- the present Gate 2 position of the solar generating element and the separate Gate status of the BESS;
- the current preferred point of connection;
- whether Site 1B remains NGET's preferred location;
- whether the six-hectare and four-pylon envelope represents the full presently anticipated requirement;
- whether other Gate 2 projects may alter the solution;
- the relationship between Site 1B and North Anglia Node A/the Norwich–Tilbury reinforcement;
- the respective responsibilities of East Pye and NGET;
- the current programme for finalising the connection solution;
- and the point at which NGET expects to be able to confirm the size, location and configuration finally required.

Commercially sensitive pricing does not need to be disclosed. What matters is the factual and contractual basis upon which development consent and compulsory powers are sought.

4.5.9 DCO controls required

Unless the connection solution is finally confirmed during Examination, the Order should contain safeguards preventing uncertainty from being transferred into the post-consent period.

At minimum, commencement of the National Grid substation and associated overhead-line works should be prohibited until NGET has confirmed the final connection solution in writing. Compulsory powers over the Site 1B land should not be exercisable until NGET confirms that the land is required. Cable infrastructure whose sole purpose is to serve Site 1B should not be compulsory purchased or constructed before the connection point is fixed.

Any final NGET design must remain within the environmental parameters assessed. A materially different location, footprint, pylon requirement or transmission configuration should require the appropriate further consent rather than being treated as detailed design.

The Order should also secure the allocation of ownership and environmental responsibility, ensure that permanent drainage, landscape and other mitigation obligations bind the future owner or operator, and require restoration of any connection works commenced but subsequently rendered redundant.

Most fundamentally, the generating station should not be commissioned unless a lawful and technically deliverable transmission connection has been secured.

4.5.10 Conclusion

The application presents the Site 1B National Grid substation as an essential and geographically defined component of East Pye Solar. It seeks consent and compulsory powers for a substantial six-hectare transmission site, deep foundations, associated access and drainage, overhead-line modification and up to four new pylons reaching approximately 61 metres.

NGET's own evidence demonstrates that the position is materially less settled. The final size, design and location of the point-of-connection solution remain subject to wider regulatory, commercial and technical decisions. Other Gate 2 projects may influence the required infrastructure. The proposed replacement connection agreement is not expected to retain the Applicant's existing obligation to secure the substation land or consent. Most importantly, NGET expressly states that DCO consent for Site 1B would not oblige it to accommodate East Pye through that substation.

The emergence of North Anglia Node A on the proposed Norwich–Tilbury reinforcement further strengthens the need to examine the long-term strategic justification for constructing a separate permanent National Grid substation on the existing transmission line for a generating project promoted as temporary.

The resulting uncertainty affects more than grid engineering. It goes directly to the definition and deliverability of the Scheme, the adequacy of the environmental assessment, the proportionality of compulsory acquisition, construction sequencing, stranded-infrastructure risk, ownership, environmental enforcement and the long-term justification for infrastructure which may remain after East Pye itself has been decommissioned.

The correct sequence is therefore important. The final transmission solution should determine the land, infrastructure and powers required. The DCO should not authorise the widest connection solution and compulsory powers first, leaving NGET to determine afterwards whether that infrastructure is actually needed.

Unless the Applicant and NGET can demonstrate during Examination that Site 1B forms a sufficiently defined and deliverable connection solution, the associated development and compulsory powers should be narrowed and made subject to binding hold points which prevent construction or acquisition before that necessity has been established.

4.6 The change from a 132 kV to a 400 kV project substation

The change to the project substation at Site 1B remains a material alteration to the Scheme, but the distinction between the project substation and the adjacent National Grid substation must be stated accurately. The infrastructure presented during statutory consultation was a 132 kV project substation with a materially smaller scale. The targeted consultation subsequently confirmed relocation and upgrade to a 400 kV project substation. The relevant maximum project-substation busbar height is

approximately 13 metres; the separate 15-metre busbar parameter applies to the National Grid substation.

ISH1 has since exposed uncertainty within the Applicant's own presentation of those parameters, and the ExA required correction of the relevant ES table. That correction matters because two adjacent but legally and operationally distinct 400 kV installations must not be conflated when assessing their landscape, heritage, aviation, drainage, noise and cumulative effects.

The design evolution was therefore not simply a move from one nominal voltage designation to another. The position progressed from a smaller 132 kV installation, described at consultation as approximately 7 metres high, to the 400 kV project substation now proposed with an approximately 13-metre maximum busbar height, alongside the separate National Grid substation for which the maximum busbar height is 15 metres.

4.6.1 Comparison of the consulted and applied-for designs

Parameter	Statutory consultation	Targeted consultation and final application	Assessment updated?
Voltage	132 kV project substation	Upgraded to 400 kV	The Applicant must identify every ES chapter amended to reflect the voltage change
Location	Earlier 132 kV position within or near Site 1B	Relocated eastwards within Site 1B	A location-specific audit is required for all nearby receptors
Maximum height	Approximately 7 m	Approximately 13 m in the targeted consultation; 15 m in final ES Chapter 4	It is not demonstrated that every final assessment used the 15 m envelope
Maximum compound area	No directly comparable final parameter identified in the targeted change note	Final ES permits up to 1.1 ha	The Applicant must show that the final footprint, not the earlier design, was assessed
Transformer number	Not clearly fixed	Not clearly fixed	Not demonstrated; maximum transformer number must be stated

Transformer dimensions and rating	Based on a 132 kV installation	400 kV equipment required	Not demonstrated through a consolidated before-and-after schedule
Transformer oil inventory	Not stated	Not stated	No clear maximum oil inventory identified
Busbars and switchgear	Lower-voltage substation configuration	400 kV busbars up to 15 m and associated switchgear	Must be checked against final landscape, noise and major-accident assumptions
Control and switch-room buildings	Earlier design not clearly quantified in the targeted material	Relay/control room and 33 kV switch room each up to 7 m × 19 m × 4.2 m	Applicant must confirm inclusion in all relevant assessments
Foundations	Earlier foundation envelope not clearly reconciled	Concrete base or plinth up to 1 m, or piling up to 12 m	Groundwater and piling assessments must be shown to use the final foundation case
Hardstanding	Smaller 132 kV design presumed	Larger 400 kV installation and access infrastructure	Maximum impermeable area is not consolidated
Drainage area	Based on earlier footprint	Must accommodate the 1.1 ha compound, hardstanding, access and oil containment	LLFA concerns indicate that adequate space and calculation were not demonstrated at targeted consultation
Operational noise sources	132 kV transformer and switchgear assumptions	400 kV transformers, switchgear and auxiliary equipment	South Norfolk Council expressly required an updated noise assessment
Lighting	Earlier substation design	Larger and taller operational compound with safety, security and maintenance lighting	Maximum lighting design and revised effects are not clearly compared
Fire and oil containment	Earlier voltage and equipment arrangement	Potentially larger transformers and oil inventory	Maximum inventory and containment volume remain unclear

Firewater containment	Not clearly defined	Must reflect final equipment and worst-case incident	No clear final design parameter identified
AIL requirements	Smaller 132 kV equipment assumptions	Larger 400 kV transformers and associated equipment	Final equipment weights, routes and delivery requirements must be stated
Construction plant and duration	Earlier design assumptions	Potential for greater piling, concrete, crane and AIL requirements	No transparent comparison has been provided
Landscape mitigation	Designed around smaller structure	Must mitigate a 15 m structure within a 1.1 ha compound	Applicant must show that mitigation was redesigned for the final envelope
Heritage assessment	Earlier 132 kV structure	Larger and taller development closer to Great Moulton assets	South Norfolk Council stated that updated heritage information was needed
Aviation assessment	Earlier lower structure	15 m substation and associated 61 m pylon infrastructure	Applicant must demonstrate assessment of the final combined vertical envelope

The absence of information in a cell is itself material. Where the Applicant has not stated the maximum transformer number, oil inventory, hardstanding area, firewater volume or source sound-power level, it is not possible to confirm that the final 400 kV installation falls within a complete environmental envelope.

4.6.2 The voltage change altered the physical project

The Applicant's final parameters demonstrate why the change cannot be dismissed as an internal electrical-design matter. The 400 kV project substation may include a compound of up to 1.1 hectares, busbars reaching approximately 13 metres, buildings, switch rooms, access, fencing and major foundations.

A 400 kV installation may require materially different:

- transformers;
- busbars and switchgear;
- electrical clearances;
- gantries;

- protection and control equipment;
- foundations;
- access for maintenance and replacement;
- oil containment;
- drainage;
- lighting;
- and abnormal-load delivery arrangements.

The relevant environmental question is therefore not simply whether both designs are described as ‘substations’. It is whether the final design has a greater physical, operational or risk envelope than the design on which earlier consultation and assessment were based.

4.6.3 The project and National Grid substation parameters must be kept distinct

The application contains two materially different 400 kV infrastructure components at Site 1B: the Applicant’s project substation and the National Grid substation. The project-substation parameter is approximately 13 metres to the top of the busbars, whereas the National Grid substation may reach 15 metres. The ExA has required the Applicant to correct the application material so that those parameters are presented consistently.

The distinction must be carried through every environmental assessment and visualisation. The Applicant should identify which height, footprint and layout were used for each structure in the LVIA, heritage assessment, aviation work, noise assessment and cumulative assessment, and confirm that the two adjacent compounds were assessed simultaneously in their respective reasonable worst-case forms.

The material design change remains significant even at 13 metres. The relevant comparison is between the smaller 132 kV installation consulted upon and the substantially larger 400 kV project substation now proposed, together with the adjacent 15-metre National Grid infrastructure. The environmental issue is therefore one of scale, massing and cumulative electrical infrastructure, not an incorrectly stated two-metre increase in the project-substation busbar height.

4.6.4 Landscape and visual effects

Norfolk County Council considered that the move from a 132 kV to a 400 kV substation would result in a more visible structure and that the footprint appeared significantly larger. It raised concerns about effects on Great Moulton and the surrounding countryside and requested clarification of the final scale and mitigation.

The final assessment should therefore demonstrate that it used:

- the full 1.1-hectare compound;

- the 15-metre busbars;
- all control and switch-room buildings;
- fencing;
- access;
- lighting;
- maximum transformer and switchgear massing;
- and the combined effects of the adjacent National Grid infrastructure.

The issue is cumulative even within Site 1B. The project substation would not be perceived in isolation from the six-hectare National Grid substation, BESS, overhead-line diversion and pylons.

4.6.5 Heritage effects

South Norfolk Council's heritage evidence identified concern that the upgraded substation would be larger and taller and that its final massing had not been explained. The Council considered that it could be visible and intrusive in the settings of designated heritage assets around Great Moulton and Moulton Farmhouse and stated that more detail and assessment were required.

The final heritage assessment must therefore identify:

- the assets from which the substation may be experienced;
- whether the 15-metre maximum is visible;
- the extent to which the larger compound changes the rural backdrop;
- effects of lighting and moving maintenance activity;
- and the combined effect with the National Grid substation and pylons.

A heritage assessment derived from the earlier 132 kV or 13-metre design would not assess the final application envelope.

4.6.6 Operational noise

South Norfolk Council's Environmental Management Officer stated that confirmation of the BESS and substation locations required the noise assessment to be updated. The officer considered that the BESS and substation could materially affect amenity and potentially amount to statutory nuisance unless substantial mitigation were secured.

The noise assessment must identify the final 400 kV source inventory, including:

- the maximum number of transformers;
- transformer sound-power levels;
- tonal corrections;
- switchgear;
- cooling systems;
- auxiliary equipment;
- control-building ventilation;
- emergency equipment;
- and simultaneous operation with the BESS and National Grid substation.

The application should not rely on generic substation data or equipment information derived from the former 132 kV design. The DCO should secure a receptor-based noise limit and require replacement plant to perform no worse than the equipment assessed.

4.6.7 Air quality and construction emissions

A larger substation may require more:

- excavation;
- piling;
- concrete;
- aggregate;
- crane activity;
- HGV deliveries;
- and abnormal loads.

South Norfolk Council stated that additional air-quality information was required following confirmation of the revised BESS and substation design. The Applicant should identify whether construction dust, plant emissions and traffic modelling were recalculated using the final 400 kV design and its delivery requirements.

4.6.8 Fire, oil and major-accident consequences

A 400 kV transformer compound may contain a larger transformer and oil inventory than the earlier 132 kV design. Yet the final Scheme Description does not provide a consolidated maximum transformer number or oil inventory for the Site 1B project substation.

That prevents clear identification of the worst case for:

- transformer fire;
- oil release;
- contaminated firewater;
- smoke generation;
- separation distances;
- emergency access;
- and pollution containment.

The Applicant should provide the maximum:

- transformer number;
- oil volume per transformer;
- total oil inventory;
- firewater demand;
- bund and containment volume;
- and credible accident scenario.

The fire and major-accident assessment must then demonstrate that it is based on those maxima.

4.6.9 Drainage and impermeable area

Norfolk County Council's LLFA stated that the enlarged project substation and the National Grid substation would create substantial impermeable areas requiring surface-water management. At targeted consultation, it found insufficient information to determine whether adequate space had been reserved for attenuation or whether existing surface-water storage would be displaced.

The final application identifies a compound area of 1.1 hectares but does not, in the Scheme Description, provide a complete breakdown of:

- impermeable hardstanding;
- permeable aggregate;
- building roofs;
- transformer bases;
- access;
- bunds;
- attenuation;
- firewater storage;
- and exceedance routes.

The Applicant should provide a final drainage-area schedule for the 400 kV design and demonstrate that the land required for SuDS and contaminated-water containment lies within the authorised and controlled compound.

4.6.10 Groundwater and foundation effects

ES Chapter 4 permits a concrete base or plinth up to one metre deep or piles to a maximum depth of 12 metres for major project-substation infrastructure.

The final groundwater and ground-conditions assessment should therefore consider:

- the maximum number and diameter of 12-metre piles;
- concrete volume;
- interaction with aquifers;
- preferential pathways;
- piling fluids or grouts;
- contaminated runoff;
- and cumulative effects with the adjacent BESS and National Grid foundations.

A generic statement that piling will be subject to later risk assessment does not demonstrate that the final 400 kV worst case has been assessed. The need for a consolidated foundation envelope is reinforced by Revision 2 of the draft DCO, which preserves additional flexibility in foundation and piling technology elsewhere within the Scheme, including the BESS.

4.6.11 Aviation consequences

The project substation forms part of the enlarged Site 1B electrical complex near Tibenham Aerodrome. The final aviation assessment should consider the combined maximum envelope of:

- a 13-metre project substation;
- a 15-metre National Grid substation;
- up to four 61-metre pylons;
- lighting;
- solar arrays;
- and associated cranes during construction and replacement.

The question is not whether a 15-metre substation alone would necessarily breach a formal safeguarded surface. It is whether the Applicant's aviation assessment used the actual final layout and considered pilot visibility, emergency operations and the cumulative concentration of infrastructure beneath or near relevant flight paths.

4.6.12 Construction traffic and abnormal loads

The change to 400 kV may alter the dimensions and weights of transformers, switchgear and ancillary equipment. It may therefore affect:

- the number of AIL deliveries;
- trailer length and width;
- bridge and junction requirements;
- crane capacity;
- access-track design;
- and local highway alterations.

The local and strategic AIL routes were not agreed at the time of the targeted consultation and remained the subject of objection by Norfolk County Council and National Highways. The Applicant should provide a component-specific delivery schedule for the Site 1B project substation and demonstrate that the final 400 kV equipment can be delivered through the assessed route.

4.6.13 Audit required of the final Environmental Statement

The Applicant should provide a topic-by-topic audit showing whether the final ES assessed the 400 kV Site 1B project substation using the following parameters:

Topic	**Final parameter that must be demonstrated**
Landscape and visual	1.1 ha compound, 15 m busbars, full buildings, fencing and lighting
Heritage	Final massing and combined effect with National Grid infrastructure

Noise	Maximum transformer, switchgear, ventilation and auxiliary source inventory
Air quality	Construction plant, HGV and AIL requirements for the final design
Major accidents	Maximum transformer number, oil inventory and fire scenario
Drainage	Maximum impermeable area, attenuation and firewater containment
Groundwater	Maximum 12 m piling and foundation footprint
Aviation	15 m structure and combined Site 1B vertical infrastructure
Traffic	Final transformer weights, AIL numbers and delivery routes
Climate and materials	Concrete, steel, equipment and replacement assumptions
Waste	Transformer, oil and equipment replacement and decommissioning

Where an assessment was not updated, the Applicant should explain why the earlier design remained a valid worst case. A bare assertion that the voltage change did not alter likely significant effects is not sufficient.

4.6.14 Conclusion

The Site 1B project substation changed materially after statutory consultation. The development evolved from a 132 kV installation approximately 7 metres high to a 400 kV design described at targeted consultation as approximately 13 metres high and finally to a 15-metre, 1.1-hectare maximum envelope in ES Chapter 4.

The change was capable of altering:

- landscape and visual effects;
- heritage setting;
- operational noise;
- air quality;
- transformer-fire and pollution risk;
- drainage;
- groundwater effects;
- aviation safeguarding;
- construction traffic;
- and AIL requirements.

The Applicant must demonstrate that every relevant ES chapter assessed the final 400 kV design rather than carrying forward assumptions derived from the earlier 132 kV proposal. Until that audit is supplied, the Examining Authority cannot safely conclude that the submitted Environmental Statement consistently assesses the development now authorised by Work No. 3A.

4.7 Uncertainty over the boundary between Applicant works and NGET works

The application seeks consent for substantial transmission infrastructure which would ultimately form part of the national electricity transmission system, but it does not yet provide a sufficiently clear and enforceable account of where responsibility passes from East Pye Solar Limited to National Grid Electricity Transmission plc.

That boundary matters because it determines who may exercise the powers in the DCO, who is responsible for detailed design and construction, which body is bound by the Requirements, who owns and maintains the resulting infrastructure, and against whom environmental obligations can ultimately be enforced.

The issue is therefore not one of private commercial allocation. It goes directly to whether the DCO provides a complete and legally effective control mechanism for Works Nos. 4 and 5.

4.7.1 The DCO authorises the transmission works themselves

Work No. 4 includes the National Grid substation, associated landscaping, sustainable drainage, biodiversity measures, construction compound and access. Work No. 5 includes construction and reconfiguration of the overhead transmission line, gantry and pylon works, temporary compounds and the dismantling or modification of existing transmission infrastructure.

The application is therefore not confined to providing land or enabling works for a future NGET project. It seeks development consent for the principal transmission infrastructure itself.

That makes it necessary to identify which body is responsible for each stage of its delivery and operation.

The Scheme Description presently identifies the physical components more clearly than it identifies the institutional responsibilities attached to them. It is not sufficient to state that the substation will ultimately be operated by NGET. The Examination must understand who designs it, who constructs it, who obtains approval of the detailed design, whose contractors carry out the works, when ownership transfers, and which body remains responsible for the environmental obligations that survive that transfer.

4.7.2 The delivery model remains insufficiently defined

The likely division of responsibility may involve the Applicant securing land and undertaking some civil works while NGET or its contractors install and commission the transmission equipment. The precise boundary has not yet been stated clearly.

That matters because the civil and electrical elements cannot sensibly be treated as environmentally separate projects. Site clearance, access construction, compound formation, foundations, drainage, busbars, switchgear, transformers, pylon foundations, conductor stringing and testing together comprise the authorised development.

All such works must therefore remain subject to the relevant construction and environmental controls irrespective of which organisation or contractor physically undertakes them.

The DCO should not create a position in which the Applicant's contractors are subject to construction hours, traffic limits, ecological safeguards, pollution controls and archaeological requirements, while materially similar works undertaken by NGET are treated as falling outside those same controls because responsibility has transferred.

The Applicant and NGET should accordingly identify the intended delivery model during Examination, including the point at which responsibility for the land, civil works, electrical plant and transmission-line works changes hands.

4.7.3 Detailed-design approval must be legally identifiable

This question is particularly important in relation to detailed design.

The Applicant relies on the Design Principles and Parameters and the DCO Requirements to ensure that later design remains within the assessed environmental envelope. However, South Norfolk Council has identified that Works Nos. 4A and 4B do not appear to be included within the principal detailed-design Requirement and has queried how those works will instead be approved.

That issue should be resolved expressly.

The Applicant should identify the statutory approval mechanism governing the final design of the National Grid substation and associated works, the approving authority, the mandatory consultees and the environmental parameters against which approval will be tested.

If the works are to be approved under the DCO, the relevant Requirement should be identified and should bind the body responsible for delivering them.

If any part of the transmission infrastructure is instead expected to require a separate planning permission under the Town and Country Planning Act 1990 or another statutory regime, the Applicant should identify precisely which works are affected and explain the relationship between the two consent regimes.

A work should not simultaneously be presented as authorised development under the DCO while its essential form remains to be determined under a separate planning process without a clear legal hierarchy between those approvals.

In particular, any separate consent route must not enable a later transmission design to exceed the environmental envelope examined in this DCO.

The current NPPF DP4 provides additional policy context for that problem. Design quality relied upon in the assessment should not be materially diminished during delivery merely because detailed engineering is undertaken by a different undertaker. The division between EPS and NGET therefore cannot create a regulatory gap in which National Grid detailed design falls outside the environmental parameters and design controls relied upon by the DCO.

4.7.4 NGET engineering flexibility must remain within the assessed envelope

NGET will necessarily retain a degree of technical control over infrastructure which must comply with transmission-system standards and wider network requirements. That does not remove the need for the DCO to establish the maximum environmentally assessed envelope.

The final design may involve choices concerning switchgear technology, busbar configuration, bay numbers, transformer arrangements, gantries, control buildings, pylon geometry and other technical matters. Those choices may properly be refined after consent provided that they remain within the parameters assessed.

What must not occur is a transfer of the Order to NGET which effectively creates a power to redesign the transmission component beyond those limits.

The Applicant should therefore identify which technical matters remain subject to NGET determination and demonstrate that the retained discretion cannot increase the footprint, height, pylon requirement, access requirement, foundation depth, lighting, drainage discharge or other material environmental parameter beyond the assessed maximum.

Any design change which materially exceeds that envelope should not be capable of treatment as ordinary detailed design. It would require further environmental assessment and, where necessary, further consent.

4.7.5 Transfer of the Order must transfer the obligations as well as the powers

The draft DCO must also address the possibility that the benefit of the Order, or part of it, is transferred to NGET.

The ExA should establish whether East Pye Solar Limited will initially be the undertaker for all Works and whether NGET will subsequently become the undertaker for Works Nos. 4 and 5, either wholly or in part.

The critical principle is that the environmental liabilities must follow the powers.

A transfer should not enable the original undertaker to cease responsibility before the receiving body has become legally bound by the corresponding Requirements and mitigation obligations. There should be no period during which construction or operation is authorised but responsibility for compliance is uncertain.

This is particularly important for obligations concerning construction environmental management, drainage, pollution control, access, traffic, lighting, landscaping, biodiversity, noise and emergency response.

The DCO should therefore ensure that any transfer of the transmission works automatically transfers or otherwise preserves every relevant environmental obligation applying to those works.

4.7.6 Land ownership and compulsory powers must reflect the actual delivery model

The division of responsibility also bears directly upon the compulsory-acquisition case.

The application should state whether East Pye Solar Limited intends to acquire the freehold of the National Grid substation land and transfer it to NGET; retain the land and grant NGET a lease or rights; enable NGET to acquire the land directly; or adopt some other arrangement.

That information is particularly important in light of NGET's evidence that the replacement connection agreement may no longer require the Applicant to secure the substation land or consent.

If NGET will ultimately require and control the land, the Applicant must explain why East Pye Solar Limited itself needs the compulsory powers now sought and whether permanent freehold acquisition is necessary.

The land interest, the party requiring it and the ultimate owner should therefore be identified consistently. Compulsory powers should not be granted to one body merely as an interim convenience where the need for the land arises from the requirements of another.

4.7.7 Long-term ownership creates continuing environmental obligations

The issue continues beyond construction.

The Applicant states that the National Grid substation and Grid Connection Infrastructure may remain after the solar generating station has been decommissioned. The environmental obligations associated with those permanent assets must therefore survive the end of East Pye itself.

That includes responsibility for access, surface-water drainage, oil containment, firewater systems, security, lighting, landscape mitigation, biodiversity measures and emergency response.

These matters cannot be treated as temporary construction obligations if the underlying infrastructure remains indefinitely.

The final DCO should therefore identify which body becomes responsible for the permanent transmission assets and ensure that the obligations necessary to maintain their environmental acceptability remain enforceable against that body and any successor.

This is especially important for drainage and landscaping.

Drainage infrastructure may require long-term maintenance, inspection of attenuation systems, pollution response and management of contaminated water. Likewise, landscape and biodiversity measures relied upon to reduce visual or ecological effects may require establishment, replacement planting and continuing management long after East Pye Solar Limited has ceased to operate the generating station.

The environmental assessment cannot rely on those measures unless responsibility for maintaining them is legally durable.

4.7.8 Enforcement responsibility must be unambiguous

The present uncertainty also creates an enforcement risk.

If a pollution incident, drainage failure, traffic breach, ecological impact, unauthorised design change or mitigation failure occurs, the enforcing authority must be able to identify immediately which body is responsible.

The DCO should not create a position in which the Applicant says that the matter lies with NGET, NGET says that the infrastructure was authorised and constructed under East Pye's DCO, and the local authority is left without a clearly identifiable party against whom to enforce.

That risk is particularly acute where assets, land and operational responsibilities transfer at different stages.

The Applicant and NGET should therefore provide an agreed responsibility and approvals schedule during Examination covering the principal stages of the transmission works: design, land acquisition, construction, environmental management, testing, commissioning, ownership, operation, maintenance, emergency response and permanent retention.

The purpose is not to expose private commercial arrangements. It is to demonstrate that every authorised activity has an identified responsible body and a corresponding enforceable DCO control.

4.7.9 Decommissioning and permanent retention must be divided expressly

The same clarity is required at the end of the Scheme's life.

East Pye's solar generating station is proposed for a finite operational period, whereas the National Grid infrastructure may remain permanently.

The Applicant and NGET should therefore identify which assets would be removed by East Pye, which would transfer or remain with NGET, which temporary areas would be restored, which access routes would be retained and who would remain responsible for the environmental mitigation associated with the permanent infrastructure.

That division should be established now rather than deferred until decommissioning several decades hence.

A decommissioning obligation directed only at East Pye Solar Limited is insufficient if the relevant infrastructure has previously transferred to NGET and is intended to remain in operation.

4.7.10 Information and DCO controls required

The uncertainty can be resolved without an elaborate activity-by-activity matrix if the Applicant and NGET provide a single agreed responsibility and approvals schedule during Examination.

That schedule should identify, for each principal component of Works Nos. 4 and 5:

the body responsible for detailed design; the body constructing it; the approval mechanism; the landowner or rights-holder; the owner and operator following commissioning; the Requirements and other environmental controls which apply; the point of any transfer; and the body responsible for long-term maintenance and permanent retention.

It should also identify any part of the works proposed to be approved separately under the Town and Country Planning Act or another statutory regime and explain how that approval is reconciled with the DCO.

The final Order should then secure four essential principles.

First, no transmission work should fall outside an identifiable detailed-design and environmental approval mechanism.

Secondly, any transfer of the benefit of the Order must carry with it the corresponding environmental obligations and liabilities.

Thirdly, NGET's technical discretion must remain within the environmental envelope assessed in this application unless further consent is obtained.

Fourthly, responsibility for permanent drainage, landscape, biodiversity, access, pollution and emergency obligations must remain enforceable for as long as the retained infrastructure exists.

4.7.11 Conclusion

The application authorises major permanent transmission infrastructure but does not yet define with sufficient precision the legal and operational boundary between East Pye Solar Limited and NGET.

That uncertainty affects detailed design, land acquisition, construction, environmental management, ownership, operation, maintenance, transfer, decommissioning and enforcement.

It is particularly significant because South Norfolk Council has already identified uncertainty over the detailed-design control applying to Works Nos. 4A and 4B, while NGET's own evidence indicates that the future contractual and connection arrangements remain in development.

The problem is therefore not simply that commercial responsibilities have yet to be finalised. The DCO must ensure that every authorised Work remains subject to an identifiable approval route, an identifiable responsible undertaker and enforceable environmental obligations throughout its life.

BEPS accordingly submits that the Applicant and NGET should provide an agreed responsibility and approvals schedule before the close of Examination and that the final DCO should secure the resulting allocation of powers, responsibilities and environmental liabilities.

The governing principle should be straightforward: the power to construct, own or operate the transmission infrastructure must never become separated from the legal responsibility to comply with the environmental case on which that power was granted.

4.8 Unresolved interaction with National Gas Transmission infrastructure

The Order Limits intersect nationally significant gas-transmission infrastructure owned and operated by National Gas Transmission plc ("NGT"), including the FM05 Yelverton–Stowmarket high-pressure feeder main and associated cathodic-protection equipment. The application seeks works, compulsory-acquisition, temporary-possession and rights

powers over land in which NGT has existing statutory, property and operational interests.

NGT's Relevant Representation identifies the feeder main and associated protection systems within or close to a number of Order plots, including plots 16-003, 16-004, 15-009, 11-036, 06-003, 06-002, 05-049, 06-001 and 05-048. NGT maintains an objection until satisfactory protective provisions and related protections are agreed.

The issue is therefore not simply the existence of a buried pipeline. It is whether East Pye's development envelope, land powers and long-term management arrangements have been shown to be compatible with the safe operation, maintenance and emergency accessibility of nationally significant gas infrastructure.

4.8.1 The FM05 feeder main is a fixed operational constraint

The FM05 feeder main forms part of the national high-pressure gas-transmission system. Its safe operation requires protection from incompatible loading, excavation, piling, ground disturbance, obstruction and loss of emergency access.

The Applicant must therefore demonstrate, in a single authoritative interface plan, how every relevant element of the Scheme relates to the pipeline easement and operational protection zone.

That interface is potentially extensive. It includes solar arrays and foundations, fencing, conversion equipment, access tracks, internal haul roads, cable trenches, trenchless crossings, drainage infrastructure, earthworks, compounds, soil storage, landscaping, habitat creation and permissive paths.

The problem with the present application is not that those activities are necessarily incompatible with the pipeline. It is that many are authorised through broad Work descriptions and associated-development powers without a consolidated plan showing where NGT's restrictions apply and which works are prohibited, constrained or subject to prior approval.

That uncertainty goes directly to physical deliverability. If parts of the solar, cable, drainage, access or biodiversity design cannot lawfully or safely occupy the NGT easement, the Scheme may require redesign.

4.8.2 Cathodic-protection infrastructure must also be protected

The pipeline is not the only relevant NGT asset. NGT also identifies cathodic-protection groundbeds, transformer-rectifier equipment and associated cabling.

Those systems are integral to the long-term corrosion protection of the pipeline and may themselves impose electrical, spatial and access constraints.

The Applicant should identify their precise locations and demonstrate adequate separation from East Pye's electrical and civil infrastructure. Particular attention is required where piling, buried cables, access tracks, drainage alterations or high-voltage equipment may interact with cathodic-protection systems.

The environmental and engineering assessment should not treat the pipeline corridor as though only the physical pipe itself matters. Interference with its protection systems may also affect operational safety.

4.8.3 The easement restrictions engage a wide range of East Pye works

NGT's easement rights and restrictions appear to control structures, changes in ground level, material storage and continuing access. Those restrictions potentially affect a substantial range of authorised works.

Solar development may involve driven piles, concrete foundations, fencing, gates, CCTV, electrical compounds, tracks, drainage and buried cables. Construction may additionally require excavations, HDD compounds, cranes, stockpiles, welfare areas and temporary storage.

The Applicant should therefore demonstrate that the DCO envelope has been designed around those pre-existing legal and operational constraints rather than leaving compatibility to detailed design.

In particular, the final plans should identify any permanent structure, foundation, pile, cable, drainage feature, compound, stockpile or planting proposed within or close to the easement. Where a work depends upon NGT approval, that should be stated expressly and secured through the Order.

A general commitment to consult NGT later is not equivalent to demonstrating that the authorised development can be implemented.

4.8.4 Ground levels, loading and access require specific control

Three interfaces require particular attention: ground levels, construction loading and continuing NGT access.

First, alterations to ground levels may change cover depth, loading, erosion conditions and emergency accessibility. Earthworks, swales, bunds, attenuation features, track construction and reinstatement therefore require specific control wherever they intersect the pipeline corridor.

Secondly, temporary and permanent vehicle loading may be materially greater than existing agricultural use. Internal haul roads, HGV routes, cranes and abnormal loads crossing the feeder main should therefore be subject to an agreed crossing design based on actual axle loads, pipeline depth, crossing frequency and NGT's technical standards.

Thirdly, NGT must retain continuous access for inspection, repair and emergency intervention. Solar fencing, security systems, construction compounds, landscaping or habitat measures must not create a situation in which NGT depends upon discretionary consent from the Applicant or site operator before entering the easement.

The DCO should therefore ensure that NGT's emergency and maintenance access takes priority over site-security and landscape-management arrangements.

4.8.5 Cable and drainage crossings must be fixed and controlled

Work No. 6 authorises substantial underground electrical infrastructure, including cables up to 132 kV and 400 kV, trenches, joint bays and trenchless crossings.

Every crossing of the FM05 feeder main or associated cathodic-protection infrastructure should be identified before the close of Examination, together with the proposed method, separation distances, crossing angle, bore or trench depth, construction plant and NGT supervision requirements.

Open-cut and trenchless methods present different risks. Open-cut works may affect support, cover or protection systems, while HDD and other trenchless methods introduce risks from drilling deviation, vibration and drilling-fluid migration. The crossing method should therefore not remain wholly undefined where its safety implications differ materially.

Drainage infrastructure requires equivalent scrutiny. Swales, infiltration systems, attenuation features, drains and outfalls may alter moisture conditions, erosion patterns or access. No infiltration, concentrated discharge or excavation within the relevant pipeline protection area should therefore occur without NGT approval.

4.8.6 Landscaping and BNG cannot conflict with pipeline safety

East Pye also relies extensively upon landscaping, ecological mitigation and biodiversity enhancement. Those measures must remain compatible with the operational requirements of the feeder main.

Deep-rooting trees, wetland creation, dense scrub, fencing or long-term habitat-management prescriptions may interfere with access, excavation, drainage or pipeline protection.

The Landscape and Ecological Management Plan should therefore identify the easement as a permanent operational constraint. It should make clear where trees and deep-rooting vegetation are prohibited, confirm NGT's right to remove vegetation where necessary, and ensure that biodiversity calculations do not rely upon habitat which cannot lawfully or safely be maintained for the required management period.

BNG obligations cannot override the continuing operation and safety requirements of nationally significant gas infrastructure.

4.8.7 Protective provisions remain unresolved

The most important legal issue is that the Applicant's Statement of Reasons appears to proceed on the basis that statutory-undertaker protections are adequate, while NGT itself maintains an objection because satisfactory provisions have not been agreed.

The Statement of Reasons relies upon sections 127 and 138 of the Planning Act 2008, article 33 of the draft DCO and the protective provisions in Schedule 14. It asserts, in substance, that those provisions prevent serious detriment to statutory undertakers.

NGT's Relevant Representation demonstrates that this conclusion is not agreed by the affected undertaker. Generic protective provisions may provide a starting point, but they cannot simply be assumed to satisfy the statutory tests where the relevant undertaker identifies unresolved safety, access or asset-protection concerns.

The ExA should therefore require the Applicant and NGT to identify clearly which provisions remain disputed and what site-specific protections are required in relation to the FM05 feeder main and its associated systems.

Those protections may need to address stand-off distances, structural loading, crossing design, prior written approval, supervision, access, emergency intervention, indemnity, cost recovery, as-built information, vegetation management and the treatment of future replacement and decommissioning works.

ISH1 identified a further unresolved interface at Site 7. BEPS asked how the proposed haul-road arrangement would cross the high-pressure gas transmission pipeline, and the Applicant was unable at the hearing to provide the engineering answer. The matter became a formal action point.

That is important because a haul-road crossing is not simply a traffic-management detail. It may require assessment of loading, protection slabs or bridging, depth of cover, construction sequencing, pipeline operator access, cathodic protection, drainage and emergency arrangements. If the engineering solution requires additional land, structures or route alteration, those consequences must remain within the assessed environmental and DCO envelope.

4.8.8 Compulsory-acquisition powers require particular scrutiny

The unresolved protective-provisions position also affects the compulsory-acquisition case.

The Applicant seeks powers capable of acquiring land or rights, imposing restrictions, taking temporary possession and potentially interfering with existing statutory-undertaker interests.

Where NGT's easement rights are integral to the safe operation of national gas infrastructure, those powers cannot be treated as ordinary third-party land interests.

The Applicant should therefore identify, plot by plot, the precise NGT interest affected, the Work No. said to require interference, the power sought and whether that power could extinguish, suspend, override or materially constrain NGT's existing rights.

The question is not merely whether the Applicant presently intends to move the pipeline. A power capable of overriding or constraining NGT's access or easement protections may itself have legal significance.

The Statement of Reasons should therefore be reconciled with NGT's objection before the ExA reaches any conclusion under sections 127 or 138. A finding that serious detriment has been avoided should rest on agreed or otherwise demonstrably sufficient protection, not on an assumption that agreement will be reached later.

4.8.9 The interface must remain safe for the whole life of the Scheme

The NGT interaction is not confined to initial construction. The application anticipates complete panel replacement, repeated BESS replacement, transformer replacement and eventual decommissioning. Each of those stages may reintroduce HGV movements, cranes, excavation, stockpiles, compounds, cable works and access restrictions.

Protective provisions and asset-protection controls must therefore apply throughout construction, operation, replacement and decommissioning, and must bind any successor or transferee of the DCO.

The same applies to emergency planning. The Applicant's management plans should address accidental pipeline strike, excessive loading, interference with cathodic protection, erosion, flooding, fire near the easement and any event requiring simultaneous coordination between solar, BESS, electrical and gas infrastructure operators.

The DCO should not assume that protection agreed for initial construction automatically covers materially different plant, loading or working methods several decades later.

4.8.10 Information and controls required

The remaining uncertainty should be resolved through one consolidated NGT interface package rather than multiple disconnected schedules.

BEPS submits that the Applicant should provide:

- a single detailed plan showing the FM05 feeder main, cathodic-protection infrastructure, easement and operational protection zones against all relevant East Pye works;
- a plot-by-plot reconciliation with the Book of Reference identifying the NGT interest, Work No., land power sought and potential interference;

- the agreed or disputed protective provisions;
- any required asset-protection agreement;
- a drawing and engineering methodology for every proposed construction or operational crossing of the FM05 pipeline, including the Site 7 haul-road crossing.
- and confirmation from NGT that the final solar, cable, access, drainage and biodiversity proposals are compatible with its operational requirements.

The DCO should then secure four core principles.

First, no work within the NGT protection zone should commence without the approvals required by NGT.

Secondly, no compulsory power should extinguish, suspend or materially interfere with NGT's rights or apparatus except in accordance with agreed protective provisions.

Thirdly, NGT must retain unrestricted operational and emergency access throughout the life of the Scheme.

Fourthly, all protections must continue to apply to replacement, decommissioning and any successor undertaker.

4.8.11 Conclusion

East Pye intersects nationally significant gas-transmission infrastructure and associated protection systems, yet the application does not presently demonstrate in one coherent document how the authorised development, land powers and mitigation measures are reconciled with those pre-existing constraints.

The issue extends beyond the physical pipeline. It includes cathodic-protection systems, easement rights, loading, ground-level changes, cable and road crossings, drainage, long-term access, biodiversity proposals, replacement works and compulsory-acquisition powers.

The Applicant's Statement of Reasons treats adequate statutory-undertaker protection as established. NGT's Relevant Representation demonstrates that, at submission, it was not.

That unresolved position has consequences for physical deliverability, environmental control and the statutory tests governing interference with NGT's land, rights and apparatus.

BEPS therefore submits that the NGT interface should be resolved during Examination through a detailed interface plan, plot-specific land and rights reconciliation, agreed protective provisions and any necessary asset-protection agreement.

Until those matters are resolved, the ExA cannot safely assume that the full development envelope can be implemented as authorised, that the compulsory powers sought are necessary and proportionate, or that serious detriment to NGT's undertaking has been excluded.

4.9 Cable Route Corridors and unresolved connection geography

The cable network is the physical system intended to connect the dispersed solar generating areas, the BESS and the project substations to the proposed National Grid substation at Site 1B. It is therefore not a secondary or incidental part of the Scheme. Its route, capacity, construction method and final destination determine whether the authorised generating station can operate and whether the environmental effects of the connection infrastructure have been assessed accurately.

ES Chapter 4 identifies fourteen Cable Route Corridors. The Applicant states that the precise cable alignments would be selected at detailed-design stage and that, unless otherwise stated, the Environmental Statement has assessed cables as capable of being installed anywhere within the relevant corridor. The DCO therefore does not authorise one fixed cable alignment. It authorises a broad spatial envelope within which one or more cable systems, construction works and associated infrastructure may later be placed.

That flexibility must be considered together with the uncertainty identified in Section 5.5. The cable network is designed around the proposed Site 1B National Grid substation, but NGET has not confirmed that Site 1B will be the final connection solution. The application must therefore establish whether the cable corridors are genuinely fixed to a confirmed point of connection, whether they may be constructed before that solution is settled, and what prevents unused or duplicated underground infrastructure from being installed.

4.9.1 Cable works authorised by the DCO

Work No. 6 authorises electrical cables with voltages up to 132 kV and 400 kV, together with associated construction and supporting works. ES Chapter 4 describes a cable system that may include:

- DC and low-voltage AC cabling within the solar sites;
- communications and fibre-optic cables;
- 33 kV collection cables;
- 132 kV cables;
- 400 kV export or connection cables;
- open-cut trenches;
- ducts;
- joint bays;
- link boxes;
- fibre chambers;
- trenchless crossings;

- horizontal directional drilling;
- launch and reception pits;
- temporary compounds;
- working areas;
- access and haul roads;
- dewatering;
- drainage;
- soil storage;
- and reinstatement.

The Work No. is accompanied by broad associated-development powers for excavation, trenching, tunnelling, boring, drilling, drainage, access and temporary works. The actual authorised cable development is therefore wider than the buried conductors alone.

4.9.2 Number and voltage of cables

The application identifies the maximum voltage classes but does not provide a complete consolidated schedule of the number of circuits or individual cables authorised.

The cable network may include cables operating at:

- low voltage and DC within the solar arrays;
- 33 kV between solar areas and project substations;
- 132 kV between substations or project components;
- and 400 kV between project infrastructure and the proposed National Grid connection.

However, the Scheme Description does not clearly state:

- the maximum number of 33 kV circuits;
- the maximum number of 132 kV circuits;
- the maximum number of 400 kV circuits;
- the number of individual cables per circuit;
- whether spare ducts may be installed;
- whether multiple parallel trenches may be used;
- or whether additional circuits may be constructed for the BESS or future connection configuration.

Those quantities are material because they determine:

- trench width;
- working width;
- soil disturbance;
- thermal output;
- number of joint bays;

- construction duration;
- dewatering;
- spoil storage;
- and the extent of later replacement or decommissioning.

The Applicant should provide a Cable Schedule identifying, for every corridor, the maximum voltage, circuit number, conductor number, duct number and intended destination.

4.9.3 Trench width and depth

ES Chapter 4 states that trenches for the principal 132 kV and 400 kV cable works may be up to approximately seven metres wide and two metres deep, except where additional space is required at joint bays, crossings or trenchless-work approaches.

Lower-voltage trenches may be approximately 1.6 metres wide and 1.2 metres deep. In agricultural land, the Applicant generally assumes a minimum burial depth of approximately 1.2 metres, while cables crossing existing apparatus may be installed up to approximately two metres below it.

These figures provide some maximum parameters, but they do not define the complete excavation envelope. In particular, the application should state:

- whether seven metres is the width of one trench or the total width of all parallel trenches;
- how many trenches may be open simultaneously;
- the maximum depth at joint bays;
- the maximum side slopes required in unstable ground;
- the width required for trench support;
- and the extent of additional excavation where cables pass beneath roads, rivers, gas pipelines or other utilities.

Without that information, the stated trench dimensions cannot be translated into a reliable maximum land-disturbance figure.

4.9.4 Overall working width

The Applicant identifies a typical cable working width of approximately 25 metres. That width may accommodate:

- the trench;
- stripped topsoil and subsoil;
- construction plant;
- access;
- cable drums;
- temporary drainage;
- safety zones;

- and working space.

Chapter 4 also states that the working width may be widened locally at roads, watercourses, existing utilities and other constraints. No clear absolute maximum is stated for those widened areas.

That omission is important because the environmental effects of cable construction arise largely from the working corridor rather than the final buried cable. A locally widened area may affect:

- additional hedgerows;
- watercourses;
- archaeological remains;
- protected habitats;
- agricultural soils;
- flood storage;
- public rights of way;
- and private land.

The DCO should therefore secure:

- a maximum ordinary working width;
- a maximum widened working width;
- the locations at which widening is permitted;
- and a requirement for further approval where the stated maximum must be exceeded.

4.9.5 Freedom to route cables anywhere within the corridors

The Applicant states that the final cables may be placed anywhere within the Cable Route Corridors unless a more specific restriction applies.

This is a wide form of micro-siting flexibility. It means that a corridor may contain numerous possible alignments, each with a different relationship to:

- watercourses;
- hedgerows;
- trees;
- archaeology;
- groundwater;
- residential receptors;
- statutory undertaker apparatus;
- roads;
- and designated habitats.

The Applicant should demonstrate that every materially different alignment within each corridor was capable of producing effects no worse than those assessed.

A general corridor-level assessment may be inadequate where one side of the corridor crosses a sensitive feature and the other does not. In those circumstances, the DCO should identify an exclusion area or fixed crossing rather than leaving the final choice to detailed design.

Norfolk County Council's evidence supports this concern. Its LLFA identifies a lack of detail concerning cabling associated with the solar arrays and uncertainty over the cumulative below-ground effects of cabling, piling and drainage infrastructure. The County Council's criticism is not confined to the main export corridors. It concerns the absence of a coherent account of the overall buried infrastructure across the Scheme.

BEPS has also identified that CRC4 is shown against outdated base mapping which does not depict the completed Long Stratton Bypass and associated biodiversity mitigation. The proposed cable corridor intersects newly established mitigation land including planted woodland blocks and wildlife ponds which were not present on the earlier mapping and have not been surveyed as part of the original baseline.

The final cable alignment therefore cannot be approved merely by reference to the existing broad corridor. The Applicant must update the mapping and ecological baseline, identify the bypass mitigation features and demonstrate whether they can be avoided. If avoiding them requires movement outside the assessed corridor or materially different construction methods, that must be resolved during Examination.

4.9.6 Joint bays

ES Chapter 4 states that joint bays may be required at intervals of approximately 250 to 500 metres. A typical joint bay may be approximately:

- 20 metres long;
- seven metres wide;
- and three metres deep.

Joint bays are therefore substantial excavations. They may require:

- reinforced concrete;
- dewatering;
- access;
- drainage;
- link boxes;
- fibre chambers;
- temporary compounds;
- and later maintenance access.

The application does not clearly state:

- the maximum number of joint bays;
- their final locations;

- total compound area;
- whether they remain permanently accessible;
- whether above-ground markers or link boxes are required;
- or whether they will be removed at decommissioning.

If the corridors extend over long distances, a spacing of 250 metres could produce materially more joint bays than a spacing of 500 metres. The Environmental Statement should therefore assess the maximum realistic number, not merely provide a typical interval.

4.9.7 Fibre chambers and link boxes

Chapter 4 also contemplates fibre chambers at intervals of approximately 500 to 2,000 metres. Typical dimensions are approximately 1.5 metres by one metre by 1.5 metres deep.

The application should identify:

- the maximum number;
- whether any above-ground apparatus is required;
- permanent access;
- drainage;
- and decommissioning treatment.

Although individually smaller than joint bays, these installations contribute to the cumulative permanent below-ground infrastructure and may constrain later land use.

4.9.8 Trenchless crossings and HDD

The Applicant may use HDD, boring or other trenchless techniques beneath:

- watercourses;
- roads;
- rail or utility infrastructure;
- environmentally sensitive features;
- and existing apparatus.

Chapter 4 gives a maximum individual bore diameter of approximately one metre and a maximum depth of approximately 12 metres. It also refers to a minimum depth of approximately five metres below the surveyed bed of a main river.

However, the application does not provide a complete maximum envelope for trenchless works. It does not clearly state:

- the maximum bore length;
- the maximum number of parallel bores;
- the maximum number of crossings;

- the dimensions of every launch and reception pit;
- the maximum drilling-fluid volume;
- drilling-fluid composition;
- the maximum dewatering requirement;
- or the area required for drilling rigs, storage and spoil.

Launch and reception areas may themselves require substantial temporary compounds. The final dimensions should be fixed for each crossing or controlled by a stated maximum.

The Environment Agency specifically identifies inadequate definition of trenchless works and their interaction with groundwater and other foundations. It is concerned about the potential for drilling and cable works to create preferential pathways, disturb groundwater and interact cumulatively with piling.

A generic commitment to prepare later method statements does not replace assessment of the maximum physical crossing envelope.

4.9.9 Fixed crossing locations

Crossings of sensitive or constrained features should not be left entirely open within a corridor.

Fixed or narrowly controlled locations are required where the cables cross:

- main rivers;
- ordinary watercourses;
- the FM05 gas feeder main;
- roads;
- protected hedgerows;
- ancient woodland buffers;
- archaeological sites;
- or other major utilities.

The crossing method and location may determine whether the impact is temporary, permanent or avoidable.

For example, an open-cut watercourse crossing and a deep HDD crossing involve different:

- habitat effects;
- groundwater risks;
- drilling-fluid risks;
- construction compounds;
- and reinstatement requirements.

The DCO should therefore identify fixed crossing points and the assessed method, with any alternative requiring approval and demonstration of no materially worse effects.

4.9.10 Cable thermal properties

The Environment Agency has raised concerns about the thermal effects of underground cables.

The application does not clearly state:

- the maximum conductor temperature;
- cable loading;
- heat loss;
- thermal resistivity assumptions;
- spacing between circuits;
- duration of peak loading;
- or the resulting change in surrounding soil temperature.

These parameters may affect:

- soil moisture;
- soil biology;
- agricultural productivity;
- groundwater;
- nearby watercourses;
- buried ecological features;
- and the performance of adjacent infrastructure.

The issue may be particularly significant where several high-voltage circuits run in parallel or where both solar and BESS flows use the same route.

The Applicant should provide a maximum thermal-loading assessment based on the full number and capacity of circuits. A later choice of cable manufacturer or conductor size is acceptable only if it remains within that assessed thermal envelope.

4.9.11 Preferential groundwater pathways

The Environment Agency also identifies the possibility that cable trenches, ducts, bedding materials and trenchless works may create preferential groundwater pathways.

A cable trench may introduce permeable aggregate or disturbed material through soils or geological layers that previously restricted water movement. This may:

- redirect groundwater;
- increase drainage along the trench;
- alter spring or watercourse flows;

- transport contamination;
- and affect private water supplies or groundwater-dependent habitats.

The application should identify:

- groundwater conditions along each corridor;
- locations where geological layers are penetrated;
- trench backfill materials;
- seals or cut-off barriers;
- dewatering;
- and long-term monitoring.

The interaction with piling is also relevant. Cable trenches and deep foundations may together create connected pathways not apparent when each work is considered separately.

4.9.12 Dewatering

Open trenches, joint bays and HDD pits may require dewatering.

The Scheme Description does not provide a scheme-wide maximum for:

- dewatering volume;
- duration;
- pumping rate;
- discharge location;
- settlement treatment;
- or number of simultaneous dewatering operations.

These omissions matter because dewatering can affect:

- groundwater levels;
- nearby wells;
- watercourses;
- sediment;
- contamination;
- and ground stability.

The Environment Agency should approve dewatering methods and discharge arrangements before relevant works commence. The DCO should also require cumulative assessment where several work fronts may dewater simultaneously.

4.9.13 Spoil and soil storage

Cable construction requires separate stripping and storage of:

- topsoil;

- subsoil;
- trench arisings;
- drilling spoil;
- and potentially contaminated material.

The 25-metre working width appears intended to accommodate some storage, but the application does not state:

- maximum stockpile height;
- maximum storage duration;
- total volume;
- additional land required at joint bays and HDD compounds;
- or how wet or contaminated material will be handled.

This information is material to:

- soil compaction;
- drainage;
- landscape effects;
- dust;
- agricultural restoration;
- and NGT easement restrictions.

No spoil or material storage should be permitted over statutory undertaker apparatus or within protected easements without written agreement.

4.9.14 Haul roads and access

The cable corridors may require temporary haul roads or use the working width for construction traffic.

The Applicant should identify:

- maximum haul-road width;
- total length;
- surfacing;
- crossing points;
- vehicle loading;
- drainage;
- and restoration.

Where a corridor crosses minor roads, watercourses or private accesses, temporary bridges or reinforced crossings may be required.

These works form part of the cable-development envelope and should not be treated as incidental construction detail.

Permanent access may also be required to joint bays, link boxes or other infrastructure. The application should distinguish clearly between:

- temporary construction access;
- emergency access;
- and permanent maintenance rights.

4.9.15 Is the cable network fixed to Site 1B?

The fourteen Cable Route Corridors are described as connecting the Scheme to the proposed National Grid substation at Site 1B. The route geography therefore appears to depend upon that connection point.

NGET's Relevant Representation, however, states that the final point-of-connection solution remains subject to wider regulatory and commercial considerations and that other Gate 2 offers may affect the size, design and location of the National Grid infrastructure.

The Applicant must therefore confirm:

- whether every corridor is designed exclusively for Site 1B;
- whether any corridor could be redirected to another connection point;
- whether the Order Limits include alternative routes;
- and whether the cable design would remain technically usable if Site 1B is not selected.

If the final connection point moves outside the present corridors, additional land and consent may be required. If the corridors are wide enough to permit a materially different destination, the DCO may authorise a wider connection geography than the Environmental Statement describes.

4.9.16 Could cables be constructed before the NGET solution is confirmed?

The draft DCO must be examined to determine whether Work No. 6 may commence independently of Works Nos. 4 and 5.

If so, the Applicant could potentially:

- strip land;
- excavate trenches;
- install ducts;
- construct joint bays;
- install cables;
- and reinstate land

before NGET confirms that Site 1B is the final connection point. That would create an obvious risk of stranded infrastructure.

The DCO should prevent commencement of any high-voltage cable route serving the National Grid connection until:

1. NGET has confirmed the final point of connection;
2. the final cable destination is fixed;
3. the relevant connection agreement is effective;
4. and the cable design has been approved.

Internal solar-array cabling may be capable of proceeding separately, but the Applicant should distinguish it from export infrastructure whose utility depends on the unresolved NGET solution.

4.9.17 Duplicate or stranded cable infrastructure

The current broad powers may permit ducts or cables to be installed that later become unnecessary if:

- the Site 1B solution changes;
- the BESS is not connected;
- the number of project substations changes;
- or NGET requires a different configuration.

The Applicant should identify whether spare or redundant ducts may be installed as part of the initial works and whether new cables could later be laid within the same corridors under maintenance or replacement powers.

There should be an express prohibition on constructing:

- duplicate circuits;
- speculative ducts;
- or cable infrastructure disconnected from the approved final connection solution

unless their environmental effects and operational need have been established.

4.9.18 What happens if the connection point moves?

If NGET selects a different point of connection, the Applicant must explain whether:

- the existing corridors remain usable;
- cables would need to be extended;
- new corridors would be required;
- installed cables would be abandoned;
- joint bays and ducts would remain;

- or a material change to the DCO would be necessary.

This is not a theoretical issue. The entire cable network has been designed around Site 1B while NGET has not confirmed that the location or configuration will be used.

The Examining Authority should not grant broad cable powers on the assumption that any later connection solution can be accommodated through detailed design.

4.9.19 Are the powers wider than the assessed alignment?

A corridor-based DCO may lawfully retain route flexibility, but the assessed alignment must encompass the worst realistic effects of every permitted route.

The Applicant should therefore reconcile:

- the Works Plans;
- cable figures;
- environmental constraints plans;
- land plans;
- and the final cable schedule.

For each corridor, it should identify:

- environmentally constrained areas;
- prohibited areas;
- fixed crossings;
- maximum working width;
- maximum circuit number;
- and permanent infrastructure.

Without that reconciliation, the power to route ‘anywhere’ within the corridor may be wider than the alignment actually considered in the technical assessments.

4.9.20 Cumulative below-ground effects

Norfolk County Council identifies uncertainty over the cumulative below-ground impact of:

- solar piling;
- substation piling;
- BESS foundations;
- cable trenches;
- HDD;
- drainage;
- and other buried infrastructure.

The effects should not be assessed in isolation. In some locations, several work types may overlap or run close together.

The final assessment should therefore map and assess the combined maximum below-ground envelope, including:

- excavation depth;
- pile depth;
- cable depth;
- groundwater interaction;
- soil displacement;
- concrete;
- aggregate;
- and retained infrastructure.

This is particularly important around Site 1B, where the BESS, project substation, National Grid substation, pylons and cable routes converge.

4.9.21 Cable lifespan and replacement

The Environment Agency identifies uncertainty over cable lifespan and the need for replacement.

The Scheme has a proposed 60-year operational life, but the application does not provide clear evidence that every cable and joint will remain serviceable for that period.

The Applicant should identify:

- assumed life of each cable type;
- joint-bay life;
- whether replacement is anticipated;
- whether replacement requires re-excavation;
- whether ducts permit cable pulling;
- and whether replacement traffic and waste

4.10 The Rochdale Envelope is insufficiently defined or controlled

4.10.1 The Applicant's reliance on a design envelope

The Applicant relies upon the Rochdale Envelope to retain flexibility over the detailed design of the Scheme. That approach is not objectionable in principle. It is not necessary for a DCO application to identify the manufacturer, model or precise final position of every panel, transformer, cable or item of electrical plant.

However, a lawful and reliable design envelope must do more than identify broad development areas and a selection of indicative or maximum dimensions. It must:

1. define the principal physical and operational characteristics of the development;
2. identify the realistic range of designs that may ultimately be constructed;
3. assess the environmentally worst realistic outcome for each relevant receptor;
4. prevent combinations of parameters that were not assessed;
5. and contain enforceable controls ensuring that the detailed development cannot produce materially different or worse effects.

ES Chapter 4 states that the Environmental Statement is based upon maximum and, where relevant, minimum parameters intended to represent the realistic worst case. The Applicant relies upon the Design Principles, Parameters and Commitments document and the draft DCO Requirements to ensure that the detailed design will produce environmental effects that are the same as or no worse than those assessed.

The revised Explanatory Memorandum now makes one aspect of that flexibility explicit. The Applicant deliberately seeks no upper electrical-output limit for the generating station. It states that future technological improvements may permit a greater generating capacity to be achieved within the assessed physical parameters and considers an output cap unnecessary provided the consent envelope is adequately secured. BEPS does not contend that the absence of a MW cap is unlawful in itself. Its significance is that the Applicant must demonstrate that every potentially output-sensitive environmental effect remains bounded by parameters independently secured within the DCO, including inverter and transformer specification, electrical plant, cooling requirements, operational noise, heat, EMF, replacement activity and associated grid infrastructure.

The evidence examined in the preceding sections demonstrates, however, that the retained flexibility extends beyond ordinary equipment selection. It affects:

- the technology used across the solar fields;
- the number and distribution of electrical units;
- the capacity, duration and chemistry of the BESS;
- the number and configuration of project substations;
- the location, necessity and final form of the National Grid connection;
- the alignment and scale of underground cable works;
- the number and extent of temporary construction areas;
- the timing and scale of replacement works;
- and the identity of infrastructure that would remain permanently after decommissioning.

In several instances, no complete maximum parameter has been stated. In others, the parameter stated in the final application differs from that presented during consultation. In still others, the future infrastructure owner has not confirmed that the work described and assessed by the Applicant will form the final solution.

The issue is therefore not simply whether some details may properly be chosen later. It is whether the Order defines and controls one assessable project, or instead authorises a range of materially different projects whose combined environmental and operational consequences have not been demonstrated.

ISH1 has materially strengthened this issue. The Applicant confirmed that the Illustrative Masterplan is "entirely indicative" in the sense that important infrastructure siting remains capable of detailed-design change. The ExA consequently sought further information concerning panel overplanting and ratings, panel type and location, minimum panel spacing, AIS/GIS substation technology, switchrooms and conversion units, fencing, lighting, Site 6 construction use and construction-compound phasing.

This does not make the Rochdale Envelope unlawful. It does, however, make the control question more acute: the Examination must be able to identify the set of materially different configurations which the DCO permits and demonstrate that each remains within the reasonable worst cases assessed.

4.10.2 Consolidated assessment of the retained flexibility

The following table brings together the principal areas in which the Rochdale Envelope remains incomplete, internally inconsistent or insufficiently controlled.

Scheme component	Uncertain parameter	Why it matters	Evidence	Required control
Overall generating capacity	The Scheme is promoted as approximately 500 MW, but the authorised generating station is described only as exceeding 100 MW and the Applicant expressly states that no upper electrical-output limit is sought.	The need and benefits case may rely on a 500 MW project, while the Order may permit a materially smaller or potentially larger generating station; this also affects severability and compulsory acquisition	Revised Explanatory Memorandum APP/3.2, §1.4.3–1.4.4.	Maximum solar export capacity and any minimum implementation capacity secured in the DCO

Solar development extent	Total developed panel area, maximum panel number, table number and equipment density	Determines landscape coverage, runoff, construction materials, traffic, replacement waste and land-use intensity	ES Chapter 4 provides spacing and dimensional parameters but no consolidated equipment total	Site-by-site maximum developed area and equipment schedule
Solar-panel technology	Fixed panels, single-axis trackers or a mixture of both	The technologies differ in height, movement, orientation, glare, landscape effect, aviation interaction, vegetation management and runoff behaviour	NCC notes that both technologies remain permitted; SNC distinguishes 4.5 m trackers from lower fixed panels; NGC and GAAC raise aviation concerns	Field-by-field technology schedule and sensitive-area restrictions
Tracker height and movement	Trackers may reach 4.5 m and move through a wide operational angle	Maximum inclination produces a different visual, glare and aviation profile from the horizontal position	ES Chapter 4; SNC; NGC; GAAC	Maximum movement and angle secured; tracker exclusions around sensitive receptors
Fixed-panel height and orientation	Fixed panels may reach 3.5 m and be installed at slopes between approximately 10 and 35 degrees	Height and slope affect visibility, heritage setting, glare and runoff direction	ES Chapter 4; SNC seeks lower fixed panels in sensitive areas	Lower field-specific height limits and secured orientation

Panel row spacing and density	Final row separation and density remain adjustable within broad limits	Affects panel number, vegetation, soil exposure, runoff, maintenance access and landscape character	ES Chapter 4	Maximum field density and binding minimum spacing
Panel foundations	Driven piles, screwed piles, concrete feet or non-penetrative foundations; pile number and diameter not fixed	Different methods produce different noise, vibration, archaeological, groundwater, soil and drainage effects	NCC identifies cumulative below-ground impacts; EA seeks clearer foundation information	Location-specific foundation method; maximum depth, diameter, number and concrete volume
Conversion units and inverters	Equipment may be standalone or integrated; maximum total number and distribution are not stated	Determines cumulative noise, transformer oil, hardstanding, drainage, material use and visual clutter	ES Chapter 4 gives individual dimensions but not total quantities	Site-by-site maximum equipment count and cumulative noise and hardstanding limits
Solar-site fencing	Final alignment, gate locations and total length	May fragment habitat, obstruct emergency or statutory access and affect landscape character	ES Chapter 4; NGT access concerns; NGC emergency-landing concerns	Approved fencing plan, ecological permeability and access safeguards
CCTV and security infrastructure	Final number and location of cameras and poles	Affects visual amenity, ecology, privacy and	ES Chapter 4 states maximum	Maximum numbers and an approved security layout

		aviation perception	heights but not quantities	
Lighting	Number, height, brightness, direction and duration of operational, emergency and temporary lighting	Affects dark skies, ecology, residential amenity, landscape and aviation	ES Chapter 4; SNC; NGC and GAAC	Binding lux limits, hours, shielding, height and emergency-lighting protocol
BESS connection status	Solar has Gate 2 status while BESS remains Gate 1	The project is presented as integrated solar and storage, but the components do not share the same connection certainty	NGET Relevant Representation	BESS connection entitlement before commencement and a works-severability schedule
BESS capacity	MW, MWh, discharge duration, import capacity and export capacity are not clearly fixed	Determines stored energy, system benefits, connection requirements, fire consequences and compound scale	ES Chapter 4; NGET; NCC	Maximum and minimum MW/MWh, duration and import/export limits
BESS technology	Battery chemistry, cell type, enclosure type and energy density	Different technologies may have materially different fire, emission, cooling, waste and emergency consequences	EA raises firewater, damaged battery and replacement concerns	Defined technology envelope and measurable fire, pollution, heat and noise limits

BESS enclosure number and size	Maximum number, length and width of battery enclosures	Determines compound area, spacing, fire propagation, access and drainage	NCC LLFA states enclosure number and dimensions were unknown	Maximum enclosure dimensions and number, with minimum separation distances
BESS compound area	No complete numerical maximum for the total BESS compound and associated plant is clearly stated	Determines land take, visual effect, impermeable area and firewater requirements	ES Chapter 4; NCC LLFA	Certified maximum compound boundary and impermeable-area limit
BESS cooling and auxiliary plant	Number, rating and sound-power level of cooling systems, inverters and transformers	Determines night-time noise, heat rejection, oil inventory and drainage	SNC requires updated noise assessment; NCC and EA identify unresolved plant detail	Maximum equipment schedule and receptor-based operational noise limits
BESS drainage and firewater containment	Containment volume, isolation arrangements, sealed drainage and suppression system	A fire could produce contaminated water affecting groundwater and watercourses	EA seeks impermeable drainage, penstocks and worst-case containment; NCC LLFA identifies insufficient space and detail	Approved quantified firewater and drainage design before battery installation
BESS emergency access	Final access, secondary access, turning and separation	Determines whether emergency services can respond safely	NCC fire and emergency evidence	Fire-authority-approved access and emergency-response plan
BESS replacement	Up to five replacement cycles, with	Later equipment may produce different fire,	ES Chapter 4; EA	Replacement technology-equivalence test

	future technology unspecified	noise, waste, traffic and pollution effects		and updated risk approval
132 kV project substations	Number, transformer configuration, equipment layout, foundation method and oil inventory	Affects landscape, noise, drainage, pollution and groundwater	NCC identifies uncertainty over single or double configurations; EA seeks foundation and pollution information	Maximum layout, transformer number, oil inventory and foundation envelope
400 kV project substations	Number, configuration, equipment, foundations, control buildings and hardstanding	These are major industrial compounds with substantial operational and environmental consequences	NCC; SNC; EA	Substation-specific maximum layouts and equipment inventories
Site 1B project-substation voltage	Changed from 132 kV to 400 kV after statutory consultation	The higher-voltage development may require larger plant, foundations, oil containment and AIL deliveries	NCC and SNC targeted responses	Final 400 kV design schedule and topic-by-topic assessment audit
Site 1B project-substation height	Approximately 7 m at statutory consultation, approximately 13 m at targeted consultation and 15 m in final ES Chapter 4	Affects landscape, heritage, aviation and the reliability of consultation and assessment	NCC and SNC commented on the 13 m design; final ES permits 15 m	Binding 15 m maximum and proof that all assessments used it

Project-substation transformer number	Maximum number and configuration are not stated clearly	Determines noise, oil inventory, fire risk, drainage and AIL requirements	NCC; SNC; EA	Maximum transformer schedule and source sound-power levels
Project-substation oil inventory	Total transformer oil volume and credible spill scenario	Determines bunding, firewater and pollution consequences	EA	Maximum oil inventory and containment volume
Project-substation drainage	Maximum impermeable area, attenuation area and firewater containment	Larger 400 kV compounds may displace flood storage and require substantial SuDS	NCC LLFA	Compound-specific drainage calculations and fixed SuDS area
National Grid substation location	Whether Site 1B is the final point of connection	Determines the cable destination, pylons, landscape effects, land take and compulsory-acquisition case	NGET states that the final solution remains subject to wider regulatory and commercial considerations	Written NGET confirmation of Site 1B before commencement or compulsory acquisition
National Grid substation necessity	Whether NGET will construct, adopt or use the proposed substation	Consent would not oblige NGET to accommodate a connection at it; the work could become stranded	NGET Relevant Representation	Binding connection agreement and NGET confirmation before works or land powers are exercised
National Grid substation footprint	Approximately 3 ha at consultation and up to 6 ha in the final application	Doubling the area affects drainage, landscape, land take,	NCC targeted response; ES Chapter 4	Six-hectare absolute maximum and proof that the

		construction and compulsory acquisition		final footprint was assessed
National Grid substation layout	Number of bays, busbar arrangement, switchgear, buildings and electrical plant	Other Gate 2 projects may alter the final size and configuration	NGET	NGET-approved design confined to the assessed envelope
National Grid substation foundations	Raft or piles up to 12 m, but pile number, diameter and layout remain open	Affects groundwater, geology, concrete, piling noise and construction traffic	ES Chapter 4; EA	Maximum pile number, diameter, depth and concrete volume
Additional National Grid infrastructure	Further bays, pylons, line works or a different connection arrangement may be needed	Further infrastructure may fall outside the DCO and alter cumulative effects	NGET	Full final network solution and separate consent for any out-of-envelope works
Applicant/NGET works boundary	Who designs, constructs, owns, operates and maintains Works 4 and 5	Determines liability, enforcement and whether DCO Requirements bind the body undertaking the work	NGET; SNC	Joint responsibility and approvals matrix
Detailed approval of NGET works	Requirement 5 appears not to include Works 4A and 4B	Major permanent works could fall outside the principal design-control Requirement	SNC	Express DCO approval mechanism or identified equivalent statutory control

Transfer of DCO powers to NGET	Which powers and obligations transfer and when	A transfer could leave mitigation or liability with the wrong body	NGET; SNC	Transfer provisions carrying all environmental obligations
Pylon number	Up to four new pylons, with temporary works also contemplated	Number affects landscape, heritage, aviation, foundations and construction access	ES Chapter 4; NCC targeted response	Fixed absolute number and certified pylon schedule
Pylon location	Final position within broad limits	Relocation may change effects on views, heritage assets, homes and aviation	NCC	Approved alignment and restricted limits of deviation
Pylon height	Up to approximately 61 m, compared with existing towers understood to be approximately 53 m	Greater height affects long-distance visibility, heritage setting and aviation	NCC targeted response	Binding maximum height and final visual and aviation assessment
Cable circuit number	Maximum number of 33 kV, 132 kV and 400 kV circuits is not consolidated	Determines trench width, heat output, joint bays, construction duration and replacement effects	NCC; EA	Corridor-by-corridor maximum circuit and conductor schedule
Cable alignment	Cables may be routed anywhere within fourteen broad corridors	Different alignments may affect different watercourses,	ES Chapter 4; NCC; EA	Approved final alignment, exclusions and fixed sensitive crossings

		habitats, archaeology, utilities and properties		
Cable trench width and depth	Principal trenches may be up to approximately 7 m wide and 2 m deep, but the relationship between trench number and total width is unclear	Multiple parallel trenches could materially increase excavation and soil disturbance	ES Chapter 4	Maximum trench number and total excavation width
Cable working width	Typical width approximately 25 m, with local widening permitted	Local widening may increase land take and affect additional receptors	ES Chapter 4	Absolute ordinary and widened working-width limits
Joint bays	Typical dimensions and spacing are stated but maximum number and location are not	Joint bays are substantial permanent or semi-permanent excavations requiring access and drainage	ES Chapter 4; EA	Maximum number and approved locations, with removal obligations
Fibre chambers and link boxes	Number, location and above-ground elements remain open	Contribute to permanent infrastructure and access requirements	ES Chapter 4	Maximum number and approved layout
HDD and trenchless works	Maximum depth is stated, but bore length, bore number, pit dimensions and compounds are not fully defined	Affects groundwater, drilling-fluid risk, habitats and construction land	EA	Crossing-specific approval and maximum depth, length, bore number and pit area

Cable thermal effects	Conductor temperature, loading, circuit spacing and heat loss	May affect soils, groundwater, watercourses and adjacent infrastructure	EA	Maximum thermal-loading assessment and performance limit
Preferential groundwater pathways	Trenches, ducts and bedding may redirect groundwater or contaminants	Could affect springs, watercourses, private water supplies and habitats	EA	Groundwater assessment, seals, cut-offs and monitoring
Cable dewatering	Maximum rate, duration, discharge and simultaneous operations	May alter groundwater levels and watercourse conditions	EA	Quantified dewatering limits and approved discharge plan
Cable spoil storage	Volume, height, location and duration	Affects soil quality, drainage, dust, archaeology and statutory easements	NCC; NGT	Quantified soil plan and exclusion from protected easements
Cable connection dependency	Whether export cables may be constructed before Site 1B is confirmed	Could create stranded or duplicated underground infrastructure	NGET	Prohibition on export-cable commencement before final connection approval
Cable lifespan and replacement	Whether cables last for 60 years and whether re-excavation will be required	Replacement may amount to a further major construction phase	EA	Cable-life and replacement schedule
Construction compounds	Number, size, location, hardstanding and simultaneous use	Affects traffic, noise, flood risk, lighting, ecology and total temporary land take	NCC LLFA	Certified compound plans and maximum individual and cumulative footprints

Temporary laydown areas	Number, location and cumulative extent	Broad powers may permit disturbance beyond principal compounds	Work No. 8; NCC LLFA	Maximum total area and approved locations
Temporary haul roads	Total length, width, surfacing and restoration	Affects soils, drainage, hedgerows, utilities and long-term land recovery	ES Chapter 4; NCC	Maximum route network and restoration controls
Construction phasing	Number of simultaneous work fronts and degree of overlap	Greater concurrency may increase peak noise, traffic and ecological disturbance	ES Chapter 4 retains programme flexibility	Phasing plan and simultaneous-work-front limit
Construction duration	Approximately 24 months, but major components may be delivered separately	Delayed BESS or NGET works may extend disturbance beyond the assessed period	NGET; solar/BESS Gate-status evidence	Work-specific commencement and completion controls
Construction HGV movements	Daily figures are stated, but distribution, cumulative traffic and enforceable caps remain unclear	Determines local highway, noise, air-quality and residential effects	NCC; National Highways	Binding daily and hourly caps and route monitoring
AIL routes	Strategic and local routes remain unresolved	Determines physical deliverability and impacts on conservation areas, vegetation and rural lanes	National Highways; NCC; SNC	Agreed port-to-site AIL strategy before commencement

Highway works	Exact visibility works, vegetation removal and temporary alterations	May affect conservation areas, rural character, drainage and biodiversity	SNC and NCC targeted responses	Route-specific highway design and vegetation schedule
Outdated mapping	Works Plans omit the operational Long Stratton Bypass	The authorised geography and environmental baseline may be inaccurate	NCC targeted response	Corrected certified Works Plans
Inconsistent mapping	Scheme, access, infrastructure and cumulative development are depicted differently across documents	Makes it difficult to establish the exact development assessed and authorised	NCC; application plans	Formal plan-reconciliation schedule
Panel replacement	All panels may be replaced once over approximately 12–24 months	May create a second scheme-wide construction phase	ES Chapter 4; NCC; SNC	Replacement Management Plan and maximum simultaneous replacement area
BESS replacement	Up to five replacement cycles	Creates repeated traffic, noise, waste, fire and pollution effects	ES Chapter 4; EA	Maximum replacement cycles and updated technology approval
Transformer replacement	Replacement once is assumed, but route and final equipment remain open	May require further AIL movements and oil handling	ES Chapter 4; National Highways and NCC route evidence	Transformer Replacement Plan and approved route
Construction compounds for replacement	Whether original compounds may be reinstated and how large they may be	Repeated temporary land take and disturbance are not defined	NCC LLFA; ES Chapter 4	Replacement-compound limits and reinstatement controls

Decommissioning duration	Approximately 12–24 months, with method deferred	Effects depend on the final method and the infrastructure removed	ES Chapter 4; EA	Binding final Decommissioning Strategy
'Substantially in accordance with'	Final plans may only need to be substantially rather than strictly in accordance with outline controls	Adds an undefined tolerance to an already broad envelope	EA	Remove 'substantially' or define a narrow, objective amendment mechanism
Solar and BESS removal	Main above-ground works are proposed for removal, but below-ground treatment remains flexible	Determines agricultural restoration and permanent effects	ES Chapter 4; NCC; EA	Definitive removal-depth and restoration schedule
Cable and duct retention	Cables may remain or be pulled out; ducts and joint bays may remain	Leaves permanent infrastructure under agricultural land	EA; NCC	Presumption of removal unless retention is specifically justified
National Grid infrastructure after decommissioning	Substation, pylons and associated grid works remain permanently	Permanent landscape, drainage and maintenance effects continue beyond the solar project	ES Chapter 4; NCC	Permanent-infrastructure and long-term management schedule
Retained foundations	Foundations may be cut off below ground rather than removed	May constrain agriculture, drainage and future land use	ES Chapter 4; EA	Material-specific removal requirements

Permissive paths	May be removed at decommissioning	Claimed recreational benefits may not be permanent	ES Chapter 4	Clear duration and closure controls
Aviation panel-free areas	No fixed emergency landing or operational exclusion area is clearly secured	Panels may reduce emergency landing options and affect aerodrome operations	NGC; GAAC	Aviation Safeguarding Plan and certified panel-free areas
Panel reflectivity	Final module type and reflectivity are not fixed	Glare may impair pilot lookout and visibility	NGC; GAAC	Maximum reflectivity standard and site-specific glare assessment
Tracker movement near flight paths	Time-dependent panel angles and reflections	Moving surfaces may create changing glare and visual effects	NGC; GAAC	Tracker restrictions or prohibition in aviation-sensitive areas
Pylon and substation aviation effects	Final location and combined vertical envelope	May affect pilot awareness and emergency operations	NGC; GAAC; NCC	Final aviation assessment of the complete Site 1 infrastructure
Emergency landing land	Extent of land retained free of panels, fences and structures	Human safety consequences may be severe even where events are infrequent	NGC	Binding emergency-landing and access plan
Gas-pipeline setback	Exact exclusion zones for panels, foundations, compounds, planting and storage	Incompatible development could threaten national gas infrastructure	NGT	Plot-specific interface plan and agreed stand-off distances

Gas-pipeline crossings	Cable, road and drainage crossing locations and methods	Risks loading, physical damage and cathodic-protection interference	NGT	NGT-approved crossings and supervision
Ground-level changes above pipeline	Earthworks, swales, access tracks and reinstatement may change cover and loading	May affect pipeline integrity and emergency access	NGT	Prohibition without NGT approval
Material storage over pipeline	Flexible soil, plant and laydown locations	Existing easements restrict material storage and loading	NGT	Storage exclusion zones
BNG and planting over pipeline	Trees, scrub, wetland or fencing may obstruct access or introduce deep roots	Could conflict with statutory duties and emergency excavation	NGT	Planting exclusions and priority for pipeline access
Compulsory acquisition over NGT rights	Extent to which easements, rights and access may be acquired, restricted or overridden	Statutory rights could be affected before protective provisions are agreed	NGT; Statement of Reasons; Book of Reference	Agreed protective provisions and plot-specific limitation of powers
Partial implementation	Whether individual solar sites, the BESS, project substations or grid works may be omitted	The delivered Scheme may differ materially from the integrated project assessed and promoted	Solar/BESS Gate-status evidence; NGET	Works-severability and minimum-implementation schedule
Delayed implementation	Whether BESS, substations or NGET works may	May create repeated construction	ES Chapter 4; NGET	Longstop dates and updated

	commence years after the solar arrays	and changed environmental baselines		surveys before delayed works
Ownership and operation	Which body owns and operates the National Grid infrastructure and associated land	Determines long-term maintenance, liability and enforcement	NGET; SNC	Binding ownership and operational responsibility matrix
Environmental obligations after transfer	Whether mitigation and Requirements bind NGET or another transferee	Controls may become ineffective if obligations remain only with the Applicant	SNC; NGET	Transfer provisions carrying every relevant environmental obligation

4.10.3 The uncertainties cannot be considered independently

The Applicant may contend that each individual matter is a conventional question of detailed design. That does not address the combined effect of the retained flexibility.

At Site 1, for example, the final development could include:

- trackers reaching 4.5 metres and changing angle throughout the day;
- an undefined BESS capacity and number of battery enclosures;
- project 400 kV infrastructure subject to the applicable approximately 13-metre busbar parameter, together with the separate National Grid substation capable of reaching 15 metres;
- a National Grid substation occupying up to six hectares;
- up to four new pylons reaching approximately 61 metres;
- high-voltage cable infrastructure;
- permanent and emergency lighting;
- acoustic barriers;
- and substantial drainage and access works.

The final massing, appearance, noise, fire risk, drainage requirement, aviation interaction and construction demand of that combined complex cannot be established merely by considering each individual maximum in isolation.

The same applies below ground. The Scheme may combine:

- solar piles up to four metres;
- BESS and substation piles up to 12 metres;
- cable trenches up to two metres deep;
- trenchless works reaching 12 metres;

- joint bays;
- drainage;
- dewatering;
- and existing utility infrastructure.

Norfolk County Council and the Environment Agency are therefore correct to identify cumulative uncertainty concerning underground works. A separate assessment of piling, cabling and drainage does not necessarily assess their combined operation within the same geological and hydrological area.

4.10.4 Discipline-specific worst cases may not produce a controlled whole-project worst case

The Applicant states that each environmental discipline selected the design option it considered to represent its relevant worst case. That may be appropriate for individual topics, but it is reliable only if the DCO prevents a combination of parameters that would produce materially different or greater effects overall.

For example:

- a landscape assessment may treat trackers as the worst case because of their height;
- a runoff assessment may rely on fixed panels because of their continuous drip line;
- an ecology assessment may assume a different row spacing;
- and an aviation assessment may depend upon a particular panel orientation or reflective characteristic.

The Applicant must show that the final permitted combination of:

- panel type;
- panel height;
- spacing;
- orientation;
- drainage;
- fencing;
- access;
- and lighting

was either assessed directly or cannot produce effects worse than the separate scenarios considered.

A collection of discipline-specific worst cases is not necessarily a whole-project worst case. The application therefore requires a configuration audit showing that no permitted combination falls between or outside the scenarios assessed.

4.10.5 The final ES may not consistently use the final design

The design continued to evolve after statutory consultation. The Site 1B project substation changed from the smaller 132 kV installation presented during consultation

to a 400 kV installation with an approximately 13-metre busbar parameter, while the adjacent National Grid substation is subject to a separate 15-metre maximum. ISH1 has required correction of inconsistent presentation of those parameters. The National Grid substation increased from approximately three hectares at consultation to a maximum of six hectares. New pylons may reach approximately 61 metres. Further panels and land were added.

The Applicant should provide a chapter-by-chapter schedule identifying:

- the design version assessed;
- the date of the assessment;
- the maximum parameter used;
- and whether it was updated following the targeted consultation.

The schedule should cover, at minimum:

- landscape and visual effects;
- heritage;
- noise;
- glint and glare;
- aviation;
- transport;
- flood risk and drainage;
- groundwater;
- ecology;
- archaeology;
- major accidents;
- and cumulative effects.

Where an earlier parameter was retained, the Applicant must demonstrate why it remained a valid worst case.

4.10.6 The envelope cannot cure uncertainty over the identity of the connection solution

The most serious issue is the proposed National Grid connection.

A Rochdale Envelope may permit NGET to choose switchgear or refine equipment positions within a confirmed substation compound. It cannot determine after consent:

- whether Site 1B is the final point of connection;
- whether NGET will construct or use the proposed substation;
- whether other Gate 2 projects require a different configuration;
- whether a larger or differently located solution is needed;
- or whether the Applicant remains responsible for providing the land and consent.

Those are questions about the identity, necessity and delivery of the development, not its detailed design.

NGET's evidence that DCO consent would not oblige it to use the Site 1B substation demonstrates why this cannot be treated as ordinary Rochdale flexibility. The Applicant seeks consent and compulsory powers for a specific connection solution without confirmation from the future operator that this is the solution it will implement.

4.10.7 The envelope cannot cure severability

The Scheme is presented as an integrated solar, BESS and grid-connection project. However, the DCO appears capable of permitting different components to be commenced, delayed, reduced or omitted independently.

A design envelope controls how an authorised work may be constructed. It does not determine whether that work must be constructed.

The Applicant must therefore establish whether the Order permits:

- solar without BESS;
- reduced or partial BESS;
- BESS constructed many years later;
- solar works before the National Grid solution is confirmed;
- omission of individual project substations;
- cable works before their final destination is fixed;
- or construction of connection infrastructure that NGET does not adopt.

Those are realistic implementation scenarios. They require a severability and phasing assessment separate from the ordinary detailed-design envelope.

4.10.8 Broad associated-development powers increase the uncertainty

The numbered works are supplemented by broad associated-development powers covering:

- earthworks;
- bunds;
- embankments;
- trenches;
- tunnelling;
- boring and drilling;
- drainage;
- services;
- accesses;
- private-track works;
- and mitigation works.

Norfolk County Council's LLFA has identified inconsistent uses of 'associated development' and a lack of clarity concerning the 'arrangement' of major components.

Where Work Areas overlap and associated works may be placed broadly, it is not sufficient to specify only the maximum dimension of the principal structure. The DCO must also control:

- the compound serving it;
- the access;
- hardstanding;
- drainage;
- temporary works;
- lighting;
- landscaping;
- and construction footprint.

Otherwise, the real development envelope is materially wider than the principal dimensions stated in Table 4.1.

4.10.9 The Works Plans do not provide an adequate geographical control

The Works Plans define broad geographical areas but do not fix much of the final infrastructure within those areas. The known use of outdated base mapping, including omission of the operational Long Stratton Bypass, further undermines their reliability.

The mapping inconsistencies across the application also make it difficult to confirm:

- the relationship between Work Nos.;
- the relationship with existing roads and infrastructure;
- the extent of cumulative development;
- the location of sensitive receptors;
- and whether the environmental figures use the same geography as the certified plans.

A broad Work Area cannot provide a sufficient Rochdale control where movement within it could materially change effects on:

- a dwelling;
- heritage asset;
- aerodrome;
- watercourse;
- gas pipeline;
- ancient woodland;
- or public right of way.

Sensitive areas should be protected by certified exclusions and restricted limits of deviation.

4.10.10 The Design Principles cannot substitute for absent parameters

The Design Principles, Parameters and Commitments document may properly control matters such as materials, finishes, orientation and local layout. It cannot substitute for an essential maximum parameter that has not been stated.

A requirement that development must have effects ‘no worse than’ those assessed is difficult to apply where the application does not identify:

- the BESS capacity against which fire and noise effects are measured;
- the number of battery enclosures;
- the number and oil content of transformers;
- the number of cable circuits;
- the maximum widened working area;
- the maximum number of construction compounds;
- or the final connection solution.

The hearing evidence confirms the practical significance of those omissions. The Applicant was unable to identify a fixed Scheme-wide number or final location for the conversion units and switchrooms and accepted that these would be determined through detailed design. The ExA expressly raised the risk of visual accumulation or “clutter”. A maximum dimension for an individual unit therefore does not define the whole effect; the DCO also needs to constrain the number, distribution and relationship of those units to sensitive receptors.

The controls must be objective, measurable and capable of enforcement without reconstructing assumptions from multiple technical chapters.

4.10.11 ‘Substantially in accordance with’ weakens the control further

The Environment Agency objects to the use of the expression ‘substantially in accordance with’. Its concern is particularly important in this application.

The present structure appears to combine:

1. broad Work Areas;
2. overlapping works;
3. generic associated-development powers;
4. substantial equipment and layout flexibility;
5. outline management documents;
6. and an undefined ability to depart substantially from those documents.

The cumulative result risks authorising development outside the precise assumptions relied upon in the Environmental Statement.

The final DCO should require accordance with the maximum parameters and environmental commitments. Any amendment mechanism should be narrowly defined and should require evidence that the change would not:

- produce new or materially different significant effects;
- affect another land interest;
- undermine mitigation;
- or alter the compulsory-acquisition justification.

4.10.12 Required parameters, assessment and control schedule

The Applicant should provide a final consolidated schedule for every material Scheme component. The schedule should state:

Required field	**Information to be supplied**
Component	The physical or operational element
Work No.	The authorised work under which it falls
Maximum parameter	Maximum height, area, capacity, number, depth or other relevant limit
Minimum parameter	Any minimum implementation needed to support the benefits case
Location	Fixed location or limits of deviation
Technology	Technology or range of technologies permitted
Assessment assumption	Exact design used in each environmental chapter
Environmental worst case	Why the selected assumption represents the realistic worst case
Consultation version	Parameter presented at statutory and targeted consultation
Final version	Parameter now sought
DCO control	Requirement, article or certified plan securing it
Approval body	Body approving detailed design
Responsible undertaker	Applicant, NGET or another body
Severability	Whether the component may be delayed, reduced or omitted
Replacement	Permitted replacement frequency and technology limits
Decommissioning	Removal or retention obligation

This schedule should reconcile:

- ES Chapter 4;
- ES Chapter 5;
- the Works Plans;
- the Land Plans;
- the Design Principles, Parameters and Commitments document;
- the Commitments Register;

- the draft DCO;
- the outline management plans;
- the Book of Reference;
- and the final technical assessments.

4.10.13 Required DCO controls

The DCO should, at minimum:

1. identify any locations in which environmental assessment requires a particular panel technology or excludes another, and otherwise demonstrate that each permitted technology remains within the assessed reasonable worst case;
2. prohibit or restrict trackers in aviation, heritage, landscape and residentially sensitive areas;
3. limit the number of panels, conversion units, inverters and transformers;
4. define the environmental performance envelope applicable to any permitted battery technology, including capacity, duration where material, dimensions, noise, thermal characteristics, fire and pollution-control parameters;
5. fix the number, configuration, equipment, oil inventory, footprint and height of each project substation;
6. prevent commencement of the National Grid substation, pylons and export cables until NGET confirms the final connection solution;
7. fix the maximum number, height and approved alignment of pylons;
8. fix the number of cable circuits, trench number, working width, joint-bay number and crossing locations;
9. require approval of all HDD and trenchless methods within fixed maximum dimensions;
10. limit the number, footprint and simultaneous use of construction compounds and laydown areas;
11. secure construction-equivalent controls for panel, BESS, transformer and cable replacement;
12. require a definitive removal and retention schedule for decommissioning;
13. secure panel-free aviation areas, reflectivity limits and operational safeguards;
14. incorporate agreed NGT protective provisions and plot-specific exclusions;
15. correct and reconcile the certified plans;
16. remove or narrowly define ‘substantially in accordance with’;
17. prevent unassessed partial or severed implementation;
18. ensure that all environmental obligations bind any transferee, including NGET;
19. prohibit speculative, duplicate or stranded infrastructure;
20. and require further consent for any materially different connection solution or technology outside the assessed envelope.

4.10.14 Evaluative conclusion

The Rochdale Envelope relied upon by the Applicant is insufficiently defined and controlled.

The difficulty is not simply that some equipment selections remain open. The combined effect of the retained flexibility is that different configurations could produce materially different environmental and operational consequences without a clear demonstration that each falls within the assessed worst case.

The application retains uncertainty over matters central to the identity and effects of the Scheme, including:

- the solar technology deployed in each field;
- the number and density of panels and electrical units;
- the capacity, duration and chemistry of the BESS;
- the number and configuration of transformers and substations;
- the final National Grid connection location and design;
- the number and alignment of cable circuits;
- the scale and concurrency of construction infrastructure;
- the timing and nature of replacement works;
- and the permanent infrastructure retained after decommissioning.

These uncertainties are cumulative. A final design combining the maximum tracker, BESS, substation, pylon, cable, compound and replacement parameters may produce a materially different whole-project outcome from the separate scenarios assessed by individual technical disciplines.

The Applicant has not yet provided a transparent audit demonstrating that:

- every material parameter has been identified;
- the final parameter was used in each relevant assessment;
- every permitted combination remains within the assessed worst case;
- and every limit is secured by an enforceable DCO control.

Uncertainty over whether Site 1B will form the final NGET connection solution cannot be cured through a Rochdale Envelope. Nor can the envelope cure uncertainty over whether the BESS, substations or connection works must be constructed at all.

The Examining Authority should therefore require a complete parameters, assessment and controls schedule. Any parameter that cannot be demonstrated to have been assessed and secured should be fixed, restricted or removed from the authorised development. Where the uncertainty concerns the location, necessity or identity of an essential work, consent should not be granted on the basis that the matter can be resolved as detailed design after the Order is made.

4.11 Aviation-sensitive design parameters and Site 1

4.11.1 Scope of this section

The full aviation-safety case is addressed in Chapter 18. This section concerns whether the physical design envelope for Site 1 was developed and controlled with adequate regard to the operational and emergency-landing environment around Tibenham Airfield. This question belongs within the Scheme Description because the aviation consequences depend upon the final:

- extent of the solar arrays;
- panel technology;

- panel height;
- panel orientation;
- tracker movement;
- panel reflectivity;
- fencing;
- lighting;
- substation structures;
- pylon positions;
- and construction-crane envelope.

The Applicant cannot demonstrate that aviation effects are controlled merely by undertaking a glint-and-glare calculation against an indicative solar layout. The DCO must define a final development envelope that cannot later be altered in a way that creates greater aviation risk.

4.11.2 Relationship between Site 1 and Tibenham Airfield

Tibenham Airfield is an active aerodrome used by Norfolk Gliding Club for gliding and powered-aircraft operations. The Club's evidence states that the closest part of Site 1 lies approximately 1.5 to 1.6 kilometres from the relevant east–west runway threshold and that solar development lies on or close to the extended runway centreline. The Club also explains that actual operations cannot be represented adequately by a single standard powered-aircraft circuit because Tibenham accommodates mixed glider and powered-aircraft activity and operates in an environment constrained by other nearby aviation activity.

The proximity matters because the Site 1 design includes or lies close to:

- extensive solar arrays;
- the BESS compound;
- a 400 kV project substation;
- the proposed National Grid substation;
- overhead-line diversion works;
- new pylons;
- cable infrastructure;
- construction compounds;
- access roads;
- security fencing;
- and operational or emergency lighting.

The final Scheme parameters permit tracker panels up to 4.5 metres high at maximum inclination, fixed panels up to 3.5 metres, a Site 1B project substation up to 15 metres, a National Grid substation occupying up to six hectares and new pylons up to 61 metres high.

The aviation issue is therefore not confined to solar reflection. It concerns the complete change in the obstacle and emergency-landing environment created by the combined Site 1 infrastructure.

4.11.3 The original glint-and-glare work pre-dated meaningful engagement

Norfolk Gliding Club states that the original Pager Power assessment was dated March 2024, but that Pager Power did not contact the Club until October 2024 to seek operational information. The Club's position is therefore that the original assessment was prepared before the consultant had obtained information from the aerodrome operator about the actual mixed gliding and powered-aircraft operations at Tibenham.

NGC states that it subsequently explained:

- the mixed nature of flying activity;
- actual circuit patterns;
- the effect of Priory Farm Airfield to the west;
- the need for gliders to adapt their circuits to wind, lift, sink and traffic;
- and the fact that gliders cannot simply go around following an unstable or obstructed approach.

The Club considers that the Applicant's consultant nevertheless continued to rely upon an overly simplified operational model derived from powered-aircraft circuit assumptions.

GAAC similarly states that the Applicant did not engage adequately and directly with the operator of Tibenham Aerodrome and did not provide a properly site-specific appraisal of its operations. GAAC considers that the assessment should have addressed the actual aviation environment rather than treating the issue principally as a generic glint-and-glare exercise.

The significance for Chapter 5 is that the Site 1 layout may have been developed before the relevant operational constraints were understood. The Applicant must therefore demonstrate that the final Site 1 design was revisited after receiving the Club's evidence, rather than merely adding a later report to support a substantially fixed layout.

4.11.4 Norfolk Gliding Club's allegation concerning Pager Power

NGC has made a serious allegation about the provenance and adequacy of Pager Power's work. The Club states that it was told that an assessment had been based on work undertaken previously for a powered-aircraft airfield and adapted for Tibenham. BEPS does not adopt an allegation of falsification as an independently established fact. It records the allegation because it is relevant to the reliability of the design evidence and should be answered directly by the Applicant and Pager Power.

The Applicant should therefore provide:

- the original terms of instruction;
- the chronology of each aviation assessment;
- the data supplied before the March 2024 report;
- the modelled runway and circuit assumptions;

- all subsequent revisions;
- the source files and model inputs;
- and a clear explanation of how Tibenham-specific operations were incorporated.

The issue is not resolved by a general assertion that the consultant has experience of solar glint and glare. The relevant question is whether the final design was tested against the actual operational circumstances of this aerodrome.

4.11.5 Wider operational risks identified by NGC

NGC states that the relevant aviation risks include:

- glint and glare;
- engine failure after take-off;
- glider launch failure;
- aborted aerotow;
- thermal updraft effects;
- turbulence or wind shear;
- bird strike;
- and loss of usable emergency-landing land.

The Club's objection is that the original assessment concentrated principally on glint and glare and did not provide an adequate operational assessment of those wider risks.

For Chapter 5, the relevant point is not to determine the final aviation merits. It is that each of those risks may require a different design response.

For example:

- glare risk may require limits on orientation, reflectivity or tracker movement;
- emergency-landing risk may require panel-free land;
- bird-strike risk may affect habitat and waterbody design;
- turbulence concerns may affect structure location;
- and obstacle concerns may affect pylons, substations, lighting and cranes.

The design envelope should therefore identify the aviation constraint first and secure the corresponding physical restriction. It should not defer the existence and extent of mitigation until after consent.

4.11.6 The photographic and mapped evidence

The submitted photographic appendix illustrates the relationship between the runway, Site 1 and the surrounding proposed energy developments. It includes mapping said to show:

- the extended runway centreline;
- an approximately 60-degree departure or emergency sector;
- an asserted EFATO or launch-failure area extending from the runway;
- East Pye solar and BESS development;

- other solar or energy developments;
- and land said to be unavailable or unsuitable for emergency landing.

The mapping is material because it illustrates the cumulative reduction in open land within the relevant operational sector. However, the map must be treated as explanatory evidence rather than accepted uncritically as a regulatory safeguarding plan.

The Applicant should respond by producing a georeferenced plan agreed, so far as possible, with the aerodrome operator showing:

- runway thresholds;
- extended runway centrelines;
- normal and variable circuit areas;
- launch and aerotow paths;
- realistic emergency-landing sectors;
- existing obstacles;
- proposed solar arrays;
- fences;
- substations;
- pylons;
- lighting;
- other committed developments;
- and land retained free from development.

The cockpit photograph illustrating severe low-angle glare is similarly relevant as an illustration of the type of visual effect that may concern a pilot. It does not, by itself, prove that East Pye would create glare of that intensity at a specified location or time. That requires site-specific modelling using the final panel design.

4.11.7 Was the emergency-landing environment incorporated into Site 1 design?

The Applicant must explain whether the Site 1 design process treated emergency-landing land as a design constraint.

The questions are:

1. Was land beneath or close to the extended runway centreline mapped as a potential emergency resource?
2. Were EFATO, glider launch failure and aborted aerotow scenarios considered before the panel areas were selected?
3. Was the suitability of fields assessed by reference to size, slope, crop, obstacles, fences and approach?
4. Were cumulative losses from other solar and BESS schemes considered?
5. Was any solar area removed or reduced in response?
6. Was the Club asked to identify the land of greatest operational importance?
7. Is any such land protected by the Works Plans or DCO Requirements?

An assessment that calculates only the percentage of a broad sector occupied by panels may not answer whether the development removes the particular land realistically reachable during an emergency. The location and configuration of obstacles may be more important than the overall percentage of land remaining open.

4.11.8 No defined aviation-safe maximum panel extent

The DCO identifies broad solar Work Areas but does not appear to define a separate aviation-safe maximum panel extent around Tibenham. That creates a risk that the final detailed design could:

- increase panel coverage toward the runway centreline;
- infill open areas shown on indicative plans;
- substitute trackers for fixed panels;
- relocate fencing;
- add conversion units;
- or move internal access and drainage into land relevant to emergency use.

A maximum solar envelope cannot be considered aviation-safe merely because it lies within the outer Work No. 1 boundary. The relevant control must identify the parts of the Work Area in which panels and other obstacles are prohibited.

The Applicant should therefore provide a certified Aviation Safeguarding Plan for Site 1 showing:

- land on which no solar panels may be placed;
- land on which trackers are prohibited;
- development-free emergency corridors;
- maximum fence positions;
- limits on electrical compounds;
- lighting restrictions;
- crane consultation zones;
- and the relationship with substations and pylons.

4.11.9 Is there a panel-free corridor?

No binding panel-free corridor has yet been identified in the evidence considered by BEPS. The need for such a corridor should be determined through a site-specific operational assessment undertaken with NGC. The correct geometry may not be a simple rectangle along the runway centreline. It may need to reflect:

- runway use;
- wind direction;
- aerotow paths;
- winch-launch failure;
- glider performance;
- surrounding obstacles;
- other airfields;
- and land suitability.

If the evidence demonstrates that defined land is reasonably required to preserve emergency options, that land should be excluded from:

- solar panels;
- fences;
- CCTV;
- substations;
- drainage basins;
- planting that creates obstacles;
- and other structures.

A statement that sufficient agricultural land remains elsewhere would not constitute equivalent mitigation unless that land is realistically usable in the relevant emergency.

4.11.10 Tracking panels must be assessed expressly

ES Chapter 4 permits tracker panels throughout the solar development unless more specific restrictions apply. Trackers may reach 4.5 metres at maximum inclination, align in north–south rows and move east or west by up to 60 degrees from horizontal. Trackers are not equivalent to fixed panels for aviation purposes. Their:

- angle;
- apparent surface area;
- reflected-light direction;
- obstacle profile;
- and visual presentation

change during the day.

The Applicant should establish:

- whether tracker panels were modelled throughout their full operational movement;
- whether all relevant seasons and times were considered;
- whether the model used their maximum height and inclination;
- whether simultaneous reflections from multiple fields were assessed;
- whether stow positions were considered;
- and whether control-system failure could leave panels at a problematic angle.

If fixed panels represent a lower-risk option near the aerodrome, the DCO should prohibit trackers in the relevant Site 1 fields rather than leave the choice to detailed design.

4.11.11 Panel orientation and movement require binding controls

The glint-and-glare result depends upon the final panel:

- azimuth;
- tilt;
- tracking algorithm;

- movement range;
- backtracking behaviour;
- stow angle;
- and surface characteristics.

These matters cannot be left solely to manufacturer selection where aviation safety is disputed.

The DCO should define:

- permitted row orientation;
- maximum tilt;
- maximum tracker movement;
- mandatory backtracking or stow protocols where necessary;
- and any time-based operating restrictions required by the final safeguarding assessment.

Any later alteration to the tracking algorithm or replacement panel design should remain within the assessed aviation envelope.

4.11.12 Reflectivity is not adequately controlled by colour alone

ES Chapter 4 states that the panels will be bifacial and dark in colour. Colour is not a complete control on glare.

The Applicant should specify:

- maximum specular reflectance;
- maximum hemispherical reflectance;
- anti-reflective coating standard;
- surface roughness or treatment;
- degradation assumptions;
- and replacement-panel equivalence.

The control should apply to both faces of bifacial modules and to replacement panels installed during the proposed 60-year operating period.

A later statement that the selected product is ‘typical’ or ‘low reflective’ would not provide an objective, enforceable standard.

4.11.13 Fencing and obstacles within emergency areas

Even where a pilot could theoretically land between or near panels, fencing may make the land unusable or materially more hazardous.

Site 1 may include:

- deer fencing up to 2.5 metres;
- palisade fencing up to 3 metres;

- CCTV poles;
- electrical equipment;
- drainage features;
- access tracks;
- and planting.

The aviation assessment should therefore consider the complete obstacle environment, not panel surfaces alone.

Any land relied upon as retained emergency-landing space must be protected from later:

- fencing;
- hedgerow planting;
- woodland;
- drainage basins;
- equipment compounds;
- lighting columns;
- CCTV poles;
- or material storage.

4.11.14 Pylons and substations must form part of the aviation envelope

The Site 1 aviation assessment must also include the final electrical infrastructure.

The application permits:

- a project substation reaching 15 metres;
- a National Grid substation occupying up to six hectares;
- electrical structures reaching approximately 15 metres;
- and up to four new pylons reaching approximately 61 metres.

Those structures may affect:

- visual acquisition of obstacles;
- emergency route choice;
- approach and departure judgement;
- low-level powered-aircraft operations;
- and the cumulative concentration of obstacles.

The Applicant should show that the aviation assessment used the final 15-metre and 61-metre parameters, not the earlier lower substation design or existing pylon heights.

The assessment should also include construction cranes. Crane height and duration may exceed the permanent substation envelope and may create a temporary risk during sensitive construction phases.

4.11.15 Later design changes could worsen aviation risk

The current Rochdale Envelope allows later selection of:

- fixed or tracking panels;
- precise panel position;
- conversion-unit location;
- fencing;
- BESS equipment;
- substation layout;
- lighting;
- and other associated development.

Without aviation-specific restrictions, a later design could comply with the general maximum parameters while worsening risk to the aerodrome.

Examples include:

- replacing fixed panels with trackers;
- increasing panel extent toward the centreline;
- placing a conversion unit within an open strip;
- altering fence geometry;
- selecting a more reflective replacement module;
- changing tracker control;
- repositioning substation structures;
- or introducing taller construction cranes.

The standard ‘same or no worse than assessed’ formulation is not sufficient unless the aviation parameters against which ‘no worse’ is judged are objective and measurable.

4.11.16 The Examination has now treated aviation as a wider safety issue

ISH1 materially developed the aviation issue beyond the Applicant’s original focus on glint and glare. The ExA required the Applicant to identify what aviation matters beyond glint and glare had been scoped out and why, and to produce a standalone aviation-safety document.

The resulting examination issue expressly extends to matters raised concerning emergency landing and engine-failure-after-take-off scenarios, glider launch, obstacles, turbulence or wind effects and the interaction of panels, fencing, substations, pylons and BESS with the operational environment of Tibenham Airfield.

This materially strengthens BEPS’s existing submission that aviation-sensitive parameters must be treated as design constraints rather than matters to be considered only after the solar layout and electrical infrastructure have otherwise been fixed.

4.11.17 Required aviation design evidence

The Applicant should provide:

1. a site-specific aviation safeguarding assessment prepared with direct input from NGC;
2. a complete chronology of the Pager Power assessments and consultation;
3. the precise operational data used;
4. a georeferenced obstacle and emergency-landing plan;
5. tracker-specific and fixed-panel-specific glare modelling;
6. modelling of cumulative solar development;
7. assessment of the 15-metre substations and 61-metre pylons;
8. construction-crane safeguarding;
9. an assessment of fencing, planting and other obstacles;
10. and a clear response to the photographic and mapped evidence submitted by the Club.

The assessment should distinguish between:

- normal operations;
- engine failure after take-off;
- glider launch failure;
- aborted aerotow;
- unusual circuit variation;
- and other foreseeable non-routine events.

4.11.18 Required DCO controls

The DCO should provide that:

1. No solar or grid works at Site 1 may commence until an Aviation Safeguarding Plan has been approved.
2. NGC and GAAC must be consulted on that plan.
3. Certified panel-free or development-free areas must be shown where required by the assessment.
4. Trackers must be prohibited in specified areas unless demonstrated to be no worse than fixed panels.
5. Panel height, orientation, movement and reflectivity must be controlled objectively.
6. Replacement panels must meet the same or more protective reflectivity standard.
7. Fencing, CCTV, drainage, planting and compounds must be prohibited in safeguarded emergency areas.
8. Substation and pylon positions and heights must remain within the assessed aviation envelope.
9. Cranes and other tall temporary plant must be subject to an aerodrome-notification and approval protocol.
10. Lighting must comply with aviation-specific limits.
11. No material amendment may reduce retained emergency-landing land.
12. Any unresolved disagreement must be recorded in the NGC/GAAC Statement of Common Ground.

4.11.19 Conclusion

Site 1 is aviation-sensitive because of its proximity and operational relationship to Tibenham Airfield. NGC states that it lies approximately 1.5 kilometres from the east–west runway threshold and on or close to the extended runway centreline. It further states that the original glint-and-glare assessment pre-dated meaningful consultation with the aerodrome operator and did not initially reflect the mixed gliding and powered-aircraft operations at Tibenham. GAAC similarly identifies inadequate engagement and the absence of a sufficiently site-specific operational assessment. The design question is therefore whether the final Site 1 envelope was altered and controlled in response to the actual aviation environment.

The application does not yet demonstrate:

- an aviation-safe maximum panel extent;
- a binding panel-free corridor;
- a tracker-specific worst case;
- objective reflectivity controls;
- protection of emergency-landing land;
- or a complete aviation assessment of the panels, fences, substations, pylons, lighting and cranes as one obstacle environment.

Those matters should be resolved through direct engagement with NGC and secured by an Aviation Safeguarding Plan and express DCO restrictions. They should not be left to ordinary detailed design after the principle and outer extent of Site 1 development have already been authorised. If it is not possible for NGC to agree an Aviation Safeguarding Plan with the infrastructure at Site 1, an alternative location for this infrastructure should be found which is safe for aviation, or the project should not be recommended for approval.

4.12 Construction description and missing quantities

The Environmental Statement must assess the construction project actually authorised by the DCO, not merely describe the typical activities involved in building a large solar scheme.

East Pye's construction description contains useful assumptions. It anticipates an approximately 24-month construction period, commencement in 2028, completion by the end of 2030 and energisation in 2031. It also assumes, for assessment purposes, substantial concurrency between Scheme elements and estimates an average workforce of 278 workers per day, equivalent to approximately 233 full-time jobs.

Those assumptions do not, however, amount to a complete quantified construction envelope.

Important parameters remain dispersed across chapters, expressed only indicatively or deferred to later management plans. As a result, it is difficult to establish whether the

transport, noise, air quality, groundwater, drainage, materials, waste and carbon assessments are all based on the same maximum construction case.

The issue is therefore not whether every contractor detail must be fixed now. It is whether the DCO defines the reasonable worst-case construction project with sufficient precision for its likely significant effects to have been assessed.

4.12.1 Programme, phasing and simultaneous construction

The stated 24-month programme is indicative rather than an absolute DCO limit. The Applicant should therefore explain whether that period includes all solar Sites, the BESS, all fourteen Cable Route Corridors, the project substations, National Grid works, commissioning and energisation, or whether substantial elements may be constructed later.

That uncertainty matters because the BESS remains at Gate 1, the NGET connection solution is unresolved and the Scheme may be implemented in stages. Chapter 4 itself states that subsystems may be commissioned separately or simultaneously depending on the technology and programme adopted.

The environmental assessment should therefore distinguish the principal construction phase from delayed BESS works, delayed NGET works, commissioning, replacement and eventual decommissioning. Otherwise a Scheme capable of generating several major periods of construction disturbance is presented as though it comprised one approximately 24-month event.

The same problem arises at Site level. The application does not provide a consolidated programme showing how long each solar Site, cable corridor, substation, compound, BESS work area, pylon location or highway intervention may remain active.

Local effects depend on duration at receptors rather than only on the Scheme-wide programme. A resident may experience access works, piling, cable trenching, HGV traffic, substation construction and reinstatement consecutively or concurrently. The maximum duration and overlap of those activities should therefore be identified.

Nor is maximum workforce concurrency necessarily the environmental worst case. Different effects may arise from different combinations of activity. The maximum workforce may not coincide with the maximum number of piling rigs, HGV streams, HDD operations, concrete pours, dewatering locations or simultaneous cable trenches.

The Applicant should therefore identify the maximum simultaneous work fronts and the construction scenario relied upon for each environmental topic.

ISH1 has since required greater clarity concerning construction-compound phasing and the maximum simultaneous development case. That reinforces the need for a

programme-linked worst-case scenario rather than a nominal overall construction duration.

4.12.2 Construction sequencing must reflect environmental and safety dependencies

The construction sequence is itself environmentally material.

Access, drainage and ecological safeguards may need to precede intrusive works. Firewater containment and emergency access must be available before hazardous BESS equipment is introduced. NGET works may need to reach a defined stage before the generating station can be commissioned.

The present BESS sequence is particularly important because Chapter 4 describes battery, inverter and switchgear installation before completion of fire-safety measures. The Environment Agency has objected to that approach and seeks appropriate sealed containment and fire-safety infrastructure before battery equipment is introduced.

The DCO should therefore secure essential construction hold points. In particular, drainage isolation, firewater containment, emergency access, fire detection and any required suppression or cooling systems should be completed and tested before battery units are brought onto the BESS compound.

The same principle applies elsewhere: environmental protection should precede the activity creating the risk, not follow it.

4.12.3 Workforce and traffic assumptions require reconciliation

The workforce and transport assumptions should also be reconciled in one authoritative construction scenario.

Chapter 4 gives the average workforce figure of 278 workers per day, while the transport assessment relies on separate assumptions concerning vehicle occupancy, shuttle buses, car sharing, parking and arrival patterns.

The Applicant should identify the peak workforce, maximum simultaneous workforce and the resulting maximum vehicle demand. Where traffic mitigation depends upon car sharing, shuttle buses, parking restrictions or travel planning, those assumptions should be secured rather than left as aspirational behavioural measures.

The same issue arises with HGV traffic.

The application provides average and peak figures for particular Sites and cable works, but the relevant assessment must establish the maximum total and route-specific daily and hourly movements where different construction activities overlap.

That should include the full range of construction traffic: articulated and rigid HGVs, concrete mixers, tippers, tankers, fuel bowsers, cranes, LGVs, minibuses, shuttle buses and private cars.

Statements that deliveries will avoid peak periods “where practicable” do not themselves impose a traffic limit. If the assessment depends upon restricted timing, those restrictions should be secured.

The actual shift pattern also matters. Core works beginning at 07:00 may generate a worker traffic peak before the conventional 08:00–09:00 network peak, while departures may occur after 18:00. The traffic assessment should therefore reflect the Scheme’s own operational peaks rather than only standard highway peaks.

4.12.4 Abnormal-load construction remains insufficiently quantified

The BESS, project substations, National Grid substation and transmission works may require abnormal indivisible loads.

The construction description should therefore identify the principal AIL components, their anticipated dimensions and weights, number of deliveries, destinations, routes, crane requirements and any temporary highway works required.

This is particularly important because Chapter 4 permits abnormal-load movements outside normal construction hours. Unless the number and timing of such movements are bounded, occasional exceptions may in practice become a recurring source of night-time or early-morning disturbance.

The AIL assumptions should therefore be reconciled with the transport chapter and secured through the DCO or CTMP.

4.12.5 Solar piling is not sufficiently quantified

The solar mounting structures may use piles up to approximately four metres deep, but the application does not provide a consolidated maximum number of piles, piles per Site, pile section or diameter, installation rate, number of rigs operating simultaneously, duration of piling at individual receptor areas or the proportion of foundations likely to require an alternative method.

Those parameters are directly relevant to noise, vibration, archaeology, soil disturbance, groundwater and construction traffic.

The application also retains flexibility between driven piles, screw piles and other foundation methods. Those techniques may differ materially in noise character, vibration, duration, plant requirements and below-ground disturbance.

The treatment of refusal is similarly important. Pre-drilling, relocation, screw piles, concrete feet or excavation do not have identical effects.

The Applicant should therefore define the assessed foundation envelope rather than leaving the response to ground conditions wholly to detailed design.

4.12.6 Deep foundations for BESS and substations require the same discipline

The BESS, project substations and National Grid substation may require foundations or piles extending to approximately 12 metres.

No consolidated maximum is provided for pile number, diameter, spacing, rig numbers, concrete volume, spoil generation or installation duration.

That omission is material because the Environment Agency has sought location-specific foundation-risk assessment and Norfolk County Council has raised concerns about cumulative below-ground effects from foundations, drainage and cables.

Revision 2 of the draft DCO has widened, rather than narrowed, this uncertainty by amending Work No. 2 expressly to permit flexibility in the type of piling used for the BESS, including possible steel piling.

The Applicant should therefore identify the maximum piling parameters encompassed by the ES assessments and demonstrate that every foundation system authorised by the DCO remains within those effects.

4.12.7 Concrete and civil works need a quantified maximum

Revision 2 now expressly includes “foundations” within the authorised descriptions of solar conversion infrastructure, project substations and the National Grid substation.

The application contemplates concrete feet, plinths, slabs, reinforced BESS bases, substation foundations, pile caps, control buildings and joint bays, yet provides no scheme-wide maximum concrete volume.

That omission has consequences for HGV demand, construction duration, water use, pollution risk, embodied carbon and decommissioning.

The Applicant should therefore provide maximum concrete quantities by principal component, together with the corresponding delivery assumptions and pollution-control arrangements. This is particularly important given the Environment Agency’s concern that the application contains insufficient detail concerning concrete activities and associated pollution prevention.

4.12.8 Cable excavation and below-ground works are not fully quantified

The Scheme contains extensive internal, 33 kV, 132 kV and 400 kV cabling, together with joint bays, fibre chambers and trenchless crossings.

Although individual trench and joint-bay dimensions are provided in places, the application does not state the total maximum trench length, excavation volume, simultaneous open-trench length, aggregate bedding, imported fill or displaced spoil.

Those quantities matter because cable construction is one of the Scheme's principal sources of soil disturbance, groundwater interaction, haul-road requirements, spoil generation and construction traffic.

The Applicant should therefore quantify the maximum below-ground construction envelope across the Scheme, not merely the dimensions of an individual trench section.

4.12.9 HDD and trenchless construction remain underdefined

The application treats HDD as a reasonable worst-case trenchless method and allows launch and reception areas of approximately 25 metres by 25 metres, with drilling structures up to approximately six metres high.

However, it does not provide the maximum number of HDD operations, simultaneous operations, bore lengths, number of bores at each crossing, duration, water demand or drilling-fluid volumes. It also retains other possible methods, including tunnelling, pipe jacking and auger boring.

Those alternatives may have different noise, groundwater, spoil and construction-compound implications.

The Environment Agency has specifically raised concerns about drilling-fluid management, while South Norfolk Council has identified uncertainty over HDD operations and noise.

The Applicant should therefore provide a crossing schedule defining the assessed trenchless construction envelope.

The same applies to drilling fluids. Monitoring for loss of returns and stopping work after a leak is detected is an incident response, not a complete risk assessment. The maximum fluid volumes, composition, pressure, storage, recycling, disposal and frac-out controls should be established, particularly where crossings affect watercourses, groundwater or statutory infrastructure.

4.12.10 Dewatering is a potentially material but unquantified activity

Trenches, joint bays, foundations and HDD pits may all require dewatering, yet the application does not identify maximum pumping rates, durations, simultaneous locations, discharge volumes or treatment arrangements.

Those parameters are directly relevant to groundwater, private water supplies, contaminated land, watercourses and ground stability.

Given the Environment Agency's concerns regarding groundwater pathways and foundation and trenchless works, dewatering cannot safely remain an unspecified contractor matter.

A quantified reasonable worst case should be provided and reflected in the water assessment and relevant control plans.

4.12.11 Earthworks, compounds and hardstanding require clearer limits

Chapter 4 states that site-wide reprofiling is not anticipated but accepts that local levelling, excavation and platform construction will occur for substations, BESS, tracks, cable works and compounds.

The application does not provide a consolidated maximum for cut and fill, imported material, platform height, bunding or permanent ground-level change.

The same uncertainty applies to construction compounds and laydown areas. Their locations are often indicative, and the total number, cumulative footprint, impermeable area, hardstanding, duration and simultaneous operation are not comprehensively fixed.

Norfolk County Council's LLFA has specifically raised concern about incomplete compound information and associated drainage.

That matters because drainage design depends on the area, surfacing, duration and contaminant risk of the compounds concerned. A Rochdale envelope that leaves those parameters substantially undefined makes it difficult to verify the associated flood-risk and water-quality assessment.

The Applicant should therefore define maximum compound, laydown and hardstanding footprints and demonstrate that the corresponding drainage assumptions have been assessed.

Site 6 now requires particular clarification. Although solar development has been removed from Site 6, the Applicant proposes to retain construction-compound use there. The ExA has required explanation of that use, its possible operational reuse and its relationship with biodiversity land intended to mature over a 25-year period. A temporary construction function cannot simply be assumed compatible with long-term ecological commitments occupying the same or adjoining land.

4.12.12 Haul roads and temporary access also need a defined envelope

The Scheme requires internal solar tracks, cable haul roads, BESS and substation access, pylon access and temporary highway works.

No consolidated maximum is provided for total temporary haul-road length, aggregate requirement, statutory-apparatus crossings or temporary bridge requirements.

Those works are environmentally significant because they affect soils, drainage, hedgerows, watercourses and statutory infrastructure and generate substantial material movements.

The Applicant should therefore identify the maximum temporary and permanent access footprint, including width, surfacing, loading, drainage and restoration assumptions.

4.12.13 Pollution-control infrastructure cannot remain generic

Several construction-control measures remain described only at a generic level.

The Environment Agency has identified insufficient detail concerning wheel washing, fuel and chemical storage, drilling fluids and concrete activities.

For wheel washing, the construction case should identify the location, capacity and drainage arrangements of facilities and explain how wash water and silt are contained and disposed of.

For fuel and chemicals, the Applicant states that above-ground tanks will be bunded to 110% capacity but does not identify the maximum number or total pollutant inventory across compounds.

That matters because the reasonable worst case depends upon the amount and location of material capable of causing pollution, not merely the construction standard of the tank in which it is stored.

These inventories should therefore be quantified and reconciled with flood risk, watercourse proximity and the environmental management plans.

4.12.14 Welfare and water demand should reconcile with the workforce case

Chapter 4 estimates total construction water demand at approximately 16,872.2 cubic metres and a maximum potable demand of approximately 13.97 cubic metres per day. Tanker supply and self-contained welfare facilities are anticipated.

Those figures should be reconciled with the peak workforce and the traffic assessment.

The Applicant should demonstrate that the assumed water-storage, foul-water removal and tanker movements are consistent with the maximum construction population and do not generate additional traffic beyond that assessed.

4.12.15 Materials, spoil and waste remain only partially quantified

The application should also provide a more complete account of the principal material flows associated with construction.

Concrete, aggregate, sand bedding, steel, aluminium, panels, cabling, fencing, batteries, road stone, imported fill and transformer oil all have consequences for HGV movements, storage, carbon, waste and eventual decommissioning.

The same applies to excavated materials.

Chapter 4 anticipates reuse of spoil and removal of contaminated material where necessary, but does not provide maximum stockpile footprints, heights, durations or a reasonable worst-case contaminated volume.

Those matters are particularly important where stockpiles interact with drainage, soils or NGT easements.

Construction waste is also described largely in qualitative terms. Packaging, cable drums, pallets, plastics, timber, damaged panels, rejected batteries and hazardous absorbents should be included within the maximum construction waste case, with appropriate arrangements for damaged battery units.

4.12.16 Vegetation removal should be quantified as part of construction

Access works, AIL routes, visibility splays, cable works, compounds and grid infrastructure may require removal of hedgerows, trees, scrub and verge vegetation.

Those losses should be quantified as construction parameters rather than appearing only within landscape or ecology chapters.

South Norfolk Council has already raised concern regarding mature vegetation removal for temporary AIL purposes and effects within conservation areas.

The maximum construction case should therefore identify the hedge length, tree numbers and vegetation areas capable of removal, together with reinstatement assumptions.

4.12.17 Construction lighting and working hours require enforceable limits

The application anticipates mobile lighting towers of approximately 8 kVA and lighting at construction compounds but does not define the maximum number, height, operating hours, lux levels or duration at individual locations.

Those parameters are material in a dark rural landscape and in relation to bats, residents and aviation.

Working hours require similar precision.

The stated core hours are 07:00–18:00 Monday to Friday and 08:00–13:30 Saturday, with no routine Sunday or Bank Holiday working. However, start-up and shutdown are expressly excluded from those periods.

The Applicant should therefore define the earliest permissible start-up, latest shutdown and the activities and vehicle movements permitted during those periods.

The out-of-hours exceptions are also broad. HDD, abnormal-load deliveries, concrete pours, public-highway cable works and emergency activities may all occur outside normal hours.

Those exceptions should be bounded by maximum frequency or duration, notification arrangements and appropriate noise and lighting limits. 'Emergency' should not extend to ordinary programme recovery or commercial delay.

The ExA has separately required further information concerning operational and construction lighting. That evidence must identify not merely fixture types but the locations, duration, trigger conditions, illumination levels and environmental limits necessary to keep lighting effects within the assessed landscape, ecological, residential and aviation envelope.

4.12.18 Commissioning is a separate construction-stage effect

Commissioning may occur separately for solar, BESS and transmission infrastructure and may involve energisation testing, transformer operation, BESS cooling, alarms, lighting, emergency-system testing and associated traffic.

Where commissioning occurs outside normal construction hours or before the Scheme enters ordinary operation, its effects should be identified and controlled separately.

The Applicant should therefore state the maximum commissioning duration, hours and principal noise and lighting sources.

4.12.19 A consolidated Construction Parameters Schedule is required

The recurring difficulty across the construction description is not the absence of every contractor detail. It is the absence of one authoritative schedule identifying the maximum construction parameters relied upon across the Environmental Statement.

BEPS submits that the Applicant should provide a consolidated Construction Parameters Schedule covering, at minimum:

- overall and Site-specific duration;
- maximum simultaneous work fronts;
- peak workforce and traffic;
- HGV and AIL limits;
- pile numbers, methods and rigs;
- maximum concrete quantities;
- cable-trench and joint-bay excavation;
- HDD and drilling-fluid parameters;
- dewatering;

- earthworks;
- construction compounds and hardstanding;
- haul roads;
- water and welfare demand;
- pollutant inventories;
- materials, spoil and waste;
- vegetation removal;
- construction lighting;
- out-of-hours activity;
- and commissioning.

The purpose of that schedule is not administrative convenience. It is to demonstrate that each environmental chapter has assessed the same maximum construction project and that the DCO does not authorise a materially more intensive construction scenario.

4.12.20 DCO controls required

The final Order should secure the construction parameters material to the environmental conclusions.

That should include a maximum construction period and controlled phasing; Site-specific duration and concurrency limits where material; enforceable workforce and vehicle assumptions; HGV and AIL controls; quantified foundation, HDD, dewatering, compound and hardstanding envelopes; pollution and lighting limits; defined out-of-hours exceptions; appropriate BESS safety sequencing; and updated surveys and management plans where materially delayed components such as the BESS or NGET works are constructed substantially later than the baseline assessed.

Where a parameter was relied upon to reach a conclusion of no significant effect, it should not remain merely indicative.

4.12.21 Conclusion

East Pye's application provides a substantial narrative description of construction, but it does not yet provide one complete quantified account of the maximum construction project which the DCO would permit.

The principal uncertainties concern duration and phasing, simultaneous work fronts, piling, deep foundations, concrete, cable excavation, HDD, drilling fluids, dewatering, compounds, haul roads, pollutant inventories, spoil, vegetation removal, lighting, out-of-hours activity and commissioning.

Those matters are not simply contractor preferences. They determine the intensity, duration and location of effects assessed in the Environmental Statement.

The concern is reinforced by statutory consultees. Norfolk County Council has identified insufficient works descriptions, uncertain compound arrangements and unquantified supporting infrastructure. The Environment Agency has sought additional detail concerning concrete activities, drilling fluids, temporary works, wheel washing, fuel and chemical storage, foundations and BESS safety sequencing. South Norfolk Council has identified uncertainty concerning HDD, piling, construction noise and spoil handling.

The Applicant should therefore provide a consolidated and binding Construction Parameters Schedule before the close of Examination.

Until the maximum quantities, methods and durations are reconciled across the ES and secured through the DCO, the ExA cannot be satisfied that the construction effects reported represent the full development which the Order would authorise.

4.13 Unresolved end-to-end transport and AIL deliverability

4.13.1 Purpose of this section

The detailed environmental effects of construction traffic are addressed in Chapter 11. The narrower issue for this chapter is whether the Scheme Description establishes a complete and physically deliverable construction scenario for the major components authorised by the DCO.

East Pye Solar would require the delivery of substantial electrical and construction equipment, including:

- solar panels and mounting structures;
- conversion units;
- battery enclosures;
- BESS transformers and inverters;
- 132 kV and 400 kV project-substation equipment;
- National Grid substation plant;
- cable drums;
- piling and drilling equipment;
- cranes;
- aggregate;
- and potentially transformers and other components qualifying as abnormal indivisible loads (‘AILs’).

ES Chapter 4 defines AILs by reference to vehicles or loads exceeding specified ordinary dimensions or weight and identifies transformers and cable drums as likely examples. It also anticipates temporary highway alterations, removal of street furniture, vegetation clearance, visibility works and access modifications. The Applicant nevertheless leaves the precise AIL routes and detailed delivery arrangements to later approval.

The evidence of National Highways and Norfolk County Council demonstrates that, at submission, neither the strategic nor the local highway authority had confirmed a complete and acceptable route from the port of entry and Strategic Road Network to each BESS, project-substation, National Grid substation and overhead-line work location.

The uncertainty is therefore not confined to traffic mitigation. It concerns whether the major components forming part of the assessed Scheme can physically reach their intended locations using routes that are lawful, structurally suitable, environmentally assessed and included within the Order Limits.

4.13.2 The route must be assessed from port to final compound

A deliverable AIL strategy must identify the complete journey for each abnormal load:

1. port of entry;
2. Strategic Road Network route;
3. motorway or trunk-road junctions;
4. local A- and B-road route;
5. minor-road sections;
6. temporary highway alterations;
7. site access;
8. internal haul road;
9. destination compound;
10. unloading and crane area.

It is not sufficient to demonstrate that an AIL can enter the general Scheme area. The Applicant must show that each item can reach the exact compound at which it will be installed.

The final route may differ between:

- the Site 1B project substation;
- the National Grid substation;
- the BESS;
- the Site 5A 400 kV project substation;
- the remaining project substations;
- cable joint bays;
- and overhead-line and pylon work areas.

Each destination has different access constraints, turning requirements and surrounding receptors.

4.13.3 National Highways had not agreed the strategic AIL route

National Highways identifies the A47 and A140 as the principal Strategic Road Network routes relevant to the Scheme. Its Relevant Representation states that the proposed

AIL routes had not been finally determined and that constraints might exist on the Strategic Road Network.

The outstanding matters include:

- identification of the port of entry;
- the route from the port to the A47 or A140;
- route suitability;
- structures and junctions;
- swept paths;
- temporary works;
- and the interaction with other traffic.

National Highways also refers to the policy preference for transporting large equipment by water where practicable and, where road transport is necessary, using an appropriate port and the shortest suitable road route. The Applicant must therefore justify the selected port and demonstrate why the proposed strategic route represents the appropriate and deliverable option.

The existence of more than one possible port or strategic route is not itself problematic. The difficulty is that the application does not identify a confirmed route against which all resulting highway and environmental effects can be assessed.

4.13.4 Strategic-road constraints must be identified before consent

Potential constraints on the Strategic Road Network may include:

- bridge capacity;
- vertical clearance;
- carriageway width;
- central reservations;
- roundabout geometry;
- road signs and street furniture;
- traffic signals;
- safety barriers;
- temporary closures;
- police escort requirements;
- and interaction with planned highway works.

The Applicant should provide structural and swept-path evidence demonstrating that the largest anticipated component can pass each constraint.

Where temporary works are required, the DCO must identify:

- the location;
- land required;
- authority responsible;

- duration;
- reinstatement;
- traffic-management arrangement;
- and whether the works lie within the Order Limits.

An assumption that the final equipment supplier or haulier will resolve those matters later does not establish that the Scheme presently described is deliverable.

4.13.5 Junction effects require assessment

National Highways also requires further assessment of junction effects.

The Scheme will draw construction traffic from the A47 and A140 into the local highway network. The relevant assessment must identify the distribution of traffic through the principal junctions rather than relying upon average Scheme-wide totals.

National Highways considers that the application has not established with sufficient confidence that the additional traffic at relevant strategic junctions would remain below the assessment thresholds relied upon by the Applicant.

The outstanding evidence should include:

- daily construction traffic by junction;
- peak-hour traffic;
- worker traffic;
- HGV traffic;
- AIL movements;
- directional distribution;
- cumulative projects;
- and the effect of route changes.

This matters to Scheme Description because the construction traffic case depends upon where individual sites and compounds are served from. A change in route distribution may change both junction performance and the local roads affected.

4.13.6 Greater granularity is required for cumulative construction traffic

National Highways also states that cumulative construction traffic requires greater granularity.

East Pye would not be constructed in isolation. Other proposed or consented energy and infrastructure projects may use the same strategic and local routes during overlapping periods.

The cumulative assessment should identify, for each relevant junction and road section:

- East Pye traffic;
- traffic from each cumulative project;
- overlapping construction periods;
- peak combined flows;
- AIL conflicts;
- and any shared mitigation or restrictions.

A general allowance for cumulative growth is not equivalent to a project-specific construction overlap assessment.

The issue is particularly important where East Pye's own programme remains flexible and where the BESS, National Grid substation or other components may be constructed later than the principal solar works.

4.13.7 Traffic limits must be enforceable

National Highways seeks enforceable controls over the level and distribution of construction traffic.

The application should not rely solely upon traffic forecasts that are not reproduced as binding limits in the DCO. Without enforceable limits, the Applicant or its contractors may change:

- delivery frequency;
- route distribution;
- work-front sequencing;
- worker transport;
- compound allocation;
- or construction concurrency.

The DCO should therefore secure:

- maximum daily HGV movements;
- maximum hourly HGV movements;
- route-specific caps;
- maximum worker-vehicle movements;
- AIL numbers;
- construction delivery hours;
- monitoring;
- reporting;
- and corrective action.

The Construction Traffic Management Plan should not merely record traffic after it occurs. It should contain enforceable measures requiring intervention if the assessed limits are approached or exceeded.

4.13.8 Norfolk County Council rejects important parts of the local routeing strategy

Norfolk County Council, as local highway authority, states that important parts of the proposed access and construction routeing strategy are unacceptable.

Its targeted-consultation response records that construction traffic should, wherever reasonably possible:

- enter the Scheme from B-class roads;
- transfer onto internal haul roads;
- and avoid prolonged use of narrow minor rural roads.

The County Council rejects or raises substantial concerns about several proposed local routes and access arrangements. Its position is that the construction strategy should reduce movement through villages and along lanes that are not suitable for sustained HGV traffic.

This is material because the Applicant's construction case depends upon multiple dispersed sites being supplied simultaneously or sequentially. Where one proposed route is rejected, the traffic cannot simply disappear. It must be transferred to another route, haul road or access point, with corresponding changes to:

- land requirements;
- environmental effects;
- crossing works;
- route capacity;
- and traffic distribution.

4.13.9 Hall Lane and Fairstead Lane

Norfolk County Council objects to the use of Hall Lane and Fairstead Lane as proposed construction routes.

The concerns include:

- narrow carriageway width;
- constrained geometry;
- limited passing opportunities;
- roadside vegetation;
- residential and heritage receptors;
- drainage;
- and the inability to accommodate sustained two-way construction traffic safely.

The Applicant's continued inclusion of such roads in the routeing strategy indicates that the local access solution had not been settled.

The DCO should not authorise a traffic scenario based on use of roads that the responsible highway authority considers unacceptable unless the Applicant demonstrates:

- why no suitable alternative exists;
- what physical improvements are proposed;
- that those improvements are authorised;
- that their environmental effects have been assessed;
- and that the highway authority accepts the final design.

4.13.10 Other minor rural routes

The County Council's concerns are not limited to Hall Lane and Fairstead Lane. It identifies a wider need to avoid unsuitable minor roads and to use internal haul routes between Sites wherever possible.

The final route schedule should therefore distinguish:

- routes authorised for ordinary HGVs;
- routes authorised only for LGVs;
- routes authorised only for emergency or local access;
- routes prohibited for construction traffic;
- and routes authorised for AILs.

This should be shown on certified plans rather than left to a later CTMP.

4.13.11 Routes for Sites 7–10 remained unresolved

Norfolk County Council records that access arrangements for Sites 7–10 remained unresolved.

These Sites include development around settlements and rural roads where construction traffic, AILs and access works may affect:

- Saxlingham Nethergate;
- Saxlingham Green;
- Tasburgh;
- Hempnall;
- Fritton;
- and surrounding lanes.

The Applicant must identify how each Site will be reached without relying on routes that the highway authority has rejected.

The issue is particularly acute where the proposed internal haul-road solution requires:

- new road crossings;

- private-land rights;
- temporary bridges;
- vegetation removal;
- or additional land not presently within the Order Limits.

The construction scenario is incomplete until those internal connections and crossings are defined.

The ExA has separately required further information concerning operational and construction lighting. That evidence must identify not merely fixture types but the locations, duration, trigger conditions, illumination levels and environmental limits necessary to keep lighting effects within the assessed landscape, ecological, residential and aviation envelope.

The ExA has also required further response concerning The Krons, including the relationship between the proposed access solution, ecological effects and NCC's highway position. That issue should remain open until the revised access arrangement and its environmental consequences are demonstrated.

4.13.12 AILs should use approved haul routes

Norfolk County Council's targeted-consultation response states that AILs should be directed through suitable approved routes and internal haul roads rather than unsuitable minor roads.

That approach may reduce effects on villages, but it creates its own design requirements. An internal haul route capable of carrying a major transformer may require:

- substantial width;
- reinforced construction;
- large-radius bends;
- bridge or culvert crossings;
- vegetation removal;
- level changes;
- drainage;
- and crane or recovery access.

The application must demonstrate that the internal routes have been designed for the largest load, not merely for ordinary construction HGVs.

A six-metre-wide general access-track parameter does not necessarily establish that a long, heavy AIL transporter can negotiate the full route.

4.13.13 No complete route to the BESS has been established

The BESS may require delivery of:

- battery enclosures;
- transformers;
- inverters;
- cooling plant;
- control buildings;
- and fire-safety infrastructure.

The application does not define the maximum BESS enclosure number or dimensions. It follows that the number and characteristics of BESS deliveries are also not fixed.

A route cannot be confirmed without knowing:

- the longest component;
- maximum width;
- maximum height;
- maximum gross weight;
- axle configuration;
- and turning requirements.

The BESS remains at Gate 1 and may also be constructed later. The Applicant must therefore explain whether the same routes will remain available and suitable if BESS construction occurs after the principal solar works and temporary highway alterations have been removed.

4.13.14 No complete route to each project substation has been established

The Scheme includes up to three 132 kV and up to three 400 kV project substations.

The 400 kV substations may require very large transformers and associated equipment. The Site 1B project substation changed from 132 kV to 400 kV after statutory consultation, potentially altering:

- transformer dimensions;
- transformer weight;
- AIL number;
- crane requirements;
- and route geometry.

The Applicant should provide a separate delivery schedule for each project substation. A generic assumption based on one transformer or one access cannot demonstrate deliverability to all six potential compounds.

4.13.15 No complete route to the National Grid substation has been established

The proposed National Grid substation may occupy up to six hectares and contain large transmission equipment. ES Chapter 4 provides an access-track width of up to eight metres, but the end-to-end delivery route remains dependent upon the unresolved National Grid design and equipment schedule.

NGET has not confirmed the final substation configuration. Other Gate 2 offers may change the number and type of bays or equipment. The AIL strategy therefore cannot be final until the equipment and connection solution are confirmed.

The Applicant should not rely on a route assessed for the current indicative substation if NGET may require materially different equipment.

4.13.16 Pylon and overhead-line construction access

Works Nos. 5A–5D require access to pylon locations and overhead-line working areas.

These works may involve:

- piling or deep foundations;
- cranes;
- tower sections;
- conductor drums;
- winches;
- temporary compounds;
- and temporary pylon infrastructure.

The route to each pylon work area must be shown. It may not coincide with the route to the National Grid substation. The Applicant should identify:

- the largest crane;
- component dimensions;
- bearing-pressure requirements;
- temporary access;
- conductor-stringing areas;
- and any road or field crossings.

4.13.17 Swept-path assessments

A complete swept-path assessment should be supplied for every constrained junction and access used by an AIL. It should use the actual or assessed maximum vehicle envelope, including:

- tractor and trailer length;

- steerable axle configuration;
- overhang;
- width;
- height;
- ground clearance;
- and escort space.

Swept paths based on a generic articulated HGV are not an adequate proxy for a transformer transporter.

Where the final equipment is unknown, the Applicant should assess a defined maximum vehicle envelope and secure it through the DCO.

4.13.18 Structural assessments

The route may cross:

- bridges;
- culverts;
- retaining structures;
- buried utilities;
- gas pipelines;
- drainage infrastructure;
- and weak rural road foundations.

The Applicant should provide structural assessments confirming the maximum permissible load.

Where strengthening or temporary bridging is required, the application should specify:

- design;
- location;
- land;
- environmental effects;
- duration;
- ownership;
- and reinstatement.

Those works cannot be left to later traffic management if they require additional development or rights.

4.13.19 Highway works and vegetation removal

The targeted consultation added land for:

- visibility splays;
- AIL manoeuvres;

- temporary highway works;
- removal of street furniture;
- and vegetation clearance.

South Norfolk Council identifies concern about removal of trees and hedgerows, including within or near conservation areas. Norfolk County Council also requires greater detail about the highway boundary and physical works.

The final AIL schedule should identify for each route:

- carriageway widening;
- verge reinforcement;
- tree or hedge removal;
- sign removal;
- wall or fence alteration;
- temporary surfacing;
- utility protection;
- and reinstatement.

The Applicant should distinguish permanent highway alterations from temporary works.

4.13.20 Conservation areas and sensitive rural roads

Some proposed routes pass through or close to conservation areas and settlements with historic buildings close to the carriageway.

The detailed heritage and amenity effects belong in the relevant chapters. For Scheme Description purposes, the Applicant must demonstrate whether the proposed transport can be delivered without:

- damaging buildings or boundary features;
- permanently altering rural verges;
- removing mature vegetation;
- or requiring works outside the Order Limits.

A route should not be described as available where the necessary physical alterations have not been identified and assessed.

4.13.21 Fallback routes

The Applicant should identify any fallback route for each AIL.

A fallback route may be necessary if:

- a bridge is unavailable;
- utility works intervene;
- another infrastructure project occupies the route;

- vegetation or structures cannot be removed;
- or the preferred access proves technically unsuitable.

Fallback routes must themselves be assessed and authorised. They should not be introduced later through a CTMP where they affect different communities or require different highway works.

4.13.22 Land and rights within the Order Limits

For every highway alteration, visibility splay, haul-road section and access, the Applicant should confirm that all necessary land and rights are included within the Order Limits.

The schedule should identify:

- permanent acquisition;
- temporary possession;
- new rights;
- highway powers;
- vegetation rights;
- access rights;
- and statutory-undertaker interfaces.

Where the preferred route requires land outside the Order Limits, it is not presently an authorised delivery solution.

4.13.23 Required AIL and transport deliverability schedule

The Applicant should provide the following schedule for every abnormal load:

Required information	Detail to be provided
Component	Transformer, cable drum, battery enclosure, pylon part or other equipment
Destination	Exact Site, compound or pylon location
Number of loads	Maximum number
Dimensions	Length, width and height
Weight	Gross and component weight
Axle configuration	Maximum axle load and transporter type
Port of entry	Identified port

Strategic route	Port to A47/A140 and onward route
Local route	A- and B-roads and any minor-road section
Internal route	Access and haul road to destination
Swept path	Every constrained junction and access
Structural assessment	Bridges, culverts, roads and utilities
Highway works	Widening, reinforcement, removals and reinstatement
Vegetation removal	Trees, hedges and verges
Escort and closure	Police escort, temporary closure and timing
Fallback route	Fully assessed alternative
Land and powers	Confirmation within the Order Limits
Approval status	National Highways and NCC position
DCO control	Requirement or certified plan

4.13.24 Required DCO controls

The DCO should provide that:

1. No AIL-dependent component may be constructed until an approved end-to-end AIL strategy exists for that component.
2. The strategy must identify the port of entry and complete route.
3. National Highways and Norfolk County Council must approve the parts of the route within their respective networks.
4. Maximum AIL dimensions, weight and number must be secured.
5. Swept-path and structural assessments must use the maximum vehicle envelope.
6. All required highway works and land must be included in the Order.
7. Unassessed fallback routes may not be used.
8. Hall Lane, Fairstead Lane and other routes rejected by the highway authority must be prohibited unless subsequently approved on evidence.
9. Construction traffic must use approved B roads and internal haul routes.
10. Daily, hourly and route-specific traffic limits must be enforceable.
11. Traffic monitoring and corrective-action procedures must be secured.
12. Delayed BESS or NGET construction must use an updated and approved transport plan.
13. Vegetation removal and reinstatement must be limited to approved locations.

14. Temporary highway works must be removed and restored within a fixed period.

4.13.25 Conclusion

The application does not yet establish a complete and accepted end-to-end transport and AIL solution.

National Highways states that:

- the AIL routes had not been finally determined;
- constraints may exist on the Strategic Road Network;
- the port of entry and strategic route require further work;
- junction effects need further assessment;
- cumulative construction traffic requires greater granularity;
- and traffic limits and monitoring require enforceable control.

Norfolk County Council states that:

- substantial parts of the proposed local access strategy are unacceptable;
- construction traffic should use B roads and internal haul routes;
- Hall Lane, Fairstead Lane and other unsuitable minor roads should not be used;
- and access arrangements for Sites 7–10 remained unresolved.

Neither authority had confirmed a complete and acceptable route from the Strategic Road Network to the BESS, each project substation, the National Grid substation and the overhead-line work areas.

The uncertainty is material to the Scheme Description. The DCO seeks consent for components whose delivery depends upon large and abnormal loads, but the application has not yet shown that those components can reach their destinations within the authorised and assessed construction envelope.

The Applicant should provide a complete AIL schedule, identified port of entry, end-to-end routes, equipment dimensions and weights, swept-path and structural assessments, detailed highway works, vegetation-removal plans, fallback routes and confirmation that all required land is included in the Order Limits.

Until those matters are resolved, the Examining Authority cannot safely conclude that the physical Scheme described in Chapter 4 is deliverable through the construction scenario assessed in the Environmental Statement.

4.14 Operational replacement and repowering

4.14.1 Replacement is a foreseeable part of the authorised development

The application does not describe East Pye as a static installation constructed once and then operated unchanged for 60 years. It anticipates extensive replacement of core generating and storage equipment during the operational period.

ES Chapter 4 assumes that:

- all solar panels may be replaced once;
- complete panel replacement may take approximately 12–24 months;
- the BESS may be replaced up to five times;
- and transformers may be replaced during the operational life.

The Applicant states that solar panels are expected to have an operational life of approximately 40 years. It also assumes a shorter life for BESS equipment and an approximately 30-year life for transformers. The replacement assumptions therefore form part of the realistic development scenario, not merely speculative maintenance.

Norfolk County Council's LLFA records those assumptions and identifies uncertainty over the replacement of supporting compounds and infrastructure. The Environment Agency specifically seeks clarity regarding damaged and end-of-life battery handling and notes that BESS replacement may occur up to five times. South Norfolk Council seeks noise controls ensuring that replacement equipment does not create worse operational effects.

Replacement must therefore be assessed and controlled as recurring construction activity.

4.14.2 Complete panel replacement resembles a second construction phase

The Applicant assumes that every solar panel may be replaced once. Chapter 4 states that complete replacement may last between 12 and 24 months and require a substantial workforce.

That is not a minor maintenance exercise. It may require:

- removal of every panel;
- import of replacement panels;
- cranes, telehandlers and lifting equipment;
- HGV and LGV movements;
- temporary storage;
- waste segregation;
- packaging disposal;

- welfare facilities;
- temporary lighting;
- and renewed activity across all solar sites.

The likely impacts may resemble a second Scheme-wide construction phase, even where the existing mounting structures and foundations remain.

The Applicant should therefore identify whether the initial construction assessment includes:

- all panel-removal movements;
- all replacement-panel movements;
- removed-panel transport;
- packaging;
- temporary compounds;
- worker traffic;
- and waste processing.

4.14.3 Meaning of ‘replacement’

The DCO should define what replacement permits. The term could mean:

1. like-for-like substitution of individual failed units;
2. replacement of a complete panel table;
3. replacement of every panel while retaining mounting structures;
4. replacement of panels and mounting structures;
5. redesign and reorientation of complete fields;
6. introduction of larger or more powerful modules;
7. or material repowering of the generating station.

Those possibilities have different environmental consequences.

The Applicant should state whether replacement powers permit:

- altered panel dimensions;
- altered panel height;
- a change between fixed and tracking technology;
- increased output;
- altered row spacing;
- new mounting structures;
- new foundations;
- or changes to conversion units.

If complete redesign is permitted, the activity is more properly characterised as repowering than maintenance.

4.14.4 Maximum simultaneous replacement area

The application does not clearly state what proportion of the Scheme may undergo replacement at the same time.

A programme replacing panels sequentially within small areas may produce different effects from simultaneous activity across several sites.

The DCO should secure:

- the maximum number of Sites active simultaneously;
- the maximum number or percentage of panels removed at one time;
- the maximum replacement compound area;
- and the maximum replacement duration at any receptor.

The Applicant should explain which simultaneous scenario was assessed for:

- traffic;
- noise;
- ecology;
- soils;
- landscape;
- and drainage.

4.14.5 Re-establishment of compounds and laydown areas

Panel and BESS replacement will require temporary work areas.

The application should identify whether the undertaker may:

- reopen original construction compounds;
- construct new compounds;
- restore removed haul roads;
- use Work No. 8 laydown areas;
- or establish temporary storage elsewhere within the Order Limits.

Where original compounds have been restored to agriculture or habitat, re-establishment could cause:

- renewed soil disturbance;
- loss of established vegetation;
- drainage changes;
- ecological effects;
- and conflict with BNG commitments.

Replacement compounds should therefore be identified and limited in advance, or subject to strict approval based on updated baseline information.

4.14.6 Re-establishment of haul roads and accesses

Some permanent access tracks may remain, but other temporary haul roads are expected to be removed after construction.

The Applicant should explain whether replacement permits:

- reconstruction of temporary roads;
- renewed vegetation removal;
- temporary bridging;
- road widening;
- or reinstatement of highway works.

If replacement plant or panels differ in dimensions, the original route may no longer be suitable.

The Replacement Management Plan should include:

- authorised routes;
- maximum vehicle size;
- maximum road footprint;
- statutory-apparatus crossings;
- and restoration.

4.14.7 Replacement traffic limits

Replacement traffic should be subject to enforceable limits equivalent to those governing initial construction.

The Applicant should state the maximum:

- panel delivery movements;
- removed-panel movements;
- battery enclosure deliveries;
- battery-removal movements;
- transformer AILs;
- worker vehicles;
- waste vehicles;
- and daily and hourly HGV flows.

The application should not allow replacement traffic to be treated as ordinary operational maintenance and therefore excluded from the initial construction caps.

A replacement phase lasting up to 24 months could materially affect roads and communities even if it occurs only once.

4.14.8 Updated transport information may be required

Replacement may occur decades after the initial construction phase.

By that time:

- road layouts may have changed;
- bridges may have aged;
- traffic patterns may differ;
- other development may have occurred;
- and the equipment may be larger or heavier.

The Applicant should therefore be required to submit an updated Replacement Traffic Management Plan before each major replacement cycle.

The plan should use the then-existing highway baseline while remaining within the maximum environmental limits assessed for the DCO.

4.14.9 Updated noise controls

South Norfolk Council seeks controls ensuring that replacement equipment does not produce operational noise greater than the equipment assessed.

That is necessary because later:

- inverters;
- transformers;
- BESS cooling systems;
- switchgear;
- and auxiliary plant

may have different acoustic characteristics.

Replacement approval should require:

- equipment sound-power data;
- tonal and impulsive corrections;
- cumulative modelling;
- night-time assessment;
- and compliance with receptor-specific limits.

It is insufficient to require only that replacement equipment be of ‘equivalent’ capacity. Electrical equivalence does not establish acoustic equivalence.

4.14.10 Updated soil and agricultural controls

Major replacement may involve:

- repeated HGV access;
- cranes;
- temporary compounds;
- panel storage;
- waste storage;
- and reconstruction of haul roads.

Those works may affect soils differently from initial construction because the soil structure and drainage will have changed during decades of operation.

A replacement plan should therefore include:

- soil-condition surveys;
- weather restrictions;
- ground-protection measures;
- access controls;
- storage locations;
- and restoration.

Replacement should not proceed on waterlogged soil merely because the original DCO authorised construction decades earlier.

4.14.11 Updated ecological controls

Replacement may occur after hedgerows, grassland, woodland and mitigation habitats have become established.

Reopening construction areas could affect:

- protected species;
- nesting birds;
- bats;
- reptiles;
- great crested newts;
- invertebrates;
- and habitat relied upon for BNG.

The DCO should require updated ecological surveys and method statements where a replacement phase may affect habitats or species not present or established during initial construction.

A construction method based on the original baseline cannot safely be applied unchanged after 20, 30 or 40 years.

4.14.12 Updated drainage controls

Replacement compounds, haul roads and storage areas may alter surface-water runoff.

The Applicant should identify:

- whether original drainage remains suitable;
- whether temporary attenuation is required;
- where damaged batteries or electrical equipment are stored;
- and how contaminated runoff will be contained.

Replacement of BESS equipment is particularly significant because the drainage and firewater systems must remain operational throughout battery removal and installation.

4.14.13 BESS replacement up to five times

The Applicant assumes that BESS equipment could be replaced up to five times during the 60-year operational period.

That could result in a replacement cycle approximately every 10–15 years, depending on equipment life and commissioning date.

Each cycle may involve:

- removal of large numbers of battery enclosures;
- import of replacement enclosures;
- disconnection and recommissioning;
- crane operations;
- transformer or inverter changes;
- cooling-system changes;
- hazardous waste;
- damaged batteries;
- and temporary storage.

Five complete cycles represent a substantial cumulative construction and waste burden.

The Environmental Statement should identify whether its traffic, waste, carbon, materials and accident assessments include all five cycles.

4.14.14 Storage of removed batteries

The Environment Agency specifically seeks clarity about the handling of damaged and end-of-life batteries.

The Applicant should identify:

- whether batteries are removed directly from Site;
- whether temporary storage is permitted;
- maximum number or mass stored;
- storage duration;
- separation distances;
- weather protection;
- fire detection;
- temperature monitoring;
- firewater containment;
- and damaged-battery quarantine.

End-of-life batteries should not be stored on ordinary laydown areas without dedicated safety and pollution controls.

4.14.15 Damaged batteries

Damaged batteries may present greater fire and pollution risk than intact operational units.

A Battery Handling and Replacement Plan should provide for:

- identification;
- isolation;
- thermal monitoring;
- packaging;
- fire-resistant containment;
- emergency access;
- specialist transport;
- and receipt at an authorised facility.

The plan should distinguish between:

- normally depleted equipment;
- physically damaged equipment;
- recalled equipment;
- and batteries affected by fire, flooding or thermal events.

4.14.16 Different battery chemistry

The application does not fix the battery chemistry for initial construction or future replacement.

A later replacement could introduce a chemistry with different:

- energy density;

- thermal-runaway behaviour;
- combustion products;
- cooling requirements;
- firewater demand;
- spacing;
- mass;
- and waste classification.

The Applicant should not be allowed to rely upon technological development as a reason to leave the replacement envelope unlimited.

The DCO should identify measurable performance limits applying to any replacement technology, including:

- maximum stored energy;
- maximum heat release;
- maximum toxic-emission assumptions;
- minimum separation;
- maximum firewater demand;
- maximum noise;
- and maximum equipment dimensions.

A materially different technology outside those limits should require further assessment and approval. Where a future replacement technology differs from that assessed at consent, compliance should be demonstrated by environmental-performance equivalence rather than by technology label alone. The relevant equivalence parameters should include physical dimensions, electrical capacity where environmentally relevant, noise, heat rejection, EMF, fire behaviour, hazardous materials, pollution potential, traffic and waste consequences.

4.14.17 Environmental-performance equivalence

Replacement equipment should be required to perform no worse environmentally than the equipment assessed.

That requirement should cover:

- operational noise;
- fire risk;
- pollutant inventory;
- drainage;
- heat output;
- lighting;
- traffic;
- dimensions;
- visual effects;

- and waste.

The comparison should be based on objective parameters rather than a general judgment that the replacement is ‘similar’. The relevant equivalence parameters should include physical dimensions, electrical capacity where environmentally relevant, noise, heat rejection, EMF, fire behaviour, hazardous materials, pollution potential, traffic and waste consequences.

The approving authority should be supplied with:

- manufacturer data;
- risk assessment;
- noise data;
- drainage implications;
- and evidence of compliance with the secured envelope.

4.14.18 Transformer replacement

The Applicant assumes that transformers may be replaced during the operational period.

Replacement of a large 400 kV transformer may require:

- AIL transport;
- cranes;
- oil removal;
- temporary storage;
- drainage isolation;
- road works;
- and night-time delivery.

The DCO should require:

- an approved route;
- maximum replacement transformer dimensions and weight;
- oil-management plan;
- fire and spill controls;
- and operational noise compliance.

Transformer replacement should not be treated as ordinary maintenance where it involves major transport and construction activity.

4.14.19 Replacement of conversion units and other electrical plant

Inverters, switchgear and conversion units may have shorter lives than the 60-year Scheme period even where Chapter 4 does not identify complete replacement cycles for each.

The Applicant should provide a life-cycle schedule for:

- inverters;
- switchgear;
- conversion units;
- control systems;
- cooling plant;
- transformers;
- cables;
- and communications equipment.

The EIA should not account for panel and BESS replacement while omitting foreseeable replacement of the supporting electrical system.

4.14.20 Cable replacement

The Environment Agency identifies uncertainty over cable lifespan.

If cables or joints require replacement, works may involve:

- pulling new cables through retained ducts;
- opening joint bays;
- excavation;
- new trenches;
- dewatering;
- and replacement access.

The DCO should distinguish between:

- cable pulling within existing ducts;
- local joint repair;
- and complete route re-excavation.

Complete re-excavation should require an updated assessment and should not automatically fall within ordinary maintenance powers.

4.14.21 Waste calculations

The waste assessment should include:

- all original construction waste;
- complete replacement of all panels;
- up to five BESS replacement cycles;
- transformer replacement;
- inverter and switchgear replacement;
- cable replacement where foreseeable;
- and final decommissioning.

The Applicant should state the maximum:

- panel mass;
- glass;
- aluminium;
- silicon;
- battery mass;
- hazardous components;
- transformer oil;
- packaging;
- cables;
- and electronic waste.

A waste calculation based only on initial construction and final decommissioning would materially understate the lifetime waste stream.

4.14.22 Carbon and materials calculations

Replacement also affects the claimed carbon benefits.

The life-cycle assessment should include emissions associated with:

- manufacturing replacement panels;
- up to five replacement BESS systems;
- transformer and inverter replacement;
- transport;
- construction plant;
- waste processing;
- recycling;
- and disposal.

The Applicant should explain whether the carbon-payback and net-benefit calculations incorporate every replacement cycle assumed in Chapter 4.

4.14.23 Required Replacement Management Plan

The DCO should require a Replacement Management Plan before any major replacement phase.

The plan should contain:

Required matter	Information to be approved
Equipment	Type and quantity being replaced
Reason	Failure, end of life, upgrade or repowering

Technology	Existing and proposed technology
Environmental equivalence	Noise, fire, pollution, heat, dimensions and traffic
Programme	Duration and sequencing
Simultaneous area	Maximum Sites or compounds active
Workforce	Average and peak
Traffic	HGV, LGV, AIL and waste movements
Compounds	Location, area and drainage
Access	Permanent or reinstated haul roads
Soils	Survey and protection measures
Ecology	Updated surveys and mitigation
Drainage	Temporary and permanent controls
Waste	Storage, transport, recovery and disposal
Batteries	Damaged and end-of-life handling
Lighting	Hours, height and lux
Noise	Construction and operational compliance
Restoration	Removal of temporary works
Carbon	Materials and emissions account

4.14.24 Required DCO controls

The DCO should provide:

1. A maximum of one complete solar-panel replacement cycle.
2. A maximum of five complete BESS replacement cycles.
3. A maximum number or percentage of panels capable of replacement simultaneously.
4. A maximum number of BESS enclosures capable of removal or installation simultaneously.
5. Replacement compounds limited to approved locations and areas.
6. Replacement traffic subject to enforceable daily, hourly and route-specific caps.
7. An approved Battery Handling and Replacement Plan.
8. Dedicated controls for damaged batteries.
9. Objective environmental-performance equivalence for replacement equipment.

10. No change from fixed to tracking panels, or vice versa, without approval against the assessed envelope.
11. No increase in panel, BESS or export capacity through replacement unless expressly authorised.
12. Updated noise, ecology, soil, drainage, traffic and fire assessments where required.
13. Cable replacement involving excavation to require specific approval.
14. Transformer replacement to require an approved AIL and oil-management plan.
15. All replacement waste and carbon emissions to be included in lifetime calculations.
16. Replacement works to comply with construction hours, noise, lighting and community controls.
17. Temporary works to be removed and land restored after each cycle.

4.14.25 Conclusion

Foreseeable replacement is a recurring construction activity forming part of the authorised development. The Applicant assumes:

- an approximately 40-year life for solar panels;
- complete replacement of all panels once;
- a replacement programme lasting up to 24 months;
- up to five BESS replacement cycles;
- and replacement of transformers and other electrical equipment.

Those assumptions could produce several substantial construction phases over the 60-year operating period.

The application does not yet define:

- the meaning and limits of replacement;
- the maximum simultaneous replacement area;
- the compounds and haul roads used;
- replacement traffic;
- battery storage;
- changed technology;
- or the requirement for updated environmental assessment.

The Environment Agency specifically seeks clarity regarding damaged and end-of-life battery handling. South Norfolk Council requires controls ensuring that replacement equipment does not worsen noise. Norfolk County Council identifies uncertainty over the replacement of associated compounds and infrastructure.

The DCO should therefore secure maximum replacement frequencies, simultaneous-area limits, a Replacement Traffic Management Plan, a Battery Handling and Replacement Plan, objective environmental-performance equivalence and updated topic assessments where technology or conditions have changed.

Replacement must not become an uncontrolled power to reconstruct or repower the Scheme on materially different terms after the original environmental assessment has ceased to reflect the development on the ground.

4.15 Decommissioning, permanent infrastructure and restoration security

The Applicant relies substantially upon the proposition that East Pye Solar is temporary: the principal solar generating development is intended to operate for 60 years and then be decommissioned over approximately 12–24 months, with the land returned to its former use as far as reasonably practicable. That description requires important qualification.

The Applicant's own material confirms that significant infrastructure may or will remain after solar generation ceases. The National Grid substation and associated Grid Connection Infrastructure are intended to remain; underground ducting is anticipated to remain in situ; other below-ground structures may be retained; and access, drainage and established landscape mitigation may also survive decommissioning. The Applicant's original scoping material expressly anticipated removal of the solar and BESS infrastructure while retaining the National Grid substation and underground ducting.

Norfolk County Council's LLFA has reached the same conclusion. It records that the National Grid substation, pylons, overhead lines, sealing-end infrastructure, underground cable infrastructure and some access arrangements may remain and considers those elements to constitute permanent rather than temporary development. It also notes that the Applicant's own qualification that the Site will be returned to its original use only "as far as practicable" acknowledges that complete restoration may not occur.

The Examination should therefore distinguish rigorously between the infrastructure that will be removed, that which may be retained, and that which is intended to remain permanently. The environmental consequences of those categories are materially different.

The August 2026 NPPF adds further relevant policy context. Policy W3 expressly expects proposals for time-limited renewable-energy development to include arrangements for decommissioning and restoration of the site. That reinforces the need to define the post-operational end state now, rather than treating it as a matter capable of wholesale resolution approximately six decades later.

4.15.1 The 60-year description does not define the whole life of the development

The temporary character of East Pye is further complicated by the drafting of Requirement 21.

Revision 2 provides for the 60-year period to run by reference to final commissioning of "each part" of Work No. 1. If different parts of the generating station are commissioned at different times, their individual 60-year periods may therefore end at different dates.

The Applicant should identify the maximum whole-Scheme operating period permitted by that drafting. The DCO should not allow staggered commissioning to extend industrial use across different Sites materially beyond the project lifetime assessed and presented to the Examination.

Replacement should not reset that period. Nor should delayed BESS, substation or other works create a series of rolling operational periods whose cumulative duration exceeds the environmental case before the ExA.

A project relied upon as temporary in the planning balance requires a clear and objectively ascertainable end point.

4.15.2 The post-decommissioning development must be defined now

The Applicant's present decommissioning case remains partly contingent upon decisions to be made decades later.

Solar panels, mounting structures, conversion equipment, BESS plant and project substations are generally proposed for removal. The position is materially less certain for underground cables, ducts, joint bays, foundations, access infrastructure, drainage and associated grid works.

That uncertainty matters because retained below-ground development is still development. Empty cable ducts may alter drainage or constrain future excavation. Joint bays may constitute substantial reinforced structures. Foundations left beneath fields may interfere with agricultural restoration. Retained tracks and drainage continue to occupy and influence the land. Permanent National Grid infrastructure creates its own access, lighting, drainage, maintenance, security and landscape requirements.

The Applicant should therefore provide one definitive removal-and-retention schedule before the close of Examination. It should identify the treatment of the principal solar and BESS components, project substations, panel and equipment foundations, underground cables and ducts, joint bays and chambers, National Grid infrastructure, overhead lines and pylons, sealing-end or connection compounds, accesses, drainage, landscaping and ecological mitigation.

For each category, the schedule should identify whether it is removed, retained or subject to later decision; the depth and method of any partial removal; the permanent land required; the future owner; and the continuing environmental control.

Infrastructure not expressly justified for permanent retention should be removed.

4.15.3 The National Grid infrastructure is permanent development

The proposed National Grid substation is capable of occupying approximately six hectares and includes substantial electrical structures, buildings, fencing, access, drainage, lighting and foundations. The associated grid works may include new pylons reaching approximately 61 metres and permanent overhead-line reconfiguration.

The Applicant does not propose to remove that infrastructure when East Pye Solar ceases generation.

It must therefore be assessed and weighed as permanent development.

Its landscape, heritage, agricultural, drainage and ecological consequences do not become temporary merely because the generating station to which it was originally connected operates for 60 years.

That distinction is particularly important because the future role of the substation remains unresolved. If it is expected to remain because NGET anticipates wider network use or future connections, that purpose should be identified. If no future use has been established, the Applicant and NGET should explain why permanent retention is nevertheless assumed rather than removal.

The emergence of other network infrastructure and connection nodes in South Norfolk makes that question more, not less, important. The ExA should understand what continuing transmission function justifies leaving substantial permanent infrastructure in the landscape after the generating project which prompted it has ceased.

4.15.4 Permanent infrastructure requires permanent environmental assessment

The post-decommissioning landscape will not necessarily resemble either the present baseline or the operational solar landscape. The solar arrays and BESS may disappear while a six-hectare National Grid substation, pylons, overhead lines, permanent access, drainage and mature screening vegetation remain.

That scenario should be assessed expressly. The landscape and visual assessment should show the post-solar condition and should not extend conclusions about the reversibility of solar panels to grid infrastructure that remains indefinitely.

The same applies to heritage. Removal of the arrays does not reverse any continuing effect of permanent substations, pylons, access or mature screening upon the setting of churches, listed buildings, conservation areas, historic farmsteads and the wider historic landscape.

Drainage and flood risk require equivalent treatment. Permanent roofs, hardstanding, tracks and electrical infrastructure need permanent drainage. The assessment should identify the impermeable area, attenuation, discharge arrangements, climate-change

allowance, maintenance responsibility and failure arrangements applicable for the full life of the retained infrastructure, not merely the 60-year solar period. NCC's LLFA expressly considers infrastructure left after decommissioning to require permanent design and surface-water management.

4.15.5 Agricultural restoration is not established by equipment removal

The Applicant's restoration case also requires closer examination.Earlier assessment material assumes that soils affected during decommissioning can generally be restored using normal agricultural management and refers to restoration to pre-existing land grades. But after 60 years of construction, operation, replacement and eventual removal, the relevant question is not whether the panels can be dismantled. It is whether the agricultural land can actually be restored to the condition and capability relied upon in the planning case.

The land may by then have experienced repeated construction traffic, compaction, altered field drainage, trenching, foundation works, tracks, substations, local contamination, replacement activity and long-term changes in soil structure.

Some areas will not return to agriculture at all because permanent transmission infrastructure, access or other retained development will remain. Other areas may be returned to agricultural use while still containing ducts, foundations, drainage or other buried infrastructure.

The Applicant should therefore distinguish between land fully restored to its former agricultural capability, land returned to agricultural use but containing retained infrastructure, land retained for ecological purposes, and land remaining permanently in infrastructure use.

For BMV land in particular, restoration should be judged by an objective agricultural standard, not simply by removal of equipment and return of possession.

4.15.6 'As far as reasonably practicable' is not an adequate restoration standard

The Applicant's formulation that land will be returned to its former use 'as far as reasonably practicable' is particularly important. That wording leaves open the possibility that complete restoration proves technically difficult or disproportionately expensive decades later.

The LLFA has already identified the inconsistency: the Applicant uses the language of restoration while simultaneously identifying infrastructure that will remain. Where reversibility is relied upon to reduce the weight of long-term landscape or agricultural harm, the DCO should define the required restoration outcome objectively.

For agricultural land, that should include soil profile and structure, drainage, contamination status, ground levels and agricultural capability. Where BMV land has

been affected, comparable agricultural quality should be demonstrated rather than assumed.

There should also be a clear mechanism for determining whether restoration has succeeded and for requiring further works where it has not. The undertaker should not be able to discharge its obligation merely by completing the works in a DEMP if the resulting land remains compacted, poorly drained, contaminated or materially degraded.

4.15.7 The new private decommissioning securities alter, but do not resolve, the financial-security issue

The Applicant's recent Examination material materially changes the financial-security position. The Applicant now states that its private landowner agreements contain decommissioning securities intended to protect against default, including insolvency, and that those securities are capable of periodic revaluation and top-up. BEPS therefore does not contend that no financial provision whatsoever exists.

The issue is now more specific: whether a series of private landowner securities demonstrates that East Pye can be decommissioned and restored as one coordinated NSIP if the undertaker defaults, becomes insolvent or no longer exists.

NCC had already identified precisely this underlying risk, expressing concern about decommissioning over the long life of the project and the consequences for future generations if the project financially fails, and concluding that a financial bond would be needed.

The existence of private contractual securities is relevant to that concern, but it is not self-evidently equivalent to a Scheme-wide bond or other financial mechanism available to the public authority responsible for enforcing the DCO.

The Applicant should therefore explain the structure and practical operation of the arrangements sufficiently for the ExA to determine whether they provide equivalent protection.

4.15.8 Private landowner security may fragment a Scheme-wide liability

East Pye will be constructed and operated as one integrated infrastructure project. Its decommissioning cannot safely be assumed to become a collection of unrelated private land-restoration exercises. If a landowner security becomes callable because the undertaker defaults, the first question is who actually procures the physical decommissioning.

A landowner receiving financial security cannot automatically be assumed to possess the technical expertise, environmental permits, waste contracts, specialist contractors or project-management capacity required to remove utility-scale electrical infrastructure and restore the land.

Nor can individual landholdings necessarily be decommissioned independently. Cable routes, accesses, drainage networks and ecological measures cross ownership boundaries. Contractors may need to travel through adjoining holdings. HGV and waste movements use the same rural road network. Protected-species and water controls apply across the Scheme. Removal of infrastructure on one holding may depend upon plant or access located on another.

If separate landowners were required to enforce and implement their contractual protections individually, restoration could occur at different times, under different contracts and potentially to different standards.

That would not replicate the coordinated 12–24 month decommissioning phase assessed by the Applicant. The DCO should therefore retain one identifiable body responsible for coordinating whole-Scheme decommissioning even if private securities sit behind that obligation.

4.15.9 The security must cover restoration, not merely equipment removal

There is also a fundamental distinction between paying to remove electrical equipment and paying to restore the land to the standard assumed in the ES. The latter may be substantially more expensive.

At decommissioning, landowners may discover that tracks and compounds require deep remediation; field drainage needs reconstruction; soil structure has deteriorated; compaction extends below normal cultivation depth; imported material needs removal; contamination requires treatment; or several years of agricultural rehabilitation are needed before former capability is restored.

The Applicant should explain whether its securities cover those liabilities in full. In particular, the Examination should establish what happens if the security is sufficient to remove the panels and associated equipment but proves inadequate to restore the soils and drainage afterwards.

The same question arises where costs materially exceed the estimates on which the security was originally calculated. A security lasting six decades cannot safely be treated as adequate merely because it is linked to an original cost estimate and indexed. Its periodic review should reflect the actual configuration of the Scheme at that time, current decommissioning methods, waste liabilities, replacement technologies, environmental standards, labour and transport costs, and the actual condition of the land. The relevant amount is the reasonable cost of fulfilling the obligations then existing, not simply the historic estimate adjusted for inflation.

4.15.10 Consistency, insolvency protection and public enforcement remain unproven

The Examination also needs to know whether the private arrangements provide consistent protection across the Scheme. It is unnecessary to disclose commercially

sensitive rents or land payments. It is necessary to establish whether every relevant landholding benefits from materially equivalent security; whether the same restoration standard applies; whether the security survives assignment, refinancing, insolvency and transfer of the DCO; whether it follows the land or the project; and whether it remains available until restoration has been independently certified as complete.

The relationship between the private securities and public enforcement is particularly important. Requirement 21 can impose an obligation upon the undertaker to prepare and implement a decommissioning scheme. But an enforceable obligation and the financial ability to perform it are separate things.

If the undertaker becomes insolvent, the relevant planning authority may have a public-law enforcement power but no direct access to securities held for the benefit of individual private landowners.

The Applicant should therefore explain whether the enforcing authority can call or otherwise access the security where necessary to secure compliance, or whether only individual contracting landowners can do so.

If only landowners can enforce the financial security, the Applicant must explain how the DCO secures coordinated decommissioning where some landowners act, others do not, or disputes arise under different private contracts.

Private security is not necessarily inadequate. It simply has not yet been demonstrated to perform the same function as a DCO-secured, Scheme-wide, insolvency-remote restoration mechanism.

BEPS has also been informed that at least some of the private agreements with participating landowners contain provisions relating to development uplift or equivalent financial protection where land subsequently acquires a higher-value development use. The Applicant should clarify whether that is correct, the circumstances in which any such provision operates, and whether it applies during or following the operational life of the Scheme.

The point is potentially material because the environmental and planning case for East Pye repeatedly relies upon the proposition that the solar development is temporary and that the land will, following decommissioning, be restored to its former agricultural use so far as practicable. A contractual arrangement which expressly anticipates or protects against subsequent development of the land would not of itself demonstrate that such development will occur, nor would it override the DCO or ordinary planning controls. It would, however, indicate that a materially different post-decommissioning land-use outcome has been contemplated between the Applicant and participating landowners.

That possibility should be reconciled with the restoration case presented to the Examination.

The Applicant should therefore state whether its land agreements contain development-uplift clauses, development-value protections, options, overage provisions or other arrangements which contemplate non-agricultural use of the land after or during the Scheme. If they do, the Applicant should explain whether those provisions are purely precautionary commercial terms or reflect an expectation that some land may not return to agriculture following decommissioning.

This issue is particularly relevant where permanent grid infrastructure, retained access, drainage, buried infrastructure or other development may already prevent complete restoration of parts of the Order land. It would be inconsistent for the planning case to rely upon the reversibility of a 60-year solar use while the underlying contractual structure simultaneously preserves or anticipates a materially different development future without that possibility being explained.

The DCO must in any event determine the planning position independently of private commercial arrangements. Land should not cease to be subject to the restoration obligations relied upon in the Environmental Statement merely because a landowner and developer have contemplated a later higher-value use. Any subsequent development would require whatever separate consent is legally necessary at that time.

The Applicant should therefore confirm unequivocally whether the post-decommissioning assumption underpinning the ES remains restoration to agricultural use across all land not expressly authorised for permanent retention, irrespective of any private development-uplift or overage arrangements. If that is not the intended outcome, the environmental assessment and the claimed reversibility of the Scheme require reconsideration.

The existence of private farmer-specific security therefore changes the evidential position but does not answer the whole-Scheme question. The Applicant should identify whether every relevant landholding benefits from materially equivalent security; the amount and costing methodology; indexation and review provisions; the circumstances in which the security can be called; whether it covers drainage, soil reconstruction, contamination remediation and aftercare as well as physical equipment removal; and whether the public authority responsible for enforcing the DCO can access or rely upon it.

4.15.11 Responsibility must survive transfer and permanent retention

Decommissioning responsibility also interacts with the Applicant/NGET boundary considered elsewhere in this Chapter. The solar and BESS infrastructure may ultimately be owned by a successor to East Pye Solar Limited. The National Grid substation and associated transmission infrastructure may transfer to NGET and remain permanently. The DCO must therefore identify the point at which responsibility changes.

East Pye Solar or its successor should remain responsible for removing and restoring the temporary generating and storage infrastructure. NGET or the future transmission

owner should bear the continuing obligations associated with infrastructure formally transferred and retained permanently, including access, drainage, pollution control, security, lighting, landscape mitigation and ecological management.

There must be no gap in which an asset remains but neither body is clearly responsible for its environmental consequences. Similarly, transfer of the project company or benefit of the Order must not separate valuable operating assets from decommissioning liabilities or weaken any financial security.

4.15.12 Evidence and DCO controls required

The remaining issues can be addressed without attempting to fix the precise technology or waste regime that will exist six decades from now. The Applicant should provide, before the close of Examination, a definitive removal-and-retention schedule; a post-decommissioning plan showing all permanent infrastructure; a clear allocation of responsibility between the project undertaker and NGET; and sufficient evidence about the common structure of the private decommissioning securities to establish their scope, beneficiary, insolvency protection, review methodology, enforceability and treatment upon transfer. The DCO should then secure the essential outcomes.

Infrastructure not expressly justified for permanent retention should be removed. Retention of underground cables, ducts, joint bays or foundations should require specific environmental and agricultural justification. Permanent National Grid assets should be treated and assessed as permanent development. Agricultural restoration should be governed by objective standards and independently verified. A coordinated Scheme-wide DEMP should remain the responsibility of an identifiable undertaker or successor, notwithstanding any private landowner security.

Financial provision should remain sufficient throughout the Scheme's life to meet the actual reasonably foreseeable cost of the decommissioning and restoration obligations then outstanding. It should not be released until the relevant restoration standard has been achieved.

The Environment Agency's objection to reliance upon documents being merely 'substantially in accordance with' their outline versions is particularly relevant here. The final DEMP should not be capable of materially weakening the removal and restoration commitments upon which the environmental assessment depends.

4.15.13 Conclusion

East Pye Solar cannot accurately be treated as a wholly temporary development followed by straightforward restoration.The generating and BESS infrastructure may have a finite operational life, but substantial grid infrastructure is intended to remain permanently; cables, ducts, joint bays, foundations, access and drainage may also remain; mature ecological and landscape mitigation may alter the land permanently; and Requirement 21 may permit different parts of the solar development to reach their 60-year endpoints at different times.

NCC's LLFA has already concluded that infrastructure remaining after decommissioning should be treated as permanent and has questioned the Applicant's assertion that the Site will return to its original condition. The Applicant's own earlier assessment acknowledges both substantial uncertainty about future decommissioning methods and a qualified commitment to restore the land only as far as reasonably practicable.

The Applicant's newly disclosed private decommissioning securities are relevant and should be acknowledged. They answer the narrow proposition that no financial provision exists.

They do not yet demonstrate that a project extending across numerous landholdings can be decommissioned coherently if the undertaker fails; that every landowner is protected to the same standard; that actual restoration costs after 60 years will be covered; that soil and drainage remediation is included as well as equipment removal; or that the public authority enforcing the DCO has access to the financial resource necessary to secure compliance.

The critical issue is whether the Order guarantees that the temporary parts of East Pye will actually be removed, the permanent parts clearly identified and controlled, and the affected land restored to the agricultural and environmental standards on which the Applicant's planning case relies, notwithstanding insolvency, transfer, technological change or restoration costs materially exceeding present expectations. On the evidence presently before the Examination, that has not yet been demonstrated.

4.16 Severability and materially different implementation scenarios

4.16.1 The DCO must be tested against what it permits, not only what the Applicant presently intends

The application describes East Pye Solar as a single integrated development comprising multiple solar sites, a BESS, project substations, an extensive cable network, a new National Grid substation and associated overhead-line works. The Environmental Statement and need case are generally presented on the basis that those components will operate together as one Scheme.

That presentation does not establish that the draft DCO legally requires the whole Scheme to be constructed in that form. The numbered works are geographically and functionally separable, and the application anticipates phasing, separate commissioning and substantial flexibility over the timing and detailed design of individual components. The Examination must therefore identify which components are mandatory, which may be omitted, and which may be commenced or completed independently.

This is not a purely drafting issue. The development that is environmentally assessed must correspond with the development that the Order permits. Assessment of the full Scheme does not automatically establish that every materially different subset, sequence or severed implementation would have equivalent effects or deliver the same claimed benefits.

The Applicant should therefore explain, by reference to the operative provisions of the draft DCO, whether each realistic implementation scenario is legally permitted, environmentally assessed, technically connectable and consistent with the mitigation relied upon in the Environmental Statement.

4.16.2 Construction of only some solar sites

The Scheme comprises multiple geographically separated solar sites and sub-sites. The draft DCO must be examined to determine whether the Applicant could construct only selected solar areas while leaving others permanently unimplemented

A reduced geographical build-out could have lower effects in some respects, but it would not necessarily represent a simple proportionate reduction of the assessed Scheme. It could alter the balance between development and mitigation, the location and utilisation of project substations, the use of cable corridors, the distribution of construction traffic and the justification for compulsory acquisition.

The Applicant should identify whether there is any minimum number of solar sites or minimum developed area that must be delivered. It should also explain whether each solar site is capable of operating independently, which substation and cable infrastructure would serve it, and whether unused cable routes or electrical compounds could nevertheless be constructed.

If only some solar sites proceed, the effects on particular communities may be concentrated rather than reduced. A smaller project constructed primarily around one village could produce a different local balance of harm and benefit from the dispersed full Scheme assessed in the ES.

4.16.3 A reduced total generating capacity

The application is promoted as a project of approximately 500 MW, but the generating station is described legally as exceeding the 100 MW NSIP threshold. The Applicant should clarify whether the DCO secures any minimum or maximum operational capacity and whether it could construct a materially reduced generating station while retaining the full Order Limits and compulsory powers.

That matters because the need and benefits case may rely upon electricity generation associated with the full approximate capacity, while the environmental and land-take consequences arise from the authorised envelope. A materially smaller operational project could therefore retain extensive land rights and infrastructure while delivering fewer of the benefits advanced to justify those powers.

A lower capacity could also alter the requirement for:

- project substations;
- cable circuits;
- the BESS;
- the National Grid connection;
- and permanent transmission infrastructure.

The Applicant should identify the minimum implementation necessary to justify each major Work No. and each category of compulsory-acquisition power.

4.16.4 Solar without BESS

The solar generating component has Gate 2 status, while NGET's Relevant Representation records that the BESS remains at Gate 1. That creates a realistic possibility that the solar farm could progress without the storage component.

The draft DCO must therefore be tested to determine whether Work No. 1 may be constructed, commissioned and operated without Work No. 2. If it can, the authorised development includes a solar-only implementation scenario.

That scenario may not deliver the storage benefits relied upon in the alternatives and need case, including:

- time-shifting of solar output;
- grid balancing;
- reduction of curtailment;
- resilience;
- and dispatch of electricity at periods of higher demand.

Mitigation may also have been designed around the combined development. Drainage, access, landscaping, project-substation capacity and construction phasing may differ if the BESS is omitted.

The Secretary of State should not give weight to the benefits of an integrated solar-and-storage project unless the Order secures delivery of a defined storage component or the solar-only scenario is expressly assessed and weighed.

4.16.5 Delayed BESS

Even if the BESS is eventually constructed, the DCO may permit it to be delayed for a substantial or indefinite period.

A delayed BESS could create a separate major construction phase involving renewed:

- HGV and AIL movements;
- piling and concrete works;

- temporary compounds;
- noise;
- lighting;
- ecological disturbance;
- and traffic through local communities.

The environmental baseline may also have changed by the time the BESS is constructed. Habitats may have established, roads and cumulative development may have changed, and residents may have experienced years of solar operation before a further industrial construction phase begins.

The Applicant should identify the latest date by which the BESS must commence and become operational, and whether the initial construction traffic, noise and ecology controls apply to a delayed phase. If no longstop or updated-survey obligation exists, the ES cannot safely be treated as assessing the full temporal range permitted by the Order.

Delayed BESS is now not merely a hypothetical severability scenario. The solar and storage elements have different Gate positions. The Applicant should therefore demonstrate the environmental and benefits case for the period during which solar could operate without storage, rather than assuming contemporaneous commissioning simply because both Works are authorised in one Order.

4.16.6 Omission of some project substations

The application permits up to three 132 kV project substations and up to three 400 kV project substations. The wording ‘up to’ indicates that fewer may be built.

The Applicant should explain which solar sites and BESS infrastructure each substation would serve, which are essential, and whether omission of one would require a materially different cable configuration or electrical arrangement.

The omission of a substation could alter:

- cable lengths and routes;
- circuit numbers;
- the location of transformer noise;
- drainage and oil-containment requirements;
- landscape effects;
- AIL traffic;
- and operational resilience.

If fewer substations are constructed, the remaining substations may require greater capacity or a different configuration. The ES must therefore demonstrate that both the maximum-number and reduced-number configurations fall within the assessed envelope.

4.16.7 Omission of the National Grid substation

The application presents the Site 1B National Grid substation as the connection point for the Scheme, but NGET has not confirmed that it will use that solution. NGET also states that DCO consent would not oblige it to accommodate the connection at the proposed substation.

The draft DCO must therefore be tested to determine whether the Applicant could construct other parts of the Scheme while omitting Works Nos. 4 and 5. If those works are legally optional, the application must explain how the generating station could be energised without them. If they are legally essential, their present lack of confirmation goes directly to deliverability.

The Applicant should also explain whether the solar sites, BESS, project substations or export cables may commence before the National Grid solution is fixed. The Order should not permit substantial construction to proceed in the expectation of transmission infrastructure that may never be built or adopted.

4.16.8 A different NGET connection solution

NGET states that the final connection solution remains subject to wider regulatory and commercial considerations and that other Gate 2 offers may affect its size, design and location.

A different solution could involve:

- a larger substation;
- a different site;
- additional bays;
- different overhead-line works;
- more pylons;
- a revised cable destination;
- or separate future consent.

That is not simply a variation in detailed design. It may change the geographical and functional identity of the connection infrastructure.

The Applicant must identify whether the draft DCO could accommodate a materially different NGET solution within the existing Works Plans and limits of deviation. If it cannot, the Scheme may depend on a later consent. If it can, the Order may authorise a wider range of connection development than the ES has assessed.

Neither outcome can be left unexplained.

4.16.9 Cables constructed but not used

Work No. 6 authorises an extensive network of high-voltage and internal cables within broad corridors. If the BESS is omitted, a project substation is not constructed, or the NGET connection changes, some cable infrastructure may become unnecessary.

The DCO should therefore be examined to determine whether the Applicant could:

- install ducts speculatively;
- construct joint bays;
- lay cables before the final destination is confirmed;
- or leave unused underground infrastructure in place.

Unused cable works would still cause:

- soil disturbance;
- archaeological effects;
- groundwater risks;
- construction traffic;
- land-rights interference;
- and permanent below-ground constraints.

The Applicant should identify a legal and technical dependency between each cable route and the confirmed work it serves. High-voltage export cables should not be capable of commencement before the final connection solution is approved.

4.16.10 Staged implementation over many years

The DCO may allow different parts of the Scheme to commence at materially different times within the Order's commencement period. The Applicant must identify the maximum period over which initial construction could be staged.

A prolonged staged implementation could produce a sequence of separate construction campaigns rather than the approximately 24-month concurrent programme described in the ES. That could alter:

- the duration of disturbance;
- the number of mobilisation events;
- traffic distribution;
- cumulative effects with other projects;
- ecological baselines;
- soil conditions;
- and community impacts.

The assessment of a two-year construction phase does not automatically assess repeated construction over a much longer period.

The DCO should therefore contain clear commencement, phasing and completion controls for each principal component. Revision 2 of Requirement 2 now requires a construction phasing scheme, timetable and plan identifying phasing areas. That amendment is relevant but does not remove this scenario from the DCO envelope. It does not establish a maximum interval between phases, a whole-Scheme construction long-stop or an expiry mechanism for materially independent Works which remain unimplemented. The Applicant must therefore demonstrate the maximum temporal implementation scenario assessed by the ES and secure that maximum through the DCO.

4.16.11 Abandonment of works after commencement

The Applicant may commence a work by undertaking limited enabling activity and then decide not to complete it.

Possible examples include:

- constructing an access or compound but not the solar field;
- installing ducts but not cables;
- forming a BESS platform without installing batteries;
- acquiring and clearing land for a substation that is not built;
- or commencing pylon foundations before the connection solution changes.

The application should identify what constitutes commencement for each work and what restoration obligations arise where the work is then abandoned.

A generic decommissioning obligation at the end of the 60-year operational period may not apply to works that never become operational. The DCO should require prompt restoration of abandoned or stranded works and prevent land remaining indefinitely in a partially developed condition.

4.16.12 Biodiversity net gain and ecological mitigation

BNG calculations and ecological mitigation may assume full build-out of the Scheme and delivery of habitat measures across several sites.

If only part of the development proceeds, the Applicant must explain:

- which habitat measures remain mandatory;
- whether the BNG calculation is recalculated;
- whether mitigation associated with an omitted site is still delivered;
- and whether habitat connectivity remains effective.

There is a risk that development proceeds on the most commercially attractive land while mitigation linked to later or omitted components is not delivered.

The DCO should therefore secure ecological mitigation by phase and require each commenced component to deliver the mitigation necessary for its own effects before or alongside that development.

4.16.13 Landscape mitigation

The landscape strategy may similarly depend upon coordinated planting across the full Scheme.

Partial implementation could produce:

- isolated compounds;
- unmitigated substations;
- incomplete screening;
- planting without the development it was intended to screen;
- or development without the planting allocated to another work phase.

The Applicant should identify which landscape measures are tied to each Site and major electrical component and whether they remain mandatory if other parts of the Scheme are omitted.

Planting required to mitigate the BESS, project substations or National Grid substation should be delivered before or contemporaneously with those works, not deferred until full Scheme completion.

4.16.14 Drainage and flood-risk mitigation

Drainage systems may be designed on the basis of full site layouts and shared infrastructure. Partial implementation could result in:

- temporary drainage becoming long-term;
- attenuation not being built;
- incomplete outfall arrangements;
- or impermeable compounds being constructed without the wider drainage network.

The Applicant should identify whether each Site and compound is hydrologically independent and whether all necessary drainage can operate safely if later phases never proceed.

No component should commence unless its permanent drainage and pollution-control systems are complete and independently functional.

4.16.15 Construction traffic under prolonged phasing

The transport assessment generally relies on an approximately 24-month construction period and defined average and peak traffic flows.

If the Scheme is staged over many years, the daily peak may be lower but the duration and repetition of traffic may be materially greater. Local roads may be repeatedly reopened to construction vehicles, and temporary highway works may be reinstated several times.

The Applicant should therefore assess both:

- the maximum concurrent construction scenario; and
- the maximum-duration phased scenario permitted by the DCO.

The relevant traffic controls must apply cumulatively across all phases rather than resetting for each Work No.

4.16.16 Claimed benefits may not arise

Claimed benefits must be attached to the implementation scenario which actually produces them. Solar generation benefits may arise without BESS, but balancing, storage and co-location benefits cannot be credited during a period in which Work No. 2 is not connected or operational.Those benefits may be reduced where:

- fewer solar sites are built;
- total generation is lower;
- the BESS is omitted or delayed;
- storage capacity is reduced;
- the connection is delayed;
- or the project never becomes fully operational.

The Applicant should state which benefits arise under each permitted implementation scenario and which depend upon complete delivery.

It would be inappropriate to weigh the full generation, storage, resilience and network benefits if the DCO permits a materially smaller or solar-only project without corresponding adjustment.

4.16.17 Compulsory-acquisition powers may outlast the need for individual works

The Applicant seeks compulsory powers across the full Order Limits.

If components are omitted, reduced or redirected, some land and rights may no longer be necessary. The DCO should not allow the Applicant to exercise powers for:

- unused cable routes;
- an unconfirmed National Grid substation;
- omitted substations;
- abandoned access routes;
- or BESS infrastructure that cannot connect.

The compulsory-acquisition case must be tied to the confirmed implementation scenario. Powers should lapse or be incapable of exercise where the relevant work is no longer required.

4.16.18 Required severability evidence and controls

The Applicant should provide a formal severability assessment addressing every realistic combination of development. It should state whether the scenario is permitted by the DCO, whether it was assessed in the ES, whether it is technically and contractually connectable, and whether the mitigation remains effective.

The assessment should cover at least:

- full Scheme;
- partial solar build-out;
- reduced capacity;
- solar-only;
- delayed BESS;
- reduced BESS;
- omission of one or more project substations;
- omission or relocation of the National Grid connection;
- partial cable construction;
- extended staged construction;
- and abandonment after commencement.

The DCO should then secure the necessary dependencies. In particular, it should prevent commencement of a component where its connection, drainage, access or mitigation depends on another unconfirmed work. It should require prompt restoration of abandoned works, phase-specific delivery of ecological and landscape mitigation, and the release or non-exercise of compulsory powers for omitted development.

4.16.19 Conclusion

The application describes one integrated Scheme, but the draft DCO may permit multiple materially different implementation scenarios.

Those scenarios include:

- construction of only some solar sites;
- a reduced generating capacity;
- solar without BESS;
- delayed or reduced BESS;
- omission of project substations;
- omission or relocation of the National Grid substation;
- construction of unused cable infrastructure;
- prolonged staged implementation;
- and abandonment of works after commencement.

Assessment of the full Scheme does not automatically establish that every subset, sequence or severed implementation is environmentally equivalent.

Partial implementation may alter:

- BNG;
- landscape mitigation;
- drainage;
- ecology;
- construction duration;
- traffic;
- connection viability;
- compulsory-acquisition necessity;
- and the benefits relied upon in the planning balance.

The Applicant should therefore provide a complete severability assessment and the DCO should secure minimum implementation, work dependencies, phasing, mitigation, restoration and land-power controls. Without those measures, the development lawfully authorised could differ materially from the integrated Scheme presented and assessed.

4.17 Consequences for the Environmental Statement

4.17.1 Introduction

The uncertainties identified in this chapter have direct consequences for the reliability and legal adequacy of the Environmental Statement.

They do not concern isolated drafting errors or minor equipment choices. They affect the principal physical components of the Scheme, their locations, their interdependence, their construction and replacement, their connection to the transmission system and the infrastructure remaining permanently after solar decommissioning.

The central question is whether the Environmental Statement assesses the development that the draft DCO would actually authorise. That requires consistency between:

- the Scheme Description;
- the design envelope;
- the Works Plans;
- the environmental assumptions;
- the mitigation;
- the compulsory-acquisition case;
- and the operative DCO controls.

The evidence of Norfolk County Council, South Norfolk Council, the Environment Agency, National Highways, NGET, NGT, Norfolk Gliding Club and GAAC demonstrates material uncertainty in each of those areas.

4.17.2 Worst-case assessment

The Applicant relies on the Rochdale Envelope and states that the ES assesses realistic worst-case parameters. The preceding analysis shows that it is not yet clear that the same final worst case has been used consistently across all environmental topics.

The solar design permits both fixed and tracking panels. Trackers may reach approximately 4.5 metres and move through a substantial operational range, while fixed panels are lower and differently oriented. Different topics may therefore have assessed different panel technologies. The Applicant must demonstrate that every permitted field-level configuration remains within the combined worst case, including landscape, glare, aviation, ecology and runoff.

The Site 1B project substation changed from a 132 kV structure of approximately seven metres during statutory consultation to a 400 kV structure described as approximately 13 metres at targeted consultation and 15 metres in the final ES. It is not sufficient for Chapter 4 to state the final parameter. The Applicant must establish that the final:

- landscape;
- heritage;
- noise;
- aviation;
- drainage;
- groundwater;
- fire;
- and transport

assessments all used the 400 kV, 15-metre design.

The National Grid substation increased from an earlier footprint of approximately three hectares to a final maximum of six hectares. The Applicant must show that the full compound, impermeable area, buildings, access, drainage and pylon works were assessed in every relevant chapter.

The same concern applies to foundations. The application permits panel piles up to four metres and BESS or substation piling up to 12 metres, but does not provide a complete schedule of pile number, diameter, density or concrete volume. An assessment of maximum depth alone does not establish the maximum groundwater, archaeological, noise or materials impact.

BESS replacement may occur up to five times, but it is unclear whether the lifetime traffic, waste, carbon, fire and drainage assessments include all replacement cycles. Nor is the future battery chemistry fixed.

The application also permits or anticipates permanent retention of National Grid infrastructure, pylons, overhead lines, cables, ducts, joint bays, access and drainage. Those permanent effects must be assessed separately from the temporary 60-year solar development.

Finally, NGET has not confirmed that the Site 1B connection solution will be used. A materially larger, differently configured or differently located solution has not been shown to fall within the assessed envelope. The Rochdale approach cannot treat the identity, location and necessity of the final transmission connection as an ordinary matter of detailed design.

The Applicant must therefore provide a chapter-by-chapter worst-case audit identifying the precise parameters used in each assessment. That audit should state, for every relevant topic, the panel technology, panel height and orientation, BESS capacity and equipment assumptions, substation footprint and height, transformer number, pylon number and height, foundation method, cable working width, construction compound extent, replacement scenario and decommissioning assumptions used.

It should also demonstrate that the DCO prevents combinations of parameters that were not assessed together. A collection of separate topic-specific worst cases does not necessarily amount to a coherent whole-Scheme worst case. For example, a landscape chapter may assess trackers because of their height, while a drainage chapter assumes fixed panels, a noise chapter assumes an indicative number of electrical units and an aviation chapter relies on a particular orientation or module type. Unless the permitted final configuration is constrained, the constructed Scheme could combine characteristics from several scenarios in a way that produces materially different effects.

Where the final parameter differs from the assumption used in a technical chapter, that chapter must be updated or the DCO envelope reduced. It is not sufficient to rely on a general commitment that detailed design will be ‘no worse than assessed’ where the assessment baseline and comparison parameters are not expressly identified.

The Examining Authority should therefore require the Applicant to demonstrate that:

- each final maximum parameter has been assessed in every relevant topic;
- all realistic combinations of those parameters remain within the assessed envelope;
- permanent retained infrastructure has been assessed as permanent development;
- replacement and repowering assumptions cover the full operational life;
- and any materially different NGET connection solution would require further environmental assessment and consent.

Until that exercise is completed, the ES cannot be assumed to represent the realistic worst case of the development authorised by the draft DCO.

The reasonable worst case is therefore not confined to the maximum physical dimensions of each component. It must include the materially different implementation permutations which the DCO permits. A smaller physical Scheme is not necessarily environmentally or operationally equivalent if, for example, solar proceeds without BESS, one substation is omitted, mitigation dependent upon a later phase is delayed, or infrastructure intended to serve an omitted Work remains constructed. The ES should identify and assess those realistic implementation cases expressly.

4.18 Remedies sought

The defects identified in this chapter concern the definition, control, deliverability and environmental assessment of the authorised development. They cannot be addressed adequately through broad assurances that detailed design will remain within the Rochdale Envelope or that outstanding matters will be resolved after consent.

The Applicant should be required to provide a single, reconciled and enforceable account of the Scheme before the close of the Examination. Where an essential parameter, connection dependency, access arrangement or statutory interface cannot be confirmed, the corresponding work, land or power should be restricted or removed from the draft DCO.

4.18.1 Consolidated scheme definition

The Applicant should provide a single consolidated Maximum Design Parameters Schedule covering every principal and ancillary component of the Scheme. The schedule should state the maximum and, where relevant, minimum number, height, footprint, depth, capacity, voltage, duration and operational parameter for each authorised work.

The schedule should include the solar arrays, conversion units, BESS, project substations, National Grid infrastructure, pylons, overhead lines, cables, joint bays, compounds, access tracks, drainage works, landscaping, ecological mitigation, replacement works and decommissioning infrastructure. It should distinguish permanent development, temporary construction development, replacement infrastructure and works intended to remain after the solar project is decommissioned.

The Applicant should also provide a definitive list of every permanent and temporary work authorised by the draft DCO. Generic references to ancillary or associated development should not be used to authorise material works whose location, scale or environmental effects have not been identified.

A formal reconciliation should be produced between ES Chapter 4, the Works Plans, Land Plans, Book of Reference, Design Principles, Parameters and Commitments document, Commitments Register and draft DCO. Every inconsistency in terminology, mapping, work numbering or parameter should be resolved. The corrected plans

should use an up-to-date base map and should accurately show existing infrastructure, including the operational Long Stratton Bypass.

Terms capable of materially widening the authorised development should be defined. In particular, the Applicant should explain what is meant by ‘arrangement’, ‘associated development’, ‘ancillary works’, ‘maintain’, ‘replace’, ‘repower’ and ‘substantially in accordance with’. The definitions must prevent those terms from becoming a route to authorise additional or materially different development after consent.

The Applicant should identify every application document containing a binding parameter or commitment and state the DCO provision through which it is secured. Parameters should not be dispersed across multiple documents without a clear hierarchy or mechanism for resolving conflict.

4.18.2 Grid connection and NGET responsibilities

The Applicant should disclose the operative connection agreement, the proposed replacement agreement and all relevant variations, subject only to justified redaction of commercially sensitive financial terms. The disclosed material should establish the connection capacity, connection location, Gate status, responsibilities for land and consent, works required from the Applicant and works required from NGET.

NGET should confirm whether Site 1B remains an acceptable and technically sufficient final point-of-connection solution. That confirmation should address the proposed six-hectare substation envelope, the anticipated number and configuration of bays, the overhead-line works and the maximum number and height of pylons.

The Applicant and NGET should identify any other Gate 2 offers capable of changing the size, design, location or function of the proposed National Grid infrastructure. Where those projects may require a materially different or larger solution, the Applicant should explain whether that solution is within the assessed and authorised envelope.

A joint responsibility and ownership matrix should identify who will design, approve, construct, own, operate and maintain every element of Works Nos. 4 and 5. It should cover civil works, electrical equipment, access, drainage, oil and firewater systems, landscaping, biodiversity mitigation, overhead lines, pylons, emergency response and long-term environmental compliance.

A programme should be provided for finalising the NGET connection design. It should identify milestones for the replacement connection agreement, confirmation of the point of connection, completion of the NGET option-selection process, final land requirements, detailed design, approval, construction, adoption and energisation.

The DCO should prevent commencement of the National Grid substation, overhead-line works and dependent export cables until NGET has approved the final connection solution in writing. Compulsory-acquisition powers should not be exercisable for the

proposed connection infrastructure until NGET confirms that the relevant land and rights are required.

Any land, rights or powers not necessary for the confirmed connection solution should be removed from the Order. The Applicant should not retain powers over land merely because it may be useful for an alternative or future network arrangement.

4.18.3 Solar and BESS severability

The Applicant should confirm whether the solar generating station may lawfully and technically be constructed, commissioned and operated without the BESS. It should also confirm whether the BESS may be delayed, reduced, constructed partially or omitted permanently.

Every realistic severed implementation scenario should be assessed. That assessment should include solar-only development, solar with delayed BESS, solar with materially reduced BESS, construction of BESS civil infrastructure without an operational connection, and replacement by materially different battery technology.

The Applicant should identify the minimum BESS capacity, duration and operational capability relied upon in the need, climate and grid-benefits cases. If no minimum is secured, the Secretary of State should not attribute material weight to benefits dependent upon delivery of a fully integrated storage system.

The DCO should prevent reliance on BESS benefits unless delivery of a defined and connected BESS is secured. Alternatively, the decision-making balance should be undertaken on the basis of the realistic solar-only case.

4.18.4 Design parameters

The panel technology permitted within each solar field should be defined. The Applicant should specify whether the field contains fixed panels, tracking panels or a controlled combination.

Maximum panel height, orientation, movement, tilt and row spacing should be secured. Trackers reaching 4.5 metres should be prohibited or restricted in areas sensitive to landscape, heritage, residential amenity, ecology or aviation unless the Applicant demonstrates expressly that they represent the assessed and acceptable worst case.

The BESS envelope should define the maximum and minimum MW and MWh capacity, duration, maximum import and export, battery chemistry or chemistry envelope, enclosure number, enclosure dimensions, stored energy, compound area, transformer and inverter number, cooling equipment and sound-power limits.

Each 132 kV and 400 kV project substation should be subject to a defined maximum layout. The Applicant should state the transformer number, transformer rating,

maximum oil inventory, buildings, switchgear, busbars, height, compound area, hardstanding, drainage, lighting and foundation design.

The final 15-metre maximum height of the Site 1B project substation should be secured expressly. The Applicant should demonstrate that the Environmental Statement assessed that height rather than the earlier 13-metre targeted-consultation design.

The DCO should fix the maximum number, location and height of new pylons and should restrict their limits of deviation. Any materially different overhead-line alignment should require further assessment.

Maximum piling and foundation depths should be accompanied by maximum numbers, diameters, installation methods and concrete quantities. The use of driven, screwed, bored or concrete foundations should be controlled by location-specific environmental constraints rather than left entirely to detailed design.

4.18.5 Cable and below-ground works

The Applicant should provide a corridor-by-corridor cable schedule identifying the maximum number of circuits, individual cables, ducts and trenches at each voltage.

The DCO should secure maximum ordinary and widened working widths, trench width and depth, maximum simultaneous open-trench length and the maximum number and dimensions of joint bays and fibre chambers.

Crossings of main rivers, roads, the FM05 gas pipeline, protected habitats and other major infrastructure should be fixed on certified plans. The crossing method should be defined where open-cut and trenchless alternatives have materially different effects.

Maximum HDD depth, bore diameter, bore length, number of parallel bores, launch and reception pit dimensions and compound area should be secured. Trenchless methods should require prior approval from the relevant regulator and statutory undertaker.

Maximum foundation type, plan dimensions, depth, piling method and density for each principal infrastructure type, including the BESS, Project Substations and National Grid Substation.

High-voltage cable works serving the transmission connection should not commence until the final NGET connection point and cable destination have been approved. The DCO should prohibit speculative ducts, duplicate circuits and cable infrastructure that is disconnected from an approved final connection solution.

The Applicant should define the assumed life of each principal cable system, the circumstances in which replacement excavation may occur and the decommissioning treatment of cables, ducts, joint bays and chambers. Removal should be the default unless retention is justified through a specific environmental and agricultural assessment.

4.18.6 Statutory undertakers

Protective provisions for NGT should be agreed before the close of Examination. They should address the FM05 Yelverton–Stowmarket feeder main, cathodic-protection infrastructure, transformer-rectifier equipment, access rights, crossings, loading, ground-level changes, vegetation and emergency operations.

The DCO should preserve NGT's existing access and easement restrictions. No panel, foundation, cable, access track, drainage work, compound, material store or planting should be placed within the protected corridor without NGT's written approval.

The Applicant should provide a plot-by-plot schedule identifying every work and compulsory power affecting gas and electricity infrastructure. That schedule should identify the statutory apparatus, existing interest, proposed Work No., construction method, permanent or temporary effect and applicable protective provision.

No work within a protected statutory-undertaker corridor should commence until the undertaker has approved the detailed design and method. No existing statutory right should be extinguished, suspended or materially interfered with without the undertaker's written agreement.

Equivalent clarity should be provided for NGET, NGT and every other affected statutory undertaker whose apparatus or rights are crossed by the Scheme.

4.18.7 Aviation safeguards

The Applicant should provide a revised, site-specific aviation-safety assessment addressing the actual mixed gliding and powered-aircraft operations at Tibenham Airfield.

The assessment should be undertaken through direct engagement with Norfolk Gliding Club and should respond to the evidence of the General Aviation Awareness Council. It should address normal operations, engine failure after take-off, glider launch failure, aborted aerotow, variable circuit patterns, glare, obstacles, fencing, emergency-landing land and cumulative development.

The final assessment should define any land that must remain free from panels, fences, substations, planting, drainage structures or other obstacles. Those areas should be secured through a certified Aviation Safeguarding Plan.

Binding controls should be imposed on panel type, height, orientation, tracker movement, reflectivity and replacement technology. Trackers should be prohibited in aviation-sensitive areas unless demonstrated to be no worse than fixed panels.

The assessment should include the combined aviation envelope of solar panels, BESS, substations, pylons, overhead lines, lighting and construction cranes.

If the Applicant cannot demonstrate that Site 1 can be developed without unacceptable aviation risk, the affected parts of Site 1 should be removed or reduced. Safety should not depend upon mitigation that remains unidentified or unenforceable at the point of consent.

4.18.8 Construction and transport

The Applicant should provide a complete AIL schedule covering every large transformer, battery enclosure, cable drum, pylon component and other abnormal load.

For each AIL, the schedule should identify dimensions, weight, axle configuration, number of deliveries, port of entry, Strategic Road Network route, local route, internal haul route and final destination.

End-to-end route plans should be agreed in principle with National Highways and Norfolk County Council. The plans should include swept-path analysis, structural assessments, junction alterations, bridge or culvert works, vegetation removal, traffic management, fallback routes and confirmation that all necessary land and rights fall within the Order Limits.

Routes rejected by the local highway authority, including Hall Lane, Fairstead Lane and other unsuitable minor roads, should not remain available through a later CTMP unless the authority approves them on the basis of new evidence. Construction traffic should use appropriate B roads and internal haul routes wherever required by Norfolk County Council.

The DCO should impose enforceable daily, hourly and route-specific construction traffic caps. Monitoring should include corrective action where the assessed limits are approached or exceeded.

The Applicant should define the maximum number of simultaneous construction work fronts, piling rigs, HDD operations, compounds and active haul routes. A programme should identify the maximum duration of construction at each solar site, cable corridor, substation and grid-work area.

Maximum compound footprints, hardstanding areas, haul-road lengths, temporary access works and drainage requirements should be secured.

The construction assessment should quantify pile numbers and installation methods, concrete volumes, excavation, trenching, HDD operations, drilling-fluid use, spoil storage and dewatering. Those figures should be reconciled with the noise, traffic, air-quality, groundwater, drainage, waste and carbon assessments.

4.18.9 Replacement and decommissioning

The DCO should define the maximum number of major replacement cycles. It should limit complete solar-panel replacement to the assessed cycle and BESS replacement to the assessed maximum.

The maximum area or number of sites capable of undergoing replacement simultaneously should be fixed. Replacement traffic, compounds, temporary access, lighting and working hours should be subject to controls equivalent to those applying during initial construction.

Replacement equipment should be required to perform no worse environmentally than the assessed equipment. Objective limits should cover dimensions, capacity, noise, stored energy, chemistry, heat release, pollutant inventory, drainage, firewater, traffic and lighting.

A Battery Handling and Replacement Plan should govern the removal, temporary storage, quarantine, transport and disposal or recycling of damaged and end-of-life batteries. Dedicated fire, monitoring and pollution controls should apply throughout replacement.

The Applicant should provide a definitive removal-and-retention schedule identifying what will be removed at decommissioning and what is intended or permitted to remain. It should cover panels, foundations, BESS infrastructure, project substations, the National Grid substation, pylons, overhead lines, cables, ducts, joint bays, access, drainage, landscaping and altered ground levels.

The National Grid substation, retained pylons, overhead lines, access and drainage should be assessed and controlled as permanent development. Their long-term owner and operator should accept responsibility for maintenance, drainage, landscape mitigation, biodiversity, safety and environmental compliance.

The DCO should secure independently costed, index-linked and insolvency-protected financial security for decommissioning and restoration. That security should be reviewed periodically to reflect the actual equipment, waste and restoration liabilities.

4.18.10 Updated environmental assessment

The Applicant should update the Environmental Statement wherever the final parameter exceeds, differs from or was not demonstrably included in the assessed design.

A revised noise assessment should address the full 400 kV Site 1B project-substation envelope, the maximum BESS compound and equipment inventory, the National Grid infrastructure and cumulative operation of all major electrical plant. Replacement equipment should be assessed against binding receptor limits.

Drainage and groundwater assessments should be updated to reflect the final impermeable areas, SuDS land, firewater containment, maximum foundations, piling, cable trenches, HDD, dewatering and statutory-infrastructure crossings.

The aviation assessment should use the final Site 1 layout, panel technology, tracker parameters, reflectivity, fencing, substations, pylons, lighting and construction cranes.

Landscape and heritage assessments should be updated where they relied on earlier substation heights, footprints, panel layouts, pylon assumptions or mitigation. The assessment should include the permanent post-decommissioning landscape in which National Grid infrastructure remains.

The transport assessment should be updated using the final port of entry, AIL routes, local accesses, haul-road strategy, construction programme and enforceable traffic caps.

The cumulative assessment should use the final East Pye construction and implementation programme and should address Norwich to Tilbury, Tasway, other solar and BESS projects, highways schemes and other grid infrastructure. It should include realistic delayed BESS, delayed NGET and replacement scenarios.

The Applicant should also provide a final audit demonstrating that every material parameter in the DCO was assessed in the relevant environmental chapter and is secured by an enforceable provision.

The word ‘substantially’ should be removed from Requirements where it weakens compliance with approved parameters, environmental plans or mitigation. Any amendment mechanism should be narrow, objective and incapable of authorising new or materially different significant effects.

4.18.10A Examination-stage Scheme Definition Schedule

In light of ISH1 and ExQ1, the Applicant should provide one consolidated schedule identifying:

- the final maximum parameter for every material component;
- the number and permitted locations of conversion units and switchrooms;
- panel technology, rating, overplanting assumption and relevant capacity limits;
- AIS/GIS alternatives and the discipline-specific worst case;
- the correct separate parameters for project and National Grid substations;
- Site 6 construction and operational use;
- lighting parameters;
- fencing;
- the final Sites 7–10 haul-road strategy;
- the Site 7 gas-pipeline crossing solution;
- the BESS Gate status and assumed commissioning scenarios;
- the National Grid substation’s delivery timing and potential third-party role;

- and every inconsistency corrected between the Works Plans, Illustrative Masterplan and environmental figures.

For each item the schedule should identify the ES assessment relied upon and the DCO provision which prevents a materially worse outcome.

4.18.11 Consequence if the remedies are not satisfied

These remedies are not requests for unnecessary detail or premature manufacturer selection. They concern the definition of the authorised development, the realistic worst case, the physical ability to construct and connect it, the protection of statutory infrastructure and the enforceability of mitigation.

If the Applicant cannot confirm an essential design parameter or connection dependency, the corresponding flexibility should be removed. If a route, crossing or statutory interface is not agreed, the relevant work should not be authorised. If a materially different implementation scenario has not been assessed, it should be prohibited. If the final NGET solution is not confirmed, the associated commencement and compulsory-acquisition powers should not be available.

Unless the Applicant provides the required evidence and the draft DCO is amended accordingly, the Examining Authority cannot be satisfied that the development authorised would be the development assessed, that its essential components are deliverable or that the compulsory powers sought are necessary and proportionate.

Chapter 5: Reasonable Alternatives and Design Evolution

5.1.1 Introduction

This section objects to the Applicant's treatment of reasonable alternatives and design evolution on the basis that it is legally, evidentially and strategically deficient. The Environmental Impact Assessment must do more than describe how the Applicant arrived at its preferred scheme. It must identify the reasonable alternatives actually studied, explain the main reasons for choosing the proposed option and compare their environmental effects. The alternatives exercise must also be sufficiently transparent to show that materially less harmful options were not excluded merely because they were inconsistent with the Applicant's pre-existing commercial model, assembled land interests or preferred scale of development.

On the evidence contained in Chapter 5 and the Site Selection Assessment, that standard has not been met. The alternatives case is structured around a narrow and self-serving scheme rationale: a 500 MW transmission-connected solar development, with associated substations, extensive cabling and a co-located Battery Energy Storage System, fixed to a particular part of South Norfolk and defended by reference to an asserted urgent need and supposed grid logic. The Applicant then treats any option that would not reproduce that same project concept as unreasonable.

The Applicant expressly states that its alternatives assessment is conducted in the context of what it calls the 'clear and urgent need for the Scheme' and for development 'at the proposed scale.' It consequently declines to consider either a 'no development' scenario or a smaller development because those options would not deliver the generation and storage capacity selected by the Applicant. That reasoning is circular. It defines the objective as delivery of the preferred Scheme and then excludes any alternative that does not deliver the preferred Scheme.

The central evidential problem is more fundamental. The land comprising East Pye was not selected because a viable grid connection existed at Norwich Main. Norwich Main had insufficient capacity and could not be expanded to accommodate the project. Nor has the Applicant demonstrated that the land was selected because it represented an ecologically or environmentally preferable location. The evidence instead shows that the Applicant first searched for, identified and secured a sufficiently large package of land from willing landowners around an assumed Norwich Main connection. When that connection premise failed, it retained the assembled land and searched for a new National Grid substation capable of serving it.

Site selection was therefore led principally by land availability. The actual point of connection was adapted to preserve the existing land package. Environmental constraints were subsequently managed through buffers, setbacks, landscaping and mitigation, rather than being allowed to determine whether the Scheme should be located in this sensitive landscape at all.

That is particularly serious because East Pye is not proposed on unconstrained or low-conflict land. The Scheme would occupy a very large area of productive agricultural land, much of it Best and Most Versatile, and would affect a historically and environmentally sensitive rural landscape. It engages overlapping constraints relating to ecological networks, ancient woodland, protected species, watercourses, private water supplies, heritage settings, settlement character, aviation, public rights of way, narrow rural roads and cumulative infrastructure pressure.

Those environmental effects must also be considered against the regional need position. The Applicant has not shown that a further 500 MW transmission-connected solar project is required in South Norfolk or in the T7 East Anglia transmission region. The evidence assembled by BEPS indicates that T7 is already heavily subscribed for solar overall and particularly for transmission-connected solar. In those circumstances, the environmental consequences of the Scheme cannot be justified merely by invoking an abstract national need for renewable energy. The relevant question is whether this project, in this place, is required despite the regional capacity and pipeline position. The Applicant has not answered that question.

The ‘do nothing’ alternative is therefore not an artificial or irrelevant comparator. Where refusal has not been shown to create a regional shortfall, but would avoid extensive agricultural, ecological, landscape, heritage, hydrological and community harm, non-development is a reasonable and potentially preferable alternative which required proper assessment.

5.1.2 The applicable alternatives requirement

The Applicant relies upon NPS EN-1 paragraph 4.3.9, which states that there is no general policy requirement to consider alternatives or demonstrate that a development represents the absolute best option. That does not dispose of this objection.

Paragraph 2 of Schedule 4 to the Infrastructure Planning (Environmental Impact Assessment) Regulations 2017 requires a description of the reasonable alternatives studied by the developer, including alternatives in terms of development design, technology, location, size and scale, together with the main reasons for selecting the chosen option and a comparison of environmental effects. The Applicant reproduces that requirement in Chapter 5. It also acknowledges that NPS EN-5 requires applicants to consider carefully the location and design of associated substations, and that the Planning Inspectorate’s guidance expects a good Environmental Statement to explain the alternatives considered and the reasons for the chosen option by reference to environmental effects.

The objection is not that the Applicant had to investigate every theoretically conceivable parcel of land in England. It is that the alternatives it did study were framed and screened through criteria which predetermined the outcome. The Applicant fixed the technology, capacity, broad location, land requirement and commercial structure before assessing whether materially less harmful alternatives existed.

Commercial feasibility and land availability may legitimately form part of an alternatives exercise. They cannot, however, replace environmental comparison or be used to

define ‘reasonable’ so narrowly that only land already secured by the Applicant qualifies.

5.1.3 The land search preceded confirmation of a viable grid connection

Chapter 5 establishes the sequence clearly. The Applicant initially considered Norwich Main Substation as the point of connection and, in parallel, commenced a search for solar sites. It adopted a 20 km radius from Norwich Main and conducted an exercise within that area to identify landowners willing to participate in the Scheme. The Applicant states that its search produced the requisite amount of land and that voluntary agreements were secured.

Only subsequently did NGET advise that Norwich Main had neither sufficient existing capacity nor any opportunity for expansion to accommodate a 500 MW solar project. Norwich Main was therefore discounted as a viable point of connection.

This sequence is critical. The East Pye land package was not assembled because Norwich Main had confirmed capacity. It was assembled while the availability of that connection remained unresolved. The Applicant therefore selected and secured the land before establishing the infrastructure premise said to justify the location.

Once Norwich Main was ruled out, the original rationale for the 20 km search area disappeared. That should have triggered a fresh assessment of whether South Norfolk remained the appropriate broad location, whether a 500 MW scheme remained justified, whether the project should be materially reduced or reconfigured, whether a more compact scheme could be located around the actual point of connection, whether other regions or projects offered materially lower environmental impacts, and whether the Scheme should proceed at all.

The Applicant did not undertake that fundamental reassessment. Instead, it preserved the sites already identified and searched along the Bramford–Norwich 400 kV line for a new point of connection capable of serving them.

5.1.4 Failure to restart the site-selection exercise after Norwich Main failed

Chapter 5 states that, after Norwich Main was rejected, the Applicant moved southwards along the transmission line and ultimately selected a point of connection south of Great Moulton. It then concluded that the sites already identified around Norwich Main were ‘still viable’ because they also happened to fall within 20 km of Great Moulton and because the relevant landowners remained willing to enter agreements.

That is not a fresh or neutral site-selection exercise. It is retrospective validation of a land portfolio assembled under a failed grid assumption.

The 20 km radius is itself an Applicant-defined commercial parameter. The fact that the original sites fell within 20 km of both Norwich Main and Great Moulton does not establish that they were environmentally preferable, that the new connection strategy was optimal, or that the original search remained rational once Norwich Main was unavailable.

The process was therefore reversed. The Applicant did not identify the most appropriate solar land around a confirmed point of connection. It identified a point of connection partly by reference to land which it had already assembled.

That circularity is confirmed by the Applicant's treatment of alternative National Grid substation locations. Chapter 5 states that the transmission-line search was limited north of Diss because the Applicant preferred a location close to the solar sites already identified and for which willing landowners had been established. It accepts that land in Siting Zone 3 could constitute a reasonable alternative, but regarded it as less preferable because of its distance from the initially identified solar sites.

The Applicant therefore used the pre-existing land package to constrain the search for the new connection infrastructure and then relied upon the new connection infrastructure to justify retaining the pre-existing land package. That is a self-reinforcing process, not a transparent comparison of alternatives.

ISH1 has now clarified the chronology. The Applicant confirmed that four of the six stages of its siteselection exercise had already been completed while Norwich Main remained the geographi cal basis of the search and that, by that point, a suitable solar site had been established. When the connection strategy subsequently moved to Great Moulton, the exercise was not restarted t hrough a fresh unrestricted search from that new point of connection. The previously identified Sites were retained because they remained within approximately 20 km of Great Moulton.

BEPS does not contend that a complete restart was automatically required as a matter of law. T he material question is whether retaining the previously identified land was supported by an ad equate environmental comparison once the connection geography had changed. Continued inc lusion within approximately20 km of Great Moulton establishes geographical eligibility under th e Applicant's methodology; it does not, by itself, demonstrate that the same Sites would have e merged from an environmentally informed search beginning at Great Moulton.

ExQ1 now requires the Applicant to explain why a fresh Great Moulton-centred site-selection exercise would not have produced a materially different Scheme, extent or configurati on. That is the appropriate examination question.

5.1.5 Land availability was a materially conditioning factor

Landowner willingness was a legitimate deliverability consideration. BEPS does not contend that the Applicant was required to use compulsory acquisition to assemble speculative alternative solar sites. The issue is the weight given to land availability relative to environmental suitability, and whether the existing land package materially narrowed the environmental alternatives subsequently considered. The Applicant's own evidence shows that voluntary land availability was not merely one consideration among many. It was a decisive threshold criterion.

The Applicant states that it searched for landowners willing to participate, sought a land package of approximately 1,100 hectares and secured Sites 1–10 and the BESS site through voluntary agreements. It also explains that assembling land from as few ownerships as possible

was desirable in order to minimise project complexity, engineering issues, legal arrangements, mitigation requirements and cost.

At Stage 6 of the solar alternatives exercise, four Alternative Development Zones were identified which might in principle accommodate solar development and which could have offered shorter cable routes. However, the Applicant did not consider them further because sufficient land had not been made available to it. Chapter 5 states that, without alternative land sufficient to accommodate the Scheme being made available within those zones, the land was not considered further as a reasonable alternative.

The same approach was applied to the National Grid substation search. Land in Siting Zone 2 south of Station Road and west of the railway was not selected because a willing landowner was not forthcoming.

The Applicant further relies on its preference to avoid compulsory acquisition as far as practicable. That may explain its commercial preference, but it does not establish that land unavailable by voluntary agreement was environmentally unsuitable or technically incapable of accommodating development.

The statutory alternatives requirement is not limited to sites already controlled by the developer. Land availability may affect whether an option is ultimately deliverable, but the Applicant must still distinguish between land which is environmentally unsuitable, land which is technically unsuitable, land which is unavailable following a meaningful and documented inquiry, land which has not been tested because the Applicant already controls sufficient acreage elsewhere, and land which is simply less convenient or more expensive to acquire.

Chapter 5 does not maintain that distinction. It repeatedly treats ‘not made available to the Applicant’ as equivalent to ‘not a reasonable alternative.’

Nor is it sufficient to say that no alternative land came forward during consultation. Public consultation is not a comprehensive land-market exercise. Landowners cannot reasonably be expected to identify, assemble and volunteer an alternative 1,100-hectare scheme in order to correct deficiencies in the Applicant’s site-selection methodology.

The conclusion is unavoidable: East Pye was selected because the Applicant was able to secure a sufficiently large land package from willing owners. Environmental suitability was then assessed within that commercially assembled area.

The ExA has now required the Applicant to provide the early desktop planning review, clarify when landowner engagement began and explain how landowner agreement fed into the site-selection process. Those documents are directly relevant to determining the relative influence of environmental screening and land availability.

5.1.6 The Great Moulton point of connection was selected to preserve the land package

After Norwich Main failed, the Applicant focused its search along the Bramford–Norwich 400 kV line. The stated considerations included proximity to the overhead line, road access, reduction

in the length of diversion works and capital cost. Those are relevant factors, but the search was also explicitly constrained by the location of the solar sites already assembled.

Chapter 5 states that the stretch of transmission line considered was limited to north of Diss because the Applicant preferred a location close to the solar sites it had already identified and secured. It also states that Siting Zone 3 was less preferable because it was further from those sites.

Great Moulton has therefore not been demonstrated to be the environmentally preferable or strategically necessary place for a new National Grid substation. It was the location that best maintained the viability of the Applicant's existing land interests.

The circularity is clear. The land was first assembled around Norwich Main. Norwich Main was subsequently found to be unavailable. The Applicant retained the land, selected a new connection area partly because it was close to that land, and then relied on proximity to the new connection to justify the Scheme's location.

That process does not demonstrate that the Great Moulton substation or the associated solar sites represent an environmentally appropriate combination. It demonstrates only that they preserve the commercial scheme already assembled.

5.1.7 The site-selection process was not ecologically led

The Applicant states that statutory ecological designations, ancient woodland and other constraints were mapped and that designated sites were avoided. Avoiding the direct footprint of internationally or nationally designated land is a necessary starting point. It does not demonstrate that East Pye was selected through a comparative ecological assessment.

The Scheme remains spread across a complex and sensitive rural ecological network involving ancient and replanted ancient woodland, County Wildlife Sites, mature hedgerows and field-boundary trees, ponds and ghost ponds, protected-species habitat, bat commuting and foraging networks, rare arable flora, established stewardship habitat, watercourses, riparian corridors and functionally connected farmland and woodland habitats.

Chapter 5's design-evolution table records numerous later changes involving buffers, offsets, habitat corridors, woodland setbacks, removal of limited panel areas and the designation of mitigation land. Those changes demonstrate that ecological constraints were encountered after the land package had been selected. They do not establish that ecology led the original selection.

The Applicant's methodology therefore largely followed a pattern of identifying and securing sufficient willing land, removing the most obviously prohibited or designated areas, retaining the overall distributed scheme, responding to ecological evidence through buffers, landscaping and mitigation, and then concluding that the residual land was suitable. That is mitigation-led design, not ecological avoidance-led site selection.

The proper alternatives question was not simply whether panels could be kept outside the boundary of a statutory designation. It was whether a scheme of this scale should be located

across this ecological network at all, when materially less sensitive locations, reduced-scale options or non-development might avoid fragmentation and disturbance.

The Applicant has not provided a transparent comparative assessment showing that East Pye was ecologically preferable to other regions or alternative land areas. Nor has it shown that the ecological network affected by East Pye is capable of accommodating a 500 MW dispersed solar scheme without unacceptable fragmentation and cumulative harm.

5.1.8 Agricultural-land constraints were relaxed to preserve the Scheme

The treatment of agricultural land provides a clear example of project delivery overriding the Applicant's initial environmental screening.

The Applicant initially applied a preference against the use of BMV land. However, when the initial screening did not identify sufficient land to accommodate the preferred 500 MW scheme, Grade 3 land was reintroduced into the search.

The resulting Scheme contains approximately 829.1 hectares of BMV land, representing about 78.7% of the solar sites. The methodology therefore moved from an initial stated preference to avoid higher-quality land to a final scheme overwhelmingly occupying it.

The sequence is important. BMV land was initially treated as a constraint. Applying that constraint prevented the Applicant from assembling sufficient acreage. The constraint was then relaxed, land already secured from willing owners was retained, and alternative land was rejected where it was not available voluntarily.

That does not demonstrate that poorer-quality land was preferred where possible. It demonstrates that the Applicant adjusted its criteria when those criteria prevented delivery of the fixed 500 MW project.

The March 2026 Land Use Framework is not itself planning policy and expressly states that its principles are not intended to constitute a material consideration in NSIP decisions. BEPS does not rely upon it as an independent basis for refusal. It is, however, relevant evidence of the strategic land-use problem recognised by Government and the intended future direction of national spatial policy.

The Framework states that England has sufficient land to meet energy, food, infrastructure and nature objectives if land is used more efficiently and strategically. It identifies 'right use, right place' as a principle for future policy, supports the strategic safeguarding of productive farmland and records that its modelling did not direct renewables and other major land-use changes towards the most productive BMV land. It also anticipates a fairer and more efficient spatial distribution of solar and wind infrastructure.

The Framework does not decide this application. It does, however, reinforce the evidential question which Chapter 5 fails to answer: why should a predominantly BMV land package in South Norfolk be selected for this project when the regional need case is unproven and the Applicant's own initial methodology treated such land as a constraint?

5.1.9 The Applicant fixed the scale before assessing alternatives

Chapter 5 treats the 500 MW capacity as an immutable starting point. The Applicant calculated the land required to deliver that output, added land for substations, BESS, access, landscaping, biodiversity measures and cable infrastructure, and searched for approximately 1,100 hectares.

Alternatives were then tested according to whether they could reproduce that fixed project. 'Do nothing' was rejected because it would deliver none of the Applicant's proposed capacity. A smaller scheme was rejected because it would deliver less than 500 MW. Brownfield land was rejected because no single brownfield site could accommodate the whole scheme. Rooftops were rejected because assembling enough roofs to produce 500 MW would involve multiple ownerships. Alternative development zones were rejected unless sufficient land was available to accommodate the full Scheme. Other technologies were dismissed in part because the Applicant is itself a solar and storage developer.

That is not a meaningful assessment of alternatives in size, scale, configuration or technology. It tests only whether another option can deliver East Pye exactly as the Applicant wishes to promote it.

At minimum, the Applicant should have assessed a substantially smaller solar development, removal of the most ecologically, agriculturally and visually harmful sites, a compact scheme closer to the actual point of connection, a lower-capacity connection, phased development, solar without BESS, delayed or reduced BESS, alternative deployment through less constrained regions or projects, and no development.

None of those options can properly be dismissed solely because it would produce less than the Applicant's preferred 500 MW output.

5.1.10 No demonstrated regional need for East Pye in T7

National policy establishes an important and continuing need for low-carbon electricity infrastructure. BEPS does not dispute that general proposition. It does not follow, however, that every proposed solar NSIP is required in every transmission region, irrespective of regional capacity, queue position, environmental harm or the availability of other projects.

The Applicant relies on national need at a high level but provides no evidence that a further 500 MW transmission-connected solar project is required in South Norfolk or within T7 East Anglia.

The present strategic connections framework is regionally and technologically differentiated. The evidence assembled by BEPS indicates that the published combined solar figure for T7 in 2035 is 3,300 MW, while the transmission-only solar figure is 900 MW. Current Gate 2 solar projects in T7 total approximately 2,241.6 MW, and the wider planning, consented and under-construction T7 solar pipeline has been calculated at approximately 4,015 MW.

These figures should be supported in the final evidence schedule by consistently dated references to the relevant Ofgem, NESO, RESP and REPD material. Taken together, however, they demonstrate the central issue: T7 is already heavily subscribed for solar in aggregate, and the position is particularly pronounced for transmission-connected solar.

East Pye is not a small distribution-connected project serving a local deficit. It is a 500 MW transmission-connected scheme requiring a wholly new National Grid substation, major project substations and extensive cable infrastructure. It must therefore be considered against the transmission-specific regional position, not simply against a general national objective for more renewable electricity.

The Applicant has not identified any existing or forecast T7 transmission-solar deficit which East Pye is required to fill. It has not identified any regional capacity shortfall that would arise if East Pye were refused, which existing Gate 2 or consented T7 projects are assumed not to proceed, why East Pye should be preferred over those projects, why equivalent capacity should not be delivered in regions with a greater identified need, or why South Norfolk must bear the additional environmental burden of this Scheme.

The fact that regional capacity figures may not constitute absolute planning caps does not make them irrelevant. They are directly relevant to whether this particular project is strategically aligned, whether refusal would frustrate the regional pathway and whether the environmental harm of East Pye is necessary.

Nor can the Applicant rely on general 'optionality' or the possibility of attrition elsewhere. Optionality for developers and the system cannot be treated as a public benefit without accounting for the irreversible or long-duration environmental, agricultural and community costs imposed by preserving that optionality.

The proper question is what regional clean-power deficit would arise if East Pye Solar were not built. Chapter 5 and the Statement of Need do not provide an answer.

5.1.11 The position is particularly adverse for transmission solar

The distinction between combined solar capacity and transmission-connected solar is important.

The Applicant presents East Pye as a major national generating asset whose transmission connection allows its benefits to be experienced more widely. That characteristic also means the project must be assessed against the capacity already present in, or allocated to, the T7 transmission queue.

On the Ofgem/NESO figures relied upon by BEPS, Gate 2 transmission solar already substantially exceeds the published T7 transmission-only figure. East Pye would add a further 500 MW and would require construction of a new transmission node at Great Moulton.

The Applicant has not shown why further transmission solar should be concentrated in T7 notwithstanding the existing Gate 2 position, the wider regional pipeline, network congestion and curtailment risk, the cumulative proliferation of solar, BESS and grid infrastructure in South Norfolk, and the availability of other transmission regions with different capacity requirements.

In those circumstances, generic national need cannot establish that East Pye is required in this location.

5.1.12 The BESS does not cure the absence of a regional solar need case

Chapter 5 relies upon co-location with the BESS as part of the preferred technology solution. It states that the BESS could store electricity at times of lower demand, release it at times of need and enhance grid resilience and stability.

Those asserted benefits do not answer the regional solar-capacity issue.

The solar and BESS elements must be examined separately. The application materials identify Gate 2 prioritisation for the solar component, but do not appear to establish an equivalent Gate 2 position for the BESS. The contractual ability to import electricity is not necessarily the same as a secured Gate 2 allocation for the storage project.

The Applicant should therefore be required to clarify the precise Gate status of both the solar component and the BESS, whether the BESS may be delayed, reduced or omitted, whether the solar element may operate without it, what benefits remain if the BESS is not delivered, and whether BESS benefits are being relied upon to justify a solar project whose regional need has not been demonstrated.

The alternatives assessment should have considered solar-only, delayed-BESS, reduced-BESS and severed implementation scenarios. It cannot assume a fully integrated solar-and-storage scheme if delivery of each component is not equally secured.

5.1.13 The Applicant's own development portfolio reinforces the absence of demonstrated locational necessity

East Pye should also be considered in the context of the Applicant's own development portfolio. That context does not turn other Island Green Power projects into formal alternatives to East Pye. It does, however, materially weaken any suggestion that generic national renewable-energy need, portfolio 'optionality' or expected attrition demonstrates that this particular 500 MW Scheme must proceed in this particular location.

The Applicant's own Statement of Reasons confirms that East Pye Solar Limited is wholly within the Island Green Power corporate group. It also records that Island Green Power has delivered nearly 40 solar projects worldwide, including 21 in the UK, with more than 3 GW of developed capacity. Macquarie Asset Management increased its ownership of Island Green Power to 100% in 2025 and states that the UK business has a development pipeline exceeding 15 GW of utility-scale solar and battery-storage projects.

East Pye is therefore not a singular project upon which either the Applicant's renewable deployment programme or the national solar programme depends. It is one prospective development within a very substantial commercial portfolio.

That point is particularly important because Island Green Power is simultaneously promoting **The Droves Solar Farm**, another NSIP-scale project in Norfolk. Island Green Power describes The Droves as a proposed solar and BESS development between Swaffham and Castle Acre in West Norfolk and confirms that it is being promoted through the NSIP regime. The Droves is proposed at approximately 500 MW. East Pye is likewise a 500 MW-class

NSIP promoted by the same corporate group. The Applicant is therefore advancing approximately 1 GW through these two Norfolk projects alone.

That does not establish that The Droves is a mandatory substitute for East Pye, nor that an applicant with a large portfolio is entitled to less favourable treatment. The significance is different.

The Applicant relies upon a general national requirement for renewable generation while BEPS' preceding analysis shows no identified T7-specific solar deficit which East Pye is required to fill. The Applicant also relies upon the prospect of future attrition within the wider development pipeline. In that context, the existence of its own substantial portfolio demonstrates why a distinction must be maintained between **portfolio optionality** and **project-specific necessity**.

A developer pursuing many prospective schemes plainly obtains value from retaining multiple development options. Some schemes may obtain consent; some may be delayed by grid constraints; some may change; and some may ultimately fall away. Macquarie itself describes Island Green Power's expanding UK pipeline as the foundation for building a substantial operating portfolio. There is nothing inherently objectionable about that commercial strategy.

But it does not answer the planning question before the Examining Authority.

Portfolio optionality may explain why the Applicant wishes to preserve East Pye. It does not demonstrate why East Pye is necessary at this location or why its full 500 MW scale must be retained despite its environmental constraints.

The same distinction applies to attrition. If the generation pipeline substantially exceeds the capacity that will ultimately be required or connected, some projects will necessarily fail, be reduced, be delayed or not proceed. The possibility of that attrition cannot logically operate only as an argument for consenting every project now.

If attrition is expected, environmental suitability is an obvious consideration in determining which projects should ultimately proceed.

That is especially important at East Pye. The Applicant's own alternatives evidence shows that the broad 500 MW capacity was treated as a project requirement from the outset; sufficient land was sought to accommodate that capacity; the site-selection exercise was not restarted when the original Norwich Main connection strategy failed; land availability played a central role; and a materially smaller Scheme was not pursued as an alternative.

The result is a ten-Site development whose environmental cost is unusually high. The Applicant's own assessments acknowledge extensive significant landscape effects and irreversible loss or downgrading of BMV agricultural land. The wider evidence identifies a nationally important bat assemblage, multiple barbastelle maternity-colony landscapes, ancient woodland, sensitive water and groundwater receptors, important heritage assets, constrained rural highways and unresolved major-infrastructure interfaces.

Against that background, the Applicant cannot answer the alternatives question merely by saying that more projects are required in the national pipeline because some will fall away.

The appropriate question is the reverse:

If attrition is expected, why should East Pye—with this combination of landscape, ecological, agricultural, heritage, hydrological and infrastructure constraints—not be one of the projects that is reduced, relocated or does not proceed?

The existence of The Droves makes that question concrete. The same corporate group is advancing another approximately 500 MW NSIP in Norfolk at the same time. Island Green Power is also developing multiple other large-scale projects elsewhere in England and maintains a UK solar and BESS pipeline exceeding 15 GW. The national contribution available from the Applicant's development activity is therefore plainly not dependent upon preserving every hectare or every megawatt of East Pye.

The Applicant does not have to prove that The Droves itself could replace East Pye megawatt-for-megawatt. But the existence of that project, together with the much wider portfolio, makes it still more important to establish why East Pye's full scale is environmentally justified rather than merely commercially desirable.

This is particularly relevant to the Applicant's refusal to consider a materially smaller East Pye Scheme. If deleting the most sensitive Sites or Sub-Sites reduced East Pye below 500 MW, the Applicant cannot answer that alternative simply by pointing to the national need for solar. Its own portfolio demonstrates that the difference between a reduced East Pye and the preferred 500 MW project forms only part of a much larger development programme.

The alternatives exercise should therefore have tested whether the environmental objectives served by reduction could justify sacrificing some of the Applicant's preferred East Pye capacity. It should have asked whether development could be concentrated on the least constrained parts of the Order Limits; whether the most environmentally sensitive Sites could be removed altogether; and whether a reduced East Pye would represent a more proportionate contribution when considered alongside the substantial regional and Applicant pipelines.

It did not. Instead, the Applicant treated its 500 MW objective as something the alternatives process was required to preserve.

That is precisely why the portfolio evidence matters. It exposes the difference between what is required in the public interest and what is desirable from the perspective of maintaining a large commercial development pipeline.

The point is especially significant for compulsory acquisition. Island Green Power's ability to maintain portfolio optionality may be commercially valuable, but the same reasoning cannot establish that private land at East Pye is necessary for compulsory acquisition. The Applicant must ultimately justify the acquisition of that land by reference to the public benefits and requirements of East Pye itself, not the value to its parent company of retaining another 500 MW option within a multi-gigawatt portfolio.

Accordingly, this evidence does not establish that another Island Green Power project is a formal EIA alternative to East Pye. It establishes something more limited but directly relevant:

East Pye is one project within a very substantial Applicant portfolio, including another approximately 500 MW solar NSIP in Norfolk. Generalised national need, commercial portfolio optionality and possible attrition elsewhere therefore cannot establish that East Pye itself must retain its full 500 MW scale or occupy these ten Sites. The Applicant must demonstrate why this particular Scheme should survive the expected process of project attrition despite the exceptional environmental constraints of the landscape it has selected. It has not done so.

5.1.14 The 'do nothing' alternative is material and should be prioritised

Chapter 5 excludes the 'no development' scenario because it would have no prospect of delivering the generation and storage proposed by the Applicant. That reasoning is tautological. A no-development alternative will always deliver none of the proposed project. If that were sufficient to exclude it, the environmental null alternative could never be relevant.

The proper question is not whether East Pye would be built without consent. It is whether refusal would materially frustrate the relevant national or regional energy objectives. On the present evidence, the Applicant has not demonstrated that it would.

If East Pye were consented, T7 would receive a further 500 MW of transmission-connected solar in a region already heavily subscribed overall and particularly for transmission solar. The Scheme would require a wholly new National Grid substation and associated transmission infrastructure, occupy approximately 829 hectares of BMV land, fragment and disturb a sensitive ecological network, industrialise a wide area of rural South Norfolk, affect heritage settings, settlements and public rights of way, create risks to water resources and private water supplies, affect aviation interests and constrained rural roads, and add to the cumulative effects of other solar, BESS, transmission and development projects.

If East Pye were refused, the Applicant has not shown that the T7 regional solar pathway would fail. Refusal would avoid all direct environmental effects of the Scheme, retain productive BMV farmland, avoid a new Great Moulton transmission hub, preserve ecological, hydrological, heritage and landscape systems, allow delivery to continue through existing Gate 2, consented and other pipeline projects, and preserve future strategic options pending fuller spatial energy planning.

The Applicant may argue that some projects in the regional pipeline will not be delivered. That possibility does not establish that East Pye is required. The Applicant must identify the assumed attrition, explain why it is reasonable and demonstrate what residual deficit East Pye would fill.

It is not sufficient to impose the full environmental cost of East Pye upon South Norfolk merely to preserve speculative system or developer optionality.

In a region where solar capacity is already heavily subscribed, where transmission-connected capacity substantially exceeds the relevant regional figure, and where refusal has not been shown to create a regional shortfall, the 'do nothing' alternative is both realistic and

environmentally rational. It should therefore have been treated as a principal alternative and compared transparently against the proposed Scheme.

5.1.15 Design evolution does not cure the site-selection defect

The Applicant relies on iterative design changes, including panel removals, enlarged buffers, woodland setbacks, habitat corridors, landscape planting and changes responding to consultation. Some of those changes may reduce individual effects. They do not cure the foundational problem.

Design evolution has not altered the fact that the land was assembled before a viable connection was established, that the Norwich Main premise failed, that the Applicant retained the existing land package rather than commencing a genuinely fresh search, that Great Moulton was selected partly because it served that land package, that the Scheme remains dispersed over a very large area, that it remains predominantly on BMV land, that substantial ecological and landscape effects remain, that the new transmission-infrastructure cluster remains, and that no proper reduced-scale or no-development alternative has been assessed.

Design refinement can reduce impacts within an already selected site. It cannot demonstrate that the site itself was appropriately selected. The design-evolution exercise therefore shows how the Applicant attempted to accommodate environmental constraints within the preferred scheme. It does not show that environmental considerations determined the choice of land or the fundamental scale and location of the project.

5.1.16 Overall conclusion

The Applicant's evidence demonstrates that the East Pye Solar site was not selected because a viable grid connection existed at Norwich Main. Norwich Main had neither sufficient capacity nor any expansion opportunity for the project.

The Applicant nevertheless searched for and secured approximately 1,100 hectares from willing landowners around that assumed connection. When Norwich Main failed, it retained the land and sought a new point of connection capable of preserving it.

Great Moulton was selected partly because it was close to the already assembled sites. Alternative land and substation locations were rejected or not pursued where willing landowners had not made sufficient land available. Land availability therefore operated as the controlling criterion.

Ecological and other environmental constraints did not lead to a fresh site search. They were largely addressed through later buffers, setbacks and mitigation within the commercially assembled scheme.

The Applicant also fixed the project at 500 MW before assessing alternatives and then rejected no development, smaller-scale development, brownfield land, rooftops and alternative configurations because they would not reproduce the same predetermined project.

At the same time, the Applicant has not demonstrated that further transmission-connected solar is required in South Norfolk or T7 East Anglia. The available evidence indicates that T7 is

heavily subscribed for solar overall and particularly for transmission solar. The Applicant has not shown what regional deficit would arise if East Pye were refused.

In those circumstances, the extensive environmental, agricultural and community harm of East Pye is not justified by a demonstrated regional need. The ‘do nothing’ alternative should have been assessed seriously and, on the present evidence, should be preferred.

5.1.17 Remedies sought

BEPS requests that the Examining Authority require the Applicant to submit a supplementary and consolidated alternatives assessment which reconstructs the chronology of land assembly, grid discussions and site selection; identifies when the Applicant first knew that Norwich Main had insufficient capacity and no expansion opportunity; explains why the Norwich Main-derived land package was retained after the original connection premise failed; separates land availability and landowner willingness from environmental and technical suitability; identifies all alternative land areas considered, the inquiries made into their availability and the reasons they were rejected; and discloses the criteria, weighting, scoring and professional judgements applied to solar and National Grid substation alternatives.

The supplementary assessment should also examine whether the Great Moulton point of connection was selected principally to preserve land already assembled and should provide a comparative ecological, landscape, agricultural, heritage, hydrological, aviation, transport and public-rights-of-way assessment of the principal alternatives. It should assess reduced-scale, compact, phased, solar-only, BESS-deferred, BESS-reduced and no-development alternatives and should clarify the separate connection and Gate status of the solar and BESS components.

The Applicant should further be required to provide a complete and consistently dated comparison of East Pye with the T7 Gate 2 allocation, the transmission-specific solar figure and the wider planning and consented pipeline. It should identify the regional capacity shortfall, if any, that would arise if East Pye were not built and explain why the environmental harm of East Pye is necessary notwithstanding the existing T7 solar and transmission-solar position.

Unless the Applicant can demonstrate both a genuine regional need for this project and a defensible environmental basis for selecting this particular land, no material weight should be attached to its conclusion that the proposed Scheme is appropriately located.

If those deficiencies cannot be remedied fairly and comprehensively within the Examination timetable, the ‘do nothing’ alternative should be preferred and the application refused.

5.2 Legal and policy framework

The Applicant is correct that there is no universal planning-policy requirement to demonstrate that every nationally significant infrastructure project is the absolute ‘best option’ among all conceivable alternatives. NPS EN-1 makes that clear. That proposition does not, however, displace the separate statutory requirement imposed by the Infrastructure Planning (Environmental Impact Assessment) Regulations 2017, nor the specific policy requirements applying to the siting of electricity infrastructure.

Paragraph 2 of Schedule 4 to the 2017 Regulations requires the Environmental Statement to include a description of the reasonable alternatives studied by the developer which are relevant to the proposed project and its specific characteristics. The examples given expressly include alternatives in terms of development design, technology, location, size and scale. The Environmental Statement must also identify the main reasons for selecting the chosen option and must include a comparison of environmental effects. Chapter 5 itself reproduces that requirement.

That requirement does not oblige the Applicant to identify the objectively best or least environmentally harmful option among every conceivable alternative. Nor does it require the Applicant to undertake an unconstrained national site search. It requires the Environmental Statement to describe the reasonable alternatives actually studied which are relevant to the project and its specific characteristics, and to identify the main reasons for the option chosen, taking environmental effects into account. Technical feasibility, grid availability, land availability and other deliverability considerations may legitimately inform which alternatives are reasonable; the material question is whether their influence, and the environmental comparison between the alternatives actually studied, is sufficiently transparent.

The August 2026 NPPF reinforces the environmental relevance of that exercise. Policy N2 requires significant biodiversity harm first to be avoided through location on an alternative site with less harmful impacts where such harm cannot otherwise be avoided, and requires agricultural land quality and grade to be taken into account, with poorer-quality land used where possible. Those provisions do not create a universal requirement to identify the least harmful possible site, but they reinforce the need to demonstrate that avoidance genuinely informed the Scheme's evolution before reliance was placed upon mitigation.

The obligation is therefore not satisfied merely by narrating the history of the Applicant's preferred proposal. Nor is it satisfied by showing that design changes were made after environmental constraints were identified. The Environmental Statement must disclose a genuine alternatives exercise in which reasonable alternatives were identified, studied and compared, and in which the reasons for the chosen option were explained by reference to their environmental, social, economic, technical and commercial consequences.

NPS EN-1 also recognises that the reasonableness of an alternative may depend upon technical and commercial feasibility. That does not permit the Applicant to define the project objective so narrowly that only the preferred Scheme is capable of meeting it. An alternative cannot properly be dismissed simply because it would provide less than the Applicant's chosen 500 MW capacity, would require a different configuration, would omit or defer the BESS, would involve a different land package, or would be less convenient to the Applicant's existing commercial arrangements. To reason in that way would convert the statutory comparison into a test of whether an alternative can reproduce the preferred project exactly.

NPS EN-5 is particularly important in relation to the new National Grid substation. Chapter 5 records that NPS EN-5 recognises that there will usually be a degree of flexibility in the location of associated substations and that applicants should consider their location and design carefully. It also recognises that engineering, environmental and community constraints may

require infrastructure to follow something other than the most direct or commercially convenient route.

The Horlock guidance, which the Applicant says informed its substation assessment, similarly requires the early consideration of environmental and community constraints. It requires applicants to make use of landform and existing features for screening, to protect habitats and landscape features as far as reasonably practicable, and to keep visual, noise and other environmental effects to a reasonably practicable minimum. Chapter 5 therefore accepts that environmental suitability was required to inform substation siting from the outset, not merely to be mitigated after a commercially convenient location had been identified.

The legal objection is accordingly a focused one. BEPS does not contend that the Applicant was required to assess every parcel of land or every theoretical technology in England. The objection is that the Applicant did not study a reasonable range of alternatives on a properly defined and environmentally neutral basis. It fixed the essential features of the Scheme in advance: a 500 MW solar project, associated BESS, approximately 1,100 hectares of land, a transmission connection and a land package assembled through willing owners. It then defined reasonableness by reference to whether an alternative could accommodate that predetermined project.

That approach screened out potentially less harmful alternatives by construction. Reduced-scale development was excluded because it would not deliver 500 MW. The ‘do nothing’ alternative was excluded because it would deliver none of the proposed generation. Brownfield and rooftop alternatives were tested against their ability to reproduce the entire 500 MW Scheme. Alternative development zones were not pursued where sufficient land had not been made available voluntarily. The assessment therefore did not begin by asking what development, if any, could be accommodated with the least environmental harm. It began by asking where the Applicant’s already defined project could be preserved.

5.3 The original site search was tied to Norwich Main

The chronology disclosed in Chapter 5 is central to understanding the weakness of the alternatives exercise.

The Applicant initially considered Norwich Main Substation as the point of connection for a 500 MW utility-scale solar project. In parallel with those grid discussions, it adopted a 20 km search radius around Norwich Main and began searching within that area for landowners willing to participate in the Scheme. Chapter 5 states expressly that the Applicant conducted a search for willing landowners within that Norwich Main radius, identified the requisite amount of land and secured voluntary agreements over the sites which later became the subject of the DCO application.

The Site Selection Assessment follows the same sequence. The original 20 km radius was selected because the Applicant considered it to represent a commercially viable cable-connection distance for a project of this scale. Land agents were then used to identify large landholdings and willing landowners within that area. The search therefore began with Norwich Main as its geographical and commercial anchor.

Only after that land search had been undertaken did NGET advise that Norwich Main had neither sufficient existing capacity nor any opportunity for expansion to accommodate a 500 MW solar project. Chapter 5 expressly records that Norwich Main was therefore discounted as a viable point of connection. The Site Selection Assessment confirms the same point.

This sequence is decisive. The East Pye land package was not assembled because a viable grid connection existed at Norwich Main. It was assembled while the availability of that connection remained unresolved. The Applicant therefore secured the land before it had established the infrastructure premise relied upon to justify its location.

The site-selection narrative should not therefore be described as grid-led. The grid assumption that defined the original search area proved to be wrong. Norwich Main could not accommodate the Scheme and could not be expanded to do so. The land was nevertheless retained.

Nor can the location be said to have emerged from an environmentally led search. The first operative step was not the identification of the least constrained land around a confirmed connection. It was the identification of willing landowners within an Applicant-defined commercial radius around a point of connection which subsequently failed.

The correct conclusion is that the land was assembled before the Applicant had established a viable point of connection. East Pye was therefore not selected because grid capacity existed at Norwich Main. Norwich Main had no capacity for the Scheme.

5.4 Failure to restart the site search when Norwich Main failed

The failure of Norwich Main should have triggered a fundamental reassessment of the Scheme. The original 20 km search radius had been justified by proximity to Norwich Main and by the Applicant's assessment of a commercially viable cable distance. Once Norwich Main was found to have no capacity and no expansion opportunity, the defining rationale for the original search area disappeared.

A neutral alternatives process would then have reconsidered the appropriate broad region, the appropriate project scale, whether a 500 MW development remained justified, whether a different solar site should be selected around the actual point of connection, whether the Scheme should be reduced or reconfigured, and whether the project should proceed at all. Given that the Applicant promotes multiple solar projects across England, it should also have considered whether the same claimed generation benefit could be delivered through a less environmentally damaging opportunity elsewhere in its portfolio, while recognising that the EIA duty is directed primarily to alternatives actually studied by the developer.

That fundamental reassessment did not occur. Instead, the Applicant retained the Norwich Main-derived sites and searched southwards along the Bramford–Norwich 400 kV line for a new National Grid substation capable of serving them.

The fact that the exercise was not restarted is not, by itself, the objection. The evidential issue is whether the previously selected land remained environmentally justified once Great Moulton replaced Norwich Main as the relevant connection geography. A parcel remaining within the

Applicant's 20 km search radius establishes continued geographical eligibility; it does not establish comparative environmental suitability.

Chapter 5 states that, following NGET's confirmation that Norwich Main was unavailable, the Applicant selected the point of connection south of Great Moulton. It then treated the sites previously identified around Norwich Main as continuing to be viable because they also happened to fall within 20 km of the new Great Moulton point of connection and because the landowners had already demonstrated their willingness to enter voluntary agreements.

That reasoning does not amount to a fresh site-selection exercise. It validates the old sites against a new connection after the event. The fact that the previously assembled land happened to fall within another Applicant-defined 20 km radius does not demonstrate that the land was environmentally preferable, that Great Moulton was the best available strategic location, or that the original site search remained rational once its grid premise had failed.

The circularity becomes still clearer in the National Grid substation assessment. Chapter 5 states that the stretch of transmission line considered was limited to land north of Diss because the Applicant preferred a location in proximity to the solar sites already identified as suitable and for which a willing landowner had been established. It also accepts that areas within Siting Zone 3 could present a reasonable alternative, but says that the distance from the initially identified solar sites made that zone less preferable.

The Site Selection Assessment makes the same point. Great Moulton was preferred partly because of its proximity to the identified solar sites, while the more southerly Yaxley-area option was treated as less preferable because it was further from them.

This demonstrates that the Applicant did not conduct a fresh search from the actual grid opportunity outwards. The already assembled land was used to constrain the search for the new connection, and the new connection was then used to justify retention of the already assembled land.

The Applicant did not select the solar sites by reference to the actual point of connection. It selected the point of connection partly by reference to solar sites already assembled around a point of connection that had failed.

ISH1 has now confirmed that four of six stages had already been completed before the connection strategy changed. The Applicant's assertion that the same Sites would have emerged had Great Moulton been the original starting point therefore requires supporting evidence, particularly because a different geographical starting point potentially changes cable requirements, collecting substations, access, BMV effects, landscape and heritage relationships, ecology, hydrology and proximity to settlements.

5.5 Land availability materially conditioned site selection

Chapter 5 and the Site Selection Assessment show that land availability was not merely one consideration among several. It operated as a decisive threshold criterion throughout the process.

The Applicant states that it searched specifically for landowners willing to participate in the Scheme. It calculated that a 500 MW connection would require a substantial landholding and ultimately searched for approximately 1,100 hectares to accommodate solar arrays, substations, the BESS, access, landscaping, biodiversity measures and cable infrastructure. The search yielded the land required, and voluntary agreements were secured over Sites 1–10 and the BESS site.

The Applicant also explains that it preferred to assemble the Scheme through as few ownerships as possible. It says this would reduce engineering, design, legal and mitigation complexity. Those are intelligible commercial considerations, but they also show that the site-selection process favoured large consolidated landholdings and ease of contractual assembly, rather than beginning with a comparative assessment of environmental suitability.

The significance of this approach is confirmed by the treatment of alternative land. At Stage 6 of the solar site-selection process, the Applicant identified four Alternative Development Zones within the search area. Chapter 5 acknowledges that land within those zones might be suitable for solar development and that greater proximity to the point of connection could reduce cable length, environmental disturbance and disruption. Nevertheless, the zones were not considered further because sufficient land had not been made available to the Applicant.

The Site Selection Assessment is explicit that potentially suitable alternative development areas were not treated as reasonable alternatives where sufficient land had not been made available. This is a critical admission. It shows that potentially suitable land was screened out not because a comparative environmental assessment demonstrated that it was inferior, but because the Applicant had not secured it voluntarily.

The same approach was applied to the National Grid substation. Chapter 5 states that land in Siting Zone 2 south of Station Road and west of the railway was not selected because a willing landowner was not forthcoming. That reason is distinct from environmental or engineering unsuitability. It is a land-control reason.

The Applicant also relies on a preference to avoid compulsory acquisition. That preference may be relevant to commercial feasibility and to the proportional use of compulsory powers. It does not establish that land outside the Applicant's voluntary agreements was technically incapable of accommodating the development or environmentally less suitable. Nor does it justify treating untested land as though it were not a reasonable alternative at all.

The legal criticism must therefore remain precise. Land availability is capable of being relevant to the reasonableness and deliverability of an alternative. But it cannot substitute for identifying and comparing environmental alternatives. Nor can it be treated as determinative without evidence of what inquiries were made, whether the land was genuinely unavailable, whether different scales or configurations could have been accommodated, and whether compulsory powers or alternative commercial arrangements were realistically capable of being considered.

Chapter 5 does not draw those distinctions. It conflates land which is not already available to this developer on voluntary terms with land which is not reasonable, suitable or deliverable. That is not the same thing.

The Applicant's approach is especially weak because it did not undertake a comprehensive test of alternative availability once sufficient land had been secured. The Site Selection Assessment records that the Applicant did not approach further landowners after it considered that sufficient suitable land had already been identified. The conclusion that no better available land existed is therefore not supported by a full market or ownership inquiry. The search stopped because the Applicant already had enough land for its preferred scheme.

Nor does the fact that alternative land did not 'come forward' during consultation cure the defect. Statutory consultation is not a substitute for a properly designed site-selection process. It is not a comprehensive land-market exercise, and neighbouring landowners cannot reasonably be expected to identify, assemble and volunteer hundreds of hectares in order to demonstrate that the Applicant's preferred land package is environmentally inferior.

The overall inference is strong. East Pye was selected because the Applicant could assemble approximately 1,100 hectares from willing owners within a commercially acceptable area. The point of connection was then adapted to serve that land. Environmental constraints were assessed and mitigated within the land package after it had been secured.

The Applicant has therefore conflated 'available to this developer on voluntary terms' with 'environmentally suitable' and 'reasonable.' That is the central defect in the site-selection exercise.

5.6 The Great Moulton substation was selected to preserve the assembled sites

The Applicant presents the Great Moulton substation location as the outcome of a technical and environmental search along the Bramford–Norwich 400 kV transmission line after Norwich Main had been discounted. The underlying evidence shows, however, that the search was constrained from the outset by the location of the solar sites already assembled under the failed Norwich Main premise.

Chapter 5 states that, after NGET confirmed that a new National Grid substation would be required, the Applicant focused its search along the Bramford–Norwich 400 kV line between Norwich and Diss. Proximity to the existing overhead line, access from the strategic road network, the ability to accommodate abnormal indivisible loads and the reduction of additional connection infrastructure were all treated as relevant considerations. Those factors are legitimate. They do not, however, explain why the search was limited in the particular way chosen or why Great Moulton was preferred over all other potentially reasonable locations.

The Applicant expressly states that the stretch of transmission line considered was limited to land north of Diss because it preferred a location close to the solar sites already identified as suitable and for which willing landowners had been established. This is a significant admission. The geographic scope of the substation search was not defined solely by network capacity, engineering constraints or environmental suitability. It was defined partly by the need to preserve a pre-existing land portfolio.

The Applicant's treatment of Siting Zone 3 confirms the same point. Chapter 5 accepts that areas within Siting Zone 3 could present a reasonable alternative. It nevertheless concludes that the zone was less preferable because of its distance from the initially identified solar sites. The principal disadvantage was therefore not that the zone had been shown to be incapable of accommodating a substation or that its environmental effects were necessarily unacceptable. It was that it was less convenient for land already assembled elsewhere.

The Site Selection Assessment similarly records that the Great Moulton area was selected partly because of its proximity to the identified solar sites. By contrast, the Yaxley-area option was treated as less preferable in part because it was the furthest from those sites, which would increase cable length, electrical losses and associated environmental effects. The comparison therefore began from an assumption that the existing solar sites should be retained and asked which substation location best served them.

That approach is circular. The solar land had been assembled around Norwich Main before the Applicant knew that Norwich Main could not accommodate the Scheme. When that connection failed, the Applicant did not conduct a fresh strategic search for the most appropriate combination of solar land and point of connection. It retained the land and selected a new point of connection partly because it was close to that land. It then relied upon proximity to the new point of connection as a justification for retaining the original sites.

The later comparison between Options 4A and 4B does not cure that defect. Option 4A was affected by overlap with the consented solar development north of Station Road, while Option 4B was preferred because it lay within Flood Zone 1 and avoided a direct conflict with a public right of way through the proposed substation footprint. Those considerations may explain why Option 4B was preferred within the already selected Great Moulton area. They do not demonstrate that Great Moulton itself was the most appropriate strategic location for a new 400 kV substation.

The alternatives assessment also does not provide a transparent comparison showing that Great Moulton was preferable in landscape, heritage, aviation, ecological or community terms. The assessment largely records broad constraints and applies a high-level RAG review. It does not disclose a weighted multi-criteria analysis demonstrating how environmental harm was balanced against commercial convenience, land control, cable length and access. Nor does it show whether lower-lying or more visually contained locations were comparatively assessed against the exposed Great Moulton landform.

This omission is particularly important because NPS EN-5 recognises that there is usually flexibility in the location of associated substations and requires applicants to consider location and design carefully. Chapter 5 also invokes the Horlock Rules, which require applicants to take advantage of screening provided by landform and existing features and to keep visual, noise and other environmental effects to a reasonably practicable minimum. A search directed principally toward preserving pre-assembled solar sites does not demonstrate compliance with that environmental siting discipline.

Great Moulton was therefore not demonstrated to be the strategically or environmentally optimum location for a new National Grid substation. It was the location that best preserved the Applicant's existing land assembly.

5.7 The site-selection process was not ecologically led

The Applicant states that ecological designations and environmental constraints were taken into account through its staged site-selection process. It says that internationally and nationally designated biodiversity sites were identified and avoided and that environmental considerations informed later design evolution. That evidence shows that ecological information was considered. It does not show that ecological suitability led the selection of East Pye.

The chronology demonstrates otherwise. The original search began with a 20 km radius around Norwich Main and a search for landowners willing to participate. The Applicant then sought approximately 1,100 hectares to accommodate the fixed 500 MW Scheme and associated infrastructure. Broad environmental filters were subsequently applied, but land availability remained decisive, and alternative development zones were not pursued where sufficient land had not been made available voluntarily.

The ecological exercise was therefore conducted within a commercially assembled land package. It did not begin with a comparative landscape-scale assessment of ecological sensitivity followed by selection of the least constrained location.

The Applicant's methodology placed considerable emphasis on the avoidance of formal designations. Chapter 5 states that Special Areas of Conservation, Special Protection Areas, Ramsar sites, Sites of Special Scientific Interest, National Nature Reserves and ancient woodland were identified and avoided. It also states that no international, national or local statutory designated ecological sites lie within the solar sites.

That is not the same as demonstrating ecological suitability. Avoiding the mapped footprint of a statutory designation does not avoid effects on functionally connected land, habitat networks, protected species, groundwater-dependent habitats, ancient woodland settings, bat commuting routes, ponds, hedgerows, watercourses or locally designated sites. Nor does it establish that the chosen area was less ecologically harmful than reasonable alternatives.

The Scheme remains distributed across a sensitive ecological network involving ancient and replanted ancient woodland, County Wildlife Sites, mature hedgerows, field-boundary trees, ponds and ghost ponds, watercourses, riparian corridors, bat roosting and foraging habitat, rare arable flora, established stewardship land and other functionally connected farmland habitats. The detailed evidence is addressed in the Ecology and Biodiversity Written Representation and is not repeated here. The significance for Chapter 5 is that these constraints should have informed the choice of location and scale before the land package was fixed.

Chapter 5's own design-evolution account demonstrates that many ecological constraints were addressed only after the sites had been selected. Across the various sub-sites, the Applicant records repeated refinements to buffers from hedgerows, trees, woodland, ponds,

water features and field margins; extensions to ancient woodland offsets; creation or strengthening of habitat corridors; removal of limited panel areas; and designation of land for ecological mitigation.

Examples include the removal of Sub-Site 3A after access and ecological issues associated with Spring Wood Ancient Replanted Woodland were recognised; enlargement of buffers around Spring Wood; removal of panels between woodland blocks in Site 5 to maintain ecological connectivity; increased mitigation around Fritton Grange Meadows County Wildlife Site; and refinement of ancient woodland buffers in Site 7. These changes may reduce particular impacts. They also demonstrate that significant ecological constraints were accommodated within the design after land selection rather than used to direct the Scheme elsewhere.

The distinction is important. Avoidance in the mitigation hierarchy is not achieved merely by moving panels a short distance within the same ecological network or by placing buffers around features while retaining development on surrounding functionally connected land. Genuine avoidance may require removal of development areas, substantial reduction in scale, relocation to a less sensitive landscape or non-development.

The Applicant's approach was instead principally mitigation-led. It identified and secured sufficient land, excluded the most obvious statutory constraints, retained the overall dispersed scheme and then adjusted offsets and mitigation as further ecological evidence emerged. That process does not establish that East Pye was selected because it was ecologically preferable.

Nor has the Applicant provided a transparent comparative ecological assessment of the principal alternative areas. The Site Selection Assessment identifies potentially unconstrained land and broad development zones, but it does not present a systematic comparison of ecological network function, protected-species risk, habitat connectivity, hydrological dependence, ancient woodland setting or long-term restoration potential between East Pye and the alternative areas. The absence of voluntary land agreements then prevented those alternative areas from being examined further.

The conclusion is therefore not that ecology was ignored. It is that ecology did not control the site-selection outcome. Ecological constraints were treated primarily as matters for later design refinement and mitigation within a land package selected for other reasons.

Avoiding the footprint of a statutory designation is not equivalent to selecting the least ecologically harmful location. The Applicant has not demonstrated through comparative evidence that East Pye was preferable to reasonable alternative areas or that the residual ecological harm was unavoidable.

5.8 The agricultural-land methodology confirms that project delivery overrode environmental screening

The Applicant's treatment of agricultural land provides one of the clearest examples of the site-selection criteria being adjusted to preserve the preferred project.

NPS EN-3 states that agricultural land classification should not be the sole or predominant factor in site selection, but that where agricultural land is necessary, poorer-quality land should be preferred to higher-quality land and the use of Best and Most Versatile land should be avoided where possible. Chapter 5 acknowledges those principles and states that agricultural land classification was treated as an important site-selection factor.

The Applicant's staged methodology initially reflected that policy. At the earlier screening stage, Grades 1, 2 and 3 agricultural land were excluded in order to identify the most unconstrained land and to apply a preference against BMV land.

That approach did not identify sufficient land to accommodate the preferred Scheme. The Applicant therefore proceeded to a later stage in which Grade 3 agricultural land was brought back into the search. Chapter 5 explains that doing so introduced a substantial area of land capable of accommodating solar development and allowed the Applicant to identify four Alternative Development Zones. Those zones were then not examined further where sufficient land had not been made available voluntarily.

The resulting Scheme is overwhelmingly located on BMV land. The Applicant's detailed agricultural surveys identify approximately 829.1 hectares of BMV land within the sites, amounting to about 78.7% of the solar-site area. This is not a marginal or incidental use of higher-quality agricultural land. It is the predominant land type affected by the Scheme.

The logical sequence is significant. BMV land was initially treated as a constraint. Applying that constraint prevented the assembly of enough land for the Applicant's preferred 500 MW development. The constraint was then relaxed. The Applicant retained land already secured from willing owners and concluded that other areas were not reasonable alternatives where equivalent acreage had not been made available.

That is not evidence-led avoidance. It is the adjustment of environmental criteria to accommodate a fixed commercial project.

The Applicant says that its understanding of agricultural quality developed as detailed surveys were completed and that some areas of BMV land were removed or retained for mitigation during design evolution. Those changes do not answer the site-selection objection. Once detailed evidence showed that the Scheme was predominantly BMV, the Applicant should have reconsidered the location, extent and capacity of the Scheme. It did not conduct a new strategic search based on the actual agricultural-quality evidence.

The design-evolution table confirms that BMV land was removed only in discrete instances where it coincided with other constraints. Sub-Site 3A was removed following a combination of access, ancient woodland, ecological, unexploded ordnance, heritage and Grade 2 BMV issues. Site 6 was retained for agriculture and mitigation because it was entirely Grade 2 and affected by heritage constraints. Some BMV land was also removed from Sites 8 and 9 in response to landscape, heritage or other considerations.

Those changes show that the Applicant was capable of avoiding BMV land where multiple constraints made development especially difficult. They do not demonstrate that poorer-

quality land was preferred across the Scheme as a whole. The final outcome remains one in which nearly four-fifths of the solar sites comprise BMV land.

The Applicant also relies upon provisional mapping available during initial site selection. Chapter 5 states that the wider area was shown largely as undifferentiated Grade 3 and that later surveys provided a more detailed understanding of Grades 2, 3a and 3b. That explains why the precise proportion may not have been known at the earliest stage. It does not justify retaining the Scheme unchanged once the detailed survey evidence became available.

A lawful and environmentally credible alternatives exercise should be capable of responding to better evidence. Where later surveys reveal that a preferred land package is predominantly BMV, the Applicant should revisit whether the project can be reduced, relocated, made more compact or directed toward land of lower agricultural quality. Treating the later evidence merely as a matter for panel-level refinement is inadequate.

The March 2026 Land Use Framework must be used with appropriate caution. It expressly states that its principles are separate from the planning process and are not intended to constitute a material consideration in decisions on nationally significant infrastructure projects. BEPS does not rely upon it as an independent policy test or as a direct basis for refusal.

The Framework is nevertheless relevant as evidence of the strategic land-use problem identified by Government and the direction in which future national policy and spatial planning are intended to develop. It states that England has enough land to meet development, energy, food-production and nature-recovery objectives if land is used efficiently, multifunctionally and strategically. It identifies ‘right use, right place’ as a guiding principle and states that land use should reflect local context, including soil quality, heritage, environmental pressures and social and economic factors.

The Framework also states that its spatial analysis did not direct renewables and other major land-use changes toward the most productive BMV land. It says that change should play to the strengths of the land and records consultation support for directing non-agricultural land uses toward land less suited to high-value sustainable agriculture, thereby retaining more BMV land in food production.

Government also commits in the Framework to maintaining overall food production in England and to safeguarding the best and most versatile farmland from permanent land-use change. It recognises that efficient spatial planning should minimise trade-offs between energy, food security, nature recovery and climate resilience.

The Framework does not determine the East Pye application. It does, however, reinforce the evidential weakness of an alternatives assessment that moved from an initial preference to avoid BMV land to a final Scheme occupying approximately 829.1 hectares of it, without conducting a renewed strategic search once the true agricultural quality was known.

The Applicant has therefore not demonstrated that poorer-quality land was preferred where possible. It has demonstrated that the BMV constraint was relaxed when it prevented delivery of the fixed 500 MW Scheme, and that alternative areas were then excluded where sufficient

voluntary land agreements were unavailable. That is a land-assembly outcome, not an environmentally led agricultural-land strategy.

5.9 The project scale was fixed before alternatives were assessed

The Applicant did not begin by asking what scale or configuration of development could be accommodated in South Norfolk with the least environmental harm. It began with a 500 MW connection requirement and treated delivery of that capacity as an essential and effectively immutable project objective.

Chapter 5 states that the Applicant's grid connection agreement was for 500 MW and that, applying the land-use assumptions in NPS EN-3, an initial area of approximately 500 to 810 hectares would be needed for the solar panels alone. The Applicant then increased its search requirement to approximately 1,100 hectares to accommodate the solar arrays together with substations, the BESS, access infrastructure, landscaping, biodiversity measures and cable routes.

The scale of the Scheme therefore preceded the alternatives exercise. The Applicant first determined the output and associated land requirement and then asked whether possible alternatives could reproduce that entire predetermined project. It did not first examine the environmental capacity of the receiving area and derive an appropriate project scale from that evidence.

This predetermined scale materially affected every category of alternative considered. Chapter 5 excludes a smaller development because it would not deliver the full generating capacity sought by the Applicant. It excludes 'no development' because that scenario would not deliver any of the proposed generation or storage. It rejects brownfield land because no single identified brownfield site within the search area was large enough to accommodate a 500 MW utility-scale solar project. It rejects commercial rooftops because assembling sufficient roof area to reproduce the same 500 MW capacity would require agreements across numerous ownerships and a geographically extensive network of sites.

The same circularity affected the search for alternative agricultural land. Potential Development Areas and Alternative Development Zones were assessed by reference to whether sufficient land was available to accommodate the whole Scheme. Where approximately 1,100 hectares had not been made available to the Applicant, the land was not pursued as a reasonable alternative, even where Chapter 5 acknowledged that it might in principle be suitable for solar development or might reduce cable length and associated disturbance.

The analysis therefore does not establish that a 500 MW Scheme was environmentally appropriate at East Pye. It establishes only that alternatives unable to reproduce a 500 MW Scheme were excluded from further consideration.

This is not meaningful consideration of alternatives in size, scale or configuration. Schedule 4 to the EIA Regulations expressly identifies size and scale as examples of the alternatives which may require examination. That requirement would have little practical content if an applicant

could fix its preferred capacity in advance and then exclude all smaller or differently configured options because they would not deliver the same output.

The Applicant's reliance on NPS EN-1 does not answer that criticism. Commercial feasibility may legitimately inform whether an alternative is reasonable, but it does not permit the project objective to be defined as the delivery of the preferred Scheme in its entirety. Otherwise, the preferred capacity becomes both the premise and the conclusion of the assessment.

A smaller development could still deliver substantial renewable generation while avoiding the most environmentally harmful parts of the Order Limits. A reduced scheme might omit sites affected by the highest concentrations of BMV land, ancient woodland connectivity, protected-species activity, heritage setting harm, flood risk, residential proximity or constrained construction access. The relevant comparison is not between 500 MW and no public benefit at all. It is between different levels of renewable-energy benefit and the different environmental costs required to secure them.

The Applicant should also have assessed a more compact development concentrated closer to the actual Great Moulton point of connection. Such an option could potentially reduce the length of cable corridors, the number of affected communities, the extent of habitat fragmentation, construction traffic across the wider road network and the overall geographic spread of industrial infrastructure. The Applicant instead retained a dispersed group of solar sites originally assembled around Norwich Main because they also fell within its chosen 20 km commercial radius of Great Moulton.

The solar and BESS elements should also have been tested separately. The Applicant treated co-located solar and storage as the preferred technology solution, but did not adequately assess solar without BESS, delayed BESS, reduced BESS or a smaller storage facility. Those alternatives are particularly relevant where the solar and storage components have different Gate 2 and deliverability positions.

A lower-capacity connection should likewise have been examined. The Applicant has not demonstrated that the full 500 MW export capacity was the only technically or commercially reasonable connection option once Norwich Main failed. A reduced connection might have allowed a smaller land requirement, fewer project substations, less cable infrastructure and avoidance of the most sensitive sites.

Phased development was another obvious alternative. The Applicant could have assessed whether a smaller first phase could proceed while regional capacity, BESS deliverability, ecological effects and network requirements were reviewed. Instead, the alternatives exercise assumes delivery of the complete project concept from the outset.

The assessment should also have considered whether equivalent national benefits could be delivered through the Applicant's other projects or through deployment in regions with greater identified capacity requirements. That does not mean that the EIA Regulations impose an unrestricted obligation to compare every scheme in a developer's national portfolio. It does mean that the Applicant cannot rely upon a generic national need for solar while treating the

particular location, capacity and land package of East Pye as fixed and beyond comparative examination.

The Applicant should therefore have examined, at minimum, a substantially smaller scheme, removal of the most environmentally damaging sites, a compact scheme closer to the actual point of connection, solar without BESS, delayed or reduced BESS, a lower-capacity connection, phased development, delivery through less harmful projects or regions, and no development.

By failing to assess those alternatives, Chapter 5 does not demonstrate why the environmental harm associated with the full 500 MW Scheme was necessary. It demonstrates that the Applicant defined the project so narrowly that alternatives capable of reducing that harm were excluded by construction.

5.10 No evidence of regional need for East Pye Solar in T7

National policy does not require the Applicant to establish an unmet T7 capacity deficit as a precondition to consent. The August 2026 NPPF expressly states that applicants should not generally be required to demonstrate generic need for renewable or low-carbon energy development. The T7 pipeline evidence is nevertheless relevant to the weight which can properly be attached to claims that East Pye's Gate 2 status itself demonstrates project-specific or locational necessity. BEPS does not contend that the 3,300 MW figure is a statutory cap, although NESO clearly states that it reflects a regional capacity limit for that type of energy generation. Gate 2 status demonstrates progression through the connections process; it does not establish that this particular dispersed configuration is environmentally necessary or uniquely appropriate.

The objection is that the Applicant relies on generic national need to justify this particular 500 MW transmission-connected project while providing no evidence that additional transmission solar of this scale is required in South Norfolk or in the T7 East Anglia region.

That distinction matters because the reformed connections framework is not geographically or technologically undifferentiated. Government, Ofgem and NESO now use regional and technology-specific permitted capacities to align the connections queue with the Clean Power 2030 and 2035 pathways. T7 has a published combined transmission-and-distribution solar capacity of 3,300 MW for 2035. Within that regional figure, the published transmission solar capacity is 900 MW.

NESO's January 2026 response confirms that current Gate 2 solar projects in T7 total 2,241.6 MW, comprising 380.8 MW in Phase 1 and 1,860.8 MW in Phase 2. NESO further states that 1,365.22 MW of the Phase 2 capacity relates to transmission-connected capacity, although that figure also includes certain large distribution-connected projects and excludes small and medium distribution projects.

Those figures require careful interpretation. The 3,300 MW figure is the combined T7 regional capacity, while the 900 MW figure relates to transmission solar. The 2,241.6 MW Gate 2 total includes both transmission and distribution solar, and NESO's published transmission-related figure is not necessarily identical to the category of directly transmission-connected projects

alone. The precise comparison should therefore be presented transparently and without combining unlike categories.

Even with that qualification, the position is clear. Gate 2 solar already represents a substantial proportion of the combined T7 capacity, while the transmission-related portion of the Gate 2 allocation already exceeds the published 900 MW transmission figure. East Pye would add a further 500 MW transmission-connected project to that position.

BEPS has separately estimated, using the RESP and Renewable Energy Planning Database material assembled in its evidence, that the wider planning, consented and under-construction solar pipeline in T7 is approximately 4,015 MW. That estimate should be supported in the final evidence schedule by a project-by-project table, a consistent reference date and a clear explanation of whether each project is transmission-connected, distribution-connected, operational, under construction, consented or awaiting determination.

Subject to that final verification, the wider pipeline estimate exceeds the published 3,300 MW combined regional capacity by approximately 715 MW. That does not mean that every project in the pipeline will necessarily be built, nor that the regional capacity operates as an absolute planning prohibition. It does demonstrate that the regional context is one of substantial competition and potential over-provision, not an evidenced shortage which only East Pye can meet.

The position is particularly important for transmission solar. East Pye is not a modest distribution-connected installation serving a local demand centre. It is a 500 MW transmission asset requiring a new National Grid substation, multiple project substations, overhead-line works and extensive cable infrastructure.

The environmental burden of the Scheme therefore arises not merely from the solar panels but from creating a new transmission connection node capable of accommodating development at this scale. That burden requires a correspondingly clear explanation of why further transmission-connected solar is needed in T7.

The Applicant has not provided such an explanation. It has not produced a regional capacity balance identifying existing operational solar, consented schemes, Gate 2 projects, projects under construction and the remaining regional requirement. It has not separated transmission and distribution capacity consistently. It has not identified the anticipated attrition within the existing pipeline or demonstrated why East Pye is needed to fill any residual shortfall.

The Applicant's general reliance on national need does not answer those questions. National need establishes that substantial renewable generation is required across the system. It does not establish that every proposed 500 MW project is required in every region irrespective of the regional capacity allocation, existing queue, competing pipeline and environmental consequences.

T7 is not simply heavily subscribed when solar is considered in aggregate. The over-provision is particularly pronounced for transmission-related solar, which is the category most directly relevant to East Pye. On the published NESO figures, transmission-related Gate 2 capacity

already exceeds the 900 MW transmission figure before East Pye's further 500 MW contribution is considered.

The Applicant was therefore required to explain why East Pye remains strategically necessary notwithstanding that position. Chapter 5 and the Statement of Need do not do so.

5.11 The Applicant has not demonstrated a separate locational necessity for this configuration

The alternatives issue does not depend upon BEPS proving that East Pye is unnecessary. The relevant question is whether any claimed locational advantage of the selected configuration has been demonstrated strongly enough to explain why this particular dispersed land package was retained despite the environmental constraints now established.

The Applicant is likely to respond that the regional permitted capacities are not legal planning caps and that some projects holding Gate 2 status, planning permission or connection agreements may never be constructed. Neither proposition resolves the objection.

BEPS accepts that the T7 capacity figures do not constitute an automatic statutory prohibition on consent above a specified number of megawatts. The connections framework and the development-consent regime perform different functions. The regional figures nevertheless remain directly relevant evidence of strategic alignment, network need and the amount and type of generation already available to meet the regional pathway.

Ofgem approved the TMO4+ reforms precisely because the former queue was substantially larger than the generation capacity required and did not provide a reliable signal for efficient network investment. The reformed process applies readiness and strategic-alignment criteria and uses regional and technology-specific capacities to determine which projects should receive Gate 2 status.

It would therefore be artificial for the Applicant to rely upon its grid position when that supports the Scheme, but dismiss the wider regional allocation and competing Gate 2 capacity as irrelevant when considering whether the environmental harm of the Scheme is necessary.

The possibility of attrition also requires evidence rather than assertion. The Applicant cannot merely state that some other projects may not proceed and assume that East Pye must therefore be consented as insurance. It should identify the attrition rate relied upon, the basis for that assumption, the development status of the relevant competing projects and the residual capacity shortfall said to remain after attrition.

No such analysis is presented in Chapter 5. The Applicant has not identified which of the existing T7 Gate 2 projects are assumed to fail, why they are less likely to be delivered than East Pye, or why East Pye should be preferred over projects which may be smaller, more compact, consented, under construction or environmentally less harmful.

Nor has the Applicant compared East Pye against the wider T7 planning and consented pipeline. The fact that planning applications and connection offers do not guarantee

construction is not a reason to ignore them. It is a reason to assess their likelihood of delivery transparently.

The Applicant also cannot treat ‘optionality’ as an unqualified public benefit. Maintaining multiple competing projects may give NESO, developers or investors flexibility if some schemes fail. But preserving that flexibility has environmental consequences. In East Pye’s case, it would require a new 400 kV substation, extensive BMV land occupation, major construction activity and long-duration effects across a large rural area.

The public interest cannot be assessed by counting only the value of optional generation while disregarding the environmental and community cost of maintaining that option. If East Pye is sought primarily as a reserve against possible attrition elsewhere, that should be stated and evaluated explicitly.

The regional evidence is also relevant to the distribution of development. The Applicant has not explained why equivalent renewable capacity could not be delivered in a region with a greater identified requirement, or through projects which do not require the same level of new transmission infrastructure and environmental disruption.

This does not impose an obligation upon the Applicant to solve the national spatial allocation of solar by itself. It does, however, require a rational explanation for relying on national need to justify severe site-specific harm in a region where the relevant technology is already heavily subscribed.

The central question is straightforward: what regional deficit would arise if East Pye were not built?

The Applicant has not identified any quantified T7 solar shortfall that would result from refusal. It has not shown that the 2035 regional pathway would fail, that the transmission allocation would be unmet or that existing Gate 2 and pipeline projects would be insufficient after a reasonable allowance for attrition.

On the evidence currently available, refusal of East Pye has not been shown to frustrate the T7 pathway. The Applicant has therefore not established that the environmental consequences of this particular project are regionally necessary.

5.12 The BESS does not cure the absence of a solar need case

The Applicant relies on the co-located BESS as an important part of its preferred technology solution. Chapter 5 says that the BESS would store electricity at times of lower demand, release energy when needed and enhance grid resilience and stability. It relies upon those asserted benefits when explaining why solar PV combined with storage was selected for the Order Limits.

The BESS also cannot be relied upon automatically as an advantage of the preferred alternative. Work No. 2 remains Gate 1. Any comparison which attributes balancing, curtailment-reduction or co-location benefits to the preferred Scheme must therefore recognise that those benefits

depend upon the BESS obtaining a connection and becoming operational on a compatible timetable.

Those benefits do not establish a regional need for the solar component. Nor can they be relied upon without distinguishing the connection and Gate status of the two elements.

The application material records a grid agreement allowing up to 500 MW of solar export and up to 500 MW of import capability associated with storage. It separately identifies Gate 2 prioritisation for the solar component. On the material presently available, the Applicant has not demonstrated that the BESS has secured an equivalent Gate 2 position.

A contractual ability to import electricity is not necessarily the same as strategic alignment and Gate 2 status for a storage project. The Applicant should therefore clarify precisely what has been secured for each component and whether the BESS is presently deliverable within the same programme as the solar development.

This matters because the solar need case cannot be strengthened by assuming benefits from a storage component whose strategic position and delivery are not equivalently secured. If the BESS may be delayed, reduced, omitted or unable to obtain Gate 2 status, the Scheme may operate principally as a 500 MW solar generator without the flexibility benefits relied upon in Chapter 5.

The BESS is also potentially severable from the solar development. The draft DCO and project parameters must therefore be examined to determine whether solar could be constructed and operated without the BESS, whether the BESS could be constructed later, and whether either component could proceed at a materially different scale.

Chapter 5 does not assess those scenarios as reasonable alternatives. It does not compare the environmental and operational consequences of solar-only development, a delayed BESS, a reduced BESS or removal of the storage component. Instead, it treats solar and BESS as a single preferred concept.

The regional battery position makes that omission more significant. NESO's January 2026 figures show 1,711.6 MW of Gate 2 battery offers in T7 against initially allocated capacities of 200 MW for Phase 1 and 200 MW for Phase 2. NESO also records 4,283.1 MW of Gate 1 battery offers in T7 and expressly describes the battery position in T7 as significantly oversupplied.

The oversupply is not confined to T7. NESO reported in March 2026 that 83.2 GW of batteries had received Gate 2 status nationally and that built, operational and Gate 2 battery capacity together totalled 90.6 GW, more than three times the Government's 24–29 GW capacity range for 2035. NESO stated that, given this position, only batteries that were ready and met specified protection criteria were likely to qualify in the next application window.

NESO also identifies concrete disadvantages arising from battery oversupply, including the risk of consumer-funded network investment for projects that may not be needed and delays to other connections caused by finite network-delivery capacity and competition for substation bays and grid supply points.

The Applicant therefore cannot rely upon a generic national need for storage to assume that East Pye's BESS is strategically necessary. T7 already contains Gate 2 battery capacity substantially above the regional permitted capacities, as well as a much larger Gate 1 queue.

The correct alternatives assessment should have examined the solar and BESS components independently and in combination. It should have assessed whether either component is required regionally, whether the claimed co-location benefits are secured, whether the BESS could be omitted or reduced, and what environmental infrastructure would remain necessary in each implementation scenario.

The omission reinforces the wider defect. The Scheme was defined as 500 MW solar plus up to 500 MW BESS before the regional capacity, Gate status and deliverability of each component had been resolved. The alternatives exercise then treated that combined concept as fixed rather than testing whether either component should proceed at all or at the proposed scale.

5.13 The Applicant's own development portfolio reinforces the absence of demonstrated locational necessity

The Applicant's wider development portfolio is relevant context to the alternatives and planning-balance analysis. BEPS does not contend that The Droves, or any other Island Green Power project, had to be assessed as a formal substitute for East Pye under Schedule 4 to the 2017 EIA Regulations. The point is narrower. The Applicant cannot rely upon generic national renewable-energy need, commercial portfolio optionality or possible future attrition elsewhere as proof that East Pye itself must retain its full 500 MW scale in this particular location.

That distinction matters because Chapter 5 shows that the Applicant fixed the essential characteristics of East Pye before undertaking the alternatives exercise. It selected a 500 MW solar project with associated BESS, identified a land requirement of approximately 1,100 hectares, assembled land through willing owners and then assessed alternatives largely by asking whether they could reproduce that predetermined project. Smaller development was not considered further because it would not deliver the full generating capacity sought; "no development" was rejected because it would deliver none of the proposed generation or storage; and alternative areas close to the eventual point of connection were rejected where the land had not been made available to the Applicant. The Applicant itself records that land closer to the point of connection could have reduced cable length, disruption, environmental disturbance and cost, but was not treated as a reasonable alternative because willing-landowner agreements had not been secured.

The Applicant's own wider portfolio makes it particularly important not to confuse those commercial constraints with public necessity.

East Pye is not an isolated development upon which Island Green Power's contribution to UK renewable deployment depends. Island Green Power states that it has developed almost 40 solar projects worldwide, more than 3 GW of renewable-energy capacity, and 21 projects in the United Kingdom. In 2025 Macquarie Asset Management acquired the remaining 50% interest in Island Green Power's UK business, taking its ownership to 100%. Macquarie reports that Island

Green Power has a UK development pipeline of more than 15 GW. East Pye Solar is therefore one prospective project within a very substantial developer portfolio.

The comparison with The Droves is particularly relevant. Island Green Power is also promoting The Droves Solar Farm in West Norfolk, between Swaffham and Castle Acre. The same developer group is therefore advancing two separate solar NSIPs of up to 500 MW each in Norfolk: East Pye Solar and The Droves. Those two projects alone represent up to approximately 1 GW of prospective solar capacity.

That fact does not prove that The Droves is environmentally preferable to East Pye, nor that it is a legally required alternative. Its significance is that it exposes the distinction between maintaining a development portfolio and demonstrating the necessity of an individual project. Where the Applicant has not demonstrated an unmet regional deficit, and where the same corporate group is simultaneously advancing another 500 MW Norfolk solar NSIP and a much wider UK portfolio, there is no evidential basis for treating East Pye's full 500 MW capacity as a fixed public requirement.

A developer with a large pipeline has an understandable commercial interest in preserving multiple projects while grid arrangements, consenting outcomes, financing and construction programmes remain uncertain. Some projects may proceed, others may be reduced or delayed, and others may ultimately fall away. Maintaining a substantial portfolio therefore provides commercial optionality against future attrition.

That may be a rational development strategy. It is not evidence that every project within the portfolio is necessary in the public interest.

The same reasoning applies to any reliance upon pipeline attrition. If the response to an already substantial national or regional pipeline is that not all projects will ultimately be delivered, that proposition cannot logically establish that East Pye itself must be consented. It establishes only uncertainty about which projects will ultimately proceed. Possible attrition elsewhere does not establish necessity for East Pye Solar. If attrition is expected, the question is not why East Pye should automatically be protected from it, but why a project with this concentration of environmental constraints should survive at its full 500 MW scale. Environmental suitability is an obvious criterion by which an oversized development pipeline should ultimately be reduced.

The relevant alternatives question then becomes more, not less, important: why should East Pye be one of the projects preserved at its full 500 MW scale?

That question is particularly acute because the Applicant's own alternatives assessment did not derive East Pye's scale from the environmental capacity of the chosen landscape. It began with the 500 MW connection objective and treated the ability to reproduce that capacity as a criterion for determining whether alternatives were reasonable. Chapter 5 expressly states that a smaller generating development was not considered further. The Applicant's process therefore protected the preferred capacity from environmental comparison rather than testing whether environmental constraints justified a materially smaller project.

The portfolio evidence shows why that approach requires scrutiny. A reduction in East Pye would not mean that Island Green Power ceased to be capable of contributing materially to UK

solar deployment. It is simultaneously advancing The Droves at up to 500 MW and has a much wider UK development pipeline exceeding 15 GW.

That does not permit the Examining Authority to substitute one commercial project for another. It does, however, mean that the Applicant cannot credibly treat every megawatt of East Pye's preferred 500 MW capacity as though it were uniquely required to meet national policy.

The distinction is important when considering a materially reduced East Pye. Chapter 5 should have tested whether removing the most environmentally constrained Sites or Sub-Sites, reducing the development footprint, shortening cable routes or concentrating development nearer the eventual point of connection would produce a materially less harmful Scheme, even if the result delivered less than 500 MW. The Applicant instead excluded smaller capacity at the outset because it would not meet its chosen project objective.

The existence of the wider Island Green Power portfolio reinforces why that reasoning is circular. The Applicant has treated the preservation of 500 MW at East Pye as an essential project requirement while simultaneously pursuing gigawatts of other prospective solar development. The commercial desirability of retaining the full East Pye option cannot itself establish that the public interest requires the same outcome.

Nor does possible attrition elsewhere cure that problem. If attrition is expected within an oversized development pipeline, environmental suitability should be one of the factors determining which projects are reduced, redesigned or do not proceed. The possibility that another scheme may fail cannot be used as a generic justification for accepting avoidable harm at East Pye.

That is particularly important because the environmental consequences of retaining East Pye are not marginal. The Applicant's own site-selection policy recognises that environmental and landscape sensitivity should be avoided where possible and identifies ecology, biodiversity, landscape, water resources and cultural heritage as relevant considerations. Yet the final Scheme remains dispersed across ten Sites and requires extensive cable and grid infrastructure. Its own landscape assessment records significant adverse effects at numerous high- and medium-sensitivity receptors, including public rights of way, settlement edges and the Boudicca Way. The wider Written Representation identifies additional constraints concerning nationally important bats, BMV land, heritage, water, transport and infrastructure.

The Applicant therefore needs to establish why those specific environmental costs are justified by the additional public benefit of East Pye itself. Generic national need cannot answer that question. Nor can the commercial value of retaining East Pye within a multi-gigawatt portfolio.

The portfolio evidence is also relevant to the Applicant's reliance upon willing landowners. Chapter 5 records that potentially suitable areas nearer the final point of connection were rejected because the land had not been made available voluntarily, even though the Applicant acknowledged that shorter cable routes could reduce disruption, environmental disturbance and cost. The result was that existing commercial land arrangements helped determine which alternatives were treated as reasonable.

That may explain why the Applicant preferred to preserve the East Pye land package. It does not demonstrate that the resulting location is environmentally necessary.

A similar distinction will arise in relation to compulsory acquisition. Portfolio optionality may have commercial value to Island Green Power and Macquarie, but it cannot establish that particular private land interests at East Pye are required in the public interest. Any compulsory-acquisition case must ultimately be justified by the requirements and public benefits of East Pye itself.

The correct conclusion is therefore not that The Droves must replace East Pye or that the Examining Authority should choose between Island Green Power projects. It is that the Applicant's own portfolio makes the absence of demonstrated locational necessity for East Pye more material.

If national renewable deployment can be pursued through numerous projects within the Applicant's own portfolio, including another 500 MW NSIP in Norfolk, the Applicant must explain why the environmental constraints identified at East Pye did not justify a smaller, more compact or differently configured Scheme, or the removal of its most damaging Sites.

It has not done so.

The significance of this portfolio evidence is therefore not that The Droves or any other Island Green Power project is a mandatory substitute for East Pye. It is that the Applicant cannot rely upon generic national need, portfolio optionality or possible attrition elsewhere as proof that East Pye must retain its full 500 MW scale in this particular landscape. The Applicant must demonstrate the specific additional public benefit of preserving East Pye at that scale despite the availability of a substantial wider project portfolio. That proposition becomes still more important when the environmental consequences of the site selected for East Pye are considered.

5.14 The environmental consequences of selecting this extensive area of South Norfolk are exceptionally severe

The significance of the alternatives defects cannot be considered in isolation from the environmental consequences of the chosen Scheme. The detailed evidence is set out in BEPS's thematic Written Representations and is not repeated in full here. For Chapter 5 purposes, the relevant point is that the consequences of selecting East Pye are extensive, overlapping and geographically dispersed.

The Scheme would occupy approximately 829.1 hectares of BMV agricultural land, representing around 78.7% of the solar sites. This is not a limited encroachment onto isolated pockets of higher-quality land. BMV land is the predominant agricultural resource affected by the proposal.

The ecological effects extend beyond the direct footprint of statutory designations. The Scheme is distributed across a connected rural network of ancient and replanted ancient woodland,

County Wildlife Sites, mature hedgerows, ponds, watercourses, riparian corridors, bat commuting and foraging routes, rare arable flora, protected-species habitat and established stewardship land.

The Ecology and Biodiversity Written Representation explains why buffers and later habitat measures do not necessarily preserve the functional relationships between those features. The alternatives significance is that these constraints should have influenced whether development was located across this network in the first place, rather than being treated principally as matters for mitigation after land assembly.

The Scheme also gives rise to substantial hydrological concerns. Its dispersed layout crosses multiple catchments and watercourses and affects areas where residents and businesses depend upon private water supplies. Construction, piling, cable installation, changes to runoff patterns and potential pollution pathways create risks which are addressed in the Water Environment and Ground Conditions representations.

Landscape effects arise from the conversion of a large, tranquil and predominantly agricultural area into a dispersed energy landscape. The development would introduce extensive panel fields, fencing, substations, BESS infrastructure, access tracks, lighting and grid works across multiple settlements and parish landscapes. The Great Moulton connection area would contain particularly intensive infrastructure, including the new National Grid substation and associated project substations.

The Heritage Written Representation identifies effects on the settings and interrelationships of listed churches, farmhouses, historic settlements, conservation areas and non-designated heritage assets. These effects cannot be reduced to the absence of development within the statutory boundary of a heritage asset. They arise from altered rural surroundings, long views, construction activity and the cumulative industrialisation of historic parish landscapes.

Construction would involve prolonged HGV movements and abnormal indivisible loads over a rural road network characterised by narrow lanes, constrained junctions, residential frontages, schools, care facilities, historic buildings and limited passing opportunities. The Traffic and Transport Written Representation addresses the feasibility and amenity consequences in detail.

Aviation interests are also affected. East Pye lies close to active operations at Tibenham and Seething airfields. The submitted Tibenham mapping places parts of East Pye within the airfield's 5 km safeguarding area and close to mapped glider launch-failure areas. The Applicant's own design-evolution account records that panels were removed from part of Site 10B following discussions with Seething Airfield concerning engine-failure considerations. Those matters demonstrate that aviation was a site-suitability constraint, not merely a later design detail.

Public rights of way would be diverted, disrupted or enclosed by infrastructure during construction and operation. The effects concern not only legal continuity of routes but also the loss of tranquillity, openness, long rural views and the recreational experience of the landscape.

The Scheme must also be considered cumulatively. South Norfolk is already affected by multiple solar, BESS, transmission, housing and other infrastructure proposals. The Great Moulton substation may become a focal point for a wider energy-infrastructure cluster, while projects such as Tasway, FIELD Long Stratton BESS, Wacton BESS and other developments share environmental, transport and grid receptors with East Pye.

The effects would not be confined to a short construction period. They would arise during construction, operation, maintenance and decommissioning, with some landscape and ecological effects persisting for decades. The new National Grid infrastructure may also be permanent even if the solar arrays are ultimately removed.

The relevance to the alternatives assessment is not simply that East Pye causes harm. Most nationally significant infrastructure causes some adverse effects. The relevant point is the scale, breadth and interaction of the harms, considered against the absence of a demonstrated regional need for this particular project.

Where a proposal would affect predominantly BMV land, fragment a sensitive ecological network, alter heritage settings, create hydrological and private-water risks, industrialise a tranquil landscape, burden constrained rural roads, affect aviation interests, disrupt public access and create a new transmission-infrastructure cluster, the Applicant must provide a correspondingly rigorous explanation of why that harm is necessary.

It has not done so. It relies on generic national need, a fixed 500 MW project objective and a site-selection process led substantially by voluntary land availability. It has not demonstrated that refusal would create a T7 shortfall or that materially less harmful projects and configurations could not deliver the required strategic benefits.

The severity of the environmental consequences therefore makes the ‘do nothing’ alternative materially important. Non-development would avoid the direct and cumulative harms identified across the thematic Written Representations while, on the evidence currently available, not preventing the T7 regional solar pathway from being met.

The null alternative could not properly be excluded merely because it would deliver none of the Applicant’s preferred output. Where regional need is unproven and the environmental harm is exceptionally extensive, ‘do nothing’ must be examined as a serious and potentially preferable alternative.

5.15 The future baseline and the no-development scenario

The EIA Regulations require the Environmental Statement to describe the relevant aspects of the current state of the environment and the likely evolution of that state without implementation of the development, so far as natural changes can be assessed with reasonable effort. That future baseline is distinct from a general legal requirement to treat “do nothing” as a preferred reasonable alternative.

BEPS therefore does not contend that the Applicant was required to prove that development is preferable to no development before the application could proceed. The material point is that the environmental consequences of East Pye, and claimed benefits such as ecological

enhancement or changes in agricultural management, must be assessed against a properly characterised future baseline without the Scheme.

The relevant question is not whether East Pye would be built if consent were refused. The relevant question is whether non-development would materially frustrate the delivery of the applicable national and regional energy objectives and, if not, whether the avoidance of the Scheme's environmental effects would make that outcome preferable.

On the evidence presently available, the Applicant has not demonstrated that refusal of East Pye would prevent the T7 regional solar pathway from being met. The published T7 combined solar figure for 2035 is 3,300 MW, while the transmission-only figure is 900 MW. The Gate 2 solar capacity already allocated within T7 is approximately 2,241.6 MW, and the wider planning, consented and under-construction pipeline assembled by BEPS is estimated at approximately 4,015 MW. The transmission-related position is particularly significant because East Pye is itself a 500 MW transmission-connected project requiring a new National Grid substation and extensive associated infrastructure.

Those regional figures are not relied upon as absolute planning caps. They are relied upon as evidence that the regional context is one of substantial existing provision and competition, not a demonstrated shortfall which only East Pye can meet. The Applicant has not identified what T7 deficit would remain if East Pye were refused, which existing Gate 2 or consented projects are assumed not to proceed, or why East Pye is required as the scheme which must be retained against possible attrition elsewhere.

The comparison with East Pye is therefore materially different from the comparison presented in Chapter 5.

If East Pye proceeds, T7 would receive a further 500 MW transmission-scale solar project in a region already heavily subscribed for solar overall and particularly for transmission-related solar. The Scheme would require a new National Grid substation and connection node at Great Moulton, together with project substations, cable infrastructure and associated works. It would occupy approximately 829.1 hectares of BMV agricultural land, amounting to around 78.7% of the solar sites, and would introduce extensive development across a sensitive rural landscape.

It would also give rise to the environmental and community effects summarised in the preceding section and addressed in detail in the thematic Written Representations. Those include fragmentation of ecological networks, effects on ancient woodland and County Wildlife Sites, protected-species risks, hydrological and private water-supply concerns, heritage-setting harm, landscape industrialisation, aviation constraints, disruption of public rights of way, prolonged construction traffic and cumulative interaction with other solar, BESS, transmission and development projects.

If East Pye does not proceed, the Applicant has not shown that the T7 regional pathway would fail. Refusal would avoid the direct and cumulative effects of the Scheme, retain productive BMV land, avoid the creation of a new Great Moulton transmission cluster and preserve the ecological, hydrological, landscape and heritage systems affected by the proposal.

Non-development would not prevent renewable deployment from continuing through projects which already hold Gate 2 status, projects which are consented or under construction, and other schemes within the wider regional and national pipeline. It would also preserve the ability for future deployment to be directed through more coherent strategic spatial planning and toward projects or regions where additional capacity is demonstrably required.

That is particularly relevant because the Land Use Framework anticipates future spatial coordination of energy infrastructure and the Strategic Spatial Energy Plan is intended to consider societal and environmental factors when spatially optimising generation and storage. Although the Framework is not itself a material consideration in this DCO decision, it confirms that fuller strategic spatial planning is still developing and that future infrastructure distribution is intended to be more coherent and evidence-led.

The Applicant may contend that preserving a larger pipeline provides useful optionality because some projects may not ultimately be delivered. That cannot be treated as a complete answer. Optionality has a cost. In this case, maintaining East Pye as an additional option would expose South Norfolk to the full environmental, agricultural and community consequences of a very large transmission-connected scheme, without a demonstrated regional deficit.

The Applicant must therefore do more than assert that some other schemes may fail. It must identify a credible attrition assumption, show how that assumption affects the T7 balance and demonstrate that East Pye is required to avoid a remaining shortfall. It has not done so.

Where the relevant region already has sufficient or excessive solar capacity, particularly at transmission level, and where refusal has not been shown to frustrate the regional pathway, 'do nothing' is not an unrealistic alternative. It is an environmentally beneficial and strategically rational outcome which should have been assessed and given substantial weight.

On the evidence presently available, non-development would avoid extensive harm without creating any demonstrated regional energy deficit. It should therefore have been treated as a principal and potentially preferable alternative rather than excluded by definition.

5.16 Failure of design evolution to cure the site-selection defect

The Applicant relies heavily on design evolution as evidence that the Scheme has responded to environmental constraints and consultation. Chapter 5 records panel removals, increased buffers, revised setbacks, altered mitigation areas, changes to project substations, removal of some development from flood-risk areas, and modifications responding to heritage, ecological, residential and aviation concerns.

BEPS accepts that some of those changes may reduce particular local effects. The removal of development from discrete areas, enlargement of woodland or residential buffers and modification of layouts may all represent improvements when compared with earlier iterations. They do not, however, cure the underlying site-selection defect.

That defect became substantially more serious once the Applicant's own ecological surveys established that the Scheme area supports a bat assemblage of national importance. Barbastelle was recorded widely across the Order Limits, multiple maternity colonies occur

around the Scheme, and overlapping Core Sustenance Zones extend across the development landscape. The Norfolk Barbastelle Study Group has subsequently identified further maternity-colony evidence and called for additional survey and radiotracking to establish the full colony network and functional habitat use.

At that point the Applicant was no longer dealing with an ordinary agricultural site containing a few discrete bat features capable of protection by local buffers. It had identified a landscape-scale ecological constraint of national importance.

That should have triggered a fundamental reconsideration of the site-selection decision.

The proper response to discovering that the chosen development area lies within a nationally important bat landscape is not merely to move individual panel rows, widen isolated buffers or retain selected hedgerows. It is to ask whether the Scheme should continue to occupy that landscape at all.

The mitigation hierarchy requires avoidance before mitigation. Once the Applicant knew that the Order Limits overlapped a nationally important assemblage and a landscape supporting multiple barbastelle maternity colonies, the first question should therefore have been whether the Scheme, or substantial parts of it, could be relocated outside that functional landscape. That reconsideration did not occur.

Instead, the Applicant continued to treat the already assembled land package as the development area and sought to accommodate the ecological evidence within it through buffers, retained corridors, habitat management, planting and later protected-species controls. That is design mitigation within a selected site. It is not avoidance of the site-selection conflict.

The sequence matters because the land package itself had already been assembled before a viable point of connection was established. Norwich Main subsequently proved incapable of accommodating the Scheme. The Applicant nevertheless retained the land package and selected a new connection location partly because it preserved that existing assembly.

No amount of later design refinement alters that sequence. The essential location decision had already been made before the grid premise was resolved and before the full ecological significance of the area was understood.

The Applicant's subsequent bat evidence should therefore have operated as a second fundamental trigger for reconsideration. Discovery of national ecological importance was capable of invalidating the assumption that the existing land package should continue to define the Scheme. Instead, the project objective remained substantially unchanged.

That is particularly difficult to justify for barbastelle because the relevant receptor is not confined to an individual roost tree or woodland edge. The Applicant's own evidence demonstrates landscape-scale use. The maternity colonies depend upon connected woodland, mature hedgerows, dark commuting routes, ponds, watercourses and feeding habitat across the wider South Norfolk Claylands. The ecological function at risk therefore extends across the very landscape in which the solar sites are dispersed.

Local mitigation cannot answer a landscape-scale location problem.

A 30 m woodland buffer may reduce one edge effect. Retaining one hedge may preserve one potential flight line. A lighting restriction may protect one corridor. None of those measures demonstrates that repeated industrial development across overlapping maternity-colony support habitat is the appropriate starting point.

The Applicant should instead have undertaken a strategic avoidance exercise asking which parts of the Scheme fall within the functional landscape of the nationally important bat assemblage and whether development should be removed from that landscape altogether.

The Norfolk Barbastelle Study Group's evidence makes that obligation more, not less, pressing. It states that further work is required to establish the complete maternity-colony distribution, principal foraging areas, commuting routes and relationships between woodland and feeding habitat. That means the Applicant has proceeded with detailed layout refinement before the full spatial extent of the constraint has even been established.

The logical sequence has therefore been reversed:

- the Scheme area was selected;
- the land package was preserved;
- nationally important bat use was discovered;
- the full maternity-colony network remains incompletely understood;
- and the Applicant has responded by attempting to mitigate development within the same landscape.

The correct sequence should have been:

- identify national ecological importance;
- define the full functional landscape;
- avoid that landscape where practicable;
- then assess whether any residual development can proceed without compromising ecological function.

That distinction is fundamental.

The Scheme also remains geographically dispersed across multiple sites and parish landscapes. Although some panel areas have been removed, the proposal continues to extend over a very large area of South Norfolk and continues to require extensive cable routes, multiple access points, construction compounds and project infrastructure.

The Great Moulton infrastructure cluster also remains. The final Scheme still requires a new National Grid substation, associated overhead-line works, project substations, cable infrastructure and the BESS in the same broad connection area. Moving the National Grid substation from Option 4A to 4B does not demonstrate that Great Moulton itself was appropriately selected.

The agricultural position has likewise not been fundamentally altered. Despite limited removals of Grade 2 or Grade 3a land in some locations, approximately 829.1 hectares of BMV land remain within the solar sites. The Scheme therefore remains predominantly located on the land type which the Applicant initially sought to avoid.

Nor has design evolution altered the regional position. East Pye remains a 500 MW transmission-connected solar project in a T7 region already heavily subscribed for solar overall and particularly at transmission level. The Applicant has still not demonstrated what regional shortfall East Pye is required to fill.

Most importantly, design evolution has not produced a genuine reassessment of scale or configuration. The Applicant has not demonstrated that, after discovering the national importance of the bat landscape, it reconsidered whether whole Sites or groups of Sites should be removed; whether the Scheme should be materially reduced; whether development should be concentrated outside the principal maternity-colony support landscape; whether a different land package should be pursued; or whether East Pye should cease to proceed in this location. That is the critical failure.

Once the Applicant's own surveys established that the selected landscape supports a nationally important bat assemblage and multiple barbastelle maternity colonies, the appropriate application of the mitigation hierarchy was not simply to refine the layout within that landscape. It was to reconsider whether the landscape should be developed at all.

Design refinement can reduce effects within a selected site. It cannot prove that the site itself was appropriately selected.

ISH1 has added a further material consideration. The Applicant confirmed that the geographical spread of the Scheme itself contributes to the requirement for multiple project substations and extensive interconnecting electrical infrastructure. Those environmental effects are therefore not wholly intrinsic to generating approximately 500 MW of solar electricity; they are partly consequences of the particular dispersed configuration selected. That makes the environmental comparison of alternative configurations especially material.

Chapter 5 therefore shows that the Applicant sought to accommodate increasingly serious environmental constraints within an already chosen project. It does not demonstrate that the discovery of national ecological importance was allowed to determine the choice of land, the scale of the Scheme or the decision to proceed. On the contrary, the evidence indicates that the project was preserved and the nationally important landscape was progressively redesigned around it.

5.17 Overall conclusion

The Applicant's own evidence shows that the search for willing landowners began before a viable grid connection had been established. Norwich Main had neither sufficient capacity nor any opportunity for expansion to accommodate the proposed 500 MW project.

When that premise failed, the Applicant did not undertake a genuinely fresh site search. It retained the land already assembled and sought a new point of connection capable of serving it.

Great Moulton was selected partly because it was close to those pre-identified solar sites. Alternative locations were treated as less preferable where they were further from the assembled land, and alternative land was not pursued where sufficient acreage had not been made available voluntarily.

Land availability therefore operated as a controlling criterion. Environmental constraints were addressed principally through later buffers, setbacks, mitigation and limited panel removals rather than through a fresh comparative search for a less harmful location.

The Applicant also fixed the Scheme at 500 MW before alternatives were assessed and then excluded smaller, differently configured and null alternatives because they would not reproduce the same predetermined output and land requirement.

At the same time, T7 is already heavily subscribed for solar overall and particularly for transmission-related solar. The Applicant has not shown that refusal of East Pye would create any regional capacity shortfall or prevent the T7 pathway from being achieved.

The resulting examination question is not whether East Pye is the ‘best’ conceivable site or whether the Applicant was legally required to restart the whole exercise from scratch. It is whether the reasonable alternatives actually studied were compared transparently and on an adequate environmental basis, and whether the Applicant has satisfactorily explained why the Norwich Main-derived land package remained the appropriate configuration once the connection point and the environmental evidence had materially changed. ISH1 has made that question materially sharper by confirming that four of the six site-selection stages had already been completed before the connection strategy changed and that the Scheme’s dispersed geography itself contributes to the extent of the electrical infrastructure now required.

In light of the scale of the environmental, agricultural and community harm and the absence of demonstrated regional need, the ‘do nothing’ alternative should have been treated as reasonable, material and potentially preferable.

5.18 Remedies sought

BEPS requests that the Examining Authority require the Applicant to submit a supplementary and consolidated alternatives assessment.

That assessment should reconstruct the full chronology of grid discussions, land assembly and site selection and identify when the Applicant first knew that Norwich Main lacked sufficient capacity and could not be expanded. It should explain why the original Norwich Main-derived land search was retained after that defining premise had failed.

The assessment should distinguish clearly between land availability, commercial convenience, technical feasibility and environmental suitability. It should identify what inquiries were made

into alternative land, when those inquiries ceased and why land not already secured through voluntary agreement was treated as unreasonable.

The Applicant should disclose the criteria, weighting, scoring and professional judgements applied to every principal solar-site and National Grid substation alternative. The assessment should explain how environmental considerations were balanced against land control, cable length, cost, access and proximity to the already assembled sites.

Alternative land availability should be tested rather than treated as absent merely because landowners did not volunteer sufficient land or because the Applicant preferred to avoid compulsory acquisition. The Applicant should identify whether smaller or differently configured developments could have been accommodated on alternative land even where the full 1,100-hectare Scheme could not.

The supplementary assessment should examine reduced-scale, compact, phased, lower-capacity, solar-only, BESS-deferred, BESS-reduced and no-development alternatives. It should also assess whether the most environmentally harmful sites could be removed while retaining a materially smaller generating scheme.

A complete and consistently dated regional capacity assessment should be provided. That assessment should compare East Pye with the current T7 Gate 2 allocation, the transmission-specific solar figure, operational capacity, projects under construction, consented projects and the wider planning pipeline. It should distinguish clearly between transmission and distribution capacity and identify the assumed rate of project attrition.

The Applicant should state what regional shortfall, if any, would arise if East Pye were refused. It should identify which existing T7 projects are assumed not to proceed, explain the basis for that assumption and demonstrate why East Pye is required rather than another existing or less harmful project.

The alternatives assessment should also compare the environmental effects of the principal alternatives across agricultural land, ecology, landscape and visual effects, cultural heritage, hydrology and private water supplies, aviation, traffic and transport, public rights of way and cumulative infrastructure. It should assess those effects comparatively rather than simply describing constraints associated with the preferred Scheme.

The Applicant should clarify the separate connection, Gate and delivery status of the solar and BESS components and assess realistic severed implementation scenarios. Benefits attributed to the BESS should not be relied upon unless its delivery is secured.

The Applicant should provide the early desktop planning review requested by the ExA and a chronology showing when each of the six site-selection stages was undertaken relative to Norwich Main, Great Moulton and landowner engagement; contemporaneous evidence supporting the Applicant's assertion that the same Sites would have emerged had Great Moulton been the original connection point; and an explanation of how the environmental consequences of the Scheme's dispersed geography, including multiple substations and extensive interconnecting infrastructure, were taken into account when alternative configurations were compared.

Unless that exercise demonstrates both a genuine regional need for East Pye and a defensible environmental basis for selecting this particular land and connection location, no material weight should be attached to the Applicant's conclusion that the Scheme represents an appropriate alternative.

In those circumstances, the 'do nothing' alternative should be preferred and the application refused.

Chapter 6: Climate Change

6.1 Introduction

This objection is made on the basis that the environmental information presently available does not provide a lawful or robust assessment of climate change effects for a scheme of this scale, duration and complexity. Although presented as a climate change chapter, the current assessment appears to treat climate change in an unduly narrow way, focusing mainly on broad greenhouse-gas assertions while failing to provide a coherent, site-specific assessment of climate vulnerability, local climate resilience, and the extent to which the proposed development may itself worsen existing climate-related risks within the receiving environment.

A lawful climate assessment for a 60-year solar, BESS and substation scheme spread across a highly sensitive rural landscape should address both principal limbs of climate change assessment: first, the project's own greenhouse-gas implications across its full lifecycle; and second, the vulnerability of the project, the land, surrounding communities, infrastructure, water environment, agriculture and ecosystems to present and future climate conditions. On the information presently available, that integrated assessment has not been provided. Instead, key matters appear to have been deferred, fragmented across other topic areas, or left to future stages of assessment. This prevents consultees from reaching an informed view as to whether the scheme is genuinely climate-resilient, whether it would intensify local climate-related hazards, and whether its claimed climate benefits are reliable, evidence-based and capable of carrying material weight in the planning balance.

In particular, the current material does not provide a robust site-specific assessment of how the scheme would perform under more intense rainfall, prolonged wet periods, drought, heat stress, storm events, or changing groundwater and soil conditions over its operational life. Nor does it presently demonstrate, in a clear and integrated way, whether the introduction of extensive solar infrastructure, substations, cable corridors, access tracks and associated engineered works could alter runoff behaviour, exacerbate flash flooding, affect groundwater recharge, increase pressure on sensitive soils, or reduce the resilience of adjacent farmland, habitats and communities. These are not peripheral matters. In a rural landscape already subject to hydrological sensitivity, heavy soils, ecological constraints and growing cumulative development pressure, they are central to whether the scheme can properly be described as climate-resilient or environmentally sustainable.

There is also a broader structural deficiency in the way climate change has been addressed. Climate effects cannot lawfully be reduced to a headline claim that renewable energy is inherently beneficial. For a project of this scale, the climate case must be demonstrated through transparent and verifiable evidence. That requires proper assessment of whole-life carbon emissions, including construction, materials, embodied carbon, battery storage, maintenance, decommissioning, replacement cycles, and any reduction in claimed benefit arising from grid constraints, curtailment, or other real-world operational limitations. Until that information is provided in a form that can be properly tested, the asserted climate benefit of East Pye Solar cannot be treated as established.

Accordingly, this chapter is objected to in principle on the basis that the current assessment does not yet provide a coherent, site-specific or policy-reliable evaluation of climate change effects. It fails, at this stage, to demonstrate that the scheme would be resilient to climate change over its lifetime, fails to show that it would not worsen local climate-related risks, and fails to establish that its claimed carbon benefits are robust enough to outweigh the significant environmental harms identified elsewhere in this objection. The objection is therefore no longer that the climate case is merely incomplete at consultation stage, but that the final Environmental Statement has not demonstrated with sufficient transparency and robustness the magnitude of the Scheme-specific climate benefit relied upon in the planning balance.

The EIA fails to provide a robust, site-specific assessment of the scheme's resilience to climate change and the potential for the development itself to exacerbate local climate risks.

- There is no quantification or modelling of how the extensive area of solar panels may increase surface water runoff, exacerbate flash flooding, or alter groundwater recharge, particularly in light of climate projections for more intense rainfall events.
- Nor does the EIA consider whether the introduction of large-scale hard infrastructure could lead to localised overheating, changes in wind patterns, or drought vulnerability affecting adjacent farmland and communities.
- The absence of a detailed local climate risk assessment and adaptation strategy falls short of best practice and EN-1 requirements for demonstrating that both the project and surrounding communities will not be made more vulnerable as a result of the development.

A further concern is the reliability of developer-presented climate benefit calculations for large solar NSIPs. Independent scrutiny of comparable UK schemes has shown that such calculations can materially overstate greenhouse-gas savings once lifecycle impacts are properly assessed. In one recent inquiry submission examining a utility-scale solar project, independent reviewers identified mathematical errors, omitted inputs and unrealistic generation assumptions in the developer's carbon accounting. After correction, the revised lifecycle assessment indicated that the scheme could generate between **1.8 and 2.6 million tonnes more CO_2 than it would save** once embedded carbon in construction materials, battery storage systems and grid decarbonisation trajectories were properly incorporated. This example demonstrates that headline claims regarding carbon savings and 'homes powered' can be highly sensitive to underlying assumptions. In the absence of transparent, independently verifiable lifecycle carbon modelling—including manufacturing emissions, battery storage impacts, curtailment risk, and mid-life panel replacement—the climate benefits of East Pye Solar cannot be treated as established. Consequently, reliance on asserted carbon savings to outweigh significant ecological, agricultural, hydrological and heritage harms would be premature and contrary to the precautionary approach required by national planning policy.

Since this Written Representation was prepared, the National Planning Policy Framework was replaced on 17 August 2026. Policy W3 gives substantial weight to relevant energy-security and net-zero benefits and states that applicants should not generally be required to demonstrate generic need for renewable-energy development. That makes the accuracy of East Pye's Scheme-specific climate calculation more, not less, important. BEPS does not dispute the

generic climate benefit of renewable generation; it disputes the robustness and magnitude of the particular whole-life benefit claimed for East Pye.

6.2 Independent application of the Great North Road methodology

BEPS has applied the lifecycle-carbon methodology used by objectors to the Great North Road Solar Park to the figures disclosed for East Pye Solar. The exercise used the Applicant's stated lifetime generation of 36.33 TWh, its 2,000 MWh BESS, its assumption of five complete BESS replacement cycles, and the GNR methodology's year-by-year declining grid-emissions counterfactual.

Two cases were tested. A minimum evidenced 500 MWp case produced estimated whole-life emissions of approximately 1.96 million tCO_2e. An indicative 635.4 MWp case, derived from the Applicant's stated 977,536 modules at an assumed 650 W per module, produced approximately 2.16 million tCO_2e. Under the GNR declining-grid pathway, the lifetime grid emissions displaced by the Scheme were approximately 312,000 tCO_2e.

The resulting net balances were therefore approximately:

- **+1.65 million tCO_2e** in the 500 MWp case; and
- **+1.85 million tCO_2e** in the indicative 635.4 MWp case.

A positive figure in this sensitivity exercise represents net lifecycle emissions rather than a saving. The result is therefore materially different from the Applicant's claimed beneficial outcome.

The result is driven principally by two assumptions: first, that the grid counterfactual continues to decarbonise rather than remaining fixed at the Applicant's 2031 factor for the full 60-year life; and second, that the substantial embodied and replacement emissions associated with the BESS are included.

BEPS does not advance the Great North Road methodology as the uniquely correct forecast for East Pye. Its significance is as a sensitivity test. It demonstrates that the sign and magnitude of the claimed whole-life climate benefit are highly dependent upon the assumed future grid counterfactual and treatment of lifecycle emissions. On a declining-grid scenario, the Applicant's claimed benefit can materially reduce or become adverse. The Applicant's headline saving should therefore not be treated as robust unless its model is disclosed, reconciled and tested against transparent year-by-year declining-grid scenarios.

6.3 Failure to assess water vulnerability and water-resource resilience

Water vulnerability is a particularly important component of climate resilience in East Anglia and should have been assessed expressly and in detail. This is a water-stressed region, and the environmental material presently available does not demonstrate that the scheme's construction, operation and emergency-response water demands can be met in a lawful, sustainable or climate-resilient way. That omission is especially serious where the statutory and technical consultation material records that Anglian Water may not be able to supply all new non-domestic demands until new strategic supplies are developed, and advises that a

dedicated Water Resources Assessment is required in order to identify viable sources of supply and address restrictions on water availability.

The significance of this omission extends beyond ordinary utility planning. A scheme of this scale requires water not only for workforce welfare and routine maintenance, but also for dust suppression, construction processes, HDD works, cleaning, and fire safety infrastructure associated with the BESS and substations. Yet the current assessment does not identify, quantify and secure those water sources, nor does it assess how climate change, drought conditions, licence constraints, competing abstractions, or regional water scarcity may affect the reliability of supply over time. In that respect, the climate chapter fails to engage with one of the most basic questions of climate resilience: whether the development is viable in a future of increasing water stress.

This is not a minor technical omission. If mains water is unavailable or constrained, the developer would need to rely on alternative sources, each of which carries further environmental and climate implications, including abstraction pressure, additional traffic, higher carbon impacts from tankering, and intensified risks to groundwater, private water supplies and sensitive catchments. Those consequences are directly relevant both to climate adaptation and to the wider assessment of whether the scheme would increase the vulnerability of the receiving environment. In the absence of a completed Water Resources Assessment and a clear demonstration of a secure, lawful and sustainable water supply strategy, the scheme cannot properly be described as climate-resilient.

For East Pye Solar, water scarcity is not merely part of the background climate baseline; it is a central constraint on deliverability, resilience and environmental sustainability.

6.4 Failure to assess runoff, flood intensification and groundwater effects under future climate conditions

The current climate assessment also fails to address, in a coherent and site-specific way, whether the Scheme would worsen climate-related water risks within the receiving environment. That omission is particularly serious for a project of this scale in a landscape already characterised by water stress, sensitive groundwater conditions, extensive agricultural drainage, and known concerns regarding flood behaviour. Although flood risk is said to be addressed separately through a Flood Risk Assessment, that does not remove the need for the climate chapter to explain whether the development has been designed to remain resilient under future climate conditions and whether it may itself exacerbate those conditions. The PEIR records that climate change risk assessment has been scoped out of the chapter, with the explanation of resilience deferred to the Environmental Statement, and that a Flood Risk Assessment will be submitted later with the DCO application.

That approach is inadequate. The Planning Inspectorate expressly required the Environmental Statement to explain how the proposed development has been designed to be resilient to climate change risks, and also required consideration of cumulative climate vulnerability,

including changes in flood flows resulting from climate change and other development. The applicant's response is effectively to defer those matters to a future FRA and to other chapters, rather than presenting an integrated assessment now.

For East Pye Solar, the central issue is not merely whether flooding reaches individual pieces of equipment, but whether the extensive installation of panels, tracks, compounds, substations, cable corridors and associated engineered works would alter the hydrological behaviour of the land under increasingly extreme weather conditions. The available material does not presently quantify or model whether the development would increase the rate or concentration of surface water runoff, alter existing drainage pathways, reduce infiltration, affect groundwater recharge, or intensify off-site flood risk during heavier rainfall events. Nor does it explain how these risks interact with long operational duration, climate-driven rainfall volatility, and the cumulative presence of other major schemes in the area. That omission is especially striking where Anglian Water has emphasised that SuDS and rainfall runoff attenuation will be critical and has required proper assessment of water demand, supply and integrated water management.

The applicant's own climate baseline identifies a future of hotter conditions, much drier summers, and wetter winters, with average winter precipitation increasing over time under the UKCP18 scenario relied upon in the scoping material. Those projected shifts make runoff behaviour, drainage performance, soil saturation, erosion and groundwater response central climate issues for the scheme. Yet the present chapter does not translate those projections into any meaningful site-specific assessment of hydrological consequence. It therefore fails to show either that the project is climate-resilient or that it would not worsen flood and water-environment vulnerability for adjoining land, watercourses, habitats and communities.

In those circumstances, it is not sufficient for the applicant to rely on a later FRA or on general statements about embedded design and management plans. Until East Pye Solar provides a quantified and integrated assessment of runoff change, flood-flow effects, groundwater interaction and off-site consequences under future climate scenarios, the climate chapter remains structurally deficient. It does not presently establish that the development would avoid exacerbating climate-related water risks, and it cannot therefore be relied upon as a sound basis for consultation or future planning judgment.

Taken together, the absence of a secure water supply strategy and the absence of any robust assessment of runoff and groundwater effects demonstrate that water-related climate resilience has not yet been established for this scheme.

6.5 Failure to provide a reliable whole-life GHG assessment

The Infrastructure Planning (Environmental Impact Assessment) Regulations 2017 require the ES to describe likely significant effects arising from 'the impact of the project on climate', including the nature and magnitude of GHG emissions and the Scheme's vulnerability to climate change. Current EN-1 goes further. Paragraph 5.3.4 requires:

‘A whole life GHG assessment showing construction, operational and decommissioning GHG impacts, including impacts from change of land use.’

It also requires the Applicant to explain how climate impacts have been driven down at each stage and to measure embodied construction emissions.

Chapter 6 purports to provide that assessment, but its result is neither complete nor independently reproducible. The headline saving does not reconcile with the Applicant’s own emissions totals; important component calculations contain apparent arithmetic or unit errors; land-use change is not quantified; and the avoided-emissions case depends upon treating the 2031 grid intensity as if it remained constant throughout the 60-year operational period.

The Applicant has therefore not established the whole-life climate benefit required by EN-1. It has presented a favourable conclusion without a reliable calculation capable of supporting it.

6.6 Failure of the headline calculation to reconcile

Chapter 6 states construction emissions of 347,673 tCO_2e, operational emissions of 1,104,918 tCO_2e and decommissioning emissions of 6,390 tCO_2e. Those figures total 1,458,981 tCO_2e. The Applicant also states that the Scheme would generate 36.33 TWh over 60 years.

Those figures produce a lifecycle carbon intensity of approximately 40.16 gCO_2e/kWh, not the reported 39.67 gCO_2e/kWh. The stated operational emissions alone produce approximately 30.41 gCO_2e/kWh, not 29.74 gCO_2e/kWh.

The claimed lifetime saving of 1,294,630 tCO_2e also cannot be reproduced. Applying the Applicant’s 65 gCO_2e/kWh comparator to 36.33 TWh produces gross avoided emissions of 2,361,450 tCO_2e. Deducting all stated lifecycle emissions leaves only 902,469 tCO_2e—approximately 392,000 tCO_2e below the claimed figure. Even deducting operational emissions alone produces 1,256,532 tCO_2e, still approximately 38,000 tCO_2e below the figure reported.

The Applicant has not disclosed a reproducible route from its own inputs to its principal claimed climate benefit. That defect goes directly to the reliability and weight of the significant-beneficial conclusion.

6.7 Material arithmetic and unit errors

The underlying calculations contain further apparent errors. Chapter 6 states that 26,393 tonnes of glass assessed at 1.4028 $kgCO_2e/kg$ produces 1,371 tCO_2e. Direct multiplication produces approximately 37,024 tCO_2e. It states that 9,973 mounting structures weighing 800 kg each, assessed at 2.71 $kgCO_2e/kg$, produce 37,845 tCO_2e. Direct multiplication produces approximately 21,621 tCO_2e. The construction-worker

transport table also appears to transpose journey-distance figures, producing a recalculated total of approximately 2,479 tCO_2e rather than 2,192 tCO_2e.

Chapter 6 further records 5,632 km of electrical cable with a total mass of only 569 tonnes, while giving principal cable-material weights of 21 kg/m for copper and 10.7 kg/m for aluminium. Those figures cannot all be correct. The BESS calculation also refers to '80% degradation per year', which is unintelligible if read literally and appears to confuse annual degradation with retained capacity.

These are not harmless drafting slips. They affect major inputs and show that the model has not been adequately checked. The complete calculation workbook, formulas, source data and quality-assurance record must be disclosed.

6.8 Static use of the 2031 grid factor

Chapter 6 acknowledges that grid emissions are forecast to decline rapidly through the 2030s. Nevertheless, its headline lifetime saving applies the 2031 grid intensity of 65 gCO_2e/kWh to the Scheme's entire 60-year generation total.

That is not a credible lifetime counterfactual. Electricity produced in 2050, 2070 or 2090 cannot rationally be assumed to displace electricity with the carbon intensity of the grid in 2031. The assessment freezes the counterfactual at the opening year most favourable to the Scheme while relying elsewhere upon rapid grid decarbonisation as the policy justification for the development.

Using the Applicant's stated generation and emissions, illustrative pathways in which the grid falls from 65 gCO_2e/kWh in 2031 to 20 g by 2050 produce a net adverse balance of approximately 447,000 tCO_2e. A pathway falling to 10 g produces a net adverse balance of approximately 747,000 tCO_2e. These figures do not prove a single definitive outcome; they demonstrate that the Applicant's beneficial conclusion is driven by its chosen baseline and is not robust.

The assessment must be rerun year by year using transparent and evidenced future grid factors.

6.9 Uncertain commencement and operational date

Chapter 6 assumes construction between 2028 and 2030 and energisation in 2031, while acknowledging that the programme depends upon final investment, detailed design and environmental constraints.

The 2031 date is not a neutral programme assumption. It determines the grid factor selected and therefore the scale of the claimed carbon saving. Any delay would move generation into a lower-carbon grid and reduce the amount of emissions said to be avoided.

The Applicant has not shown that the National Grid works, project substations, grid connection and BESS can all be delivered and energised by 2031. The climate assessment must therefore test later commencement dates. A conclusion dependent upon an unsecured opening year cannot be treated as an established benefit.

6.10 Failure to assess curtailment and useful exported electricity

Chapter 6 relies on 36.33 TWh of lifetime generation, but does not transparently reduce the claimed benefit for curtailment, network constraints or periods when East Pye generation would not displace more carbon-intensive electricity.

The relevant climate quantity is not gross theoretical generation. It is electricity actually exported, delivered and used to displace a higher-carbon counterfactual after accounting for conversion losses, transformer losses, outages, clipping, export restrictions and curtailment.

This omission is particularly serious in a region with a large solar pipeline and constrained transmission capacity. Even 10% curtailment materially worsens the recalculated balance. The Applicant must disclose gross generation, net export, technical losses, assumed curtailment and the generation source actually displaced. Until that is done, both the denominator used for carbon intensity and the claimed avoided-emissions total remain unreliable.

6.11 Failure to assess the Scheme without BESS

Chapter 6 assesses a 2,000 MWh BESS as part of the Scheme and relies qualitatively upon the additional climate and system benefits said to arise from storage. Yet the BESS has only Gate 1 status and no demonstrated Gate 2 connection capable of delivery by 2031, or at all.

The ES does not assess the realistic alternatives of solar without BESS, delayed BESS commissioning, reduced BESS capacity or BESS omission. Nor does it distinguish adequately between export-only operation and a merchant import-and-export model.

The Applicant cannot rely upon BESS-enabled flexibility when claiming climate benefits while declining to assess the Scheme if that BESS is not delivered. A no-BESS case is not optional sensitivity testing. It is necessary to understand the environmental effects of a realistically severable and presently uncertain component.

This issue has become materially more important during Examination because the solar and BESS elements do not have equivalent connection status. The solar element has progressed to Gate 2, whereas the BESS remains at Gate 1. The climate assessment should therefore test not only a hypothetical no-BESS case but the reasonable implementation scenarios which the DCO may actually permit: solar operating materially before the BESS, delayed BESS, reduced BESS and solar operating for all or a substantial part of its life without Work No. 2.

For each scenario, the Applicant should identify both the change in lifecycle emissions and the change in the benefits attributed to co-location, storage, curtailment reduction and system balancing. The climate case should not simultaneously include the embodied and replacement emissions of the BESS while assuming integrated system benefits which depend upon a connection timetable that has not been demonstrated.

6.12 The BESS dominates lifecycle emissions

Chapter 6 attributes 200,000 tCO_2e to the initial BESS and 1,034,103 tCO_2e to five replacement cycles. It accepts that BESS emissions account for approximately 85% of the total Scheme emissions and that BESS replacement accounts for about 94% of operational emissions.

The Scheme's reported climate burden is therefore dominated not by the solar arrays but by an uncertain storage component whose connection, technology, chemistry, operating regime and replacement frequency are not fixed.

The Applicant nevertheless concludes that the overall effect is significantly beneficial. That conclusion cannot be robust where its dominant emissions source is subject to unresolved deliverability and operational uncertainty and has not been tested through alternative scenarios.

6.13 Unassessed BESS charging and operational emissions

Chapter 6 states that the BESS would largely be charged from low-carbon sources but expressly admits that 'the exact nature of emissions going into charging it has not been fully assessed'. It then calculates a possible saving of approximately 957,849 tCO_2e, assumes primarily solar charging, daily discharge and 85% round-trip efficiency, and refers to significant additional mitigation potential.

That is not a completed climate assessment. A BESS charging from the wider grid may import electricity at times when gas or other higher-carbon sources are marginal. Each cycle also loses energy and requires HVAC, controls and other parasitic consumption.

The Applicant must quantify solar charging, grid charging, hourly charging intensity, round-trip losses, HVAC demand, cycling frequency, degradation, augmentation and replacement. Until those matters are assessed, the claimed BESS benefit is speculative and should carry no separate weight.

6.14 Unsupported replacement and repowering assumptions

Chapter 6 assumes full replacement of the PV panels after 40 years, additional ad hoc panel replacement, up to five BESS replacements and one transformer replacement.

Those are not routine maintenance events. Each is a substantial construction and logistics campaign involving manufacture, shipping, HGV movements, temporary compounds, workers, plant, waste removal and reinstatement. The assessment

aggregates those effects without providing a transparent programme or complete activity schedule for each replacement cycle.

The Applicant also assumes current embodied-carbon factors for future replacements while suggesting that future technology will be cleaner. It cannot rely selectively upon future improvement to minimise significance without testing both lower- and higher-emission replacement cases. Distinct replacement scenarios are required.

6.15 Failure to assess land-use change and soil carbon

EN-1 expressly requires the whole-life assessment to include impacts from land-use change. Chapter 6 identifies the existing baseline as arable, agri-environment and livestock land but then assumes that existing activities generate zero emissions.

A zero baseline is not a land-use-change assessment. It does not quantify existing soil-carbon stocks, vegetation carbon, disturbance during installation, compaction, changes in infiltration and drainage, displacement of agricultural activity, proposed sequestration under grassland, or restoration at decommissioning.

The omission is especially material where other parts of the ES identify long-term damage or downgrading to agricultural soils. The Applicant has therefore not demonstrated compliance with the express EN-1 requirement.

6.16 Omitted infrastructure and operational demand

Chapter 6 excludes fencing, portacabins, security systems and other ancillary items on the assumption that each contributes less than 1% of total emissions. It states that anything not expressly referenced may be assumed not to have been quantified.

The Scheme contains extensive fencing, CCTV, access works, drainage, compounds, fire infrastructure, welfare facilities, substations, cables and grid infrastructure. The Applicant has not demonstrated that the aggregate of all excluded items remains below the stated 5% exclusion limit.

Operational electricity for CCTV, monitoring and welfare facilities is also omitted, while BESS HVAC, pumping and other parasitic loads are not transparently quantified. A whole-life assessment cannot be completed by declaring every unlisted source negligible without showing the cumulative total of the exclusions.

6.17 Failure to include water-supply and tankering emissions

Chapter 6 identifies 16,871 m^3 of construction water and 309,196 m^3 of operational water, including panel cleaning, replacement works and fire suppression. It calculates only the emissions associated with water supply and treatment and does not identify a secured source.

If water must be tankered from another region, the HGV movements are a foreseeable Scheme emission. Approximately 326,067 m^3 would require about 10,869 loads using 30 m^3 tankers. Depending upon source distance, this could add hundreds or several thousand tonnes of CO_2e, together with further congestion and rural-road impacts.

The whole-life assessment must include abstraction, treatment, pumping, tanker loading, outward and return journeys, storage, cleaning and firewater replenishment. Until the water source is identified and those emissions are included, the claimed climate balance remains incomplete.

6.18 Unsupported downstream benefits

Chapter 6 claims that the Scheme could provide sufficient electricity for up to 546,806 electric vehicles or replace household gas consumption in 58,066 homes. It also accepts that the Scheme would not itself cause the uptake of electric vehicles.

These are theoretical equivalence illustrations, not effects demonstrated to result from East Pye. The same electricity cannot simultaneously be treated as displacing grid generation, charging the BESS, supplying electric vehicles and replacing household gas without a clear boundary preventing double counting.

Those calculations do not establish additional Scheme-specific savings and should carry no separate weight in the planning balance.

6.19 Failure to provide a secured GHG Reduction Strategy

Chapter 6 says that the GHG Reduction Strategy is dispersed through the outline CEMP and OEMP rather than provided as a consolidated document. It then concludes that no additional climate mitigation is required.

That conclusion is untenable where the calculation contains unresolved errors, the BESS dominates lifecycle emissions, water supply is unsecured and no declining-grid or curtailment assessment has been undertaken.

A secured GHG Reduction Strategy should impose stage-specific carbon budgets, embodied-carbon limits, procurement standards, reporting requirements, replacement accounting, water-transport accounting, independent audit and corrective-action triggers. Generic commitments to use lower-carbon materials or vehicles ‘where possible’ do not secure the reductions upon which the claimed beneficial effect depends.

6.20 Failure to assess cumulative climate effects

PINS expressly refused to scope cumulative climate effects out and required consideration of how other developments may affect climate vulnerability, flood flows and cumulative GHG emissions or savings.

Chapter 6 nevertheless says that project-specific cumulative GHG assessment is inappropriate because the receptor is the global atmosphere and that carbon budgets are inherently cumulative. It then states that there can be no cumulative resilience effects because the receptor is the Scheme itself.

That is a methodological avoidance of the question PINS asked. Carbon-budget contextualisation does not assess the combined regional effects of multiple solar, BESS, grid, housing and transport schemes upon construction emissions, water demand, flood flows, soil resilience, replacement traffic and constrained grid operation.

East Pye is not an isolated project. The cumulative regional climate burden must be assessed directly rather than dissolved into an abstract global receptor.

6.21 Failure to assess combined climate and ecological effects

Chapter 6 does not adequately assess how the Scheme's ecological effects would interact with hotter, drier summers, more intense rainfall, drought, flooding and increased fire risk over its 60-year life. Natural England expressly required assessment of how the development would affect the ability of habitats, species and natural processes to adapt to climate change. The Applicant has not answered that question through a receptor-specific and integrated assessment.

The relevant effect is not climate change in isolation and not habitat loss in isolation. It is the combined effect of the Scheme's land take, fragmentation, shading, lighting, fencing, disturbance, altered drainage and vegetation management upon species already exposed to worsening climatic stress.

That assessment should address, at minimum, whether the Scheme would:

- sever or narrow routes used by species moving in response to changing climate;
- reduce access to cooler, wetter or more sheltered habitat;
- isolate woodland, hedgerow, pond and watercourse populations;
- alter the moisture, temperature and light conditions of retained habitats;
- intensify drought stress on hedgerows, grassland, trees and wetlands;
- increase sediment, polluted runoff or flood disturbance during extreme rainfall;
- reduce water availability for ponds, ditches, chalk-stream-connected habitats and terrestrial species;
- increase fire risk within grassland, scrub, woodland edges and BESS-adjacent habitat;
- impair establishment or survival of mitigation planting under future drought conditions; and
- reduce the resilience of protected and notable species populations already affected by habitat fragmentation.

Chapter 6 instead states that climate effects on ecology are addressed through Chapter 8 and provides only a high-level reference to climate change affecting species and habitats. That is not an in-combination assessment. It does not identify the

ecological receptors, pathways, magnitude, duration or significance of the combined effects.

6.22 Loss of ecological connectivity under climate change

Ecological connectivity becomes more important, not less, as the climate changes. Species must be able to move between feeding, breeding, roosting, shelter and wetter or cooler refuges. East Pye's extensive footprint, fencing, internal roads, substations, BESS compounds and cable works may constrain those movements even where individual habitat features are nominally retained.

This is particularly relevant to bats, great crested newts, reptiles, invertebrates, farmland birds, aquatic species and mammals dependent upon connected hedgerows, woodland edges, ponds, ditches and watercourses. A buffer around an isolated feature is not equivalent to maintaining a functioning ecological network.

The ES should therefore assess whether the Scheme would reduce the capacity of species to respond spatially to drought, heat, flood and habitat change. Without that assessment, the Applicant cannot demonstrate that retained habitats would remain functional throughout the Scheme's life.

6.23 Climate effects on bats and other mobile species

Bats are especially sensitive to combined changes in habitat connectivity, prey availability, temperature, lighting and water. Hotter and drier summers may affect insect abundance and the availability of ponds, ditches and wet woodland feeding habitat. Increased artificial lighting and fragmentation may then restrict access to the remaining feeding areas and alternative roosting habitat.

For maternity colonies and wider metapopulations, the issue is not merely whether a roost entrance is retained. It is whether the surrounding network of commuting routes, feeding habitat, water sources and dark corridors remains sufficiently resilient under future climate conditions.

The Applicant should assess the combined effect of climate change and the Scheme on maternity-roost supporting habitat, functional connectivity and population resilience. Generic hedgerow buffers and future management plans do not answer that question.

6.24 Climate effects on ponds, ditches and aquatic ecology

The interaction between climate change, drainage and ecology requires specific assessment. Drought may reduce pond permanence, ditch flow and groundwater-supported habitat. Intense rainfall may cause rapid runoff, erosion, sediment mobilisation and polluted discharges. Solar infrastructure, access tracks and compounds may alter the timing and concentration of those flows.

These combined effects may affect great crested newts, aquatic invertebrates, fish, crayfish, amphibians and terrestrial species dependent upon wet habitats. The climate chapter should therefore integrate the future hydrological assessment with the ecological assessment rather than simply cross-referencing separate chapters.

6.25 Failure to test whether ecological mitigation is climate-resilient

Much of the Applicant's ecological case depends upon future grassland, hedgerow, tree and habitat creation. Chapter 6 does not demonstrate that those measures will establish and remain functional under the climate conditions predicted over 60 years.

The ES should assess:

- drought-related planting failure;
- increased irrigation demand;
- availability and source of irrigation water;
- tree and hedge mortality;
- altered species composition;
- reduced floral resources;
- invasive-species pressure;
- flood and erosion damage;
- fire damage; and
- the time required to replace failed habitat.

Mitigation cannot be treated as secured merely because it appears in a management plan. Its ecological function must be achievable under the future climate relied upon in the ES.

6.26 Climate change and the mitigation hierarchy

The combined ecological and climate evidence strengthens the case for avoidance. Where habitats and populations are already vulnerable to drought, heat, flooding and fragmentation, additional pressure should not be accepted on the assumption that it can later be managed.

Avoidance should include removal of development from the most sensitive ecological networks, protection of wider dark and movement corridors, avoidance of hydrologically sensitive habitat and retention of climate refuges. Compensation and biodiversity net gain cannot replace established ecological networks that species need in order to respond to climatic change.

Climate change is not merely an external risk to the Scheme. It is a force that will amplify the Scheme's effects upon habitats and species. By failing to assess those combined effects at receptor level, the Applicant has not demonstrated that East Pye would maintain ecological connectivity, population resilience or the adaptive capacity of the natural environment over its 60-year life.

6.27 Heat, BESS parasitic demand and fire risk

Chapter 6 recognises that higher summer temperatures and heatwaves will increase BESS cooling requirements, but does not quantify the resulting energy demand or lifecycle emissions. It relies only on the existence of containerised HVAC systems and concludes that the residual risk is not significant.

That is inadequate. Cooling energy is a parasitic load: it reduces net export, lowers useful displaced generation and increases operational emissions. The effect is likely to be greatest during hot, high-generation periods when battery temperatures and cooling demand are both elevated. The Applicant has not disclosed the assumed HVAC load, its annual energy consumption, its degradation over time or whether it is supplied from East Pye generation or the grid.

Heat also increases the risk of battery degradation, thermal runaway and fire. Chapter 6 identifies increased fire risk under hotter and drier conditions but relies on generic references to fire suppression and assigns a ‘Very Low’ likelihood without demonstrating the water source, suppression capacity, access arrangements, firewater containment or performance under drought conditions.

The Applicant must quantify BESS cooling and parasitic demand and integrate heat-related degradation, fire risk, suppression demand and replacement consequences into the whole-life climate assessment. Until that is done, both the net-export calculation and the climate-resilience conclusion remain incomplete.

6.28 Drought-related failure of landscape and ecological mitigation

The Scheme relies heavily on future hedgerow, tree, grassland and habitat establishment to mitigate landscape and ecological harm. Chapter 6 does not demonstrate that those measures will establish and survive under the hotter and drier summers identified in its own climate projections.

Drought may cause planting failure, tree and hedge mortality, reduced floral resources, soil cracking, erosion and increased irrigation demand. Where mitigation fails, its visual screening, habitat connectivity, biodiversity and carbon-sequestration functions also fail.

The Applicant has not identified the volume or source of water required to establish and maintain planting during prolonged drought, nor assessed the emissions and traffic consequences of tankering that water. Future management plans cannot be treated as effective mitigation unless their water requirements, replacement obligations and climate resilience are secured.

The climate assessment should therefore test planting failure, repeated replanting, increased irrigation and delayed habitat establishment. Otherwise, the Scheme relies on mitigation whose delivery is uncertain under the climate conditions it is expected to endure.

6.29 Agricultural resilience and displacement of food production

Chapter 6 treats the existing agricultural baseline as generating zero emissions and does not assess the role of the land in supporting food-production resilience under climate change.

That approach is too narrow. Climate change is expected to place increasing pressure on productive land through drought, heat, flooding, soil degradation and water scarcity. The removal of a large area of agricultural land from productive use for 60 years reduces the capacity of the local and national agricultural system to respond to those pressures.

The assessment also fails to consider displacement. Food production removed from East Pye may be transferred elsewhere, potentially to less suitable land or imported from jurisdictions with higher production, transport or land-use emissions. Those consequences are not captured by assuming a zero baseline.

The Applicant must assess the Scheme's effect on agricultural resilience, soil function and displaced production. Renewable generation does not remove the need to account for the climate consequences of taking productive land out of use.

6.30 Cumulative loss of permeable and climate-resilient land

Chapter 6 does not assess the cumulative loss or functional alteration of permeable rural land arising from East Pye and other major developments in the region.

The relevant effect is wider than the footprint of formally impermeable surfaces. Panels, compacted access tracks, substations, BESS compounds, cable works and repeated construction activity may alter infiltration, soil structure, drainage pathways and runoff concentration. Those effects reduce the capacity of the landscape to absorb and attenuate rainfall under increasingly intense storm conditions.

East Pye must also be considered with other solar, BESS, grid, housing and infrastructure schemes occupying the same regional catchments. The cumulative issue is whether a progressively engineered landscape retains sufficient capacity to store water, recharge groundwater, support soils and habitats, and reduce downstream flood risk.

Chapter 6 instead treats resilience principally as a risk to the Scheme itself. It does not assess the cumulative loss of the receiving landscape's climate-regulation function. Until that is done, the Applicant cannot demonstrate that the Scheme would not increase the vulnerability of surrounding land, watercourses, communities and ecosystems.

6.31 Climate consequences of repeated mid-life replacement works

The 60-year operational period is not a continuous low-disturbance phase. Chapter 6 assumes one complete PV-panel replacement, up to five BESS replacements, one transformer replacement and further ad hoc replacement of panels and cables.

Those activities amount to repeated construction campaigns. They will require manufacturing, shipping, HGV movements, temporary compounds, cranes and plant, workforce travel, waste handling, water, drainage controls and reinstatement. They may occur during hotter, drier or wetter climate conditions than those assessed for the initial construction phase.

The Applicant has aggregated replacement emissions but has not assessed the climate resilience or environmental consequences of each campaign. It has not shown whether replacement works can be undertaken without renewed soil compaction, habitat disturbance, drainage damage, traffic impacts or additional water demand.

The whole-life assessment must therefore treat repowering and BESS replacement as distinct project phases and assess their combined carbon, hydrological, ecological and agricultural effects. Describing them as operational maintenance understates both their scale and their climate consequences.

6.32 Consequences for the significance conclusion

Chapter 6 concludes that the operational climate effect is significant and beneficial. That conclusion is not established.

The carbon case depends upon an unreconciled headline calculation, inconsistent component data, a static 2031 grid comparator applied across 60 years, uncertain energisation, no transparent curtailment allowance, an undelivered BESS, unassessed charging and parasitic emissions, unresolved water supply, incomplete land-use accounting and speculative downstream benefits.

The resilience case is equally incomplete. Chapter 6 focuses principally on risks to the Scheme's infrastructure and workers, but does not provide a receptor-specific assessment of how East Pye would interact with hotter, drier summers, more intense rainfall, drought, flooding and increased fire risk to affect habitats, species and ecological networks over the Scheme's lifetime.

It does not demonstrate that retained habitats will remain functional under future climate conditions, that species will retain access to dark corridors, water, feeding areas and climatic refuges, or that the Scheme will avoid compounding fragmentation, hydrological stress, planting failure, fire risk and loss of ecological connectivity. Nor does it establish that proposed landscape and ecological mitigation will survive prolonged drought or repeated mid-life construction and replacement campaigns.

The evidence does not presently establish that East Pye will necessarily be carbon adverse. Nor is BEPS required to prove that proposition. The burden lies on the Applicant to demonstrate the significant climate benefit and climate resilience it asks the decision-maker to place in the planning balance.

It has not done so. The claimed significant-beneficial effect is neither transparent, reproducible nor environmentally complete. The quantified Scheme-specific climate benefit should therefore be afforded no greater weight than the robustness of the calculation presently supporting it.

6.33 Remedies sought

The Applicant should be required to disclose the complete editable GHG model, formulas, source data and quality-assurance record; correct every arithmetic and unit discrepancy; and provide a fully reconciled whole-life total.

The carbon assessment should be rerun using annual grid factors and alternative energisation dates; quantified curtailment, technical losses and net useful export; full-BESS, no-BESS, delayed-BESS and reduced-BESS scenarios; solar-only and grid-charging BESS models; complete charging, cooling and parasitic demand; full replacement and repowering emissions; all excluded infrastructure and operational demand; land-use change and soil carbon; and the full emissions consequences of the secured water source, including tankering where required.

The Applicant should also provide an integrated climate-ecology assessment identifying, for each sensitive receptor, how the Scheme would interact with future heat, drought, flood, storm and fire conditions. That assessment should address habitat connectivity, dark corridors, water-dependent habitats, maternity-roost supporting function, species movement, climatic refuges, hydrological change, planting failure, irrigation demand, invasive species, fire damage and the ecological consequences of repeated replacement works.

The Applicant should demonstrate that all landscape and ecological mitigation is deliverable and resilient under the future climate relied upon in the ES, with secured replacement, irrigation, monitoring and corrective-action obligations where establishment or function fails.

A consolidated GHG Reduction and Climate Resilience Strategy should be secured through the DCO with enforceable carbon limits, procurement standards, water and energy controls, habitat-resilience measures, monitoring, independent audit and corrective-action mechanisms.

Unless and until that work is completed and independently verified, the Examining Authority should reject the finding of a significant beneficial climate effect and attach no material weight to the claimed saving of 1,294,630 tCO_2e.

Summary:

East Pye Solar should be refused because the Applicant has not demonstrated that the Scheme delivers the significant climate benefit relied upon to justify its extensive environmental harm.

First, the whole-life carbon case is not reliable. Chapter 6 contains unreconciled headline figures, apparent arithmetic and unit errors, incomplete treatment of land-use change and excluded operational sources. The claimed saving of 1,294,630 tCO_2e cannot be reproduced from the Applicant's own totals. The asserted significant beneficial effect is therefore not founded on a transparent or auditable calculation.

Second, the result depends upon an unrealistic counterfactual. The Applicant applies the 2031 grid-emissions factor across the Scheme's entire 60-year life, despite acknowledging continuing grid decarbonisation. When East Pye is tested using a year-by-year declining-grid methodology, including the approach used by objectors to Great North Road Solar, the claimed benefit reverses and the Scheme produces a substantial net lifecycle carbon burden. That does not establish one uniquely correct figure, but it demonstrates that the Applicant's favourable conclusion is highly assumption-dependent and cannot safely be treated as an established public benefit.

Third, the climate balance is dominated by the BESS, not the solar arrays. Chapter 6 attributes approximately 85% of total Scheme emissions to the BESS and its repeated replacement. Yet the BESS remains commercially and technically uncertain, its connection is not secured, and its charging source, cycling, cooling demand, degradation and parasitic losses have not been adequately assessed. The Applicant cannot rely upon BESS-related system benefits while failing to assess realistic no-BESS, delayed-BESS and grid-charging scenarios.

Fourth, the Scheme has not been shown to be climate-resilient. Water supply is unresolved in an already water-stressed region. If water must be tankered from elsewhere, those repeated HGV movements and emissions are absent from the whole-life calculation. The assessment also fails to demonstrate that the Scheme would not worsen runoff, flood flows, soil compaction, groundwater recharge, drought stress or fire risk over its lifetime.

Fifth, Chapter 6 does not adequately assess the combined effects of the Scheme and climate change upon ecology. It does not show that bats, amphibians, aquatic species, farmland birds, invertebrates and other receptors will retain functioning habitat networks, dark corridors, water sources and climatic refuges under hotter, drier and more extreme conditions. Nor does it demonstrate that proposed planting, grassland, hedgerow and habitat mitigation will establish and survive repeated drought, flood, fire and replacement works.

Sixth, the Applicant has fragmented climate effects across separate chapters and future management plans rather than providing the integrated assessment required for a Scheme of this scale and duration. Carbon, water, ecology, agriculture, flood risk,

replacement works and cumulative regional effects are interdependent. They cannot be dismissed through generic references to future CEMP, OEMP, drainage or habitat-management measures.

The result is that the central claimed benefit of East Pye Solar is unproven, while the Scheme's environmental harms are extensive, long-term and in several respects irreversible. The Applicant has not established that the Scheme is carbon-beneficial, climate-resilient or ecologically sustainable over its 60-year life.

Until the Applicant provides a corrected, transparent and reproducible calculation, the specific figure of 1,294,630 tCO_2e and the magnitude of the claimed significant beneficial effect should be afforded limited weight. In the absence of a corrected and independently verifiable whole-life assessment, secured water and resilience strategy, and integrated assessment of ecological and cumulative climate effects, the application should be refused.

Chapter 7: Landscape and Visual

7.1 Executive Summary and Principal Objection

BEPS objects to Chapter 7 because it does not demonstrate that the East Pye Solar scheme can be accommodated within the South Norfolk landscape without substantial and enduring harm. This is not a case where the objection turns principally on disagreement with the Applicant's professional judgment. The Applicant's own LVIA identifies widespread Significant adverse effects during construction, Significant operational effects at Year 1 across most of the principal Sites, and continuing Significant effects at Year 15 in several of the most sensitive parts of the scheme. At construction, Major Significant landscape effects are identified for LCA B1 Tas Tributary Farmland, LCA E2 Great Moulton Plateau Farmland, the BESS Site, Site 1 and Site 7, with Significant effects also identified for the national character area, multiple other LCAs and most individual Sites. At Year 1, Significant landscape effects remain across the BESS, Sites 1–5 and 7–10 and several LCAs. Even after fifteen years of assumed mitigation growth, Site 1 remains Major Significant, while the BESS, Site 7, Site 8, B1 Tas Tributary Farmland and E2 Great Moulton Plateau Farmland remain significantly adversely affected.

The Applicant itself therefore establishes that East Pye would not simply add discreet energy infrastructure to an otherwise unchanged rural landscape. It would alter the character of extensive areas of countryside. Chapter 7 accepts that operation would change predominantly agricultural land into an "energy production landscape"; that solar arrays may oversail normal hedgerow boundaries; that their regular engineered form may appear conspicuous against irregular field patterns; that substations and BESS introduce industrial characteristics into relatively open rural landscapes; that fencing and CCTV increase perceived human influence; and that solar development across multiple fields can alter the sequential experience of PRoW users. The maximum tracker-panel parameter is 4.5 m at greatest inclination, with panels rotating through the day, alongside major substations, security infrastructure and other built development.

BEPS considers that Chapter 7 nevertheless systematically understates the true scale, geographical extent and duration of this harm. The LVIA divides a landscape-scale intervention into separate Sites, CRC parcels and receptor assessments, rather than adequately assessing the transformation of an interconnected historic and lived landscape. The Applicant's own baseline describes plateau farmland, wooded tributary valleys, dispersed villages and farmsteads, narrow rural roads, extensive PRoWs, important hedgerows, ancient woodland, veteran trees, dark skies and areas of appreciable tranquillity. Yet the assessment repeatedly reduces these qualities to Medium site-level sensitivity and then relies upon distance, intervening vegetation and future planting to downgrade effects.

That approach gives insufficient weight to the structure of the landscape itself. The hedgerows, tree belts, ditches, lanes and historic field pattern are not simply visual screening elements around otherwise interchangeable fields. They form the fabric of the South Norfolk clayland landscape and connect its historic, ecological, hydrological and agricultural character. Evidence submitted by local landscape archaeologist David Fine describes the surviving lattice of lanes, ditches, hedges and fields as a coherent historic landscape morphology, and warns against treating the effects of trenching, access works and landscape fragmentation as superficial disturbance capable of being repaired simply through replacement planting. BEPS adopts that underlying principle. Screening an industrial development does not preserve the landscape if the screening itself changes its openness, field pattern, historic legibility or experiential character.

The assessment is also fragmented between disciplines in ways which reduce the apparent combined effect. Heritage assets inform judgments of landscape value but are then principally assessed elsewhere; private residential effects are separated into a Residential Visual Amenity Assessment applying a much higher “overbearing” or “dominating” threshold; PRoW effects are addressed through a separate route assessment; glint and glare is removed to another chapter; and night-time landscape effects are omitted from Chapter 7 altogether. This is particularly serious in relation to lighting. The Planning Inspectorate expressly required the ES to assess effects on night-time views and landscape receptors, including intermittent motion-activated security lighting, because insufficient information had been provided to scope those effects out. The Applicant’s final response is instead to rely upon a Lighting Strategy and state that no assessment of lighting effects on landscape and visual receptors is included in Chapter 7. Mitigation principles are not a substitute for an assessment of magnitude and significance.

The visual evidence should also be treated cautiously. Chapter 7 itself recognises that winter photography is the reasonable worst case because deciduous vegetation provides substantially less screening when out of leaf. However, important photomontages have been prepared from summer photography where foliage materially obscures the development. This is especially problematic around the Grade I Church of St Catherine at Fritton, where the Applicant itself acknowledges the sensitivity of the church and Conservation Area by excluding development from part of Site 5. Summer visualisations cannot reliably demonstrate the worst-case visual relationship where screening is seasonally dependent. Equivalent leaf-off photomontages are required.

The mitigation case also requires considerably greater caution than Chapter 7 gives it. Much of the predicted reduction in effects between Year 1 and Year 15 depends upon new hedgerows, tree belts and woodland becoming sufficiently established to screen or filter the scheme. Yet the Applicant simultaneously accepts that such planting may alter the openness of views and landscape character. In some locations the LVIA expressly records Significant Year 15 visual effects because the mitigation vegetation itself alters open views. This exposes a central weakness in the assessment: replacing an open agricultural landscape with enclosed planting around industrial infrastructure

is not necessarily mitigation of landscape harm; in some landscapes it is itself part of the change.

Independent professional landscape and visual impact assessments have also been commissioned on behalf of the South Norfolk community. Those assessments will be submitted separately by Hempnall Parish Council and Shotesham Parish Council. Although submitted through two Parish Councils, together they examine the East Pye scheme across its full geographical extent. BEPS supports their findings. To avoid duplication, their detailed professional analysis is not reproduced in this Written Representation and should be read alongside it as complementary independent evidence.

BEPS therefore submits that the Applicant's conclusions should not be treated as a conservative or precautionary statement of harm. They already disclose extensive and, in places, major adverse effects; the methodological weaknesses identified above are capable only of understating that harm further. The ExA should approach Chapter 7 on the basis that East Pye represents a landscape-scale industrialisation of an interconnected rural environment, not a collection of visually containable solar fields. The Applicant has not demonstrated that the scheme's scale, siting or residual effects are acceptable, nor that future screening can remedy the underlying loss of openness, tranquillity, historic landscape structure and rural visual character.

7.2 Policy and Assessment Framework

The relevant policy framework requires landscape harm to be avoided and minimised through siting, design and retention of existing landscape structure, not simply screened after the development has been fixed. Chapter 7 itself identifies EN-1, EN-3 and EN-5 as the principal national policy framework and relies on GLVIA3 and related Landscape Institute guidance. It also identifies the Greater Norwich Local Plan and South Norfolk policies concerned with environmental quality, local distinctiveness, design, amenity, landscape character, trees and hedgerows, landscape integration and heritage.

The Applicant expressly cites EN-3 paragraphs 2.10.92–2.10.93, which require consideration of how existing boundary vegetation, mature trees and hedgerows can be protected and retained and, where necessary, how schemes can be redesigned to avoid harm. The same underlying principle runs through the local policy framework: development should respond to landscape character and local distinctiveness, protect natural assets, incorporate landscape into design and avoid harm to amenity and heritage.

This matters because Chapter 7 too often treats mitigation as a later screening exercise. The relevant policy test is not whether planting can eventually obscure infrastructure from selected views, but whether the location, scale and design of the development avoid or minimise unacceptable landscape harm in the first place.

The South Norfolk Landscape Susceptibility in relation to Energy Generation, Storage and Transmission SPD is also relevant evidence. The Applicant says it is “not directly applicable” to the Scheme because it was not prepared specifically for NSIPs, but simultaneously confirms that it reviewed the SPD and incorporated updates into its own judgments on landscape sensitivity where appropriate. That is effectively an acknowledgment that the SPD is material evidence of local landscape susceptibility, even if it is not determinative of the DCO decision.

The policy framework therefore supports a simple proposition: where the scale and siting of development create enduring significant landscape effects, future planting cannot be treated as a substitute for an appropriate location and design.

Since this Written Representation was prepared, the National Planning Policy Framework was replaced on 17 August 2026. The Energy NPSs remain the primary policy framework for this NSIP, but the current NPPF materially reinforces the landscape and design issues raised here. Policy DP3 requires development to respond to the history, character and features of its site and setting and to integrate with its surroundings, while DP4 requires design quality to be maintained through project evolution, assessment and delivery. Those principles are particularly relevant where the Applicant relies heavily upon post-consent detailed design and landscape mitigation to integrate extensive infrastructure into a sensitive rural setting.

7.3 The Applicant’s Own Assessment Establishes Extensive Significant Harm

7.3.1 Construction

The scale of landscape harm is established by the Applicant’s own assessment. During construction, Chapter 7 identifies Major Significant effects on LCA B1 Tas Tributary Farmland, LCA E2 Great Moulton Plateau Farmland, the BESS Site, Site 1 and Site 7. High-sensitivity Site 8 is also assessed as Major Significant. Moderate Significant effects are identified across Sites 2, 3, 4, 5, 9 and 10, as well as NCA 83 South Norfolk and High Suffolk Claylands, A1 Tas Rural River Valley, B5 Chet Tributary Farmland, C2 Thurlton Tributary Farmland with Parkland and the Via Beata.

The Applicant itself explains that these effects arise because construction would introduce activity “totally uncharacteristic” of the receiving landscapes, including haul routes, compounds, plant, vehicle movements, temporary lighting, fencing, trenching, stockpiles, vegetation removal and PRoW closures. This is not localised or incidental harm. It is widespread across the scheme and affects both ordinary countryside and landscapes the Applicant itself judges to be highly sensitive.

That evidence is difficult to reconcile with any general claim that East Pye can simply be integrated into its surroundings.

7.3.2 Operation — Year 1

The harm does not fall away when construction ends. At Year 1, Significant landscape effects remain across B1 Tas Tributary Farmland, C2 Thurlton Tributary Farmland with Parkland and E2 Great Moulton Plateau Farmland, together with the BESS, Site 1 and Sites 2, 3, 4, 5, 7, 8, 9 and 10.

The Applicant expressly accepts that the BESS and Site 1 would experience a “total change” to key landscape characteristics. That admission is central. It confirms that these are not landscapes experiencing merely filtered or partial visual intrusion. The development changes their character in substance.

The Year 1 effects arise from the presence of the energy infrastructure itself: 4.5 m solar arrays, substations, BESS, fencing, CCTV, access tracks and grid infrastructure replacing or dominating the existing agricultural landscape. Chapter 7 acknowledges that the scheme changes the land into an “energy production landscape” and that the solar arrays increase perceived human influence, affect tranquillity and introduce conspicuous regular forms into irregular rural field patterns.

7.3.3 Operation — Year 15

The Year 15 assessment should not be presented as evidence that mitigation resolves the landscape conflict. Even after fifteen years of assumed establishment and growth, Chapter 7 still identifies Major Significant landscape effects at Site 1 and Moderate Significant effects at the BESS, Site 7, Site 8, B1 Tas Tributary Farmland and E2 Great Moulton Plateau Farmland.

Significant visual effects also remain at individual receptors at the BESS, Site 1, Site 3, Site 4, Site 7, Site 8, Site 9 and along the CRC. The Applicant therefore does not demonstrate that mitigation removes the harm. It demonstrates only that some effects reduce over time while significant adverse effects persist in key parts of the scheme.

The conclusion is straightforward: even on the Applicant’s mature-mitigation case, important parts of East Pye remain significantly harmed after fifteen years.

7.4 The Landscape Has Been Assessed as Separate Development Parcels Rather Than as a Coherent Landscape

Chapter 7 recognises that the receiving environment is a predominantly rural landscape of open plateau farmland, small wooded valleys, hedgerows, woodland, dispersed villages and farmsteads, local roads, PRoWs, long-distance routes and areas of tranquillity. It nevertheless subdivides that landscape into Sites 1–10 and CRC parcels for assessment and then evaluates each largely as a separate receptor. That approach risks missing the central effect of East Pye: the transformation of an interconnected landscape system across a very large area.

The South Norfolk clayland landscape is not simply a collection of fields separated by vegetation. Its structure is formed by long-established lanes, ditches and watercourses, hedgerows, mature and veteran trees, historic field boundaries, tributary valleys, settlement patterns and routes of movement. These features perform several functions at once. They shape visual character, agricultural use, drainage, ecological connectivity, historic legibility and the everyday experience of the countryside.

The independent landscape morphology evidence submitted by David Fine is important in this respect. It describes the surviving lattice of lanes, ditches, hedges and fields as a coherent historic structure rather than incidental boundary vegetation, and argues that this pattern has evolved over a very long period as part of the functioning landscape. That evidence accords with the Applicant's own baseline descriptions of a landscape structured by field boundaries, hedgerows, wooded horizons, dispersed settlement and tributary valleys.

This exposes a weakness in the LVIA. Chapter 7 is strong on what may be seen from individual receptors, but much weaker on what is being altered as a landscape system. Hedgerows, ditches, lanes and tree belts are repeatedly treated as screening features to be retained, reinforced or replanted. They are more than that. They are part of the landscape fabric itself.

That distinction is important because mitigation cannot be judged only by whether it hides infrastructure. If access works, cable trenches, hedgerow removals, new tree belts, substations and panel fields alter the historic field pattern, openness, lane structure and ecological or hydrological relationships of the land, the landscape has changed even where the development later becomes less visible. Chapter 7 does not adequately capture that deeper structural effect.

7.5 Underassessment of Historic Landscape Character and Artificial Separation from Heritage

Chapter 7 acknowledges that heritage assets contribute to landscape value, but then largely removes them from the LVIA as receptors in their own right because they are assessed in Chapter 10. The Applicant expressly states that conservation areas, registered parks and gardens and listed buildings inform the landscape baseline and sensitivity judgments, while substantive heritage effects are considered elsewhere.

BEPS considers that division artificial. Churches, conservation areas, halls, farmsteads, historic lanes and settlement edges are not merely heritage designations sitting within the landscape; they are part of the landscape's character, time-depth and visual structure. Their settings are experienced through the same lanes, fields, hedgerows, views, PRoWs and settlement approaches which Chapter 7 assesses. Separating "heritage" from "landscape" therefore risks understating the combined effect of changing both the setting of historic places and the rural landscape through which those places are understood.

The Applicant's own evidence demonstrates that the distinction does not work cleanly in practice. Appendix 7.4 repeatedly relies on churches, listed buildings, conservation areas and settlement edges when explaining the sensitivity of visual receptors. At Site 4, the baseline includes views around St Michael's Church and St Mary's, Tharston; at Site 5 it recognises the sensitivity of the Fritton Conservation Area and Grade I Church of St Catherine; at Site 7 it records the relationship with Saxlingham Nethergate and its conservation area; and at Site 10 the wider context includes historic parkland and listed-building groups.

The same issue arises at Wacton, where the visual and landscape context includes the conservation area, historic settlement edge and listed buildings around the scheme. These are not isolated heritage receptors whose effects can be understood independently of the surrounding countryside. Their significance is partly derived from how they sit within, and are approached through, the rural landscape.

Ditchingham Hall is particularly illustrative. Appendix 7.2 records the Registered Park and Garden approximately 2 km from Site 10 but excludes it from further landscape assessment on the basis of separation distance and claimed lack of intervisibility. Yet the same appendix identifies C2 Thurlton Tributary Farmland with Parkland as a High-sensitivity landscape characterised by large estates, halls and distinctive parkland landscapes and valued in part because of its relationship with the Broads. The parkland context is therefore integral to landscape character even where a particular registered asset is removed from the receptor assessment.

BEPS does not seek to duplicate Chapter 10. The objection is narrower and more fundamental: Chapter 7 should assess historic landscape character as an integrated resource. A church tower, conservation area edge, hall, farmstead or historic lane does not cease to be part of the landscape merely because its designated heritage significance is considered elsewhere. The present compartmentalisation tends to suppress the combined effect of industrialising the landscape while simultaneously altering the settings through which historic places are experienced.

7.6 Landscape Sensitivity Has Been Systematically Understated

Appendix 7.2 repeatedly describes a landscape of greater sensitivity than the final site-level ratings suggest. It identifies expansive skies, open plateau farmland, tranquil tributary valleys, dark skies, ancient woodland, veteran trees, high-value recreational routes, historic settlement structure, wooded horizons and locally distinctive parkland and river-valley landscapes. Yet almost every principal Site is assigned only Medium sensitivity, with Site 8 the principal exception.

That pattern matters because sensitivity directly controls the significance conclusions that follow. Where the narrative baseline describes intact rural character, tranquillity, openness and historic structure but the receptor is then rated only Medium, the assessment effectively lowers the starting point before magnitude is considered.

7.6.1 Great Moulton Plateau, Site 1 and the BESS

E2 Great Moulton Plateau Farmland is described as a flat elevated plateau with extensive arable farmland, a notable absence of boundaries, a strong sense of openness and exposure, expansive skies and distant views. Hedgerow trees remain important markers of former field boundaries, and disused airfields are identified as a characteristic feature. Despite those characteristics, E2 is rated only Medium sensitivity.

Site 1 and the BESS are treated similarly. The BESS sits within an open, exposed plateau landscape and is described as moderately tranquil and relatively dim at night. Site 1 is likewise open, elevated and defined by expansive skies, with a high level of recreational value arising from the PRoW network and with Great Moulton close to its northern edge. Both are nevertheless assigned only Medium sensitivity.

The resulting judgments are difficult to reconcile with the Applicant's later admission that Site 1 and the BESS undergo a "total change" to key landscape characteristics at Year 1. If a landscape is sufficiently open and exposed that the proposed development causes a total change to its defining characteristics, the assumption that it has only moderate susceptibility to that development requires particularly strong justification.

7.6.2 Site 7

Site 7 is another clear example. Appendix 7.2 records a landscape structured by established hedgerows, tree belts, woodland blocks and ancient woodland, with wooded horizons that create intimacy and visual interest. It records a dense PRoW network, proximity to the Boudicca Way, numerous veteran trees, and moderate to high tranquillity. Most of the Site lies in either transitional dark-sky conditions or the darkest night-sky range.

Despite that combination of landscape structure, recreational value, tranquillity, ecological interest and dark-sky character, Site 7 is assigned only Medium value, Medium susceptibility and Medium sensitivity. Yet Chapter 7 later identifies Major Significant construction effects and continuing Significant landscape effects at Year 15. The outcome itself demonstrates how limited the landscape's capacity to absorb the scheme actually is.

7.6.3 Site 10

The inconsistency is particularly stark at Site 10. Sub-Sites 10A–10D lie within or straddle C2 Thurlton Tributary Farmland with Parkland, which the Applicant rates High value, High susceptibility and High sensitivity. C2 is characterised by open views towards the Broads, parkland, halls, ancient woodland, remoteness and peacefulness. B5 Chet Tributary Farmland, within which Site 10E lies and other Site 10 parcels partly extend, is also rated High sensitivity.

Yet Site 10 and CRC14 are reduced to Medium sensitivity. The site-specific baseline still describes Site 10 as highly tranquil, sparsely settled and structured by hedgerows, tree belts and plantation woodland. The reduction in sensitivity therefore appears to arise not because those qualities disappear at Site 10, but because the assessment moves from the wider character area to the land selected for development.

That pattern should concern the ExA. Across several parts of the scheme, sensitivity becomes lower as the assessment moves closer to the actual development footprint. BEPS submits that the Applicant has not adequately justified those downward judgments and that the effect is to suppress the significance of landscape harm at source.

7.7 Site 1, BESS and Great Moulton: the Scheme's Most Serious Landscape Conflict

The Applicant's own evidence establishes Site 1, the BESS and the surrounding Great Moulton Plateau as the clearest landscape conflict within the scheme.

At Site 1, Chapter 7 identifies Major Significant landscape effects during construction, Major Significant effects at Year 1 and Major Significant effects still remaining at Year 15. The Applicant expressly states that the scheme results in a "total change" to some of the key characteristics of Site 1. At Year 15, despite mature mitigation, Site 1 remains Major Significant because of the scale of the infrastructure and the continuing alteration of its key characteristics.

The visual effects are equally serious. At Year 1 the viewpoint south-east of Great Moulton remains Major to Substantial and Significant, while the PRoW at Great Moulton FP15/RB18 is Major and Significant. At Year 15, significant effects remain from Great Moulton and nearby PRoWs because the National Grid Substation and Project Substation continue to influence the view despite mitigation planting.

The BESS follows the same pattern. It is assessed as Major Significant during construction and Major Significant at Year 1, reducing only to Moderate Significant at Year 15. A high-sensitivity residential receptor at Station Road continues to experience a Significant visual effect at Year 15 because the screening vegetation itself changes the open character of the view.

These effects arise in a landscape whose defining characteristics are openness, exposure, expansive sky and distant views. Appendix 7.2 describes E2 Great Moulton Plateau Farmland precisely in those terms. That makes extensive woodland screening a particularly problematic mitigation response. Screening a major substation, BESS and associated infrastructure behind new woodland does not preserve an open plateau landscape. It substitutes a more enclosed landscape for the existing open one in order to obscure industrial development.

The Applicant itself effectively recognises this problem. Chapter 7 acknowledges that mitigation planting may alter the open visual character of views and, in some cases,

that this effect remains Significant at Year 15. The Great Moulton area therefore demonstrates the central weakness in the mitigation case: the scheme is too large and too visually dominant to be assimilated without materially changing the character of the landscape used to screen it.

BEPS submits that Site 1 and the BESS should be treated as a fundamental siting and scale problem, not merely a planting problem.

ISH1 has since confirmed that important elements of the Site 1 infrastructure remain subject to further design, including the detailed form of project substations, AIS/GIS choice, ancillary electrical units and the National Grid substation. The ExA has also required further illustrative material and clarification of the correct height parameters. That uncertainty matters to the LVIA because the reasonable worst-case landscape assessment must reflect the combined form, massing and visibility of the 13-metre project-substation infrastructure together with the separate National Grid substation capable of reaching 15 metres, rather than assuming one preferred detailed design.

7.8 The Scale and Industrial Character of the Solar Arrays Are Understated

Chapter 7 understates the nature of the development when it treats the solar elements as comparatively low-profile infrastructure capable of ready assimilation. The assessed worst-case is single-axis tracker panels up to 4.5 m high. These are not static, ground-hugging features. They are substantial, repetitive engineered structures occupying extensive areas of open farmland.

The Applicant's own assessment identifies the characteristics that create landscape harm. It acknowledges that solar panels may be visible in open landscapes and on slopes, may appear blue or grey depending on conditions, may oversail typical hedgerow boundaries and may present regular engineered edges that appear conspicuous within irregular rural landscapes. It further accepts that panels can increase perceived human influence, affect tranquillity, and that development across multiple fields can alter the sequential experience of PRoW users. Fencing and CCTV are separately acknowledged as additional urbanising influences.

These admissions matter because the effect is more fundamental than "visual intrusion". Open agricultural fields become engineered power-generation compounds. Hedgerows cease simply to define fields and become the boundaries of securitised infrastructure. Rural lanes become construction and operational access routes. Views formerly composed of crop, hedge and expansive sky acquire repeated rows of moving industrial equipment, fencing, CCTV and substations. Chapter 7 itself describes the operational change as one from an agricultural landscape to an "energy production landscape".

The tilting nature of the arrays adds a further dimension. Their height, profile and reflected appearance change through the day as the tracking system moves. The landscape effect is therefore not simply that of inserting a fixed 4.5 m structure into a

field. It is the introduction of an ordered and mechanically expressive built form across large areas of countryside.

BEPS submits that the scale of East Pye should therefore be understood as industrialisation of the landscape rather than merely the visibility of individual panels. That distinction should inform judgments on magnitude, tranquillity, openness and cumulative change.

7.9 Inadequate Study Area and Overreliance on Distance

The final LVIA adopts a variable study area of 3 km around the National Grid Substation, grid connection infrastructure and 400 kV Project Substations, 2 km around the BESS and Sites 1–10, and only 1 km around the Cable Route Corridor. The Applicant says these distances reflect professional experience and the area in which significant effects are considered likely.

The issue is not that every view beyond those distances must be significant. It is that the assessment framework risks excluding receptors before their actual relationship with this unusually dispersed scheme has been properly examined.

That concern was expressly raised at scoping. The Inspectorate noted that the Applicant's earlier position was that significant visual effects were unlikely beyond 2 km, while the ZTVs showed panels visible beyond that distance. PINS therefore required the ES to assess potential effects within the ZTV wherever significant effects might arise and to justify the study area by reference to fieldwork, modelling and recognised professional guidance.

The final ES still relies heavily on distance as a reason for diminishing or excluding effects. Chapter 7 concludes that solar and 132 kV infrastructure are generally limited beyond 2 km, although it expressly acknowledges more distant visibility for the National Grid Substation, overhead line realignment and 400 kV substations. Appendix 7.4 confirms why caution is required: several parts of the scheme occupy open, elevated landscapes with expansive skies and long-distance views, and the Site 1 grid infrastructure has potential visibility towards the wider Tibenham area and airfield.

Distance alone does not remove landscape influence where development is large, elevated, skyline-forming or repeatedly encountered. Nor does it address cumulative experience. A receptor may see different parts of East Pye sequentially from different locations even where no single component dominates one fixed viewpoint. That is particularly relevant to the open plateau landscapes, the wider PRoW network and rural roads.

The CRC study area raises a related concern. A 1 km envelope may be proportionate to isolated underground works, but the cable route is not experienced solely as a buried final product. Construction involves trenching, vegetation removal, hedgerow crossings, stockpiles, vehicle activity and interactions with lanes and PRoWs over a large geographical area. Where those works combine visually or experientially with

nearby Sites, their effect cannot safely be treated as an isolated short-range disturbance.

BEPS therefore does not contend that the study-area distances are automatically invalid. The objection is that they have been used too readily as a proxy for insignificance in a scheme whose own ZTVs, open landscape character and tall infrastructure demonstrate a wider visual envelope. The ExA should give particular scrutiny to distant skyline effects, cumulative visibility and sequential experience rather than assuming that effects become immaterial simply because a receptor lies beyond the principal study-area boundary.

7.10 Visualisations Do Not Adequately Represent the Worst-Case Seasonal Effect

Chapter 7 expressly recognises that winter conditions represent the visual worst case because deciduous vegetation is out of leaf and therefore provides less screening. It states that both summer and winter baseline photography was taken and that the winter view is representative of the reasonable worst-case scenario.

That principle is not consistently carried through into the photomontage evidence. Where visualisations are prepared from summer photography, the scheme is shown when hedgerows, tree belts and woodland are at their maximum screening effectiveness. That matters because the Applicant's assessment repeatedly relies upon those same features to contain visibility and reduce visual effects. A summer visualisation may therefore show the development in materially more favourable conditions than those experienced for a substantial part of the year.

The issue is particularly acute around the Grade I Church of St Catherine and Fritton Conservation Area. The Applicant itself recognises this as a sensitive location and has excluded solar development from the eastern part of Site 5 because of the proximity of residential properties along The Street, St Catherine's Church and the Conservation Area. Where deciduous vegetation contributes materially to screening in these views, a summer photomontage does not demonstrate the worst-case relationship between the church, its rural setting and the development.

The existence of separate winter baseline photographs does not resolve that deficiency. A baseline photograph shows the existing landscape; a photomontage is intended to show the development within it. The relevant question is therefore what the scheme itself would look like under leaf-off conditions. A summer photomontage cannot answer that question by reference to a different winter photograph elsewhere in the appendix.

The same concern applies at settlement edges, along sensitive PRoWs, around Site 1 and the BESS, and at heritage-sensitive viewpoints where the assessment depends materially on deciduous screening. BEPS therefore considers that the visual evidence is incomplete unless equivalent winter leaf-off photomontages or verified photowires are provided for those locations. Without them, the Examination does not have a

consistent worst-case visual record on which to test the Applicant's significance judgments.

7.11 Night-Time Character, Dark Skies and Tranquillity Have Not Been Properly Assessed

The treatment of lighting is one of the clearest deficiencies in Chapter 7. At scoping, the Planning Inspectorate expressly rejected the proposal to scope out night-time lighting effects and required the ES to assess effects on landscape and visual receptors, including intermittent sources such as motion-activated security lighting. The Applicant's final response is nevertheless that, because a Lighting Strategy has been produced and lighting controls are secured through management plans, "no assessment of the effects of lighting on landscape and visual receptors is included in this Chapter."

That does not answer the Inspectorate's requirement. A lighting strategy identifies controls; it does not determine the magnitude or significance of the environmental effects those controls are intended to mitigate.

Appendix 7.11 confirms that this is a genuinely dark rural receiving environment. The Order Limits are treated as E2 "Rural", with low ambient brightness, and some parts of the scheme fall within the darkest night-sky areas or transitional dark-sky zones. It also confirms operational lighting at the National Grid Substation, BESS and Project Substations, including motion-sensing security and maintenance lighting. The BESS perimeter is to be illuminated by column-mounted luminaires, while temporary construction lighting may be required at compounds, laydown areas, parking and welfare facilities, security locations, vehicle areas and specialist works such as HDD operations.

The same strategy identifies residential receptors, roads, Tibenham Airfield and pilots, ecological receptors, conservation areas and the dark-sky environment as potentially affected receptors. Chapter 7 itself acknowledges that tranquillity increases away from the principal roads and that substantial parts of the Order Limits lie within relatively tranquil rural countryside.

The omission therefore matters. The ES does not establish what magnitude of night-time landscape change would arise from introducing lit compounds into dark countryside; whether those changes are significant; how multiple sources would operate cumulatively; how intermittent activation would affect perceptions of darkness and tranquillity; or how winter conditions, when hours of darkness are longest, affect residential, recreational and landscape receptors. Motion-activated lighting may be limited in duration, but its sudden appearance in a dark rural landscape may itself be conspicuous.

This is also a cross-cutting omission. Lighting interacts with nocturnal ecology and with aviation receptors, both of which are addressed elsewhere in BEPS's evidence. The landscape issue is distinct: the Applicant has not assessed the change from an

intrinsically dark rural nightscape to one containing periodically or permanently illuminated industrial compounds.

BEPS submits that the Applicant has confused mitigation with assessment. The Lighting Strategy may reduce effects, but Chapter 7 still needs to establish what those effects are and whether the residual effects are significant.

The Examination has since made the lighting issue more concrete. ISH1 and ExQ1 require further information on the nature, location and control of construction and operational lighting. That is material because the original scoping position proposed to scope lighting effects out on the basis that operational lighting would be limited and motion-sensitive and that construction lighting would be controlled by later management plans. The final assessment must therefore demonstrate, rather than assume, that the permitted lighting envelope will not materially alter rural night-time character, tranquillity, residential amenity or ecological darkness. The Applicant should identify the locations, duration, trigger conditions and limits applying to lighting relied upon in that conclusion.

7.12 Tranquillity Is Treated as a Descriptor Rather Than a Receptor of Harm

Tranquillity is repeatedly identified in the Applicant's own baseline as a characteristic of the receiving landscape. Appendix 7.2 records moderate, high or appreciable tranquillity across several Sites, while Figure 7.8 shows substantial parts of the scheme within comparatively tranquil countryside. Chapter 7 itself accepts that construction will affect the "perception of tranquillity and remoteness across the rural landscape".

Yet tranquillity is largely used as one factor within broader landscape sensitivity and magnitude judgments rather than being examined as a substantive experiential effect in its own right. That risks understating what East Pye changes. Tranquillity is not simply an absence of noise. It derives from the combined experience of rural openness, limited built development, dark skies, quiet lanes, sparse traffic, natural and agricultural land cover and the absence of repeated industrial infrastructure.

The scheme affects each of those components. Construction introduces compounds, HGVs, plant, haul routes, temporary lighting, fencing and PRoW closures. Operation introduces extensive tracker arrays, substations, BESS infrastructure, access tracks, security fencing, CCTV and lighting. Maintenance and equipment replacement reintroduce activity during the 60-year operational period. None of these effects is adequately captured by treating tranquillity merely as a baseline adjective.

The mitigation case also creates a paradox. New hedgerows, tree belts and woodland may screen infrastructure from some views, but in doing so may replace open rural outlooks with enclosed vegetated corridors. Chapter 7 itself acknowledges at some Year 15 receptors that mitigation planting changes the open character of the view. A landscape does not necessarily become more tranquil because the industrial infrastructure within it becomes harder to see.

BEPS therefore submits that tranquillity should be treated as a material experiential quality affected by visual industrialisation, lighting, access infrastructure, traffic, fencing and repeated encounters with energy development, not merely as a descriptor folded into other judgments.

7.13 Public Rights of Way and Sequential Landscape Experience Are Underassessed

The PRoW evidence confirms that the scheme would materially affect how the landscape is experienced on foot and on horseback. Chapter 7 records extensive Significant effects on PRoW users during construction and operation, including routes crossing or immediately adjoining the BESS, Sites 1–10 and the Cable Route Corridor. At Year 1, Significant effects remain across numerous routes at the BESS, Sites 1–5 and 7–10. Even at Year 15, significant visual effects remain at routes associated with Site 1, Site 3, Site 4, Site 7, Site 8, Site 9 and the CRC.

The more detailed PRoW assessment identifies continuing Year 15 effects on routes including Great Moulton FP13 and FP14, Great Moulton RB19, Morningthorpe FP5, Hempnall FP2 and Saxlingham Nethergate FP12, while the Boudicca Way and Via Beata are themselves treated as high-sensitivity recreational routes. The Applicant's own baseline also repeatedly describes these routes as rural, tranquil and integral to the experience of the surrounding countryside.

The weakness is methodological as well as quantitative. The separate PRoW assessment is principally focused on routes physically interacting with the scheme, while the broader LVIA represents other route users through selected viewpoints. That is insufficient for a development of this scale. Walking, riding and cycling are sequential experiences: the receptor moves through the landscape, encountering successive fields, lanes, hedgerows, settlement edges and views. A route cannot be fully understood through a single representative photograph.

This matters particularly where the scheme is dispersed. A walker may leave one field of 4.5 m tracker arrays, encounter fencing and CCTV, pass mitigation planting, approach another solar parcel, then experience a substation or construction access further along the route. Each individual view may be rated separately, but the cumulative experiential effect is a repeated encounter with industrial infrastructure over a journey which is presently rural.

The Applicant itself acknowledges that solar development across multiple fields can affect "the experience of PRoW and sequential views when moving through a landscape". BEPS considers that admission important. The assessment identifies the issue but does not adequately translate it into the significance judgments.

The harm is therefore not limited to temporary closures or individual views. East Pye changes the character of movement through the countryside. That should be given separate weight in the examination, particularly where high-sensitivity recreational

routes and locally important PRoWs pass through landscapes that the Applicant itself describes as tranquil and rural.

ExQ1 now reinforces this objection by requiring the Applicant to consider the experience of PRoW users across routes and circular journeys rather than only at isolated viewpoints or crossing points. That is important because the landscape effect of East Pye on recreational receptors is sequential: users may experience repeated enclosure, fencing, infrastructure, planting, construction traffic and altered views across substantial lengths of connected routes. The assessment should therefore address the cumulative experiential effect along the route network, not merely the significance assigned to individual viewpoints.

7.14 Residential Visual Harm Is Materially Understated

Appendix 7.8 identifies 20 residential properties within 100 m of the scheme's maximum development parameters. The initial study area was 500 m, but the Applicant undertook individual Steps 2 and 3 assessment only for properties within 100 m and, because only two of those properties were taken forward to Step 4, carried out no further initial assessment of properties beyond that 100 m offset.

That narrowing requires scrutiny. The scheme includes solar arrays and BESS up to 4.5 m high, 132 kV substations up to 7 m, 400 kV substations up to 13 m and the National Grid Substation up to 15 m. A conclusion that properties beyond 100 m need no individual initial assessment should not be assumed simply because relatively few closer properties reached the very high Residential Visual Amenity Threshold.

The two properties taken forward demonstrate the distinction. At 22 Hillcrest Court, the Applicant identifies Major to Substantial Adverse and Significant effects for the first and second floors at Year 1 and Moderate Adverse, still Significant effects at Year 15. At Oakdene Cottage in Woodton, adjacent to Site 7L, first-floor residents are assessed as experiencing Major Adverse and Significant effects at Year 1.

Neither property is found to cross the Residential Visual Amenity Threshold because the Applicant considers the scheme would not become sufficiently overwhelming, dominating or overbearing. That finding should not be confused with an absence of serious residential harm. The RVAA itself correctly distinguishes between EIA significance and the much higher threshold at which visual conditions become so oppressive that residential amenity may make the development unacceptable in the public interest.

The important point is therefore not that the Applicant has applied the wrong threshold, but that acknowledged Major and Major-to-Substantial Significant effects remain material even where that threshold is not crossed. At Hillcrest Court, the Applicant accepts that the scheme would substantially alter views from west-facing upper-floor windows and that a Significant effect remains at Year 15.

The RVAA also depends heavily on existing and proposed vegetation. Numerous properties are screened out of further assessment because hedgerows, trees or buildings are expected to restrict views, often with explicit reference to summer or winter filtering. That makes the reliability, permanence and seasonal effectiveness of the vegetated framework central to the residential conclusions.

BEPS therefore submits that the absence of a formal RVAA threshold exceedance should not be used to minimise residential visual harm. The Applicant's own evidence establishes significant adverse effects on residents, and the decision not to examine properties between 100 m and 500 m individually deserves further justification.

7.15 Trees, Hedgerows and Woodland: the Existing Landscape Framework Is Itself Under Pressure

The Applicant relies heavily on existing hedgerows, trees and woodland to support the landscape and visual case. They define field pattern, contain views and provide the existing screening which allows numerous effects to be reduced. New hedgerow and woodland planting then forms the principal mechanism by which effects are predicted to diminish between Year 1 and Year 15. Chapter 7 describes successful establishment and long-term management of that vegetation as a primary means of filtering and screening views towards the scheme.

The Preliminary Arboricultural Impact Assessment demonstrates why that assumption requires caution. It identifies 737 potentially affected tree features: 518 individual trees, 126 groups, 74 hedgerows and 19 woodlands. Of these, 139 are Category A and 389 Category B. Six areas of ancient woodland abut the Order Limits, and the survey and Ancient Tree Inventory evidence identify a substantial resource of ancient and veteran trees within or immediately adjacent to the scheme.

The same assessment identifies direct and indirect conflicts. Five individual trees are currently identified for full removal, six tree groups and 32 hedgerows for partial removal, with further works within root protection areas and facilitation pruning. It also records conflicts between proposed works or access arrangements and buffers associated with ancient or veteran trees and ancient woodland. Several of those conflicts are to be resolved only at detailed design through relocation of accesses, reduced working widths or specialist construction methods.

That creates a circularity in the LVIA. Chapter 7 relies on the existing vegetation framework to contain and absorb the scheme, while the arboricultural evidence shows that parts of that same framework are subject to removal, pruning, root-zone activity, cable crossings, access works and construction pressure. The assessment cannot safely assume the vegetation remains unchanged for screening purposes while simultaneously acknowledging unresolved impacts upon it.

The issue is wider than direct tree loss. The Preliminary AIA records survey limitations, future detailed-design requirements and ash dieback affecting a number of trees. Chapter 7 itself accepts that climate change and disease may alter vegetation

composition and result in tree loss over the lifetime of the scheme, although it concludes that such change would not be sufficient to alter its significance judgments. Given how strongly the Year 15 conclusions depend upon vegetation, that assumption requires evidence rather than assertion.

The landscape significance of these features must also be understood correctly. Hedgerows, mature trees and woodland are not merely screens between a viewer and the development. They define historic field boundaries, rural lanes, wooded horizons and the time-depth of the South Norfolk landscape. Their alteration therefore affects landscape character even where replacement planting is provided.

South Norfolk Council raised precisely these issues during consultation, seeking up-front arboricultural information, hedgerow enhancement and attention to tree protection, TPOs, hedgerow loss and long-term management. The Applicant's own subsequent evidence confirms that those concerns were well founded.

BEPS therefore considers that the landscape mitigation case cannot be separated from the arboricultural constraints. Before substantial weight is placed on Year 15 screening, the Applicant must demonstrate receptor by receptor which existing vegetation is retained, what works affect it, what seasonal screening function it actually provides, and whether that function remains credible over a 60-year operational life.

7.16 Mitigation by Screening Does Not Preserve Landscape Character

The Applicant's mitigation case depends heavily on screening. Chapter 7 and the Outline LEMP rely on hedgerow enhancement, new woodland belts, linear tree planting and long-term vegetation management to filter or conceal views of the solar arrays, BESS, substations and associated infrastructure. A 3 m target height for hedgerows is expressly identified as an embedded mitigation measure intended to screen views from nearby PRoWs, roads and residential properties.

BEPS considers that this approach repeatedly confuses visual concealment with landscape preservation. They are not the same thing. A development may become less visible while the underlying landscape character is nevertheless substantially altered. This is particularly important in open plateau landscapes, where openness and expansive sky are themselves defining characteristics.

Chapter 7 effectively acknowledges the problem. At Year 15 it accepts that, in some views, mitigation planting would itself alter the open character of the landscape. At Site 3, for example, a Significant effect remains because screening vegetation changes the open character of the view. At Site 7, the Applicant similarly records continuing Significant effects where mitigation planting influences openness. At the BESS, a Significant Year 15 residential visual effect remains because the screening vegetation itself alters the open character of the view.

The contradiction is clearest at Great Moulton. E2 Great Moulton Plateau Farmland is characterised by openness, exposure, expansive skies and distant views, yet the

principal response to the visual prominence of the BESS and substations is extensive planting. An open plateau does not retain its character simply because industrial infrastructure is eventually hidden behind new woodland. The loss of openness is itself landscape change.

The same issue applies to Site 7 and Site 8, where existing landscape character depends on a particular balance between enclosure, open views, wooded horizons, lanes and field structure. Additional screening may reduce visibility from a receptor while simultaneously changing that balance. It is therefore not sufficient to treat reduced visibility automatically as reduced landscape harm.

BEPS submits that the ExA should distinguish between mitigation which genuinely conserves landscape character and mitigation which merely obscures the development. Where screening requires the character of the receiving landscape itself to be changed, it cannot be treated as an unqualified environmental benefit.

7.17 The Year 15 Case Is Over-Optimistic and Does Not Remove the Harm

Much of the Applicant's case for acceptability depends on the proposition that effects will materially reduce by Year 15 as hedgerows, trees and woodland establish. Chapter 7 repeatedly uses mature planting to reduce magnitude and significance, and the Outline LEMP assumes active management of that vegetation over the long term.

That assumption requires more scrutiny than the assessment gives it. The Year 15 conclusions depend on planting heights, growth rates, survival, management and continued health of both new and existing vegetation. Yet Chapter 7 does not demonstrate in a receptor-specific way what planting height is required to achieve each claimed reduction in effect, how quickly that height is expected to be achieved, or how failure and replacement would affect the timetable.

The future baseline itself acknowledges that climate change may alter vegetation composition and that tree loss may occur through increasing temperatures and disease, including ash dieback. The Applicant nevertheless concludes that such loss would not be sufficient to alter the assessment. That assertion is especially important because the same assessment depends heavily on vegetation to reduce effects. Where existing trees or hedgerows form part of the screening envelope, loss through drought, disease or mortality could materially change visibility.

The arboricultural evidence adds further uncertainty because the existing framework is itself subject to removal, pruning, root-zone works and detailed-design conflicts. New mitigation also has to coexist with ecological objectives, access requirements, security infrastructure and operational maintenance. The assumption that all planting will establish exactly as required and remain effective for a 60-year operational life should not be treated as self-evident.

There is also a more fundamental problem. Even if all mitigation succeeds exactly as predicted, Significant adverse effects remain at Year 15. Site 1 remains Major

Significant; the BESS, Site 7, Site 8, B1 Tas Tributary Farmland and E2 Great Moulton Plateau Farmland remain Significant; and significant visual effects persist at multiple receptors.

The Year 15 case therefore does not demonstrate that the landscape conflict is resolved. It shows only that some effects are expected to reduce, while substantial residual harm persists even under the Applicant's most favourable mature-mitigation scenario.

7.18 Site 7 and Site 8: High Tranquillity, Dark-Sky and Recreational Sensitivity

7.18.1 Site 7

Site 7 is one of the clearest examples of a landscape whose sensitivity is greater than the final site-level rating suggests. Appendix 7.2 describes a landscape of established hedgerows, woodland blocks, ancient woodland, veteran trees and wooded horizons, with a dense PRoW network and proximity to the Boudicca Way. It also records moderate to high tranquillity and some of the darkest night-sky conditions within the scheme.

Despite these characteristics, Site 7 is assigned only Medium sensitivity. The subsequent assessment nevertheless identifies Major Significant construction effects, Significant landscape effects at Year 1 and continuing Moderate Significant landscape effects at Year 15.

The visual evidence is equally important. At Year 1, Significant effects remain at numerous receptors across Site 7, including the Boudicca Way and local PRoWs. At Year 15, Significant effects still remain at several locations, including the Boudicca Way on Fairstead Lane and routes at Saxlingham Nethergate and Shotesham.

This is therefore not a landscape which comfortably absorbs the scheme. The combination of dark skies, tranquillity, recreational use, ancient woodland and mature landscape structure makes Site 7 particularly susceptible to industrialising change. The persistence of Significant effects after fifteen years confirms that the mitigation strategy does not eliminate that conflict.

7.18.2 Site 8

Site 8 is even more difficult for the Applicant because it is expressly assessed as High value, High susceptibility and High sensitivity. The baseline describes a tranquil, wooded valley landscape with PRoWs, Boudicca Way connections, ancient woodland and very dark night skies.

The Applicant nevertheless places substantial solar development within it. Chapter 7 identifies Major Significant landscape effects during construction, Major Significant effects at Year 1 and continuing Moderate Significant landscape effects at Year 15.

Significant visual effects are also identified at several receptors, including Brooke Road, Shotesham routes and Dawsons Farm.

Site 8 is therefore a straightforward example of development being advanced in a landscape the Applicant itself accepts is highly sensitive to change. The subsequent Significant effects are not an unexpected consequence; they are the predictable result of placing large-scale energy infrastructure in a receptor with limited capacity to accommodate it.

BEPS submits that the ExA should give particular weight to Sites 7 and 8 because they combine landscape, recreational, ecological, tranquillity and dark-sky sensitivity in the same locations.

7.19 Site 10: C2, Ditchingham, the Broads Interface and Parkland Context

Site 10 is assessed too narrowly as a collection of inland agricultural parcels. Its wider landscape context is materially more sensitive than its Medium site-level rating suggests.

Appendix 7.2 confirms that Site 10 lies within or across C2 Thurlton Tributary Farmland with Parkland and B5 Chet Tributary Farmland. C2 is assessed High value, High susceptibility and High sensitivity and is characterised by parkland, halls, ancient woodland, remoteness, peacefulness and views towards the Broads. B5 is also assessed High sensitivity and derives part of its value from its relationship with the Broads.

The Applicant's own earlier scoping material records Ditchingham Hall Registered Park and Garden approximately 1.7 km south of Site 10 and identifies Tindall Wood, Ditchingham SSSI and Hedenham Wood SSSI in the same wider landscape. The scoping baseline also recognises the Broads as a landscape defined by, among other qualities, remoteness, tranquillity, wildness, big skies, historic structures and human interaction with the landscape.

Site 10 itself is described in Appendix 7.2 as highly tranquil, sparsely settled and structured by hedgerows, tree belts and plantation woodland, with enclosed lanes and tracks including Pound Lane and Wash Lane contributing strongly to local character. These are precisely the qualities that make the eastern part of the scheme distinct from the more open western plateau.

The Applicant nevertheless reduces Site 10/CRC14 to Medium sensitivity. That sits uneasily with the High sensitivity assigned to the wider C2 and B5 landscapes in which it is embedded. At Year 1, both C2 and Site 10 experience Significant adverse landscape effects on the Applicant's own assessment.

BEPS submits that Site 10 should therefore be understood as part of a sensitive transition between the South Norfolk claylands, historic parkland and the wider Broads-facing landscape, not as an isolated inland solar parcel. Its relationship with

Ditchingham, the parkland context, wooded tributary landscape and enclosed historic lanes should be given materially greater weight.

7.20 Fritton and St Catherine's Church

The Fritton area requires particular scrutiny because the Applicant itself has already accepted its sensitivity through design changes. Chapter 7 identifies the Grade I Church of St Catherine, Fritton Conservation Area and residential properties along The Street as reasons for excluding solar development from the eastern part of Site 5.

That exclusion is an acknowledgment that the relationship between Site 5 and Fritton is environmentally constrained. The remaining development must therefore be assessed with particular care.

BEPS is concerned that the visualisations around St Catherine's Church do not show a robust worst-case seasonal condition. Deciduous vegetation in summer materially obscures key views, despite Chapter 7 itself recognising that winter leaf-off conditions represent the visual worst case.

This is not a minor presentation issue. St Catherine's is a Grade I listed church whose rural setting and relationship with the surrounding fields form part of the way it is experienced. Where summer foliage conceals development that would be more visible in winter, the Examination cannot reliably assess that relationship from summer photomontages alone.

BEPS therefore requests winter leaf-off photomontages and verified wirelines from and around St Catherine's Church and Fritton, showing the remaining Site 5 development under the seasonal conditions in which existing vegetation provides least screening.

7.21 Cable Corridors, Lanes and the Structural Landscape

Chapter 7 tends to characterise the Cable Route Corridor as a temporary and reversible disturbance which, once reinstated, returns broadly to baseline. That description is too simple for a cable network extending across a landscape whose structure is defined by lanes, ditches, hedgerows, trees, watercourses and historic field boundaries.

Construction involves open-cut trenching, stockpiles, haul routes, vegetation removal, hedgerow crossings, tree-root interactions, trenchless crossings, temporary compounds and PRoW disruption. Chapter 7 itself recognises trenching and vegetation loss over long distances, but ultimately predicts No Change across several CRC landscape receptors by Year 15.

The landscape significance of those works depends on what is crossed. Appendix 7.2 assigns Low susceptibility to several CRC parcels despite their interaction with locally valued landscape structure. CRC7 is a particularly clear example: it is rated High overall sensitivity because it lies within the Tas Rural River Valley, but only Low susceptibility to the proposed works. The earlier scheme description confirms that

CRC7 crosses a landscape containing fields, woodland and a Statutory Main River. Nearby ecological evidence also identifies wet meadows, mature hedges and the Hempnall Beck system close to CRC7.

The David Fine landscape evidence is relevant here because it identifies the ditch, lane and field network as part of the historic morphology and functioning of the South Norfolk claylands, rather than as incidental surface features. Cutting across that structure can alter historic legibility, vegetation pattern, hydrological relationships and the experience of rural lanes even where the trench itself is later filled.

The key issue is therefore not whether grass can regrow over a cable trench. It is whether the structural landscape through which the corridor passes is fully restored. Where hedgerows are removed, ditches crossed, root zones disturbed or lane edges altered, “reversibility” should not be assumed without evidence that those relationships can be reinstated in function and character.

7.22 Aviation and Airfield Landscape Cross-Effects

The aviation consequences of East Pye are addressed separately in BEPS’s aviation evidence, but Tibenham Airfield also has a landscape relevance which should not disappear simply because aviation safety is assessed elsewhere.

The Applicant’s visual baseline identifies the wider Tibenham area as part of the visual context of Site 1, and the scheme’s own scoping material records Tibenham Airfield approximately 1 km west of Sub-Site 1A. The Great Moulton Plateau character assessment also identifies former and active airfield landscapes as part of the character of the wider plateau.

The Lighting Strategy separately recognises Tibenham Airfield and pilots as potentially sensitive to glare from construction and operational lighting. This confirms that the airfield lies within the perceptual envelope of the scheme.

The landscape point is therefore simple: Tibenham is not outside the landscape and visual assessment merely because its aviation function is considered elsewhere. The airfield forms part of the open plateau landscape in which Site 1, the BESS and grid infrastructure are located, and the visibility of major energy infrastructure from that landscape contributes to the wider change in character.

BEPS relies on its separate aviation subsection in Chapter 18 of this Written Representation for the safety consequences.

7.23 Ecology and Landscape Are Functionally Interdependent

The distinction drawn between landscape and ecology is useful for chapter organisation, but it should not obscure the fact that many of the same physical features perform both functions.

Hedgerows, ancient and veteran trees, woodland, ditches, riparian corridors and dark-sky areas are simultaneously landscape structure and ecological infrastructure. Chapter 7 relies on them to define character, frame views and provide screening; Chapter 8 relies on them as habitat, movement corridors and ecological connectivity. Their loss or alteration therefore creates combined effects which cannot safely be understood in isolation.

This is particularly important for bats and other nocturnal species. The dark, hedged and wooded corridors at Sites 7 and 8 are landscape features precisely because they create enclosed, tranquil and dark rural character, but they also function as ecological corridors. Lighting, vegetation removal and fragmentation therefore alter both the ecological function and the perceptual character of the same landscape.

The same issue arises at Site 10 and the wider Broome Beck/tributary landscape, where watercourses, woodland, hedgerows and wet ground form part of both the visual structure and ecological connectivity of the eastern scheme area. The Applicant's own scoping evidence identifies ancient woodland and wetland sites close to Site 10 and the cable corridors.

BEPS does not duplicate the species evidence here. The point is methodological: landscape structure is also ecological structure. A conclusion that a hedgerow, ditch or woodland belt can be altered and visually replaced does not establish that its ecological function, historic role or landscape character has been preserved. Chapter 7 should therefore be read together with the ecology, arboricultural and lighting evidence when the ExA assesses the true effect of removing, fragmenting or illuminating these features.

7.24 Cumulative Landscape Industrialisation

Chapter 7 contains a cumulative assessment, but BEPS considers that the wider landscape risk is greater than a project-by-project exercise suggests. The relevant question is not simply whether East Pye produces an additional Significant effect when placed beside one other identified development. It is what happens to the character of the South Norfolk landscape when multiple large solar schemes, BESS, substations, grid reinforcement and associated connection infrastructure accumulate within the same rural area.

This concern was identified at scoping. East Suffolk Council expressly warned that East Pye should not be assessed in isolation and that reasonably foreseeable projects should be considered even where they had not yet reached formal application stage, provided sufficient information existed to assess likely cumulative effects. It highlighted the potential for spatial and temporal overlap with other NSIPs, grid reinforcement projects and large-scale energy developments across Norfolk and Suffolk. Suffolk County Council's scoping material also included a specific cumulative-impact landscape plan identifying East Pye alongside other major energy infrastructure.

BEPS's earlier submissions similarly identified the risk of landscape-scale industrialisation through the concentration of solar, BESS and grid infrastructure in South Norfolk and called for cumulative mapping, combined ZTVs and heritage overlays rather than treating each scheme in isolation. That concern is particularly acute around Great Moulton and Tibenham, where East Pye itself already combines Site 1, the BESS, a 400 kV Project Substation, the National Grid Substation and overhead-line works within an open plateau landscape. It also applies around Long Stratton and the wider 400 kV corridor, where multiple forms of energy and transport infrastructure are already present or proposed.

BEPS does not rely here on every project previously identified during pre-application, because planning status can change. The final cumulative assessment should instead be updated at the Examination date to include only existing, consented and reasonably foreseeable developments falling within the applicable assessment tiers. The principle, however, remains unchanged: all relevant solar, BESS and grid schemes sharing landscape receptors, views, roads, PRoWs, settlement edges or transmission corridors must be assessed together.

The cumulative effect is not confined to additional panels in the same view. It includes repeated loss of open agricultural land, successive encounters with substations and BESS compounds, additional fencing and security infrastructure, cumulative lighting, repeated construction activity and the progressive conversion of rural routes into corridors through energy infrastructure. A resident or walker does not experience each development according to its planning boundary; they experience the resulting landscape.

This is especially important where individual schemes rely on the same mitigation argument. If each development is screened by additional tree belts and woodland, the cumulative result may be the loss of the very openness and long views that define the existing landscape. Cumulative mitigation can itself become cumulative landscape change.

BEPS therefore submits that the ExA should ask not merely whether East Pye can be viewed alongside other schemes, but what the receiving landscape becomes if those schemes proceed together. A landscape-scale cumulative assessment, supported where appropriate by combined ZTV mapping, is necessary before the true extent of industrialisation can be understood.

7.25 Replacement Cycles and Decommissioning Are Not Truly "Temporary"

Chapter 7 treats equipment replacement as part of operation but does not assess it separately, on the basis that its effects would be no greater than construction and are likely to be reduced once mitigation planting has matured. That approach understates the significance of repeated industrial activity over a 60-year operational period.

The Applicant's own scoping material anticipated photovoltaic panels with approximate lifespans of 25–40 years and batteries of 15–20 years. It expressly assumed that solar panels could require replacement up to twice and batteries up to four times during operation. The same material acknowledges that replacement may require HGVs and that the number of trips would exceed ordinary maintenance activity.

These are not incidental events. They form part of the foreseeable life-cycle of the development. Panel and battery replacement may entail heavy vehicles, lifting equipment, temporary working areas, storage, access activity and renewed movement through the same rural road and PRoW network. Mature planting may reduce visibility of some works, but it does not remove their activity, traffic or effect on tranquillity.

The same applies at the end of the operational period. The Applicant assumes a 24-month decommissioning phase and accepts that decommissioning would involve activity broadly similar to construction in reverse. The Applicant's own landscape assessment identifies Significant decommissioning effects across multiple receptors, including NCA 83, B1, E2, the BESS, Site 1, Sites 4, 5, 7, 8, 9 and 10.

Nor is the whole scheme necessarily removed. The original scoping material confirms that the National Grid Substation remains after the solar scheme is decommissioned, and earlier statutory-consultee comments questioned the extent to which cables, access tracks and other infrastructure might also remain.

The language of "reversibility" therefore requires care. East Pye occupies the landscape for up to 60 years, during which major components may be replaced several times, before a further period of significant decommissioning activity, while part of the grid infrastructure remains permanently. That is not temporary in any ordinary landscape sense. It is a three-generation change with repeated periods of industrial intervention.

7.26 Good Design: Screening Harm Is Not the Same as Avoiding Harm

The Applicant's Design Approach Document contains appropriate-sounding principles: respond to local landscape character, retain and enhance vegetation, consider heritage settings, protect quiet lanes and PRoWs, minimise lighting and integrate the scheme into the natural environment. The difficulty is that the final assessed scheme still produces the very harms those principles are intended to avoid.

Site 1 remains Major Significant at Year 15 and is expressly described as experiencing a "total change" to key characteristics. The BESS remains Significant after mature mitigation. Site 7 and Site 8 remain Significantly affected at Year 15. Significant visual effects remain on sensitive PRoWs and residential receptors. Dark and tranquil landscapes are still occupied by large-scale energy infrastructure.

Those outcomes are important because they show that the fundamental problem has not been designed out. The design response has largely been to increase offsets, reinforce hedgerows, add tree belts and woodland and rely on future screening. That

may reduce visibility, but it does not demonstrate that the location and scale of the infrastructure are appropriate.

Good design cannot be demonstrated merely by planting around infrastructure whose siting produces major residual harm. The proper application of the mitigation hierarchy is avoidance first, not screening last.

This is particularly important in landscapes whose defining characteristics are openness, tranquillity or historic field pattern. In those locations, extensive mitigation planting may itself alter the character the design is supposed to conserve. A scheme cannot be said to “respond to local character” if its successful mitigation depends upon replacing that character with a different one.

BEPS therefore submits that the persistence of Significant effects after design evolution is evidence of a siting and scale failure, not simply a need for more detailed landscape treatment.

Subsequent heritage evidence materially reinforces this point. David Edelston’s independent HIA (Appendix G) identifies circumstances in which screening may itself alter the openness, views and historic relationships which contribute to the significance of designated assets. The landscape mitigation case should therefore not treat additional planting as inherently beneficial merely because it reduces visibility of infrastructure. In some locations, enclosure of an historically open setting may itself constitute part of the harm.

7.27 Overall Planning Weight

BEPS asks the ExA to give substantial adverse weight to the landscape and visual effects of East Pye. The harm is geographically extensive, affects multiple landscape character areas and settlements, and is not confined to construction. Many effects are expressly assessed by the Applicant as Significant; some remain Significant after fifteen years of assumed mitigation; and Site 1 remains Major Significant even at that stage.

The harm also extends beyond visibility. It affects landscape character, openness, tranquillity, dark skies, historic morphology, PRoW experience, settlement setting and residential amenity. Several methodological choices identified in this representation — including the treatment of lighting, sensitivity, study areas, seasonal visualisation, residential receptors and mitigation planting — are capable of understating rather than exaggerating those effects.

The fact that East Pye does not lie within a nationally designated landscape does not render the South Norfolk Claylands expendable. The Applicant itself identifies High-sensitivity landscape receptors, including A1 Tas Rural River Valley, B5 Chet Tributary Farmland, C2 Thurlton Tributary Farmland with Parkland, Site 8, the Boudicca Way and Via Beata. National policy still requires landscape character to be properly assessed, protected where possible and harm minimised through appropriate siting and design.

The adverse weight is therefore not based on designation alone. It arises from the scale, persistence and character of the change which the Applicant's own evidence records.

7.28 Remedies and Requirements Sought

BEPS considers that the deficiencies identified above require more than minor clarification during Examination. The ExA should require a revised and integrated landscape assessment which addresses landscape structure, heritage setting, tranquillity, dark skies and route experience together rather than continuing to treat them as largely separate matters. A substantive night-time LVIA should assess the magnitude and significance of construction and operational lighting, including motion-activated security lighting, BESS perimeter lighting and substation lighting, rather than relying solely on the Lighting Strategy.

The Applicant should also provide equivalent winter leaf-off visualisations at sensitive receptors where deciduous vegetation materially affects screening, including St Catherine's Church and Fritton, sensitive settlement edges, principal PRoWs and the Site 1/BESS area. Landscape sensitivity judgments should be revisited for Site 1 and the BESS, Site 7 and Site 10, and Site 10 should be reassessed in its wider C2, parkland, Ditchingham and Broads-facing context.

The ExA should require a route-based assessment of cumulative and sequential PRoW experience, together with further justification for the RVAA decision not to undertake individual assessment of properties between 100 m and 500 m. The Applicant should demonstrate, receptor by receptor, that the Year 15 mitigation assumptions remain robust under establishment failure, drought, ash dieback, tree mortality and management uncertainty, and should distinguish clearly between genuine conservation of landscape character and the loss of openness caused by screening vegetation itself.

A refreshed cumulative landscape assessment should identify all existing, consented and reasonably foreseeable energy infrastructure relevant at the Examination date and should use combined ZTV mapping where necessary to show the cumulative effect on Great Moulton, Tibenham, Long Stratton, the 400 kV corridor, settlement edges and the PRoW network. Stronger DCO controls should also secure tree and hedgerow protection, replacement of failed planting, long-term landscape management, lighting limits and any mitigation on which the significance conclusions depend.

Where those assessments confirm continuing Significant harm, the appropriate remedy is scheme reduction or redesign, including removal or relocation of development from the most sensitive and harmful locations, particularly Site 1 and the BESS. Further screening should not be accepted as the default response where the screening itself changes the landscape character.

BEPS submits that Chapter 7 does not demonstrate that East Pye can be accommodated within this landscape without unacceptable and enduring harm. The Applicant's own evidence records extensive Significant adverse effects, including major long-term effects which remain after fifteen years of mitigation. Those conclusions are

already serious; the methodological deficiencies identified above mean that the true harm is likely to be greater. Where the landscape cannot accommodate the scale and industrial character of the Scheme without continuing Significant effects, the appropriate response is not more screening but reduction, relocation or removal of the offending development. Unless those conflicts are satisfactorily resolved, the landscape and visual impacts weigh materially against the grant of development consent.

Table of Contents

Chapter 8: Ecology and Biodiversity *11*

Introduction **11**

8.1 Executive summary and principal conclusions **11**

8.2 Legal and policy framework **14**

8.2.1 EN-1, EN-3 and EN-5 14

8.2.2 National Planning Policy Framework 15

8.2.3 Habitats Regulations and European Protected Species 16

8.2.4 Environment Act 2021, NERC Act 2006 and the BNG hierarchy 17

Central policy submission 18

8.3 The proper ecological characterisation of the Scheme area **19**

8.3.1 A connected South Norfolk Claylands ecological system 19

8.3.2 Priority habitats throughout the Order Limits 20

8.3.3 Existing publicly funded conservation management 22

8.4 Incomplete and unreliable ecological baseline **22**

8.4.1 Absence of a full botanical survey 23

8.4.2 Incomplete species and functional evidence 25

Breeding and wintering birds 25

Barbastelle roost networks and functional habitat 26

Trees and roosting potential 27

Great crested newt, water vole, otter, badger and other species 27

8.4.3 Aquatic assessment limitations and dry-condition bias 28

8.4.4 Failure to identify and incorporate local and specialist evidence 33

White-clawed crayfish in the River Tas 33

Botanical evidence 34

Barbastelle specialist evidence 34

8.4.5 Consequences for the Environmental Statement 38

Strategic Ecological Network Conflict 39

8.4.6 Barbastelle Bats 39

8.5 Nationally important bat assemblage and barbastelle maternity-colony landscape **40**

8.5.1 The Applicant's finding of national importance 40

8.5.2 Barbastelle abundance, distribution and significance 41

8.5.3 Multiple maternity colonies and overlapping Core Sustenance Zones 42

8.5.4 The Norfolk Barbastelle Study Group's call for further survey 43

8.5.5 SSSI and ancient-woodland maternity-roost landscape 44

8.5.6 Hibernacula, satellite roosts and year-round habitat function 46

8.5.7 Natural England's favourable conservation status guidance 47

The central conflict 54

Implications for East Pye's mitigation case 55

Required examination evidence 55
Conclusion 56
8.5.8 Peer-reviewed evidence concerning solar development and bats 56
8.5.9 Functional effects of the Scheme on the bat landscape 57
8.5.10 Protected-species licensing implications 58
8.5.11 Conclusion on bats and barbastelles 59

8.6 SSSI Woodland Context and Barbastelle Protection 60
Spring Wood and the converted Second World War bomb shelters 61
8.6.1 Hedgerow severance and loss of functional connectivity 64
8.6.2 Artificial lighting and fragmentation of dark landscapes 68
8.6.3 Construction disturbance: piling, vibration, traffic and noise 73
8.6.4 Solar infrastructure, prey availability and ecological function 80
Changes to insect abundance and prey availability 80
Peer-reviewed evidence concerning bat responses to solar development 81
Aquatic insects and food-web disruption 82
Watercourses as ecological corridors 83
Effects on woodland-edge ecology 83
Field margins and ecological productivity 84
Interaction with agricultural stewardship 85
Failure to assess ecosystem function 85
Relationship to Biodiversity Net Gain 86
Failure to apply the mitigation hierarchy 86
Conclusion 87
8.6.5 Landscape fragmentation by fencing, roads and operational infrastructure 87
8.6.6. Mitigation and BNG insufficient 94
Examination consequence 94

8.7 Ancient Woodland 95
8.7.1 Six ancient woodlands directly adjoining the Scheme 95
8.7.2 Woodland fragmentation, enclosure and loss of ecological function 100
8.7.3 Woodland buffers do not mitigate all indirect effects 108
8.7.4 Ancient trees, veteran trees and the wider tree network 120
8.7.5 The South Norfolk Tree Warden Network evidence 129
8.7.6 Irreplaceable habitats, policy conflict and the mitigation hierarchy 139
8.7.7 Conclusions and remedies sought 148

8.8 Hydrologically connected ecology and chalk streams 155
8.8.1 River Tas, Hempnall Beck and connected tributaries 156
8.8.2 River Waveney-linked systems 159
8.8.3 Incomplete aquatic baseline 161
8.8.4 Environment Agency's unresolved ecology concerns 164

8.9 White-clawed crayfish 170
8.9.1 Evidence of a breeding River Tas population 171
8.9.2 Defective Applicant baseline 174
8.9.3 Risk pathways 178
8.9.4 Legal and policy consequences 184

8.10 Botany, lowland meadow, roadside verges and field margins 189

8.10.2 Road widening and highway works 192
8.10.3 Roadside Nature Reserves and Parker's Lane 195
8.10.4 Field margins and cable corridors 197
Conclusion and remedies sought 201

8.11 Breeding and wintering birds 202
8.11.1 Countryside Stewardship Scheme 204
8.11.2 Stewardship land and public investment 214

8.12 Other protected and priority species 222
Great crested newt 222
Water vole and otter 223
Badger 224
Widespread reptiles 225
Brown hare and hedgehog 226
Terrestrial and aquatic invertebrates 226
Invasive species and biosecurity 227
Conclusion on other protected and priority species 228

8.13 Construction-phase ecological effects 229
8.13.1 The construction footprint is materially wider than the permanent footprint 229
8.13.2 Road widening, accesses and HGV movements 230
8.13.3 Haul roads and temporary access tracks 231
8.13.4 Construction compounds and laydown areas 232
8.13.5 Piling and deep foundations 233
8.13.6 Trenching and cable installation 234
8.13.7 Horizontal directional drilling 234
8.13.8 Watercourse and ditch crossings 235
8.13.9 Vegetation removal and repeated habitat severance 236
8.13.10 Dust 237
8.13.11 Noise and vibration 237
8.13.12 Construction lighting 238
8.13.13 Soil compaction and habitat degradation 238
8.13.14 Contamination and accidental spills 239
8.13.15 The mismatch between the assessment and the authorised works 239
8.13.16 Required construction assessment and controls 240
Conclusion 241

8.14 Operational, replacement and decommissioning effects 241
8.14.1 Sixty-year industrial use 242
8.14.2 Panel and BESS replacement 246
8.14.3 Decommissioning damage to created habitats 249
8.14.4 Absence of secure whole-life ecological protection 254
Overall conclusion 259

8.15 Biodiversity Net Gain 260

8.15.1 BNG does not determine ecological acceptability 261
8.15.2 Baseline undervaluation 264
8.15.3 Post-development overvaluation 267
8.15.4 Hedgerow and connectivity accounting 272
8.15.5 Watercourse units 274
8.15.6 Durability and decommissioning 276
Overall conclusion on BNG 279
NOTE: The proper conclusion 280

8.16 Outline LEMP and other deferred mitigation 281
8.16.1 The OLEMP is an outline framework, not final mitigation 282
8.16.2 Outline Protected Species Mitigation Strategy 287
8.16.3 CEMP, lighting strategy and drainage controls 291
8.16.4 Effectiveness and enforceability 294
8.16.5 Deferred mitigation and legal consequences 297

The Applicant's Chapter 19 methodology 323
8.19.1 Cumulative effects within the Scheme 323
8.19.2 Cumulative effects with other development 326
8.19.3 Effects interacting across receptors and impact pathways 328
Why point mapping and parcel-by-parcel assessment are inadequate 330
HRA in-combination effects 331
Overstatement of operational benefits 331
Required cumulative ecological assessment 332
Overall conclusion 333

8.20 Application of the mitigation hierarchy: why avoidance must be tested first 333
Avoid 334
Minimise 336
Restore 338
Compensate 339
Evaluative conclusion on the mitigation hierarchy 340

8.21 Overall conclusion 341

8.22 Remedies sought 342

8.22.1 Primary remedy: refusal 342

8.22.2 Alternative case: minimum requirements before any recommendation 343

Final remedy position 348

Chapter 9: Water Environment 350

9.1 Purpose and Overall Case 350

9.2 Hydrological and Hydrogeological Setting 353

9.2.1 The Scheme extends across two principal river systems and numerous connected drainage networks 353

9.2.2 Chalk-stream sensitivity 354

9.2.3 The Applicant itself accepts hydrological connectivity 356

9.3 Fundamental Methodological Deficiencies 357

9.3 Defective Conceptual Hydrogeological Model 357

9.3.1 No adequate conceptual site model 358

9.3.2 Over-reliance on historic and off-site borehole data 359

9.3.3 Unsupported assumptions about the Lowestoft Formation 360

9.3.4 Interaction between Chapters 9 and 16 361

9.4 Private Water Supplies: Major Unresolved Human-Health Issue 361

9.4.1 Private water supplies are groundwater and human-health receptors 361

9.4.2 What PINS required 362

9.4.3 What the Environment Agency required 362

9.4.4 What Figure 16.5 actually demonstrates 363

9.4.5 HFCL's independent findings materially undermine the PWS baseline 363

9.4.6 Different PWS types require different assessment 364

9.4.7 The Private Water Supplies Regulations reinforce the requirement for a risk-based approach 365

9.4.8 The Water Resources Assessment does not assess Scheme impacts on PWS 365

9.4.9 Material information remains absent 366

9.5 Groundwater Contamination and Preferential Pathways 367

9.5 Piling, Foundations and Ground Disturbance 367

9.5.1 PINS requirement concerning HDD and groundwater 367

9.5.2 EA requirement for Foundation Works and Piling Risk Assessment 367

9.5.3 HFCL identifies a fundamental error in the source-pathway analysis 368

9.5.4 Preferential pathways remain insufficiently characterised 368

9.6 Water Framework Directive 369

9.6 The WFD Assessment is not sufficiently precautionary or comprehensive 369

9.6.1 The Planning Inspectorate expressly required a WFD assessment because effects and crossing arrangements remained uncertain 370

9.6.2 The seven WFD waterbody receptors and the Applicant's screening decisions 371

9.6.3 HFCL concludes that the screening-out exercise is inappropriate 372

9.6.4 Broome Beck illustrates the weakness of the screening methodology 373

9.6.5 River Tas and Hempnall Beck require a precautionary assessment commensurate with chalk-stream sensitivity 374
9.6.6 Starston Brook must be considered together with the Site 1 infrastructure concentration 375
9.6.7 Screening out the Broadland Rivers Chalk and Crag groundwater body is particularly difficult to justify 375
9.6.8 The assessment lacks sufficient quantitative and catchment-scale analysis 376
9.6.9 The Applicant must demonstrate both no deterioration and no impediment to achieving future objectives 377

9.7 Chalk Streams, Aquatic Ecology and HRA Connectivity 378
9.7 Water Environment and Ecology Interface 378
9.7.1 Hydrological pathways to designated sites 379

9.8 Flood Risk and Surface-Water Drainage 380
9.8 Flood-risk evidence remains incomplete 380
9.8.1 The Planning Inspectorate required a robust assessment of flood risk, resilience and off-site effects 380
9.8.2 Starston Brook illustrates the continuing limitations of the flood evidence 381
9.8.3 Numerous surface-water pathways cross the Scheme 382
9.8.4 The Applicant's treatment of impermeable area has been directly challenged by the LLFA 383
9.8.5 The assumption that solar arrays will have negligible runoff effects requires site-specific justification 384
9.8.6 Construction compaction requires separate assessment from operational panel runoff 385

9.9 Drainage of the BESS and Substations 386
9.9 Major Infrastructure Drainage and Containment 386
9.9.1 Site 1 – BESS, National Grid Substation and 400kV Project Substation 387
9.9.2 Site 5 – 400kV Project Substation 388
9.9.3 The Applicant's reliance on Requirement 11 does not resolve the present evidential gaps 389

Chapter 8: Ecology and Biodiversity

Introduction

East Pye Solar is not proposed on ecologically ordinary farmland containing isolated features. It would industrialise a single, functionally connected ecological landscape of national importance for bats, multiple barbastelle maternity-colony networks, ancient woodland, veteran trees, priority hedgerows and field margins, chalk streams, protected aquatic species, farmland-bird habitat and unsurveyed botanical assemblages. Because those functions cannot reliably be recreated or compensated for, avoidance is the only policy-compliant response.

8.1 Executive summary and principal conclusions

East Pye Solar is not proposed on ecologically ordinary farmland containing a small number of discrete features that can be protected through standard buffers and construction controls. The Order Limits extend across a receptor-dense and functionally connected South Norfolk Claylands landscape comprising ancient and veteran trees, species-rich hedgerows, arable field margins, ponds, woodland edges, County Wildlife Sites, Roadside Nature Reserves, SSSI woodlands, lowland fen, grazing marsh, chalk-stream tributaries and extensive surface-water and groundwater networks. These features operate together as ecological infrastructure. The Scheme would introduce panels, substations, BESS infrastructure, fencing, access tracks, haul routes, compounds, cable trenches, watercourse crossings, lighting and road widening throughout that network. Its ecological effects therefore cannot properly be assessed as a series of small, isolated habitat losses.

The Applicant's own bat evidence fundamentally changes the proper characterisation of the Scheme area. The Bat Activity Survey Report assesses the bat assemblage across the Order Limits as being of national importance. Barbastelle, a nationally rare Annex II species and European Protected Species, was the third most frequently recorded bat species and was detected at every static survey location. The Applicant also records multiple barbastelle maternity colonies around the Scheme and accepts that the Order Limits fall within overlapping Core Sustenance Zones supporting those colonies. The Applicant's evidence therefore establishes that the Scheme is not merely close to isolated bat roosts: it occupies a landscape used at scale for roosting, commuting and foraging by a nationally important bat assemblage and by multiple barbastelle maternity populations.

That conclusion is inseparable from the existing woodland, hedgerow and watercourse network. The Forestry Commission identifies ancient woodland as irreplaceable habitat and has warned that woodland isolation and fragmentation are major threats, particularly where small woods become surrounded by development. Its advice emphasises that buffers must form part of wider ecological networks rather than operate as narrow separation distances. The South Norfolk Tree Warden Network similarly identifies trees and hedgerows as functional ecological infrastructure, notes 621 trees with potential to support roosting bats, and warns that repeated hedgerow gaps, access

works, haul-road disturbance and later reinstatement have not been assessed adequately in terms of cumulative functional connectivity.

The ecological baseline remains materially incomplete. Most seriously, the Applicant has undertaken no proper full-season botanical survey despite pre-application evidence from a Level 6 botanist familiar with the South Norfolk Claylands that rare and important plant assemblages occur in the area and that seasonal botanical survey was required. The omission is especially serious because the least-surveyed habitats—roadside verges, field margins, ancient hedges, ditch edges and semi-natural strips—are among those most threatened by highway widening, visibility splays, new accesses, haul routes, cable works and construction compounds. The Applicant's own extended habitat work expressly disclaims being a full botanical survey. It cannot demonstrate avoidance of botanical harm without first identifying the resource at risk.

The aquatic baseline is also incomplete. The Applicant's appraisal was habitat-led, was undertaken during unusually dry conditions and acknowledges that ephemeral headwaters and field ditches may have been under-represented. The ExA has already requested further information because concerns raised by South Norfolk Council, Norfolk Wildlife Trust and BEPS about white-clawed crayfish could not be resolved on the existing survey material. Independent evidence identifies an isolated River Tas population close to the Scheme, while the Environment Agency's earlier records and scoping advice confirmed that white-clawed crayfish required consideration. The connected River Tas, Hempnall Beck, Starston Brook, Broome Beck and associated ditch systems provide plausible pathways for sediment, pollution, disease, altered flows and hydrological disturbance.

The Environment Agency's Relevant Representation confirms that significant ecological and water-environment matters remain unresolved. It requires further consideration of effects on fish, European eel, aquatic macroinvertebrates, groundwater-dependent ecosystems and water quality; questions the assessment of electromagnetic effects on eel; identifies the potential for solar panels to affect macroinvertebrate lifecycles; and states that BNG and riparian recommendations require proper securing. It also identifies unresolved risks from piling, underground cabling, groundwater pathways and contaminated land. These are not incidental drafting matters. They demonstrate that the pathways linking construction, hydrology and ecological receptors have not yet been fully assessed or controlled.

Norfolk Wildlife Trust reaches the same broad conclusion from a landscape-scale perspective. It states that further information and design refinement are required before the Scheme can be regarded as ecologically acceptable; raises concerns about County Wildlife Sites, Roadside Nature Reserves, ancient woodland, lowland fen, non-designated verges and barbastelle habitat; and warns that HDD locations, compounds, lighting, vehicle movements and buffer distances remain unresolved. Local residents at Wood Green likewise identify ecological connectivity between Wood Green CWS, Crow Green, Tyrrell's Wood, Fritton Common, roadside reserves and hedgerows, together with breeding bats, great crested newts, water vole, turtle dove, other breeding birds and an important winter starling murmuration. Their evidence confirms that the effects feared by

professional and statutory consultees are observable landscape-scale effects, not theoretical concerns.

South Norfolk Council's consultation response also demonstrates that the mitigation case was not settled. It sought specific protection for veteran trees, important bat flight lines and dark corridors; requested clarity about which ecological enhancements would survive decommissioning; required updated ecological and arboricultural information to inform later plans; and emphasised the need for commitments concerning watercourses, ponds, bat routes and long-term habitat retention. The Norfolk Barbastelle Study Group has separately called for further work to establish the full distribution and habitat use of maternity colonies, including radio-tracking and further woodland assessment. The current baseline therefore does not provide the certainty needed to assess effects on the very species that make the area nationally important.

The four principal defects are accordingly clear.

- First, the ecological baseline is incomplete. There is no full botanical survey; the aquatic work was limited and dry-condition biased; white-clawed crayfish evidence was not adequately incorporated; and important questions remain concerning birds, bats, trees, aquatic invertebrates and other protected species.
- Second, ecological function and connectivity have been underestimated. The Applicant assesses individual habitats and crossings but does not adequately assess the Scheme-wide consequences of repeated hedgerow severance, woodland enclosure, lighting, fencing, road widening, construction disturbance and alteration of hydrological pathways across a nationally important bat and chalk-stream landscape.
- Third, mitigation is generic, deferred and insufficiently secured. The ecology case relies heavily on the Outline LEMP, future CEMPs and OEMPs, later surveys, later protected-species licensing, later lighting design, later method statements and metric-based BNG assumptions. Those documents do not presently fix the locations, standards, performance criteria and remedial mechanisms necessary to demonstrate that ecological function will be maintained. A positive BNG metric cannot answer the distinct questions posed by European Protected Species, ancient woodland, veteran trees, rare botanical assemblages, hydrological deterioration or species-population viability.
- Fourth, the Scheme has not avoided impacts that cannot reliably be mitigated or compensated. EN-1, EN-3, EN-5 and the NPPF place avoidance at the top of the mitigation hierarchy. Instead of avoiding this sensitive ecological landscape, the Applicant has selected it for industrial-scale development and then relied on buffers, habitat creation and future management to justify that choice. That reverses the proper hierarchy. Mature hedgerow networks, ancient woodland relationships, established barbastelle maternity support habitat, chalk-stream ecological function, rare plant assemblages and long-established stewardship habitat cannot be assumed to be recreated through later planting or accounted for through habitat units.

The representations of the Environment Agency, Forestry Commission, Norfolk Wildlife Trust, South Norfolk Council, local residents, the South Norfolk Tree Warden Network, the Norfolk Barbastelle Study Group and BEPS approach the Scheme from different statutory, technical and local perspectives. They nevertheless converge on the same underlying concerns: an incomplete baseline; a highly connected and unusually sensitive ecological landscape; unresolved impacts on protected species, watercourses, ancient woodland and hedgerows; and excessive dependence on later design and management. The available evidence does not establish that those effects can be avoided, effectively mitigated or lawfully compensated.

BEPS therefore submits that the ecological case for East Pye Solar has not been made. The Scheme conflicts with the mitigation hierarchy, places protected species and irreplaceable habitats at unresolved risk, and relies on incomplete evidence and deferred mitigation to support conclusions of no significant effect. Development consent should be refused on ecology and biodiversity grounds.

8.2 Legal and policy framework

The relevant legal and policy framework is not confined to a general presumption in favour of renewable energy. National energy policy expressly requires ecological harm to be identified, avoided and, only where avoidance is not possible, reduced and mitigated through measures that are effective and properly secured. Separate statutory regimes apply to European sites, European Protected Species, SSSIs, irreplaceable habitats and biodiversity net gain. Those protections are not displaced by the general need for low-carbon infrastructure or by a positive biodiversity metric.

8.2.1 EN-1, EN-3 and EN-5

EN-1 requires applicants to apply the mitigation hierarchy. Adverse effects should first be avoided, including through site selection, layout and design. Effects that cannot be avoided must then be reduced or mitigated; restoration and compensation arise only after the earlier stages of the hierarchy have genuinely been exhausted. The hierarchy is therefore sequential. An applicant cannot select an ecologically damaging location, proceed directly to habitat creation or biodiversity accounting, and treat the resulting metric uplift as equivalent to avoidance.

This is particularly important where the affected receptors are difficult or impossible to recreate. Ancient woodland, ancient and veteran trees, established protected-species networks, mature hedgerows, chalk-stream systems and long-developed botanical assemblages cannot be treated as interchangeable with newly planted habitat. EN-1 requires the direct and indirect effects on ancient woodland, ancient and veteran trees and other irreplaceable habitats to be addressed during construction and operation. The Applicant's own policy material recognises the mitigation hierarchy and the protection afforded to irreplaceable habitats, yet its ecology case relies extensively on buffers, later habitat creation and management measures rather than demonstrating that the principal harms have been avoided.

Mitigation relied upon to reduce an effect or to support a conclusion of no significant effect must also be sufficiently defined, effective and secured. It is not enough to identify broad aspirations for woodland planting, hedgerow enhancement, dark corridors, watercourse buffers or species

protection while leaving their precise location, specification, timing, monitoring and remedial mechanisms to later plans. Where mitigation is necessary to establish that the Scheme is environmentally acceptable, the Examination must be able to understand what will be delivered, how it will operate, by what legal mechanism it will be secured and what will occur if it fails.

EN-3 applies those principles to renewable energy infrastructure. Policy support for solar generation does not remove the need to select environmentally appropriate land, assess the ecological consequences of the particular proposal and follow the mitigation hierarchy. The location, scale and layout of a solar scheme remain material. National need cannot convert an avoidable impact on protected species or irreplaceable habitat into an acceptable one.

EN-5 is relevant because East Pye includes extensive linear grid and cable infrastructure. It recognises that electricity-network development can provide opportunities to reconnect habitats through green corridors, stepping stones and restored hedgerows. That policy objective is the opposite of permitting linear works to sever existing networks without a full assessment of functional connectivity. Cable corridors, access roads, highway works and grid infrastructure must therefore be assessed not merely by the area of habitat physically removed, but by their effects on continuity, permeability and the functioning of the wider ecological network.

EN-1, EN-3 and EN-5 also require consideration of indirect, secondary and cumulative effects. For East Pye, this includes not only direct habitat loss but:

- repeated hedgerow severance and woodland-edge disturbance;
- lighting, noise and vibration affecting bat roosting, foraging and commuting;
- fragmentation caused by fencing, roads and infrastructure;
- sediment, pollution and hydrological effects transmitted through connected watercourses;
- cumulative disturbance from multiple compounds, crossings and development parcels;
- and effects in combination with other solar, BESS, grid, transport and housing proposals.

A parcel-by-parcel assessment which retains individual features but fails to assess whether the landscape continues to function ecologically does not satisfy that policy framework.

8.2.2 National Planning Policy Framework

The National Planning Policy Framework was replaced on 17 August 2026. The Energy NPSs remain the primary policy framework for this NSIP, but the current NPPF materially reinforces the mitigation-hierarchy and ecological-network issues raised in this chapter.

Policy N2 requires significant biodiversity harm first to be avoided through locating development on an alternative site with less harmful impacts where such harm cannot otherwise be avoided, before moving through mitigation and, as a last resort, compensation. It also requires ecological networks extending beyond the site to be protected and strengthened and requires agricultural land quality and grade to be taken into account, with poorer-quality agricultural land used where possible. Those provisions do not mean that every ecological constraint automatically requires refusal or relocation. They do mean that avoidance must genuinely precede reliance on buffers, habitat creation and compensation where the affected ecological function cannot readily be recreated.

The NPPF affords additional protection to SSSIs. Development on land within or outside an SSSI which is likely to have an adverse effect on it should not normally be permitted. The relevant issue is therefore not limited to direct development within the designated boundary. Indirect effects—including hydrological change, fragmentation, isolation, lighting, noise, dust, pollution and disturbance—must also be considered. This is material to East Pye because several SSSI woodlands lie immediately adjacent or very close to proposed development and form part of the ecological network used by protected species.

Development resulting in the loss or deterioration of irreplaceable habitats, including ancient woodland and ancient or veteran trees, should be refused unless there are wholly exceptional reasons and a suitable compensation strategy exists. 'Deterioration' is wider than direct felling. It includes degradation of ecological condition or function through isolation, root damage, altered hydrology, edge effects, lighting, disturbance and surrounding development. The Forestry Commission's concern that small ancient woods may become isolated or enclosed is therefore directly relevant to the policy test.

Compensation does not remove the need to demonstrate wholly exceptional reasons, nor does new planting recreate ancient woodland. Newly planted woodland, hedges or scrub may provide future value, but they cannot be treated as functionally equivalent to habitats whose ecological characteristics have developed over centuries. The Applicant's own documents recognise 31 Ancient Woodland Inventory sites and lowland fen parcels within the surrounding landscape, together with SSSI woodland adjoining parts of the Scheme.

8.2.3 Habitats Regulations and European Protected Species

Two distinct legal regimes must be kept separate.

First, the Conservation of Habitats and Species Regulations 2017 govern effects on European sites. Where a plan or project is likely to have a significant effect on a European site, either alone or in combination, and is not directly connected with its management, the competent authority must undertake an Appropriate Assessment. At screening stage, likely significant effects may be excluded only on the basis of objective information. Where a credible impact pathway remains and the evidence is incomplete, uncertainty cannot be treated as evidence of no effect. The precautionary approach requires the matter to proceed to Appropriate Assessment.

At the Appropriate Assessment stage, consent may be given only where the competent authority has ascertained that the project will not adversely affect the integrity of the European site. That conclusion must be reached without reasonable scientific doubt. In the present case, the potential pathways include hydrological connectivity through the Tas, Yare, Waveney and associated groundwater and ditch networks, together with any properly evidenced relationship between European-site qualifying interests and functionally linked land.

Secondly, all bats, including barbastelle, are subject to strict species protection. It is an offence, subject to the statutory provisions, deliberately to capture, kill or disturb protected bats, to

damage or destroy a breeding site or resting place, or to obstruct access to such places. These protections apply whether or not the relevant roost lies within a European site.

Where the Scheme would otherwise risk an offence, a European Protected Species licence may be required from Natural England. A licence can be granted only where the statutory derogation tests are met, including:

- the activity is undertaken for a permitted statutory purpose;
- there is no satisfactory alternative; and
- the action will not be detrimental to maintaining the population of the species concerned at favourable conservation status in its natural range.

The DCO decision-maker does not determine the EPS licence itself, but it must have regard to the protected-species position and should not proceed on an evidential assumption that a later licence will resolve material impacts where the information presently available leaves the licensing position materially uncertain. The availability of a future contractor-led application is not evidence that the tests can be met.

That issue is especially acute where the Applicant's own evidence identifies a nationally important bat assemblage, widespread barbastelle activity, multiple maternity colonies and overlapping Core Sustenance Zones. The 'no satisfactory alternative' test is relevant to any later EPS licence application and requires the available alternatives to be considered in that licensing context. The EIA and planning assessment should therefore provide sufficient evidence about the affected population, functional habitat and design alternatives to enable that later statutory process to be approached on a properly informed basis. The favourable-conservation-status test requires evidence about the population, roost network, foraging habitat and commuting function likely to be affected. Where the Norfolk Barbastelle Study Group has called for further survey and radio-tracking, and where the Scheme-wide functional use of the landscape remains incompletely understood, the grantability of any licence cannot simply be presumed.

The precautionary principle is therefore relevant under both regimes, although in different ways. Under HRA, unresolved scientific doubt prevents the competent authority from screening out likely significant effects or concluding no adverse effect on integrity. Under EPS licensing, an incomplete population and functional-habitat baseline undermines confidence that the statutory licensing tests, particularly no satisfactory alternative and maintenance of favourable conservation status, can be met.

8.2.4 Environment Act 2021, NERC Act 2006 and the BNG hierarchy

The Environment Act 2021 strengthens the statutory framework for biodiversity recovery and establishes biodiversity net gain requirements. It does not replace the mitigation hierarchy. BNG is additional to the requirement to avoid and mitigate ecological harm. It is not a permission to cause avoidable damage wherever a numerical uplift can subsequently be calculated.

South Norfolk Council has correctly noted that the statutory Biodiversity Gain Hierarchy is distinct from, although related to, the wider ecological mitigation hierarchy. BEPS therefore does not treat the two as interchangeable. The significance of BNG here is that habitat-unit accounting cannot

displace the separate requirements to avoid and mitigate harm to protected species, designated sites and irreplaceable habitats before biodiversity gains are relied upon.

The statutory biodiversity metric is principally a habitat-accounting tool. It does not determine:

- whether an offence against a European Protected Species will occur;
- whether the Habitats Regulations tests are met;
- whether an SSSI will be adversely affected;
- whether deterioration of ancient woodland or veteran trees is acceptable;
- whether Water Framework Directive deterioration will occur;
- whether a maternity-colony support landscape will remain functional;
- or whether rare botanical or species assemblages can be recreated.

Habitat units therefore cannot override species protection, European-site duties or policy concerning irreplaceable habitats. A positive BNG result may coexist with unacceptable or unlawful harm to a protected species or an irreplaceable ecological function. This limitation is particularly material at East Pye because the Applicant relies on habitat creation and enhancement while the principal concerns involve landscape-scale barbastelle function, ancient woodland connectivity, chalk-stream ecology, white-clawed crayfish, established stewardship habitat and unsurveyed botanical assemblages. The BEPS RR already identifies that the Applicant's metric-based claims do not answer those functional and legal constraints.

Section 40 of the Natural Environment and Rural Communities Act 2006, as strengthened by the Environment Act, requires public authorities exercising their functions to have regard to what they can properly do to further the general biodiversity objective, including the conservation, restoration and enhancement of populations and habitats. Section 41 identifies habitats and species of principal importance for conserving biodiversity. These duties require more than preventing complete habitat loss. They direct attention to ecological recovery, functioning networks and the condition and resilience of priority habitats and species.

The Secretary of State must therefore consider whether granting consent would further or frustrate biodiversity conservation and enhancement. That judgment cannot be reduced to the Applicant's headline BNG percentage. It must account for the quality, location, connectivity, durability and species function of what exists, what would be harmed and what is actually secured for the lifetime of the Scheme.

Central policy submission

On the Applicant's own cited legal and policy framework, ecological harm must first be avoided. Compensation, biodiversity enhancement and metric gains arise only after genuine avoidance and minimisation have been demonstrated. East Pye Solar instead selects a highly sensitive landscape containing nationally important bat habitat, overlapping barbastelle maternity-colony networks, SSSI and ancient woodlands, veteran trees, chalk streams, protected aquatic species and potentially important botanical assemblages, and then seeks to compensate for its industrialisation through buffers, outline management plans, future planting and BNG.

That approach reverses the mitigation hierarchy. It does not demonstrate compliance with EN-1, EN-3, EN-5, the NPPF, the Habitats Regulations, protected-species legislation or the statutory biodiversity duties. Where the affected ecological functions cannot reliably be recreated, mitigated or compensated for, the lawful and policy-compliant response is avoidance.

8.3 The proper ecological characterisation of the Scheme area

A fundamental flaw running throughout Chapter 8 of the Environmental Statement is the Applicant's characterisation of the Order Limits as predominantly agricultural land of generally moderate ecological value containing a series of discrete habitats capable of being retained, buffered or recreated through mitigation. That is not supported by the Applicant's own evidence, by the wider ecological evidence available for the South Norfolk Claylands, or by the representations of statutory and specialist consultees.

The correct starting point is that East Pye Solar occupies a highly connected historic landscape whose ecological importance derives not simply from individual designated sites or priority habitats, but from the interaction between ancient landscape structure, woodland, hedgerows, field margins, ponds, chalk-stream catchments, veteran trees and extensive habitat corridors. The ecological function of this landscape depends upon connectivity across the whole network rather than upon the survival of isolated habitat fragments.

This distinction is critical. A scheme may avoid direct loss of many individual habitat parcels while nevertheless causing significant ecological harm through fragmentation, disturbance, lighting, hydrological change and the cumulative erosion of ecological connectivity.

8.3.1 A connected South Norfolk Claylands ecological system

The Applicant's own Figures 8.2, 8.3 and 8.5 demonstrate that the Order Limits overlay an extensive ecological network rather than isolated ecological receptors. These figures show a landscape containing numerous priority habitats, interconnected hedgerows, woodland blocks, ponds, watercourses and designated sites extending across the entire Scheme rather than occurring as occasional isolated features.

This reflects the historic character of the South Norfolk Claylands.

As explained by Professor Tom Williamson in Restoring the Claylands, the Claylands developed over many centuries as an intricate landscape of small fields, ancient hedgerows, numerous hedgerow trees, ponds, commons, woodland, roadside grasslands and interconnected habitats. Although agricultural intensification removed many features during the twentieth century, important fragments remain and continue to provide the framework for biodiversity across the landscape. Importantly, Professor Williamson explains that historical land management unintentionally created not merely individual habitats but ‘a wealth of connections between them’, and that restoration should work with this historic ecological framework rather than impose generic habitat creation that ignores local landscape character.

This historic ecological framework is directly relevant to East Pye Solar. Across the Order Limits there remain:

- ancient species-rich hedgerows forming continuous commuting corridors;
- mature hedgerow trees and veteran trees;
- woodland blocks and woodland edge habitats;
- ponds, ghost ponds and wet features;
- field margins managed for biodiversity;
- ditch systems, tributaries and chalk-stream headwaters;
- areas of grassland, fen and grazing marsh;
- County Wildlife Sites;
- Roadside Nature Reserves;
- ancient woodland;
- adjacent Sites of Special Scientific Interest.

These features do not operate independently. Ancient hedgerows connect woodland to woodland. Woodland edges connect to ponds and ditches. Field margins connect to roadside verges. Roadside Nature Reserves connect to County Wildlife Sites.

Watercourses connect through both surface water and groundwater into the wider River Tas and River Waveney catchments.

The Applicant's own bat surveys demonstrate that barbastelles and numerous other bat species use this connected landscape at a scheme-wide scale rather than restricting activity to isolated habitat patches. Likewise, the aquatic ecology evidence demonstrates that ecological pathways extend beyond individual watercourses through hydrologically connected catchments.

The historic landscape guidance prepared for Norfolk Wildlife Trust reinforces precisely this point. It explains that ecological restoration should seek to maintain and reinforce the historic web of biological connectivity created by hedges, trees, ponds, commons, field margins and woodland, because those connections are themselves fundamental ecological assets. It specifically identifies hedgerows as wildlife corridors, ponds as functioning parts of wider ditch and stream networks, and grassland strips, roadside verges and field margins as historically interconnected habitats rather than isolated parcels.

The Applicant's assessment largely considers the retention or enhancement of individual habitat parcels. It does not adequately assess whether the ecological network itself will continue to function after sixty years of industrial development.

8.3.2 Priority habitats throughout the Order Limits

The Environmental Statement identifies numerous Priority Habitats distributed throughout the Scheme. The significance of these habitats lies not simply in their individual presence but in the ecological relationships between them. Species-rich hedgerows provide commuting and foraging corridors for bats, nesting habitat for farmland birds, refuge for mammals and invertebrates, and

botanical diversity developed over centuries.Woodland blocks and woodland edges support roosting bats, breeding birds, veteran trees, fungi and deadwood communities while acting as ecological stepping stones across the wider landscape. Ponds, ghost ponds, ditches and tributaries provide breeding habitat for amphibians and aquatic invertebrates while remaining hydrologically linked to wider chalk-stream systems. Field margins support botanical assemblages, pollinating insects, seed-producing plants and farmland birds including skylark, lapwing and turtle dove. Grassland, fen and grazing marsh contribute additional habitat diversity and provide ecological continuity between otherwise discrete features.

The Applicant's assessment frequently treats these habitats individually. However, the principal impact pathways arise from fragmentation of the network that links them.

Throughout the Scheme, construction requires:

- road widening;
- visibility splays;
- new accesses;
- haul roads;
- cable corridors;
- compounds;
- trenching;
- HDD compounds;
- permanent access tracks;
- substations;
- BESS infrastructure;
- extensive security fencing.

Each intervention may appear individually limited. However, collectively they create repeated interruptions to the ecological network across almost the entire Order Limits.

The Forestry Commission has warned that fragmentation represents one of the greatest threats to ancient woodland, particularly where smaller woodland blocks become increasingly isolated within surrounding development. The South Norfolk Tree Warden Network similarly concludes that repeated hedgerow crossings, access works and disturbance must be assessed cumulatively because ecological infrastructure depends upon connectivity rather than the survival of isolated fragments.

The Applicant's reliance upon retaining individual habitat parcels therefore does not demonstrate that ecological function has been maintained. A retained woodland surrounded by development is not ecologically equivalent to one remaining embedded within an intact landscape. A retained hedgerow interrupted by repeated crossings does not perform the same function as an uninterrupted commuting corridor. A retained pond whose hydrological connections have altered is not functionally identical to its existing condition.

Ecological connectivity, rather than simple habitat area, is therefore the appropriate measure of likely significant effect.

8.3.3 Existing publicly funded conservation management

The ecological importance of the landscape is further demonstrated by the extensive public investment already made in habitat restoration. Large areas within the Order Limits have been managed under Countryside Stewardship agreements since 2013, with current agreements extending until 2028. The Site 5 objection identifies two alive Countryside Stewardship agreements covering Sites 5A and 5B—CSFREF1375492 and CSFREF829633—as shown on MAGIC on 5 July 2026. The ES does not assess what those agreements presently deliver or the consequences of terminating or displacing them. There are also live Stewardship agreements covering the western end of site 7.

These agreements have funded the creation and long-term management of habitats specifically intended to recover biodiversity within the South Norfolk Claylands. The Applicant's own surveys record the biodiversity value that has resulted from this management, including habitat supporting nationally important bat assemblages, farmland birds, botanical interest and wider ecological connectivity.

The timing is therefore highly significant. Construction of East Pye Solar is proposed immediately after the expiry of many stewardship agreements. Accordingly, habitat that has been established and maintained over many years through public funding would be removed, fragmented or substantially altered immediately after those agreements conclude. This creates an obvious contradiction.

The Applicant relies upon Biodiversity Net Gain calculations which credit the creation of future habitat while simultaneously proposing development that would remove or degrade habitat created through previous publicly funded biodiversity enhancement.

The purpose of Countryside Stewardship is to increase biodiversity across working farmland.It cannot represent good environmental planning to destroy functioning conservation habitat immediately after its successful establishment and then claim biodiversity gains by recreating different habitat elsewhere within the same development. This approach does not reflect genuine ecological enhancement. Rather, it substitutes existing functioning ecological networks with new habitat whose future condition, maturity and ecological function remain uncertain for many years.

8.4 Incomplete and unreliable ecological baseline

The reliability of every later conclusion in Chapter 8 depends upon the adequacy of the ecological baseline. Assessments of receptor value, magnitude of effect, significance, mitigation, residual effects, Biodiversity Net Gain, Habitats Regulations compliance and protected-species licensing can only be sound where the habitats, species populations, ecological functions and impact pathways have first been identified with sufficient completeness and accuracy.

That requirement is particularly important for East Pye because the Applicant's own evidence establishes an unusually sensitive ecological context. The Order Limits support a nationally important bat assemblage, fall within the functional landscape of multiple barbastelle maternity colonies, intersect a connected network of priority habitats and watercourses, and lie adjacent to ancient woodland, SSSIs, County Wildlife Sites and Roadside Nature Reserves. In that context, omissions cannot properly be treated as minor matters capable of correction by pre-construction surveys. They affect the identification and valuation of receptors, the design of the Scheme, the choice between avoidance and mitigation, and the ability of the Examining Authority to understand the likely significant effects before consent is granted.

The baseline is deficient in four principal respects:

- no full botanical survey has been undertaken despite specialist evidence that rare and important assemblages may occur in the areas most exposed to construction;
- important species and functional relationships remain incompletely surveyed or are deferred to later stages;
- the aquatic assessment is habitat-led, spatially restricted and affected by dry survey conditions that may understate seasonal connectivity and ecological importance; and
- relevant local, specialist and professionally verified evidence was not consistently identified, incorporated or reconciled with the Applicant's conclusions.

These are cumulative defects. Together, they undermine the confidence that can be placed in the Applicant's assessment of significance and in its assertion that ecological effects can be avoided or adequately mitigated.

8.4.1 Absence of a full botanical survey

The most conspicuous baseline omission is the absence of a proper full-season botanical survey.

The Applicant's extended habitat assessment expressly states that it is not a full botanical survey. Its principal purpose was broad habitat classification and preliminary ecological appraisal. Incidental recording of dominant or notable plants during UK Habitat Classification work is not equivalent to a systematic botanical survey designed to identify rare species, locally important assemblages, ancient-grassland indicators, species-rich verge communities or variations across the growing season.

That limitation is critical in the South Norfolk Claylands. The ecological interest of this landscape is frequently concentrated within narrow or linear features that may appear modest when mapped at a broad habitat level but support disproportionately important botanical communities. These include:

1. old roadside verges;
2. ancient lanes;
3. species-rich hedgebanks;
4. ditch banks and wet margins;

5. unploughed field margins;
6. former common edges;
7. Roadside Nature Reserves;
8. lowland meadow remnants;
9. woodland rides and edges;
10. pond margins and seasonally wet ground.

The historic-landscape evidence confirms that these features are surviving components of a much older and formerly more extensive network of grassland, commons, broad verges, field 'borders', ditches, ponds and ancient hedges. Professor Tom Williamson's Restoring the Claylands explains that roadside grasslands, field margins, hedgerows, ponds and minor watercourses historically formed continuous habitat networks, and that surviving fragments retain both ecological and historic significance. It also explains that older Claylands hedges commonly contain multiple woody species and that narrow grassland strips and roadside verges can provide important connectivity even where surrounded by arable farming.

Before the application was submitted, a Level 6 botanist familiar with this part of the South Norfolk Claylands advised that a full-season botanical survey was required because of the presence, or credible likelihood, of important and rare plant assemblages across the Scheme area. That evidence was supplied during the pre-application process. It was not answered by commissioning a comprehensive seasonal survey.

The omission is particularly serious because the greatest threat to botanical receptors does not necessarily arise beneath the solar panels themselves. It arises in the linear habitats selected for engineering and transport works. The Scheme proposes or allows:

- widening of narrow rural lanes;
- excavation or stripping of roadside verges;
- visibility splays;
- new and widened accesses;
- haul roads;
- construction compounds;
- temporary working areas;
- cable trenches and joint bays;
- HDD compounds;
- drainage works;
- hedgerow gaps;
- soil storage;
- vehicle overrunning and compaction.

These activities are concentrated in the very field margins, verges, hedgebanks, ditch edges and semi-natural strips where botanical interest is most likely to have survived.

The concern is reinforced by the representation concerning Parker's Lane and the designated Roadside Nature Reserve, where local evidence identifies lowland meadow interest and calls for a

full botanical and hedgerow survey before widening or crossing works are authorised. The historic loss of lowland meadow in the Claylands makes the remaining fragments particularly important. Broad habitat labels or desk-based priority-habitat mapping cannot determine the precise composition, quality or rarity of these communities.

- The absence of survey has several consequences.
- First, botanical receptors may be omitted entirely from the ES. A species or assemblage that was not searched for cannot be properly valued or assessed.
- Secondly, the Applicant cannot demonstrate that the design has followed the mitigation hierarchy. Avoidance requires the ecological resource to be identified before the location of roads, accesses, compounds, visibility splays and cable works is fixed.
- Thirdly, the BNG baseline may undervalue habitats that have been categorised at a broad level without understanding their botanical distinctiveness or condition.
- Fourthly, later discovery may leave no realistic avoidance option. By the time pre-construction surveys are carried out, the principle and broad parameters of development, compulsory-acquisition powers and access arrangements may already have been authorised.

The Applicant cannot claim that botanical harm will be avoided or mitigated when it has not established the botanical baseline in the places most likely to be damaged.

ISH1 has now resulted in a specific action requiring the Applicant to engage with local botanical evidence concerning rare plant records and the effects of proposed road widening and access works. That action materially reinforces the point made here: roadside verges, field margins and access routes cannot safely be treated as low-value construction margins before their botanical interest has been established through appropriate survey.

8.4.2 Incomplete species and functional evidence

The baseline deficiency extends beyond botany. The application contains a substantial quantity of ecological survey material, but volume does not itself establish completeness. Important species, population functions and impact pathways remain unresolved, while some essential matters are deferred to future surveys, licensing processes or contractor-led plans.

Breeding and wintering birds

The Scheme affects extensive arable land, field margins, hedgerows, grassland and stewardship habitat used by ground-nesting and farmland birds. Available evidence identifies species including skylark, lapwing, turtle dove, yellowhammer, linnet, reed bunting, bullfinch, song thrush and other red- and amber-listed birds. Local evidence also identifies a substantial winter starling murmuration and concern that major construction activity may disrupt its continued use of the area.

The baseline does not yet demonstrate that the different ecological requirements of these species have been fully assessed at the scale of the Scheme. Skylark, lapwing and turtle dove cannot be treated as one generic 'farmland bird' receptor:

- skylark require suitable open nesting and foraging conditions;
- lapwing require extensive open ground, appropriate vegetation structure and broad sightlines;
- turtle dove depend upon a different combination of nesting scrub, hedgerows, seed-rich foraging habitat and accessible water.

The earlier design history is also relevant. Areas previously presented as open habitat for nesting birds were subsequently reduced or altered without an equivalent updated assessment of the effect on lapwing or other ground-nesting species. BEPS' procedural evidence records that land within Site 7 identified as a stewardship priority for lapwing was reduced in later design iterations without a corresponding updated ecological assessment.

Where breeding-bird and badger appendices were not available for scrutiny at earlier stages, affected communities and consultees were unable to test the raw evidence, methodologies and conclusions. Any remaining gaps must be resolved through disclosed application-stage evidence rather than reliance upon later pre-construction checks.

Barbastelle roost networks and functional habitat

The Applicant's bat activity surveys are extensive and establish national importance, but that conclusion makes the remaining gaps more significant, not less.

Acoustic activity data demonstrate widespread use but do not, by themselves, fully identify:

- the individuals or colonies using each part of the Scheme;
- the hierarchy of commuting routes;
- seasonal switching between roosts;
- the relationship between maternity colonies and satellite day or night roosts;
- the location and use of winter roosts or hibernacula;
- the consequences of severing individual routes within an overlapping colony landscape.

The Norfolk Barbastelle Study Group has called for further survey and radio-tracking to establish the distribution and habitat use of maternity colonies more fully. Its evidence identifies known, newly confirmed and predicted colony locations and warns that additional woods remain insufficiently assessed. The Applicant's own activity report accepts that static detections within species emergence windows may indicate roosting resources close to survey locations and that bats are mobile animals whose full movement patterns cannot be captured through acoustic survey alone.

That is a material limitation where the Scheme would introduce repeated hedgerow gaps, fencing, lighting, road works, substations and construction activity across the whole functional landscape.

The evidence establishes widespread barbastelle presence, but does not yet map with sufficient certainty the colony-specific routes and resources that must be preserved to maintain ecological function and favourable conservation status.

Trees and roosting potential

The arboricultural and tree evidence also remains insufficiently integrated with the bat assessment. The South Norfolk Tree Warden Network identifies hundreds of trees with potential roost features and warns that a preliminary arboricultural assessment does not establish the effects of final access arrangements, construction traffic, root-zone incursions, soil compaction, trenching and altered hydrology.

Tree damage may not be immediately visible. Root severance, compression, waterlogging, drying or gradual decline may manifest years after construction. For bats, this matters because a tree shown as 'retained' in a plan may still lose roost suitability or become isolated from the dark, connected habitat upon which its ecological function depends.

The ecological baseline must therefore assess trees not merely as retained or removed landscape features, but as potential elements of a wider roost and commuting network.

Great crested newt, water vole, otter, badger and other species

The network of ponds, ghost ponds, ditches, streams, hedgerows and field margins provides potential habitat for great crested newt, water vole, otter, reptiles, badger, brown hare, hedgehog and terrestrial invertebrates. Earlier BEPS objections identified incomplete or deferred survey work for great crested newt and other species, including concern that some work was not conducted at the advised seasonal stage.

The issue is not that every species must be present at every location. It is that the Applicant has selected an extensive and connected habitat network and then relied in part on future pre-construction surveys and method statements. Those later checks cannot substitute for the information required now to determine:

- whether the chosen layout is acceptable;
- whether avoidance remains possible;
- whether protected-species licensing is likely;
- whether the residual-effect conclusions are robust;
- whether cumulative effects have been properly assessed.

Pre-construction surveys have a legitimate role in updating a valid baseline and identifying recent change. They should not be used to establish for the first time whether a receptor exists or whether the authorised design is capable of avoiding significant harm.

8.4.3 Aquatic assessment limitations and dry-condition bias

The aquatic baseline remains materially limited for a development extending across two connected catchment systems and involving numerous watercourse crossings, cable works, drainage alterations and potential pollutant pathways.

The Applicant's aquatic work was principally habitat-led. It relied upon walkover observations, desk-study data and inference from habitat condition and known records at connected locations. It was not a comprehensive programme of targeted species and community sampling throughout the affected aquatic network. That distinction is now expressly acknowledged in the Applicant's September 2026 Position Statement on White-Clawed Crayfish, which confirms that the aquatic surveys were habitat-suitability assessments rather than targeted presence/absence surveys using methods such as manual searching, hand-netting, night searching, trapping or eDNA. EN0110014-000572-8.5 Applicant'...

That does not make the surveys without value. Habitat-suitability assessment can provide relevant information about substrate, bank structure, refugia, hydrological permanence and potential impact pathways. The difficulty is that the limitations of that evidence must be recognised when conclusions are reached about the ecological value and connectivity of the wider network.

Survey conditions

The Applicant now expressly accepts that its original aquatic surveys were undertaken during unusually dry conditions and that the wetted extent, depth and in-channel habitat availability observed may therefore have under-represented typical conditions, particularly in ephemeral headwaters and field ditches. EN0110014-000572-8.5 Applicant'...

The Applicant argues that this does not materially undermine its habitat-suitability conclusions for white-clawed crayfish because important physical habitat features, including coarse substrate, stable refugia, root systems and persistent undercut banks, would remain identifiable notwithstanding low water levels. It also relies upon fine sediment, limited structural complexity, poor hydrological permanence and terrestrial succession as evidence that much of the ditch network is of low suitability. EN0110014-000572-8.5 Applicant'...

BEPS does not suggest that dry conditions automatically invalidate every habitat observation. The narrower concern is that dry-weather survey may underestimate the ecological and hydrological function of features whose importance is seasonal.

In the South Norfolk Claylands, ditches, tributaries, headwaters and ponds may form a more connected network during wetter periods. A feature recorded as dry or only weakly flowing during survey may nevertheless:

- convey sediment and pollutants during rainfall;
- provide seasonal aquatic or amphibian habitat;
- connect ponds, ditches and streams;
- support aquatic or semi-aquatic invertebrates adapted to variable flows;
- form part of groundwater recharge or discharge pathways;

- operate as a temporary headwater or refuge;
- and transmit construction effects downstream during wet conditions.

The survey limitation is therefore relevant not only to whether a particular dry ditch provides permanent crayfish habitat, but to whether the Scheme's ecological and pollution pathways have been characterised adequately under representative conditions.

The Applicant's revised position on white-clawed crayfish

The Applicant's September 2026 position materially changes the basis of the white-clawed-crayfish assessment.

The submitted ES originally relied in part upon the absence of records within the desk-study search area and referred to a single record approximately six kilometres downstream. The Applicant has now considered the information identified by BEPS concerning records from the River Tas at Saxlingham Thorpe and expressly states that it no longer relies upon the absence of records identified through the original desk study as evidence that white-clawed crayfish are absent from the wider River Tas catchment. EN0110014-000572-8.5 Applicant'...

Instead, the Applicant now assumes potential presence within the River Tas and other hydrologically connected suitable habitat on a precautionary basis. Its case is therefore no longer that the species has been demonstrated to be absent. Its case is that significant effects are not anticipated because the relevant pathways of harm are avoided or controlled through the Scheme design and secured mitigation. EN0110014-000572-8.5 Applicant'...

That is an important clarification and narrows the dispute.

BEPS does not contend that targeted presence/absence survey must invariably be undertaken where an applicant has genuinely assumed presence and assessed the relevant effects precautionarily. A precautionary assessment may in principle be sufficient if:

- the relevant receptors and connected habitats have been identified;
- every credible pathway of effect has been assessed;
- avoidance and mitigation measures are sufficiently defined;
- those measures are effective for the full authorised envelope;
- and the controls are legally secured before consent is granted.

The examination issue is therefore whether East Pye satisfies those conditions.

Reliance upon avoidance and embedded mitigation

The Applicant identifies the River Tas and Hempnall Beck as the principal sensitive aquatic receptors and states that both are designated as Avoidance Areas. It relies upon trenchless crossing methods, minimum stand-offs, launch and reception pits outside sensitive watercourse corridors, pollution prevention, sediment control and biosecurity measures, together with the Outline CEMP, OEMP, DEMP and Protected Species Mitigation Strategy. EN0110014-000572-8.5 Applicant'...

Those measures are relevant and potentially important.

However, protection of the riverbed and banks at an individual crossing does not by itself demonstrate that all indirect pathways from the authorised development have been controlled.

The Scheme extends across a much wider hydrological network. Potential pathways include:

- exposed soil and sediment mobilisation;
- runoff from access roads, haul routes and compounds;
- concrete and cementitious materials;
- fuels, oils and other chemicals;
- trenching and cable installation;
- preferential flow along cable trenches;
- groundwater interception and dewatering;
- altered drainage patterns;
- HDD drilling-fluid loss or other crossing failure;
- watercourse and ditch works;
- contaminated firewater;
- accidental pollution incidents;
- and biosecurity failures capable of transmitting crayfish plague or invasive species.

The relevant ecological question is therefore not confined to whether the Applicant directly excavates the bed of the River Tas or Hempnall Beck. It is whether construction and operation elsewhere within the connected catchment could generate effects capable of reaching those receptors or associated habitat.

The Applicant's precautionary assumption of presence increases the importance of that pathway assessment. Once potential presence is assumed, the conclusion of no significant effect depends upon demonstrating that the pathways capable of affecting that population are either absent or effectively controlled.

Reliance on inference and hydrological connectivity

The Applicant's aquatic assessment uses existing Environment Agency and other data from connected watercourses to infer likely ecological conditions where direct survey data are limited. That can be a reasonable precautionary approach. However, the same hydrological connectivity relied upon to infer ecological conditions must also be reflected when assessing effects.

It would be inconsistent to rely upon connection within the River Tas system when identifying the possible ecological community, but then assess sediment, pollution, altered flow or disease pathways only within a narrow survey reach or crossing location.

The relevant Zone of Influence follows the credible pathway of effect. For East Pye, that may extend through ditches, tributaries, groundwater pathways and downstream watercourses beyond the immediate footprint of individual works.

Absence of direct aquatic-community sampling

There remains no comprehensive programme of direct aquatic macroinvertebrate or other community sampling across the affected network. That limits the ability to establish:

- existing community composition;
- pollution-sensitive taxa;
- seasonal differences in ecological condition;
- baseline variation between connected reaches;
- aquatic prey availability for bats and birds;
- and the extent to which future change could be distinguished from natural variability.

This is relevant beyond white-clawed crayfish. The Environment Agency has raised wider aquatic-ecology issues, including fish, European eel, macroinvertebrates, water quality and the potential interaction between solar panels and aquatic insect lifecycles. The adequacy of the aquatic baseline must therefore be considered across the full receptor network rather than reduced to the question of whether white-clawed crayfish are physically present within a particular ditch.

Without a sufficiently robust baseline, post-construction monitoring may also have limited value because it may be difficult to determine whether observed ecological changes arise from the Scheme or from pre-existing natural variation.

Further survey and the 2026 drought

The Applicant confirms that no further targeted white-clawed-crayfish surveys were undertaken in 2026 and that none is presently proposed. It explains that the continuing drought would have produced conditions even less representative than those recorded during the original surveys and considers that further presence/absence work would not materially alter its assessment because potential presence is already assumed and the relevant impact pathways are said to be avoided or controlled.

BEPS accepts that additional survey undertaken in exceptionally dry conditions would not necessarily provide a more representative aquatic baseline. However, Norfolk Rivers Trust has since surveyed the Tas in September 2026 and again found white-clawed crayfish within 2km of the order limits.

Where the species is assumed present and representative seasonal survey by the applicant is not available, the assessment should demonstrate with particular clarity that:

- all connected receptors have been identified;
- all credible construction and operational pathways have been considered;
- the proposed avoidance areas are sufficiently extensive;
- indirect effects outside the immediate crossing locations are controlled;
- biosecurity measures are specific and enforceable;
- and the DCO controls prevent detailed design from introducing new pathways after consent.

Catchment-scale assessment remains necessary

The River Tas, Hempnall Beck, Broome Beck, Starston Brook and their associated ditch systems are not isolated receptors. They form connected surface-water and groundwater networks through which effects may propagate.

The Applicant's September 2026 position narrows the white-clawed-crayfish dispute but does not remove the need for catchment-scale assessment. The Applicant accepts potential presence in the wider River Tas system but concludes that significant effects are not anticipated because the principal receptors are avoided and indirect pathways will be controlled.

The central question for the Examination is therefore whether that conclusion has been demonstrated across the whole authorised Scheme.

In particular, the assessment must establish whether the combined effects of trenching, access works, drainage changes, temporary compounds, soil disturbance, HDD, dewatering, runoff, sediment generation and accidental pollution could create pathways extending beyond the immediate watercourse crossings.

The same issue applies cumulatively. A series of individually minor works distributed through a connected catchment may produce a materially different ecological risk from a single isolated crossing.

Conclusion

The Applicant has now appropriately moved away from relying upon an absence of desk-study records as evidence that white-clawed crayfish are absent from the wider River Tas catchment and instead assumes potential presence on a precautionary basis. That is a material improvement in the assessment position. It does not, however, resolve the wider aquatic-baseline issue.

The original survey was undertaken during unusually dry conditions; direct species and aquatic-community sampling remains limited; seasonal connectivity may have been under-represented; and the Scheme introduces numerous potential sediment, pollution, drainage, groundwater and biosecurity pathways throughout a connected catchment.

The appropriate examination question is therefore no longer simply whether a further crayfish presence/absence survey should be undertaken. It is whether the precautionary assessment is sufficiently complete to demonstrate that all credible pathways to assumed sensitive receptors have been identified and effectively controlled.

On the evidence presently available, BEPS submits that this has not yet been demonstrated with sufficient robustness. The Applicant's conclusion of no significant aquatic effect now depends materially upon the completeness of the catchment-scale pathway assessment and the certainty, effectiveness and enforceability of the avoidance and mitigation measures relied upon. Those matters should be resolved before the ExA reaches its conclusions on aquatic ecology and the water environment.

8.4.4 Failure to identify and incorporate local and specialist evidence

An Environmental Statement must present an accurate and sufficiently complete account of the baseline. The Applicant is not entitled to disregard relevant ecological information merely because it lies outside a selected search radius, has been supplied by local experts or was not initially returned by a commercial record search.

Local and specialist evidence is especially important for species that are under-recorded, difficult to survey or geographically restricted. The Applicant's own bat report acknowledges that absence of records does not demonstrate absence and may reflect under-recording. The same principle applies to botany, crayfish, wintering birds, roost trees and seasonal aquatic habitats.

White-clawed crayfish in the River Tas

The clearest example is the River Tas white-clawed crayfish evidence.

The Applicant's aquatic appendix stated that the data search did not return records of white-clawed crayfish within the two-kilometre search area. However, the evidence now before the Examination records:

- Environment Agency confirmation of a white-clawed crayfish found in 2020;
- a Norfolk Rivers Trust survey in October 2020 finding two juveniles, confirming breeding;
- a 2021 hand and eDNA survey finding three white-clawed crayfish;
- a further Norfolk Rivers Trust survey in 2022 reconfirming presence;
- a further Norfolk Rivers Trust survey in September 2026 reconfirming presence;
- habitat-enhancement work near the known population;
- records of river lamprey and native brown trout from the same system;
- evidence that the information was available from public and specialist sources and was supplied to the Applicant before submission.

The evidence summary states that the breeding population lies within two kilometres of part of the Scheme and that the Applicant's statement conflicts with information available from the Environment Agency, Norfolk Rivers Trust (Appendix C), Norfolk Crayfish Group and local documented evidence (Appendix D).

This is not simply a dispute over the appropriate interpretation of a record. It is a material baseline inconsistency involving a protected and priority species in a hydrologically connected chalk-stream system. The presence of juveniles is particularly significant because it establishes breeding rather than a single transient observation. Repeated confirmation in 2020, 2021, 2022 and 2026 indicates continuing use of the River Tas. The record also bears directly on:

- receptor value;
- survey scope;
- water-quality sensitivity;
- biosecurity and crayfish-plague risk;

- sediment and pollution pathways;
- the Zone of Influence;
- mitigation and monitoring requirements.

The failure to identify or incorporate that evidence undermines confidence in the wider desktop study. It also undermines the community's trust in East Pye Solar's genuine concern for local ecology.

Botanical evidence
The same concern arises in relation to the Level 6 botanist's advice. Specialist evidence was provided that the area supports important botanical assemblages and that full-season survey was required. The Applicant's broad habitat survey did not resolve that concern.

Local botanical evidence should not be dismissed merely because particular species are absent from the Applicant's desk-study return. Local survey results are in the possession of ecologists and have not been uploaded to NBIS, meaning that the online record is only a fraction of the local knowledge available. That is the reason targeted seasonal survey was requested by the local specialist botanist.

Barbastelle specialist evidence
The Norfolk Barbastelle Study Group has supplied specialist knowledge derived from long-term local survey, colony identification and radio-tracking. That work identifies known and potential maternity colonies and demonstrates the importance of connected woodland, hedgerows and agricultural mosaics.

Norfolk Barbastelle Study Group evidence and need for further colony and habitat-use surveys

The report Barbastelle Maternity Colonies in the East Pye Solar Scheme Area at December 2025 was prepared by Jane Harris on the basis of work by the Norfolk Barbastelle Study Group, a specialist group within the Norfolk and Norwich Bat Group. It provides new field evidence concerning maternity colonies and woodland use within and around the East Pye Order Limits.

The report describes the South Norfolk Claylands as an arable but structurally diverse landscape containing scattered woodlands, high hedges, pollarded trees, open fields and commons. Those features collectively provide roosting habitat, feeding resources and landscape connectivity sufficient to support a barbastelle metapopulation. The ecological receptor is therefore not confined to individual woodland roosts. It includes the connected woodland, hedgerow and open-land mosaic used by maternity colonies.

The report applies a six-kilometre Core Sustenance Zone around each maternity colony. It records that the CSZs of six colonies lie within or abut the East Pye Scheme area. Two colonies are beside the proposed cable route, and one of those would also be surrounded by solar arrays. It further

notes that other woodlands along the Scheme, particularly towards its eastern end, had not yet been surveyed for barbastelle maternity colonies.

The Study Group's 2025 work examined Spring Wood at Hempnall Green, Little Wood near Shotesham, the eastern and western sections of Brooke Wood, Lower Spring Wood and Round Wood. The selected woodlands lay immediately beside or approximately 100–400 metres from the Scheme. They included County Wildlife Sites, a component of the Shotesham–Woodton Hornbeam Woods SSSI and conifer plantations containing mature broadleaved compartments.

The investigation combined:

- winter assessment of potential roost features;
- acoustic monitoring during the pre-parturition or maternity period;
- trapping and radiotracking where access and woodland structure allowed; and
- emergence counts to estimate colony size.

The roost-potential assessment looked specifically for features associated with barbastelle, including loose or lifted bark, bark collars and slabs, splits, cracks and fissures, together with damaged, dying or dead trees. All surveyed woodlands contained suitable roost features. Little Wood was assessed as having high barbastelle roost potential, while Spring Wood, both sections of Brooke Wood, Lower Spring Wood and Round Wood were assessed as moderate.

The acoustic results produced evidence requiring further investigation. At Little Wood, barbastelle activity repeatedly exceeded the threshold used by the Study Group to predict a maternity colony. At Brooke Wood East, the maternity-colony threshold was reached on four nights, with a peak of 15 passes in the hour after sunset. At Lower Spring Wood, the threshold was exceeded on two nights. Barbastelles were also recorded in Spring Wood, although the evidence there was less conclusive, and in Round Wood at lower levels.

The prediction for Little Wood was subsequently confirmed through radiotracking under a Natural England project licence. Three female barbastelles were captured during a pre-parturition trapping session, two of which were assessed as pregnant and fitted with transmitters. Both used a roost in a tall, living but leaning ash whose twisted trunk had produced split and lifted bark. Emergence counts reached 36 before parturition. The report estimates that the post-parturition colony could comprise approximately 55 bats, which it describes as large in the context of known Norfolk maternity colonies.

This finding has wider implications for the Applicant's woodland assessment. The confirmed maternity roost was not dependent on a conventional hole or cavity in a visually intact veteran oak. It occurred beneath split and lifted bark in an ageing ash. The report explains that ash dieback is generating roost features in South Norfolk woodland and that the importance of ash woods as a barbastelle roost resource may therefore increase. Ash woodland should not be discounted because of poor tree condition or the prospect of future decline.

The surveys also show that small stands of mature broadleaved trees embedded within predominantly coniferous plantations may support maternity colonies. The mature oak belt in Brooke Wood generated acoustic evidence predicting a colony, notwithstanding the wider

plantation context. The Study Group expressly cautions that conifer plantations should not be dismissed without detailed assessment where mature broadleaved compartments and suitable bark or fissure features remain.

For Spring Wood at Hempnall Green, the report does not claim confirmation of a maternity colony. Trapping was constrained by the absence of suitable rides near the mature oak belt and by limited access. However, the timing of recorded calls, the capture results and previous acoustic evidence were considered sufficient to confirm that barbastelles roost and feed within the woodland. The precise roost status remains unresolved. This is a survey limitation requiring further work, not evidence of absence.

The Study Group's evidence therefore materially changes the assessment context. It confirms a previously unverified maternity colony, predicts further colonies and shows that apparently secondary woodland compartments may form part of the maternity-roost resource. The East Pye assessment cannot safely assume that only previously known or conventionally high-value ancient woodland blocks require maternity-colony investigation.

Required further barbastelle surveys

The report expressly calls for further radiotracking to confirm whether maternity colonies are present in:

- Brooke Wood;
- Lower Spring Wood; and
- Spring Wood at Hempnall Green.

It also states that other woodlands within or close to the Scheme should be assessed regardless of size. The candidate sites identified by the Study Group include:

- Hempnall Little Wood;
- Winters Grove;
- Ringers Grove;
- Tindall Wood;
- Sexton Wood;
- Hedenham Wood;
- Park Plantation; and
- the numerous smaller scattered woods to the east and west of Hempnall.

Saxlingham Grove is identified as already supporting a maternity colony. Ringers Grove is singled out because it is an ash wood of a similar age to Lower Spring Wood, while Tindall Wood, Sexton Wood, Hedenham Wood and Park Plantation are located towards the eastern end of the Scheme, where survey coverage remained incomplete.

The further work should not end once maternity roost trees have been located. The Study Group concludes that the effects of East Pye cannot be assessed properly without a full understanding of barbastelle distribution and habitat use within the Scheme area. In EIA terms, that requires survey evidence capable of establishing:

- the complete distribution of confirmed and probable maternity colonies;
- the woodland compartments and tree types used for roosting;
- the relationship between alternative roosts used by each colony;
- principal foraging areas;
- commuting routes between woods and feeding habitats;
- the use of hedgerows, tree lines, ponds, watercourses and woodland edges;
- the areas of overlap between the Scheme and the six-kilometre CSZs;
- and the effects of cable routes, access works, panel arrays, substations, fencing and lighting upon that functional network.

Radiotracking is particularly important because static acoustic detectors can establish activity and support a prediction of nearby roosting, but cannot by themselves identify the full movement network, the particular maternity colony using a route or the relative importance of different fields and linear features. Acoustic monitoring remains useful for screening additional woods, but probable colonies identified acoustically should then be tested through appropriately licensed trapping and radiotracking.

The survey programme should also be designed around the limitations encountered in 2025. Lack of rides or convenient trapping locations should not be treated as proof that a colony is absent. Alternative detector positioning, longer deployment, additional access arrangements and suitable licensed methods should be considered where woodland structure makes conventional trapping difficult.

These surveys are necessary before the Applicant can establish the reasonable worst-case effect of:

- repeated hedgerow severance;
- lighting of otherwise dark routes;
- noise and vibration near maternity woods;
- panel development surrounding a colony-support area;
- cable and haul-road works beside colonies;
- and cumulative loss or compression of foraging habitat within overlapping CSZs.

Later pre-construction checks would not provide an adequate substitute. By that point, the principal development areas, access routes and cable alignments may have been authorised. The purpose of the further work must be to inform avoidance and design, including removal or relocation of development from the most important maternity-colony support landscapes.

The Study Group's evidence therefore supports a clear conclusion: the known maternity-colony baseline has expanded, additional colonies are predicted, several candidate woodlands remain unassessed and the functional habitat use of overlapping colonies has not yet been mapped comprehensively. Until that work is complete, the Applicant cannot demonstrate that the proposed mitigation will maintain the integrity and connectivity of the South Norfolk barbastelle metapopulation.

The Applicant did use some NBSG information in its desk study, but the Study Group's call for further work remains material. Where the specialist body concludes that the maternity-colony landscape is not yet fully understood, the Applicant cannot rely solely on its acoustic survey to assert that generic buffers and retained hedges will preserve function.

8.4.5 Consequences for the Environmental Statement

These baseline defects affect the whole of the ecology case.

They undermine:

- the valuation of receptors;
- the assessment of magnitude and significance;
- the delineation of the Zone of Influence;
- the alternatives and design process;
- the ability to demonstrate avoidance;
- the formulation of species-specific mitigation;
- the BNG baseline and claimed gains;
- the HRA screening conclusions;
- the assessment of EPS licensing prospects;
- the cumulative-effects assessment;
- the enforceability and effectiveness of the OLEMP and protected-species strategies.

The Applicant may argue that later surveys can inform detailed design or licensing. That does not answer the present objection. Later surveys can update a sufficiently complete baseline; they cannot lawfully cure a situation in which the Examining Authority is being asked to approve the principle, parameters and compulsory powers of the development without knowing the full ecological resource or whether avoidance is possible. Several of the outstanding ecological matters are not questions of detailed design but questions of environmental knowledge. The Applicant still lacks, or has only recently begun to obtain or supplement, important information concerning botany, aquatic ecology and the functional use of the landscape by protected species. Those matters are capable of determining where development can safely occur, what avoidance is required, what mitigation is feasible and whether the authorised development can remain within the effects assessed. They therefore go to the environmental acceptability of the authorised envelope itself, not merely to its later implementation.

The appropriate sequence is:

- identify the receptors and ecological functions;
- establish their value and sensitivity;
- define the full Zone of Influence;
- redesign to avoid harm;
- assess the residual effects;
- specify and secure mitigation;

- consider compensation only as a last resort.

East Pye Solar has not completed that sequence. In several important respects, it has fixed the development envelope and deferred the information required to determine whether that envelope is ecologically acceptable.

BEPS therefore submits that the ecological baseline is not sufficiently complete, accurate or reliable to support the Applicant's conclusions of limited residual effect. Until the botanical, species, aquatic and functional gaps are remedied and all relevant specialist evidence is incorporated into a revised assessment, the Examining Authority cannot safely conclude that likely significant ecological effects have been identified, avoided or adequately mitigated.

Strategic Ecological Network Conflict
The Norfolk Green Infrastructure Map (NBIS, 2017) and the South Norfolk Ecological Network identify the application area as forming part of a connected landscape of Strategic GI Corridors, woodland core areas, wetland cores (including the River Tas chalk stream system), and grassland/heath cores. The East Pye Solar red line boundary and Cable Route Corridor intersect and fragment these corridors at multiple points.

The scheme is not located in an ecologically degraded or isolated landscape; it sits within an identified strategic connectivity network intended to maintain habitat permeability across South Norfolk. Industrialisation of this landscape through panel arrays, fencing, security lighting, internal roads, substations and cable corridors would:

- Sever functional habitat linkages between woodland blocks (including known barbastelle maternity areas);
- Disrupt hydrological connectivity between agricultural land and chalk stream corridors;
- Fragment grassland and farmland bird territories;
- Introduce hard barriers across mapped GI corridors contrary to the ecological network approach embedded in national and local policy.

The ES does not assess fragmentation of the Strategic GI network as a discrete impact. There is no landscape-scale connectivity analysis, no permeability modelling, and no assessment of cumulative corridor compression with other NSIP solar and grid infrastructure in the area.

In these circumstances, the scheme conflicts with the established South Norfolk ecological network framework and fails to demonstrate compliance with NPS EN-1 (2023) requirements to avoid significant harm to biodiversity and maintain ecological coherence.

8.4.6 Barbastelle Bats

Where a proposed NSIP is located wholly within overlapping Core Sustenance Zones for barbastelle bats and directly adjacent to multiple ancient woodlands supporting maternity

colonies, the impacts of construction disturbance, habitat fragmentation, lighting, noise and long-term landscape disruption are **intrinsic to the scheme** and **cannot be reduced to a level that avoids adverse effects on the local barbastelle population's favourable conservation status**.

As such, the effects are **not capable of mitigation**, and the scheme is fundamentally incompatible with the Habitats Regulations.

8.5 Nationally important bat assemblage and barbastelle maternity-colony landscape

The Applicant's bat evidence is one of the most consequential parts of the Environmental Statement. It does not describe a landscape of merely moderate value in which bats make occasional use of retained boundaries. It identifies a diverse bat assemblage of national importance, widespread and unusually high activity across the Order Limits, and scheme-wide use by barbastelle, one of the rarest and most conservation-sensitive British bats.

That finding must govern the assessment of the Scheme. It is not consistent to assign national importance to the bat assemblage and then assess the effects of industrialising the same landscape principally by reference to the retention of individual hedgerows, woodland buffers and future habitat enhancement. The issue is whether the Scheme would preserve the functional relationships between maternity roosts, satellite roosts, woodland, wetland, hedgerows, field margins and dark commuting routes across the whole landscape.

The evidence does not presently establish that it would.

8.5.1 The Applicant's finding of national importance

The Bat Activity Survey Report evaluated the bat assemblage using the geographic framework in the UK Bat Mitigation Guidelines. The Applicant recorded eleven bat species during the combined survey programme, together with calls identified to broader species groups. Those records included common and soprano pipistrelle, brown long-eared bat, noctule, Natterer's bat, Daubenton's bat, serotine, Leisler's bat, Nathusius' pipistrelle, whiskered bat and barbastelle.

The Applicant calculated an assemblage score of 22 against a maximum possible regional score of 28. That represents 78% of the maximum and exceeds the 70% threshold used by the Applicant to identify an assemblage of national importance. It accordingly concluded that the Order Limits support habitats of up to national-level importance for commuting and foraging bats.

This is a significant admission. The national value does not arise from one woodland, one roost tree or one unusually active detector. The Applicant records between seven and ten species at each detector location, with activity distributed across the Scheme. The conclusion therefore concerns the landscape as a whole.

The Applicant also states that the recorded activity was greater than would ordinarily be expected from habitats it had classified as being of only moderate quality. That apparent tension should not be resolved by downgrading the bats. It shows that broad habitat classification has failed to

capture the functional value of the South Norfolk Claylands network. Arable fields considered individually may appear commonplace, but their value changes where they are interwoven with mature hedges, woodland edges, ponds, streams, wet corridors and multiple maternity colonies.

The proper conclusion is therefore that the ecological value of the Order Limits is expressed through landscape function rather than habitat labels alone. The very features affected by the Scheme—field boundaries, dark lanes, woodland edges, margins and watercourses—combine to support a nationally important assemblage.

8.5.2 Barbastelle abundance, distribution and significance

Barbastelle is central to that national-importance conclusion. It is a rare, woodland-associated, light-averse bat protected as a European Protected Species and listed in Annex II of the Habitats Directive. It depends upon a network of roosts and extensive, connected foraging habitat rather than a single fixed roost feature.

The Applicant's static detectors recorded 11,699 barbastelle passes during the combined survey period. Barbastelle was the third most frequently recorded species, after common and soprano pipistrelle, with a reported mean Bat Activity Index of 23.12 passes per hour. The Applicant itself describes this as indicating high use of the Order Limits.

The percentage of all calls attributable to barbastelle should not be misunderstood. Common pipistrelles are among the most abundant bats in Britain, whereas barbastelles are rare and more restricted. The Applicant expressly acknowledges that activity figures must be interpreted in the context of species rarity and that lower absolute numbers for barbastelle may carry much greater ecological significance than similar numbers for common species.

Most importantly, barbastelle was recorded at every static detector location across the Order Limits. The detections extended across all principal development areas, including the BESS and substation landscape, Sites 1 to 10 and the intervening field-boundary network. Barbastelle was also encountered on thirteen of the sixteen night-time walkover routes across the combined annual survey period.

This distribution is not consistent with a small number of isolated bats occasionally crossing the Scheme. It demonstrates landscape-scale use.

The activity data include several locations with very substantial numbers of barbastelle passes, including:

- approximately 1,395 passes at the detector in Sub-Site 2B;
- approximately 1,362 passes at Site 3;
- approximately 1,170 passes around 7F/7G;
- approximately 1,119 passes at 10B;
- approximately 806 passes at 7C;
- and hundreds of further passes at numerous other locations.

The precise figures require care because an acoustic pass does not represent a unique individual. However, that limitation does not reduce the importance of the distribution. Repeated detections over several months and across the full extent of the Order Limits establish sustained and widespread habitat use.

The Applicant also recorded barbastelles within the expected emergence window at several locations, including areas associated with 7H, Site 3 and 7C. It acknowledges that these records may indicate roosting features within or immediately adjacent to the affected landscape. That raises the possibility of additional day, night or satellite roosts supporting the known maternity populations.

The Applicant's own conclusion is therefore unavoidable: barbastelle activity throughout the Order Limits is high, ubiquitous and ecologically significant.

8.5.3 Multiple maternity colonies and overlapping Core Sustenance Zones

The Scheme lies within an exceptional concentration of barbastelle maternity-colony habitat.

The Applicant's desk study records information from the Norfolk Barbastelle Study Group concerning multiple maternity colonies whose Core Sustenance Zones overlap the Order Limits. Known colonies identified in the Applicant's material include:

- Saxlingham Grove;
- Spring Wood;
- Little Wood;
- Brooke Wood;
- Tyrrells Wood;
- Smockmill Common;
- Gawdy Hall Woods;
- Tacolneston;
- and Earsham Woods.

The Applicant states that the Order Limits lie within the published six-kilometre Core Sustenance Zones of nine known colonies and that the combined zones associated with several of the closest colonies cover the entire Scheme. The colony network therefore extends far beyond the formal boundary of any single woodland.

The Norfolk Barbastelle Study Group's evidence makes the position still more important. Its work identified a newly confirmed maternity colony at Little Wood near Shotesham and indicated that further maternity colonies were likely at Brooke Wood and Lower Spring Wood. Updated radiotracking in 2025 confirmed the Little Wood colony, with a pre-parturition emergence count of approximately 36 bats and an estimated larger post-parturition population. The Study Group's mapping shows that the six-kilometre Core Sustenance Zones of at least six known maternity colonies lie within or abut the Scheme area.

Core Sustenance Zones are not exclusion zones in themselves, but they identify the landscape within which maternity colonies are expected to obtain the resources necessary to persist. Within

that landscape, the importance of any individual field cannot be understood solely by the number of calls recorded there on a limited number of nights. Maternity colonies use networks of woodland roosts, switch between trees, travel along hedges and streams and exploit changing concentrations of insect prey across the season.

The Applicant's own review of Norfolk barbastelle ecology states that tracked maternity-colony bats travel an average of approximately 3.5 kilometres from their woodland roosts and that the most intensively studied individuals did not travel beyond approximately 5.5 kilometres. It describes woodland as both roosting and foraging habitat and identifies surrounding arable mosaics, particularly those containing linear features, as important foraging landscapes. These figures explain why the whole East Pye landscape, rather than simply the woodland containing each roost tree, must be assessed as functional habitat.

The effect of multiple overlapping zones is also cumulative. A hedge, stream corridor or woodland edge may be used by bats from more than one colony. Damage to such a feature may therefore affect connectivity within a wider metapopulation network rather than a single local roost.

No colony-by-colony functional analysis has been supplied showing:

- which colonies use each part of the Order Limits;
- the principal and secondary flight routes;
- seasonal differences in habitat use;
- the proportion of each colony's core habitat affected;
- whether bats can divert around lit or obstructed routes;
- or the cumulative consequences of repeated disturbance across overlapping zones.

In the absence of that work, the Applicant cannot demonstrate that retaining selected hedgerows and applying standard woodland buffers will maintain the ecological function of the maternity-colony landscape.

8.5.4 The Norfolk Barbastelle Study Group's call for further survey

The Norfolk Barbastelle Study Group's evidence is especially important because it is based upon long-term local expertise, colony identification, trapping and radiotracking rather than acoustic activity alone.

The Study Group concluded that the impacts of East Pye Solar cannot properly be assessed without a fuller understanding of barbastelle distribution and habitat use within the Scheme area. It identified further woodlands requiring investigation and predicted additional maternity colonies on the basis of acoustic evidence and the known structure of the local population.

Further work is needed to establish:

- the complete distribution of maternity roosts;
- use of satellite and alternative tree roosts;
- the functional relationship between the known colonies;
- principal commuting and foraging routes;

- the role of individual hedges, lanes, woodland edges and watercourses;
- seasonal and weather-related variations in use;
- and the relationship between the solar sites, cable corridors and colony home ranges.

Acoustic detectors are valuable for confirming species presence and relative activity. They cannot reliably identify the colony of origin, distinguish the number of individuals responsible for repeated passes or map the complete nightly movement of bats through a complex landscape. Radiotracking is therefore particularly important where the legal and ecological question concerns the maintenance of maternity-colony function.

The Applicant should not be permitted to treat the Study Group's work merely as contextual desk-study information while declining to undertake the functional analysis that the evidence indicates is required. The Applicant's own report accepts that bats are highly mobile, may leave survey areas quickly and cannot have all their flight paths captured through the chosen surveys.

The baseline is therefore simultaneously sufficient to establish very high sensitivity but insufficient to demonstrate that the Scheme's effects can be avoided.

That distinction is important. Incompleteness cannot be used to downgrade the receptor. The known evidence establishes national importance and widespread barbastelle use. The remaining uncertainty concerns the full scale of the impact and the adequacy of mitigation. In accordance with the precautionary approach, that uncertainty weighs against authorising development rather than in its favour.

8.5.5 SSSI and ancient-woodland maternity-roost landscape

Many of the woods supporting known or likely barbastelle colonies form part of nationally designated or irreplaceable habitat networks.

The relevant woodland landscape includes, among others:

- Saxlingham Grove within the Shotesham–Woodton Hornbeam Woods SSSI complex;
- Little Wood close to the Site 7 and Site 8 landscape;
- Spring Wood adjacent to Site 3;
- Hempnall Little Wood;
- Hedenham Wood SSSI close to Site 10;
- Brooke Wood;
- Tyrrells Wood;
- and other ancient and semi-natural woodland blocks connected by hedges, streams and lanes.

The Applicant records the Saxlingham Grove maternity colony very close to the Order Limits. Historic records include peak emergence counts of up to 30 bats from roosts in ash and oak trees, further counts from a dead oak, and the discovery of a lactating female. The woodland shares boundaries with parts of the proposed development landscape.

The fact that bats may not be named in every SSSI citation does not make their use of those woods irrelevant. A SSSI citation records the notified interest features for which the site was designated; it does not exhaust the site's ecological value. Where nationally important protected-species populations use the woodland and depend upon its surrounding habitat network, effects on that use remain material to the ecological assessment, the planning balance and protected-species law.

The Forestry Commission identifies six ancient woodlands directly adjacent to the Scheme:

- Saxlingham Grove;
- Doyly's Grove;
- Popes Wood;
- Spring Wood;
- Little Wood;
- and Ringers Grove.

It warns that fragmentation is one of the greatest threats to ancient woodland and expresses particular concern about the isolation of Doyly's Grove and the near-enclosure of Ringers Grove. That concern is directly relevant to bats. Woodland does not provide equivalent ecological function where it is retained as an island inside a fenced, lit and operational energy development but separated from its former dark, permeable surroundings.

The relevant indirect effects include:

- loss or interruption of dark flight routes;
- artificial lighting at woodland edges;
- construction noise and vibration;
- increased vehicle movements;
- dust and changes to air quality;
- altered drainage and groundwater conditions;
- loss of insect-rich margins;
- security fencing and access infrastructure;
- and the cumulative enclosure of woodland by panel arrays.

Standard buffer distances do not demonstrate that these processes will be avoided. A buffer may protect roots or prevent direct excavation, but it does not by itself preserve the broader ecological setting, colony connectivity or the darkness and prey resources required by barbastelles.

Natural England's own Relevant Representation identifies protected-species licensing as an unresolved amber matter and advises that the need for licences should be clarified at the earliest opportunity. It also identifies several SSSIs and ancient woodlands that are hydrologically linked to the Order Limits and states that the measures relied upon to protect designated sites must be secured.

Although Natural England is presently broadly satisfied with the Applicant's designated-site conclusions, that position is expressly conditional upon mitigation being followed and secured. It

does not answer the separate scheme-wide question of whether the barbastelle maternity-colony network, including supporting habitat outside designated boundaries, will remain functional.

8.5.6 Hibernacula, satellite roosts and year-round habitat function

The ecological assessment should not be confined to summer maternity activity.

Barbastelles use numerous tree roosts and may switch roost frequently. The Applicant's report acknowledges that woodland populations use a network of roost sites and that barns may also be important outside the maternity period. It records evidence that Norfolk barbastelles remain active in winter and frequently use woodland rather than relying principally upon conventional underground hibernation sites.

The wider Scheme landscape also contains purpose-built bat hibernacula in former Second World War structures adjoining Spring Wood and the Site 3 landscape. The former airfield bomb shelters or bunkers were adapted by the Norfolk Bat Group for bat use and are reported to support a range of bat species. The known presence of these structures adds a further year-round function to the local bat network.

Even where the Scheme does not directly destroy a maternity roost or hibernaculum, it may affect its functionality by altering the habitats through which bats reach it and the food resources available after emergence. The legal protection afforded to breeding sites and resting places cannot be reduced to preservation of the physical cavity alone. A retained roost may nevertheless be disturbed, obstructed or rendered less viable if:

- its emergence route is lit;
- nearby vegetation is removed;
- access to commuting corridors is severed;
- construction noise or vibration causes disturbance;
- surrounding foraging habitat is degraded;
- or repeated vehicle and human activity alters use of the site.

The Applicant has not supplied an integrated year-round assessment drawing together:

- maternity-colony use;
- satellite roosts;
- potential roost trees;
- autumn activity;
- winter activity;
- known hibernacula;
- construction noise and vibration;
- and dark-corridor connectivity.

This is especially concerning because pile driving remains within the construction envelope and is identified in the Scheme's own material as a principal source of construction noise and vibration. There is no adequate species-specific analysis of whether prolonged percussive piling, HDD, heavy

traffic and compound activity could disturb roosting or hibernating bats within the surrounding woodland and built structures.

The effect cannot safely be deferred to an Ecological Clerk of Works or a pre-construction check. Those measures may reduce the risk of immediate harm to an occupied feature, but they cannot determine whether the authorised construction methodology is compatible with the continued function of the wider roost network.

8.5.7 Natural England's favourable conservation status guidance

Natural England published its *Definition of Favourable Conservation Status for barbastelle bat* (RP2974) in March 2024. It is directly relevant to the assessment of East Pye because it identifies, at national level, the ecological conditions required for *Barbastella barbastellus* to thrive sustainably and the principal pressures preventing that outcome.

Natural England defines favourable conservation status ("FCS") as the minimum threshold at which there can be confidence that a species is thriving in England and is expected to continue to thrive sustainably in the future. It assesses three interdependent parameters: natural range and distribution; population; and the extent and quality of habitat supporting that population.

The central fact is that Natural England does **not** consider barbastelle presently to be at favourable conservation status. Its assessment records a current estimated English population of approximately 21,000–42,000 individuals but defines the favourable population as 73,000–147,000 individuals. It estimates approximately 10,435 km^2 of supporting habitat within the species' predicted English range and defines the favourable supporting-habitat requirement as approximately 11,700 km^2. Favourable status therefore requires not merely maintenance of the present position but a substantial increase in population, expansion of supporting habitat and restoration into parts of the species' historic range.

This distinction is fundamental to East Pye. The appropriate conservation context is not one in which there is ecological headroom to absorb incremental deterioration of otherwise unimportant habitat. Natural England's national objective is recovery: more barbastelles, more suitable habitat, greater connectivity and expansion of the species' range.

8.5.7.1 The ecological requirements identified by Natural England

Natural England describes barbastelle as closely associated with broadleaved woodland containing substantial numbers of veteran, dead and dying trees. The species predominantly roosts beneath loose bark and within narrow splits and cavities. It switches roosts frequently and therefore requires a large resource of alternative suitable trees rather than protection of a single identified roost tree. A colony may use as many as 50 different roosts during one summer, with roosts typically distributed over approximately 100–200 hectares and, in some recorded cases, considerably more. Females show fidelity to maternity-roost areas between years.

This has an important consequence for the assessment of East Pye. The relevant breeding resource is not simply the particular tree occupied on the night of a survey. The ecological unit is a wider

roost network containing sufficient existing and future roost features to allow repeated switching throughout the breeding season and between years.

Natural England also emphasises the scale of the species' foraging requirements. Barbastelles are specialist moth predators. They favour woodland and riparian habitats with high structural diversity, but in agricultural landscapes they also depend substantially upon woodland edges, treelines, hedgerows, field boundaries, meadows and riparian vegetation. Bats repeatedly forage along the interface between dense vegetation and open ground. Most foraging occurs within approximately 7 km of roosts, but movements exceeding 20 km have been recorded. Female home ranges are generally very large, commonly approximately 400–1,500 hectares, with much larger individual ranges also documented.

Particularly important for East Pye is Natural England's evidence that individual breeding females may use largely private foraging areas and exhibit fidelity to those areas between years. Habitat cannot therefore safely be treated as interchangeable merely because another field or new grassland exists elsewhere within a six-kilometre radius. The ecological significance of particular feeding areas and connecting routes depends upon how the colony actually uses the landscape.

Natural England further identifies barbastelle as strongly light-averse. Its national modelling found light pollution to be an important predictor of both broad-scale distribution and maternity-colony habitat suitability. Genomic evidence is cited showing that artificial lighting negatively affects connectivity between barbastelle colonies, whereas broadleaved woodland and riparian habitats facilitate gene flow. Natural England identifies increasing rural light pollution as a significant future threat because of both habitat fragmentation and effects upon the moth prey on which barbastelles depend.

The FCS definition also identifies disturbance as a relevant pressure. Barbastelles generally select roost sites away from human disturbance, and Natural England records evidence of maternity roosts being abandoned following human approach, while appropriately acknowledging that sensitivity is site-specific and that some colonies can habituate to existing activity. It nevertheless concludes that increased anthropogenic disturbance at roost sites is likely to affect populations adversely, particularly during the summer breeding period when females are rearing young.

Natural England's definition therefore describes a species dependent upon a combination of:

- numerous mature and deteriorating roost trees within extensive woodland roost networks;
- structurally diverse woodland and riparian feeding habitat;
- mature hedgerows and treelines in agricultural landscapes;
- abundant moth prey;
- extensive home ranges;
- established and connected foraging areas;
- dark landscapes;
- and low disturbance around sensitive roosting areas.

Those characteristics closely correspond with the ecological features repeatedly identified within the East Pye landscape.

8.5.7.2 Natural England identifies habitat fragmentation and artificial lighting as constraints on recovery

The FCS report is particularly significant because Natural England does not simply describe suitable habitat. It identifies what must change if barbastelles are to recover.

Natural England states that low population density and slow population growth make barbastelles particularly vulnerable to loss and fragmentation of preferred woodland habitat. It identifies the availability of suitable woodland roosting habitat as likely to be the principal factor limiting population size and distribution. It further identifies lack of broadleaved woodland and the incursion of artificial lighting which prevents landscape connectivity as limiting factors on expansion.

Its prescribed ecological direction is therefore clear. Existing and potential roost sites should be protected from disturbance and development; old-growth woodland loss should be reversed; veteran, standing dead and decaying trees should increase; broadleaved woodland should increase; wetland and woodland habitat capable of supporting high moth biomass should be restored; hedgerows and treelines should be maintained and improved; and landscape connectivity should remain free from artificial-light barriers. Natural England also states that conditions should be provided which maintain gene flow between populations.

Natural England additionally stresses the importance of finding currently undiscovered maternity colonies. It concludes that locating new colonies should be a priority because substantial areas have received insufficient advanced survey effort and because reliable information on colony distribution is necessary to understand population structure.

That is directly relevant to the Norfolk Barbastelle Study Group's evidence for East Pye. Independent survey has already identified additional maternity-colony activity beyond the baseline initially understood by the Applicant, while further woodlands remain unresolved and further radiotracking has been recommended. The national FCS guidance therefore supports, rather than diminishes, the case for completing that work before conclusions are reached about the capacity of this landscape to accommodate the Scheme.

8.5.7.3 Replacement habitat is not equivalent in the short or medium term

One of the most important passages in Natural England's FCS definition concerns the assumption that habitat loss can be offset by future woodland or roost creation.

Natural England states that new woodland is unlikely to provide sufficient natural roosting opportunities for a barbastelle colony for **perhaps 50 years or more**. Even within established woodland whose management has reduced roost opportunities, it may take **at least 30 years** of favourable management before barbastelle use increases significantly. Natural England consequently concludes that there is currently **no known proven mitigation or compensation for the loss of barbastelle woodland roosting habitat over the short to medium term**.

That evidence is directly relevant to the Applicant's reliance upon new woodland, hedgerow reinforcement, habitat creation and BNG.

A habitat metric may attribute future units to newly created woodland or hedges. That does not make those habitats functionally equivalent for barbastelles when the effect occurs. A newly planted woodland cannot supply an established network of loose bark, damaged limbs, fissures, cavities, standing deadwood and alternative tree roosts. A replanted hedgerow cannot immediately reproduce the height, density, moth biomass, shelter and route familiarity of a mature boundary used by a maternity colony.

The distinction is particularly important over the reproductive timescale of an animal. A colony cannot wait 30 or 50 years for replacement habitat to acquire the features required to replace habitat lost or functionally degraded today.

8.5.7.4 East Pye Solar against Natural England's FCS requirements

When Natural England's requirements are set against the actual East Pye development, there is a marked tension between the ecological conditions necessary for national recovery and the effects which the Scheme is capable of producing.

The Applicant itself identified at scoping stage that, in the absence of mitigation and enhancement, construction, operation and decommissioning could cause:

- habitat loss, disturbance and fragmentation;
- disturbance, displacement or mortality of wildlife;
- disturbance, damage or loss of protected-species breeding sites, hibernation sites or resting places;
- noise and visual disturbance;
- dust and other pollution;
- indirect disturbance from noise, vibration and surface-water runoff;
- and disturbance associated with plant, vehicles and workers.

The Applicant expressly identified those pathways as potentially significant ecological effects. It also acknowledged that some operational effects could remain for the lifetime of the Scheme.

That is important because those pathways correspond closely with the pressures identified by Natural England as threatening barbastelle recovery.

1. Landscape-scale construction disturbance

Construction is not confined to a single compact compound. The Scheme comprises multiple solar sites, cable corridors, access routes, substations, BESS and grid infrastructure distributed through the same wider landscape used by barbastelles.

The Applicant envisaged an approximately 24-month construction programme with the possibility of multiple crews operating concurrently on larger sub-sites. Construction compounds include hardstanding, vehicle parking, secure storage, fencing and temporary lighting. Construction may also extend beyond normal daytime working for abnormal-load deliveries, concrete pours, highway cable works and HDD. Hedgerow removal is expressly contemplated where avoidance is not practicable.

The cable corridor alone was expected to involve multiple working fronts or sequential progression through the landscape, with open trenching used for much of the route and trenchless techniques at selected locations. The Applicant's scoping assumptions also contemplated substantial construction staffing and vehicle activity distributed across the Scheme.

Against Natural England's evidence, the relevant question is therefore not whether any single work site occupies a small fraction of a six-kilometre Core Sustenance Zone. It is whether multiple simultaneous or successive disturbances affect the network of roosts, feeding areas and flight paths upon which one or more maternity colonies depend.

2. Disturbance close to maternity woodlands

Norfolk Wildlife Trust has specifically advised that cabling should be kept away from woods, particularly those containing bat maternity colonies. It identifies noise and vibration as a risk to maternity colonies and recommends avoidance of working close to such woods during the maternity period from mid-June to the end of July. Importantly, it says that this restriction should apply not only during initial construction but also during large-scale maintenance and ultimate removal of the panels.

That advice corresponds closely with Natural England's warning that disturbance at maternity roosts is a particular concern during the period in which females are rearing pups.

The application must therefore demonstrate, woodland by woodland, that piling, HDD, trenching, vegetation removal, HGV movements and other high-disturbance operations will not adversely affect maternity-colony function. A generic CEMP commitment to minimise noise is not a substitute for colony-specific assessment.

3. Hedgerow severance and alteration of commuting habitat

Natural England expressly includes woody linear features—hedgerows and treelines—within the supporting habitat required by barbastelles. Its FCS modelling incorporates such features because they contribute to foraging and connectivity in agricultural landscapes. It also identifies maintaining and improving hedgerows and treelines as part of the habitat response necessary to achieve favourable status.

East Pye, however, requires cable, access and highway crossings through a landscape in which hedgerows form much of the remaining semi-natural network. The Applicant stated from the outset that some hedgerow removal would be required where avoidance was not practicable.

The ecological effect cannot be assessed merely by totalling kilometres of hedgerow retained or restored. A comparatively short gap may affect an important flight line between a maternity woodland and a feeding area, while a much greater length elsewhere may be irrelevant to that particular colony. Natural England's evidence about foraging-site fidelity makes this especially important: individual females may return repeatedly to established feeding areas and routes between years. Accordingly, the Applicant must establish the importance of the particular hedge being crossed before concluding that its removal and later reinstatement are insignificant.

4. Artificial lighting within a presently dark landscape

There is an especially direct conflict between Natural England's FCS evidence and the introduction of artificial lighting.

Natural England identifies artificial lighting as a factor reducing habitat suitability and connectivity. Its genomic evidence indicates that lighting negatively affects connectivity between colonies, and it regards increasing rural light pollution as a considerable threat to barbastelles over coming decades.

East Pye introduces both temporary and operational lighting into the same landscape. The Applicant has accepted the need for temporary construction lighting during periods of darkness, including circumstances in which works may take place outside normal hours. The wider project proposals also include lighting associated with substations, ancillary electrical infrastructure and the BESS. Earlier consultation material specifically identified motion-sensing security lighting at such infrastructure.Norfolk Wildlife Trust accordingly requests no construction or operational lighting in core areas, particularly near woodland.

For a species whose national recovery requires landscape connectivity **not impacted by artificial lighting**, it is not sufficient to say that lights will be "sensitive", directed away from hedges or switched off when unnecessary. The Applicant must demonstrate spatially, by quantitative lighting design and lux modelling, that the network used by the maternity colonies will remain dark and functional throughout construction, operation, maintenance and replacement.

5. Foraging habitat and prey resource

Natural England describes barbastelle as a moth specialist and expressly links favourable status to the availability of high-moth-biomass woodland, wetland, riparian vegetation, hedges and treelines. It identifies declines in moth populations as a serious concern and states that agricultural practices which reduce moth abundance can have considerable adverse effects upon barbastelle populations.

The potential effect of East Pye therefore extends beyond the retention or removal of trees. The Scheme changes a very large agricultural landscape through arrays, fencing, new grassland regimes, drainage alterations, new woodland and hedgerow planting, access tracks, substations and long-term vegetation management.

Some of those changes may improve prey resources; cessation of intensive agricultural inputs and new species-rich grassland could benefit moths and other insects. Those potential benefits should be acknowledged. But they do not establish that the Scheme will improve the particular foraging resource used by the existing maternity colonies.

Natural England's evidence that females display strong fidelity to individual foraging areas means that the appropriate assessment is not whether the Scheme creates more generic "biodiversity" somewhere within the Order Limits. It is whether the known colonies retain sufficient productive feeding habitat, in the locations and configurations they actually use, throughout the period before

any new habitat becomes ecologically mature. That question requires radiotracking and colony-specific habitat-use evidence.

6. Woodland-edge effects and roost-tree resource

The Applicant's original baseline recognised that hedgerows, lines of trees, woodland and ditches throughout the Scheme provide bat foraging and commuting habitat and acknowledged barbastelle maternity roosts in the surrounding landscape. It also identified trees with potential roost features for further investigation.

Natural England's FCS evidence demonstrates why protecting only a known occupied tree would be inadequate. Barbastelles may use dozens of roost trees during a season, and the high turnover of loose-bark and similar features requires a continuing supply of damaged, dying and veteran trees. Any assessment of East Pye must consequently address not only direct felling but also:

- root damage and compaction;
- altered drainage;
- lighting of woodland edges;
- pruning for accesses and visibility;
- noise and vibration;
- loss of adjacent feeding habitat;
- and long-term management that could remove dying or damaged trees for safety or operational reasons.

Natural England's FCS objective is to **increase** the availability of veteran, dead and decaying trees and protect existing and potential roost sites from development and disturbance.

That objective should be used as the benchmark against which the Applicant's proposals for every maternity woodland and associated tree network are tested.

7. Operational duration and repeated disturbance

East Pye is proposed to operate for up to 60 years. The Applicant expressly defines the operational period as including maintenance and equipment replacement. Its own ecological scoping assessment recognised potential disturbance, damage or loss of protected-species breeding or resting sites during panel replacement and acknowledged that some operational effects could remain for the lifetime of the Scheme.

This has particular significance for barbastelle because 60 years is longer than the period Natural England considers may be required for newly established woodland to begin providing sufficient natural roost opportunities.

The Scheme therefore cannot be assessed as a single two-year disturbance followed by six decades of ecological inactivity. Over that period there may be:

- repeated panel replacement;
- BESS replacement;

- transformer and inverter maintenance;
- cable repair;
- vegetation management;
- access by heavy vehicles;
- lighting for maintenance and emergencies;
- and eventual decommissioning.

Those activities must be incorporated into the assessment of each colony's long-term ability to occupy its roost network and feeding landscape.

The central conflict

Natural England's national recovery requirements and East Pye's potential effects can be stated simply.

Natural England says favourable status requires	East Pye introduces or permits
Increasing the barbastelle population substantially above its current estimate	Development through a landscape supporting multiple maternity colonies
More suitable supporting habitat	Conversion and long-term alteration of extensive colony-support landscapes
Protection of existing and potential roost sites from development and disturbance	Construction, access, cable and operational activities close to woodland and potential roost trees
More veteran, dead and decaying trees	Long-term operational interfaces in which tree safety, access and infrastructure clearance must be managed
Maintenance and improvement of hedgerows and treelines	Repeated crossings and some removal/reinstatement of hedgerows
High-quality woodland and riparian foraging habitat with abundant moth prey	Construction and operational alteration of woodland-edge, field-boundary and riparian landscapes
Landscape connectivity free from artificial-light barriers	Temporary construction lighting and permanent/occasional lighting at major infrastructure nodes
Protection of maternity colonies from disturbance	Noise, vibration, vehicles, HDD, piling and other construction or maintenance activities within the wider maternity landscape
Identification of presently undiscovered colonies	Independent evidence showing additional colonies/probable colonies and calling for further radiotracking
Expansion and recovery rather than continued fragmentation	A dispersed 60-year infrastructure project extending across the same connected landscape

The comparison does not establish that every East Pye activity will necessarily cause a population decline. Nor does Natural England's FCS document amount to a project-specific objection to East Pye. It does something different and important: it defines the ecological conditions required for the

species to recover and thrive. Against that benchmark, the burden upon the Applicant is substantial.

The Applicant cannot establish compatibility simply by showing that most woodland trees remain standing, that most hedgerow length is retained or that its BNG metric is positive. Natural England's own evidence demonstrates that favourable conservation status depends upon the **function** of a connected landscape: multiple interchangeable roosts, established feeding areas, high prey biomass, mature linear features, darkness, limited disturbance and gene flow between colonies.

Implications for East Pye's mitigation case

The Applicant's proposed habitat creation may have ecological value, but Natural England's FCS evidence demonstrates why it cannot automatically be regarded as equivalent mitigation for existing barbastelle habitat.

For woodland roosting habitat in particular, Natural England states that there is currently no proven short- to medium-term mitigation or compensation for its loss. New woodland may require 50 years or more to provide sufficient natural roost opportunities, while even favourable management of established woodland may require at least 30 years before barbastelle use increases significantly.

The same temporal problem applies, albeit less absolutely, to hedgerow and foraging-habitat replacement. The question is not whether the metric awards future habitat units but whether maternity colonies continue to have the resources they require during every intervening breeding season.

The appropriate application of the mitigation hierarchy is therefore avoidance first. Existing maternity woods, alternative roost networks, principal commuting routes, dark corridors and important foraging areas should be identified and development removed from them. New planting should enhance that retained network, not be relied upon to repair fragmentation caused by the Scheme.

Required examination evidence

BEPS submits that the Applicant should be required to demonstrate compatibility with Natural England's FCS evidence through a specific barbastelle assessment which:

1. maps every confirmed and probable maternity colony and the alternative roost network associated with it;
2. completes the further radiotracking required to establish principal flight paths, foraging areas and colony-specific habitat use;
3. overlays the complete construction and operational footprint, including compounds, access routes, cable works, substations, BESS, fencing, lighting and highway works;
4. identifies every interruption or alteration of mature hedgerows and treelines within the relevant colony landscapes;

5. provides a quantitative dark-corridor plan demonstrating that important routes and habitat remain free from artificial-light barriers;
6. assesses piling, HDD, noise and vibration against each maternity woodland and sensitive breeding period;
7. demonstrates that each affected colony retains sufficient roost-resource continuity, foraging habitat and dark connectivity throughout construction, the 60-year operational phase, replacement cycles and decommissioning;
8. separates immediate habitat functionality from future BNG habitat that may take decades to mature;
9. tests the Scheme against the cumulative effects of other development affecting the same colonies and landscape network; and
10. explains, by reference to Natural England's FCS parameters, how the Scheme would avoid impeding the recovery of a species which Natural England presently considers not to be at favourable conservation status.

Conclusion

Natural England's 2024 FCS definition sets the context in which East Pye's barbastelle effects should be judged. Barbastelle is not a species presently considered secure at a favourable level. Natural England's objective is a major increase in population, supporting habitat and connectivity. Its evidence identifies old-growth woodland, numerous veteran and deteriorating roost trees, mature hedgerows, riparian habitat, moth-rich foraging areas, darkness and landscape connectivity as central to that recovery, while identifying habitat fragmentation, disturbance and artificial lighting as important threats.

East Pye is proposed across a landscape in which those same features support multiple maternity colonies. Its own development envelope entails habitat disturbance and fragmentation, hedgerow crossings, construction compounds, plant and vehicle movements, noise, vibration and lighting, together with repeated operational maintenance and replacement over up to 60 years. Norfolk Wildlife Trust specifically identifies the need to protect connectivity, keep cabling away from maternity woods, avoid maternity-period noise and vibration and prevent operational and construction lighting in core areas. They have also called for site 3 to be removed from the scheme.

The issue is therefore not whether some habitat will remain or whether a positive BNG percentage can be generated. The relevant question is whether this nationally important colony landscape will retain the roost resource, feeding capacity, darkness and connectivity necessary for the existing colonies to persist and for the species to recover towards the favourable status Natural England says has not yet been achieved. On the evidence presently available, that has not been demonstrated. This raises the question of whether European Protected Species Licences can be obtained to construct, operate or decommission this project.

8.5.8 Peer-reviewed evidence concerning solar development and bats

The need for precaution is reinforced by Tinsley et al. (2023), published in the Journal of Applied Ecology. That study examined bat activity at nineteen paired ground-mounted solar developments and control sites in south-west England.

It found significantly lower bat activity at solar sites for six of the eight taxa analysed. The effects were not confined to activity over the open panel fields. Reduced activity was also identified along field boundaries for some taxa, including Myotis species and serotine. Reduced open-field activity was identified for soprano pipistrelle and Plecotus species, among others.

This evidence is directly relevant to the Applicant's assumption that the retention of boundary hedgerows, supplemented by buffers and habitat creation, is sufficient to maintain bat use. The study indicates that solar development may affect activity even at retained field boundaries. Possible mechanisms considered include changes in habitat structure, prey availability, microclimate, acoustic conditions and the way bats perceive and navigate through panel landscapes.

The study does not establish that every solar development will produce the same effect or that all taxa will respond identically. Its significance lies in demonstrating that ground-mounted solar cannot safely be assumed to be ecologically neutral for bats merely because hedges are retained and pesticide use is reduced.

That distinction is particularly important for East Pye. The Tinsley study considered ordinary paired solar and control sites. East Pye is proposed within a landscape that the Applicant itself has assessed as nationally important for bats and that contains overlapping barbastelle maternity-colony zones. The potential consequence of any displacement or reduction in activity is therefore greater.

The authors recommend that bat effects should be properly screened and assessed through EIA and that alternative siting may be more appropriate where important bat habitat is present. That aligns with the mitigation hierarchy: the presence of an unusually important bat resource should influence site selection before mitigation and compensation are considered.

8.5.9 Functional effects of the Scheme on the bat landscape

The principal effects on bats do not arise solely from direct removal of roosts. They arise from the interaction of multiple development components across the functional landscape.

Those components include:

- thousands of hectares of panel arrays and associated field infrastructure;
- repeated breaks in hedgerows;
- widened lanes and new visibility splays;
- access tracks and haul roads;
- extensive fencing;
- substations and BESS infrastructure;
- temporary and permanent lighting;
- construction compounds;
- trenching and HDD;
- pile driving;
- vegetation clearance;
- increased vehicle movements;

- and sixty years of inspection, maintenance and equipment replacement.

Each element may affect a different part of the same ecological system. A hedge may be physically retained but crossed by a lit access road. A woodland may be buffered but enclosed on several sides by panels and fencing. A stream corridor may remain but be subjected to crossings, compound activity and altered drainage. A roost tree may survive while its dark approach route and surrounding feeding habitat are degraded.

The ES does not supply a landscape-scale permeability assessment showing how bats will continue to move among the relevant colonies, woods, watercourses and foraging areas. Nor does it identify a hierarchy of flight routes against which every construction and operational crossing has been tested.

The absence of demonstrated direct roost loss cannot therefore support a conclusion of no significant effect. For a woodland bat using multiple roosts and extensive feeding grounds, loss of functional connectivity may be as consequential as the loss of an individual feature.

8.5.10 Protected-species licensing implications

Barbastelles and all other bats are European Protected Species. Where works risk deliberate disturbance, damage or destruction of a breeding site or resting place, obstruction of access, or another prohibited act, an EPS licence may be required from Natural England.

Natural England's Relevant Representation identifies protected-species licensing as an outstanding amber matter. It notes that licences may be required for roosting bats and strongly advises that the issue be addressed at the earliest opportunity. The Planning Inspectorate's scoping material likewise advised that, where a licence may be needed, the Applicant should engage with Natural England's pre-submission service and seek a Letter of No Impediment to provide confidence that a future licence is realistically obtainable.

The present application does not demonstrate a settled licence route for the barbastelle impacts now identified.

A licence can only be granted where the relevant statutory tests are met, including the absence of a satisfactory alternative and the maintenance of the affected population at favourable conservation status in its natural range. For East Pye, those tests require evidence addressing:

- the number and distribution of affected colonies;
- the status of the local and wider population;
- the functional importance of the affected habitat;
- the proportion of colony resources affected;
- the effectiveness and certainty of mitigation;
- cumulative effects from other projects;
- and whether a less damaging site or layout is available.

The Scheme's location within a nationally important bat landscape is directly relevant to both tests. Solar development is comparatively flexible in location, while the maternity-colony network

and ancient woodland resource are not. The existence of less ecologically constrained land elsewhere is therefore relevant to whether there is a satisfactory alternative.

Similarly, favourable conservation status cannot be assumed to be maintained where the full colony network, principal routes and satellite roost use remain incompletely understood and where Natural England's own conservation guidance identifies no proven short- to medium-term replacement for lost woodland-roosting function.

The Examination should not treat a future contractor-led licence application as a substitute for the ecological evidence needed now to understand the affected population, functional habitat and likely impact of the authorised development.

8.5.11 Conclusion on bats and barbastelles

The Applicant's own evidence establishes that:

- the bat assemblage is of national importance;
- eleven species are present;
- activity is widespread across the whole Order Limits;
- barbastelle is the third most frequently recorded species;
- barbastelle occurs at every static detector location;
- multiple maternity colonies surround the Scheme;
- overlapping Core Sustenance Zones cover the development landscape;
- known and likely colonies remain incompletely mapped;
- and the Order Limits provide supporting commuting and foraging habitat above what would ordinarily be expected from the broad habitat classifications used.

The Norfolk Barbastelle Study Group concludes that further work is required to understand colony distribution and habitat use. Natural England's favourable-conservation-status guidance demonstrates that barbastelles require extensive, dark, connected landscapes and that woodland-roosting habitat cannot reliably be replaced in the timescale relevant to this development. The Tinsley research provides empirical evidence that ground-mounted solar can reduce bat activity, including at retained field boundaries.

Against that evidence, the Applicant's reliance on buffers, retained hedges, future planting, outline lighting controls and metric-based BNG does not establish that the nationally important bat landscape will remain functional.

The appropriate mitigation-hierarchy response is avoidance. In this context, avoidance means more than preserving individual trees or adjusting isolated panel edges. It requires avoiding industrial development across the maternity-colony support landscape where the effects of fragmentation, lighting, disturbance and reduced habitat use cannot reliably be prevented or compensated.

BEPS submits that the Applicant has not yet demonstrated that the nationally important bat landscape will retain the roost resource, connectivity, darkness and foraging function necessary to

support the affected barbastelle colonies throughout construction and operation. Nor has it demonstrated, on the present evidence, that any necessary EPS licensing issues can be resolved without further survey, avoidance or redesign. Those uncertainties weigh strongly against reliance on the present conclusion of no significant residual effect.

8.6 SSSI Woodland Context and Barbastelle Protection

A number of the woodlands supporting barbastelle activity within and adjacent to the Order Limits are not only ecologically important but are designated **Sites of Special Scientific Interest (SSSIs)**. These include:

- **Shotesham Little Wood (Parcel 8b)**
- **Hempnall Little Wood (Parcel 7h)**
- **Saxlingham Grove complex (Parcels 7e, 7f, 7g)**
- **Hedenham Wood (Parcel 10b)**

These designations are of direct legal and ecological significance. SSSIs represent the highest level of national site protection for nature conservation in England and are notified specifically for their habitats, species assemblages and ecological integrity. In this case, these woodland sites form part of a wider, connected landscape that supports **barbastelle maternity colonies and associated foraging and commuting networks**.

The presence of European Protected Species within or functionally dependent upon SSSI-designated land materially elevates the level of protection. Barbastelle bats are highly sensitive to disturbance, fragmentation and changes in landscape connectivity. Their reliance on woodland roosts combined with extensive use of surrounding farmland means that impacts to adjacent land—such as those proposed under this Scheme—can directly affect the integrity and functionality of the SSSI itself, even where development lies outside the formal boundary.

This has two critical implications.

First, the assessment of effects must consider not only direct impacts on SSSI habitats but also **indirect and functional impacts**, including:

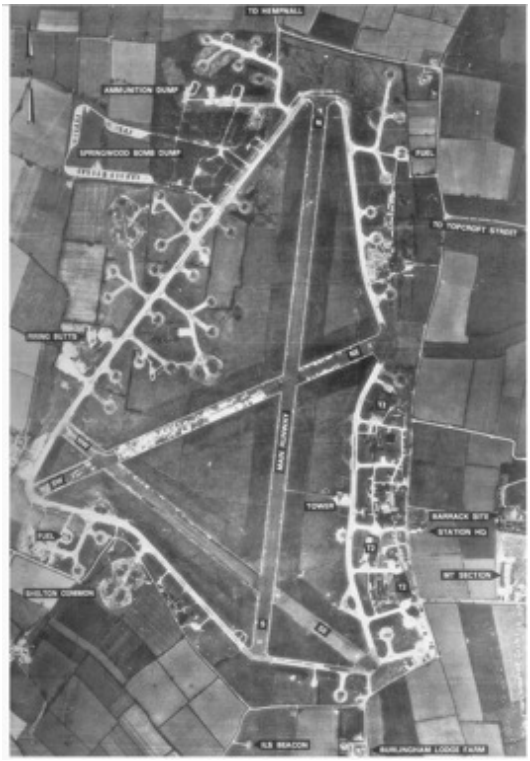
- disruption of commuting routes between SSSI woodlands;
- degradation of foraging habitat within Core Sustenance Zones;
- increased lighting, noise and activity in otherwise dark and undisturbed landscapes;
- fragmentation of the wider ecological network upon which SSSI interest features depend.

Failure to assess these pathways would be inconsistent with both EIA requirements and Natural England guidance on impact pathways affecting designated sites.

Second, the combination of **SSSI designation and EPS presence significantly constrains licence grantability**. Under the Habitats Regulations, a licence affecting barbastelle bats can only be granted where favourable conservation status is maintained. Where those populations are associated with SSSI woodlands, any adverse effect is not only a species issue but a designated site issue. Natural England, as the statutory nature conservation body, is under a duty to protect SSSIs and may object to development that would damage their notified features or the ecological processes that sustain them.

In practical terms, this means that:

- Impacts on barbastelle populations linked to SSSI woodlands are likely to be afforded **heightened scrutiny and precaution**;
- Mitigation relying on habitat replacement or off-site measures is unlikely to be considered adequate where it cannot replicate the complexity and continuity of established woodland systems;
- The threshold for demonstrating no adverse effect on favourable conservation status is materially higher;
- There is a **real prospect of objection from Natural England** where the Scheme would compromise the ecological function of SSSI-associated bat populations.



Taken together, the presence of multiple SSSI woodlands within the barbastelle metapopulation network reinforces that this is not a typical ecological constraint but a **highly sensitive, legally protected landscape system**. The Scheme would introduce industrial-scale disturbance into this system, with clear potential to undermine both the integrity of designated sites and the conservation status of a strictly protected species. This substantially reduces the likelihood that necessary consents, including any EPS licence, could lawfully be granted.

Spring Wood and the converted Second World War bomb shelters

Spring Wood and the adjoining former Hardwick Airfield structures require separate treatment because this area appears to support a combined maternity, hibernation, commuting and foraging resource for bats. The former Second World War bomb shelters bordering Sites 3A and 3B were deliberately converted by Norfolk Bat Group into bat hibernacula and are reported to support a wide range of bat taxa including Daudenton, Natterer ad other Myosotis bats. Those structures sit on the same ecological edge as Spring Wood, where the Applicant identifies a known barbastelle roost and foraging area and records barbastelle activity within the relevant emergence period. The area should therefore not be assessed merely as arable land beside woodland. It forms part of a year-round functional bat landscape in which woodland roosts, converted hibernation structures, mature trees, field boundaries and surrounding feeding habitat operate together.

Image: WWII Bunker at Spring Wood converted to a bat hibernaculum by Norfolk Bat Group.

Hardwick Airfield 16 April 1946 showing bomb loading locations (associated bunkers beneath) along the north-western edge of Spring Wood.

Image: Proposed siting of solar infrastructure on site 3, immediately adjacent to bat hibernacula.

The importance of the converted shelters is not answered by the absence of direct works to the structures themselves. A hibernaculum or resting place may remain physically intact while its ecological function is impaired by disturbance, obstruction, lighting, severance of approach routes or degradation of surrounding feeding habitat. Construction in the adjoining fields would introduce pile driving or other installation noise, HGV movements, trenching, compounds, fencing, human activity and potentially artificial lighting immediately beside a deliberately created bat refuge. The noise assessment quantifies construction noise at Lundy Green (immediately north-west of Spring Wood) as Major Adverse. The Applicant has not provided a hibernacula-specific assessment of these pathways, has not mapped the routes used by bats moving between the shelters, Spring Wood and the surrounding hedgerow network, and has not demonstrated that construction noise and vibration would remain below thresholds capable of avoiding disturbance. The general assertion that most hedgerows and woodland buffers will be retained does not answer those site-specific risks.

The scientific evidence concerning solar development makes the omission more serious. Tinsley et al. found reduced activity at solar sites for six of the eight bat taxa analysed, including reduced activity along field boundaries for Myotis species and serotine, and reduced activity over open fields for soprano pipistrelle and Plecotus species. The East Pye survey records those same taxa or guilds within the Order Limits: Myotis species, serotine, soprano pipistrelle and brown long-eared bat, the latter representing Plecotus. The Hardwick hibernacula are reported to support a broad bat assemblage rather than barbastelle alone. The taxa using this local roosting and hibernation resource therefore include, or are likely to include, the very groups for which the published solar

evidence identifies reduced activity. The Tinsley risk is consequently not generic or remote; it is directly relevant to the bat community associated with Spring Wood and the converted shelters.

This is also an area in which Norfolk Wildlife Trust has expressly sought avoidance through site selection. During consultation, NWT recommended removal of the Site 3 land because it surrounds Spring Wood County Wildlife Site and adjacent priority deciduous woodland and because of the likely effects on woodland, bats and ecological connectivity. NWT's later representation records that Site 3 had previously been recommended for removal from the Scheme and that concern remained even after design changes, particularly in relation to development immediately west of the ancient woodland and the need for wider buffers and ecotones.

The Applicant has not followed that advice in full. Only part of the affected land has been removed, leaving approximately half of the original parcel within the Scheme. Partial reduction does not amount to avoidance where the retained development remains beside the same maternity roost, hibernacula and commuting network. Nor has the Applicant demonstrated that the half retained is ecologically less important than the half removed. In the absence of colony-specific tracking, hibernation survey evidence and mapped flight routes, there is no evidential basis for concluding that an arbitrary reduction in area preserves the function of the whole bat landscape.

The planning consequence is therefore clear. Spring Wood and the Hardwick bomb shelters constitute a known and deliberately enhanced bat resource beside a nationally important bat landscape. The Applicant's own evidence identifies the area as a barbastelle roosting and foraging location; local evidence identifies converted hibernacula supporting multiple bat taxa; peer-reviewed research identifies adverse solar associations for the same taxa; and Norfolk Wildlife Trust has expressly sought removal of the relevant development parcel. Retaining half of the parcel does not meet the mitigation hierarchy because the principal conflict remains.

BEPS submits that the remaining Site 3 development adjoining Spring Wood and the converted bomb shelters should be removed from the Scheme in full. At minimum, no conclusion of ecological acceptability can be reached without dedicated hibernation surveys, radio-tracking and route mapping, a species-specific construction noise and vibration assessment, fixed dark-corridor protection and evidence demonstrating that the retained development would not disturb or reduce the functionality of the combined maternity, hibernation and foraging resource.

8.6.1 Hedgerow severance and loss of functional connectivity

The principal ecological impact of East Pye Solar is not the direct loss of individual habitats but the fragmentation of the ecological network that connects them. Throughout the Environmental Statement, the Applicant assesses hedgerows, woodland blocks, ponds and other habitats largely as discrete receptors capable of being retained, buffered or compensated. That approach fundamentally misunderstands the ecological function of the South Norfolk Claylands landscape and, in particular, the ecology of the nationally important bat assemblage that the Applicant itself has identified.

The Applicant's own surveys demonstrate that the Order Limits are not used by bats as isolated habitat patches. Barbastelle activity was recorded across the entire Scheme, at every static detector, with the Order Limits lying within the overlapping Core Sustenance Zones of multiple maternity colonies. The significance of those findings is that the landscape functions as an interconnected network of woodland, hedgerows, mature trees, field margins, ponds, streams and dark rural lanes. These linear features enable bats to move safely between roosts and feeding areas while maintaining protection from predators and exposure to artificial light. It is this functional network that supports the nationally important assemblage identified by the Applicant.

The Environmental Statement repeatedly refers to the retention of existing hedgerows as mitigation. However, retaining sections of hedgerow does not necessarily retain ecological connectivity. Connectivity depends upon whether those hedgerows continue to function as continuous, dark and undisturbed commuting routes. The Scheme introduces numerous physical and functional interruptions to those corridors through:

- new site accesses;
- widening of narrow rural lanes;
- visibility splays;
- haul roads;
- cable corridors;
- temporary construction compounds;
- permanent access tracks;
- substations;
- BESS infrastructure;
- security fencing;
- trenching and horizontal directional drilling compounds;
- construction working areas;
- and repeated crossings by construction and maintenance traffic.

Each individual crossing may appear relatively minor in isolation. However, ecological function must be assessed across the whole Scheme rather than at individual locations. A bat commuting from a maternity colony does not experience a single hedgerow crossing. It experiences a landscape containing repeated interruptions, lighting sources, vehicle movements, altered vegetation structure and barriers distributed throughout its home range. The cumulative consequence is a progressive reduction in landscape permeability.

This concern is reinforced by the historic character of the South Norfolk Claylands. Professor Tom Williamson's Restoring the Claylands explains that the biodiversity value of this landscape lies not simply in individual habitats but in the intricate pattern of connections between them. Ancient hedgerows, roadside verges, ponds, commons, woodland blocks, field margins and watercourses developed over centuries as an integrated ecological network. Restoration within the Claylands should therefore strengthen these historic connections rather than fragment them through piecemeal development. The Applicant's proposals would instead superimpose industrial infrastructure across this surviving network. That is fundamentally different from development on large, open landscapes where habitat connectivity is less dependent upon historic field patterns.

The South Norfolk Tree Warden Network reaches the same conclusion from an arboricultural perspective. Its representation explains that mature hedgerows and trees should be regarded as

ecological infrastructure rather than simply landscape features. It identifies approximately 621 trees with potential bat roost features and warns that repeated hedgerow gaps, access points, root disturbance and construction activity have not been assessed in terms of their cumulative impact upon habitat connectivity. The Tree Wardens also emphasise that ecological effects cannot be measured solely by direct tree loss. Trees retained within altered landscapes may lose ecological function through soil compaction, root damage, hydrological change, increased exposure or isolation from the surrounding habitat network.

The Forestry Commission similarly identifies fragmentation as one of the greatest threats to ancient woodland. Its representation specifically raises concern regarding Doyly's Grove and Ringers Grove, noting that smaller ancient woodland blocks become increasingly vulnerable when enclosed by development and separated from surrounding habitat. It recommends larger woodland buffers, woodland expansion and strengthened habitat connections rather than simple retention of woodland boundaries. These concerns are directly applicable to bats. Woodland retained as an isolated island within solar infrastructure cannot provide the same ecological function as woodland remaining connected to surrounding hedgerows, field margins and feeding habitat.

The Applicant has not undertaken a landscape permeability assessment demonstrating how bats will continue to move between the known maternity colonies, satellite roosts, woodland blocks and feeding areas following construction of the Scheme. Nor has it identified a hierarchy of primary and secondary commuting corridors against which every crossing, access, cable route and infrastructure element has been tested.

This omission is particularly important because the Norfolk Barbastelle Study Group has shown that the Order Limits lie within overlapping Core Sustenance Zones associated with multiple maternity colonies. Individual hedgerows and woodland edges are therefore likely to be used simultaneously by bats from different colonies. The loss or degradation of one corridor may consequently affect several maternity populations rather than a single local roost. The Applicant has not attempted to assess this cumulative landscape function.

The importance of maintaining uninterrupted commuting corridors is reinforced by Natural England's Definition of Favourable Conservation Status for Barbastelle. That guidance identifies continuous woodland networks, hedgerows, riparian corridors and dark landscape connections as fundamental components of favourable conservation status. It recognises that barbastelles are highly dependent upon structurally connected landscapes and that fragmentation of those connections may affect population viability even where individual roost trees remain physically intact. The Applicant's mitigation strategy, based largely upon retaining hedgerows in situ while introducing repeated crossings and infrastructure, has not demonstrated compliance with that guidance.

The peer-reviewed evidence also points in the same direction. Tinsley et al. (2023) found reduced bat activity associated with ground-mounted solar developments, including reduced activity along retained field boundaries for several taxa. Although the study was not specific to barbastelle, it demonstrates that retention of hedgerows does not necessarily preserve their ecological function. Changes in habitat structure, prey availability, lighting, microclimate and movement behaviour may reduce use even where the physical hedge remains. This is highly relevant to East Pye because the Applicant's principal mitigation relies precisely upon retaining existing hedgerows.

The issue extends beyond bats. The same connected network supports breeding birds, dormice where present, hedgehogs, brown hare, pollinating insects, reptiles and numerous invertebrate communities. Field margins connect to roadside verges; verges connect to hedgerows; hedgerows connect to woodland edges; woodland edges connect to ponds and streams. Fragmentation of one component therefore propagates through the wider ecological system. The Applicant's assessment largely considers these receptors separately rather than examining how repeated disruption to the connecting network affects the resilience of the landscape as a whole.

The impacts are also cumulative in time. Construction would occur over several years, involving repeated disturbance, vegetation clearance, traffic movements and engineering works. Operational impacts would continue for approximately sixty years, during which the network would remain interrupted by fencing, roads, substations, maintenance activity and periodic replacement of infrastructure. Decommissioning would introduce a further major phase of disturbance. The Environmental Statement does not evaluate the consequences of repeated interruption over the entire life cycle of the Scheme.

Nor is there sufficient evidence that proposed replacement planting would restore ecological connectivity within a meaningful timescale. Newly planted hedgerows and woodland strips require many years before they develop the structure, height, continuity, insect assemblages and microclimate associated with mature Claylands boundaries. During that period, the functional loss remains. For species such as barbastelle, whose conservation depends upon established mature landscape features, replacement planting cannot be regarded as functionally equivalent.

This illustrates the wider failure to apply the mitigation hierarchy correctly. Rather than first avoiding fragmentation of the most sensitive ecological corridors, the Applicant has selected a development footprint that extends across the functional landscape of multiple barbastelle maternity colonies and then proposes to mitigate fragmentation through retained hedgerows, replacement planting and outline ecological management. That reverses the hierarchy required by EN-1 and the NPPF. Avoidance should have informed site selection and layout before mitigation was considered.

The evidence before the Examination demonstrates that ecological connectivity is one of the defining characteristics of the South Norfolk Claylands and one of the principal reasons why the Applicant's own surveys conclude that the bat assemblage is of national importance. The Scheme would introduce repeated severance and degradation of that connectivity across the Order Limits, yet no comprehensive assessment has been undertaken of landscape permeability, colony-specific commuting routes or cumulative corridor loss. The Applicant has therefore failed to demonstrate that the functional integrity of this nationally important ecological network will be maintained.

BEPS submits that the effects of hedgerow severance and habitat fragmentation have been materially underestimated. The reliance on retaining individual hedgerow fragments does not establish that ecological connectivity will survive. In the absence of a robust functional connectivity assessment demonstrating that the network supporting multiple barbastelle maternity colonies and other protected species will remain intact throughout construction, operation, replacement and decommissioning, the Applicant has not shown that these impacts

can be avoided or adequately mitigated. This conflict with the mitigation hierarchy weighs strongly in favour of refusal.

8.6.2 Artificial lighting and fragmentation of dark landscapes

Artificial lighting is one of the most significant but consistently underestimated ecological impacts of the Scheme. Throughout the Environmental Statement, lighting is largely treated as an engineering issue capable of being controlled through future design, directional luminaires and operational management. That approach fails to recognise that darkness is itself an ecological resource. Within the South Norfolk Claylands, the maintenance of extensive, continuous dark landscapes is fundamental to the functioning of the nationally important bat assemblage identified by the Applicant.

The issue is not simply whether individual lights can be shielded from adjacent woodland. It is whether the introduction of numerous permanent and temporary light sources across a landscape supporting multiple barbastelle maternity colonies fundamentally alters the behaviour, connectivity and ecological function of that landscape.

The Applicant's own bat surveys demonstrate that East Pye Solar lies within a landscape of national importance for bats, with barbastelles recorded throughout the Order Limits and multiple maternity colonies occupying the surrounding woodlands. Barbastelles are widely recognised as one of Europe's most light-sensitive bat species. Unlike more urban-adapted bats such as pipistrelles, barbastelles characteristically avoid illuminated habitats and preferentially commute along continuous dark corridors. Their dependence upon darkness is therefore not incidental but forms an essential part of their ecological requirements.

Natural England's Definition of Favourable Conservation Status for Barbastelle reflects this ecology. It identifies the maintenance of dark, well-connected woodland, hedgerow and riparian networks as an important component of favourable conservation status. The guidance recognises that artificial lighting may alter commuting behaviour, fragment habitat, reduce access to feeding areas and isolate woodland roosts even where no direct habitat loss occurs. The relevant ecological effect is therefore behavioural fragmentation rather than physical habitat destruction.

This distinction is critical for East Pye Solar.

The Applicant relies extensively upon retaining hedgerows, woodland edges and buffer strips. However, a retained hedgerow which becomes illuminated by construction compounds, security lighting, maintenance vehicles or substation infrastructure no longer functions as the same commuting corridor. From the perspective of a light-averse species, the corridor may effectively cease to exist.

The Scheme introduces multiple potential lighting sources throughout the sixty-year operational life of the development.

These include:

- BESS compounds;

- substations;
- customer substations;
- National Grid infrastructure;
- security lighting;
- CCTV activation lighting;
- maintenance activities;
- emergency lighting;
- temporary construction compounds;
- construction welfare facilities;
- site accesses;
- vehicle headlights;
- abnormal indivisible load movements;
- temporary highway works;
- cable installation compounds;
- and possible night-time construction where operationally necessary.

Although the Applicant states that lighting will be minimised wherever practicable, the Environmental Statement largely defers the detailed assessment to an Outline Lighting Strategy and subsequent detailed design.

That is insufficient.

Lighting cannot be regarded as a minor engineering detail to be resolved after consent where the receptor concerned is the very nationally important bat assemblage identified by the Applicant.

The Planning Inspectorate's Scoping Opinion recognised this issue from the outset. It specifically required the Environmental Statement to assess ecological effects arising from construction lighting and operational lighting. Nevertheless, the Applicant's Scoping Report originally proposed that lighting effects on ecology could be scoped out because lighting would supposedly be designed sensitively. That approach was not accepted by the Inspectorate, which required lighting impacts to be considered because they could affect ecological receptors.

The Environmental Statement has still not undertaken the level of assessment that this receptor demands.

Rather than modelling landscape-wide changes in darkness, the Applicant principally relies upon qualitative statements that lighting will be:

- directional;
- shielded;
- motion activated;
- minimised;
- and designed to avoid woodland wherever possible.

Those commitments remain largely generic.

There is no comprehensive landscape lighting model demonstrating:

- cumulative illuminance across the Order Limits;
- spill along hedgerows;
- spill across woodland edges;
- spill onto ponds and streams;
- interaction between multiple lighting sources;
- seasonal variation;
- maintenance activities;
- emergency operation;
- cumulative effects with surrounding infrastructure;
- or changes to landscape permeability for bats.

Nor has the Applicant identified which commuting corridors must remain entirely dark in order to preserve connectivity between the known maternity colonies.

This omission is especially significant because the Norfolk Barbastelle Study Group has demonstrated that the Order Limits lie within overlapping Core Sustenance Zones associated with multiple colonies. Any individual hedgerow or woodland edge may therefore be important to several colonies simultaneously. Without mapping colony-specific movement patterns, it is impossible to determine which corridors can tolerate lighting and which cannot.

The concern is reinforced by the particular characteristics of the South Norfolk Claylands.

This is an exceptionally dark rural landscape.

Wood Green residents, local ecological recorders and parish representations all identify dark skies as one of the defining characteristics of the area. The Wood Green representation explains that darkness benefits both wildlife and people, that visitors are attracted to the area specifically because of its dark skies, and that construction lighting would fundamentally alter that character. Although this point was raised primarily in relation to residential amenity, it has direct ecological significance because the same darkness supports bat movement across the landscape.

Darkness functions as ecological infrastructure in exactly the same way as hedgerows or woodland edges.

The loss of darkness fragments habitat.

This is particularly important around Spring Wood and the converted Second World War bat hibernacula.

As discussed in Section 8.5, these structures provide year-round bat habitat immediately adjacent to retained Site 3 development. Construction compounds, vehicle movements, temporary lighting and operational infrastructure would all occur close to this sensitive bat resource.

The Applicant has not undertaken a hibernacula-specific lighting assessment.

Nor has it demonstrated that illumination associated with:

- compounds;
- construction traffic;
- welfare facilities;
- security requirements;
- maintenance activities;
- or emergency access

would avoid disturbance to bats using the woodland edge and converted shelters.

The omission is compounded by the findings of Tinsley et al. (2023).

The study demonstrated reduced bat activity associated with ground-mounted solar developments, including reduced activity along retained field boundaries. Although lighting was not identified as the sole causal mechanism, the research concluded that solar development changes the ecological functioning of field boundaries beyond simple habitat retention.

At East Pye, lighting represents one of several interacting mechanisms capable of producing precisely those behavioural changes.

Artificial lighting also interacts with the wider ecological network.

Many aquatic insects are attracted to artificial light.

The Environment Agency has separately highlighted concerns regarding the interaction between aquatic insects and solar infrastructure, recognising that alterations to aquatic invertebrate behaviour may affect wider food webs.

Where lighting attracts insects away from rivers, ponds or woodland edges, it may simultaneously alter prey availability for bats while concentrating insects around operational infrastructure where predation risk differs.

These interactions have not been assessed.

Likewise, the Applicant has not evaluated how lighting may alter:

- predator-prey relationships;
- nocturnal bird behaviour;
- moth communities;
- pollinator activity;
- or ecological function along watercourses.

Instead, lighting is considered primarily in engineering terms.

This compartmentalised approach fails to recognise that the nationally important bat assemblage depends upon the continued ecological integrity of the wider nocturnal landscape.

The Forestry Commission's representation provides additional support for this concern.

It expressly welcomes the intention to avoid illuminating ancient woodland but does so because lighting is recognised as capable of causing indirect deterioration of irreplaceable habitats.

That acknowledgement illustrates the wider point.

If lighting is sufficiently harmful to require protection of woodland, it must also be assessed in relation to the woodland-dependent species using those habitats.

The Applicant's assessment does not bridge that gap.

Norfolk Wildlife Trust similarly identified lighting as one of the principal remaining ecological concerns, particularly where development approaches woodland edges, County Wildlife Sites and important bat habitat.

Its request that parts of Site 3 be removed from the Scheme reflected concern not merely about physical habitat loss but about the wider disturbance regime associated with infrastructure immediately adjoining Spring Wood.

The Applicant only partially accepted that recommendation.

Approximately half of the land parcel remains within the Scheme despite the ecological rationale for avoidance remaining unchanged.

This demonstrates a broader failure to apply the mitigation hierarchy.

The appropriate response to a nationally important light-sensitive bat landscape is first to avoid introducing permanent illumination into the most sensitive areas.

Instead, the Applicant has selected development locations adjoining key woodland habitat and then proposes to control lighting through future design.

That reverses the hierarchy established by EN-1.

The Environmental Statement also relies heavily upon the Outline Landscape and Ecological Management Plan and future lighting strategy to provide reassurance.

Those documents do not currently specify:

- maximum illuminance levels;
- lux thresholds along commuting corridors;
- mapped dark corridors;
- measurable performance standards;
- monitoring requirements;
- adaptive management triggers;
- remedial action where bat behaviour changes;
- or long-term governance arrangements throughout the sixty-year operational life.

Consequently, the effectiveness of the mitigation cannot presently be tested.

The Applicant has therefore not demonstrated that lighting impacts will be avoided, nor that the proposed controls will preserve the ecological functionality of the nationally important bat landscape.

Taken together, the Applicant's own bat surveys, Natural England's favourable conservation status guidance, the Norfolk Barbastelle Study Group's evidence, the Forestry Commission's concerns regarding woodland protection, Norfolk Wildlife Trust's recommendation to remove development adjacent to Spring Wood, the Wood Green evidence concerning dark skies and the findings of Tinsley et al. all point in the same direction.

Darkness is an essential ecological characteristic of this landscape.

The Scheme would replace a largely continuous dark rural environment with numerous temporary and permanent light sources distributed throughout the functional range of multiple barbastelle maternity colonies.

The Applicant has not demonstrated that those changes can be prevented through the outline mitigation proposed.

BEPS therefore submits that the ecological effects of artificial lighting have been materially underestimated. The reliance upon future lighting design, outline management plans and generic commitments to minimise illumination does not satisfy the requirements of EN-1 for effective, secured mitigation. Nor does it demonstrate that favourable conservation status of the nationally important bat assemblage will be maintained. The appropriate application of the mitigation hierarchy would have been to avoid locating major infrastructure within this highly sensitive nocturnal landscape rather than attempting to compensate for its industrialisation through post-consent lighting controls.

8.6.3 Construction disturbance: piling, vibration, traffic and noise

The Environmental Statement materially underestimates the ecological consequences of construction disturbance. While the assessment recognises that construction activities will generate noise, vibration, lighting and increased traffic, these effects are largely considered in isolation, are assessed primarily in relation to human receptors, or are deferred to outline management plans. There is no integrated assessment of how prolonged industrial construction activity would affect a landscape that the Applicant itself has identified as supporting a nationally important bat assemblage and multiple barbastelle maternity colonies.

This omission is particularly significant because the principal ecological receptors are not species that occupy isolated habitat patches. Barbastelles and many other woodland bats depend upon stable, undisturbed woodland landscapes connected by mature hedgerows and dark corridors. Construction activity therefore has the potential to affect ecological function across a much wider area than the footprint of the engineering works themselves.

The Applicant's construction programme includes extensive activities capable of generating sustained disturbance, including:

- pile installation for solar arrays and fencing;
- piling associated with substations and infrastructure where required;
- horizontal directional drilling;
- cable trenching;
- excavation and earthworks;
- road widening;
- construction compounds;
- haul roads;
- heavy goods vehicle movements;
- abnormal indivisible load deliveries;
- cranes and heavy plant;
- vegetation clearance;
- and prolonged human presence across multiple sites simultaneously.

These activities would occur over several years across a dispersed construction footprint extending throughout the Order Limits.

The Environmental Statement acknowledges that construction noise and vibration will occur but does not evaluate their consequences for the nationally important bat assemblage. Instead, ecological mitigation largely assumes that retained woodland, retained hedgerows and pre-construction checks will be sufficient to avoid significant effects.

That assumption is not supported by the evidence.

Failure to assess species-specific responses to construction disturbance

Barbastelles are recognised as one of Britain's most disturbance-sensitive bat species. Their ecology is characterised by repeated switching between tree roosts, strong reliance upon woodland structure, avoidance of illuminated environments and use of extensive commuting networks linking multiple roosts and feeding areas.

Despite this, the Environmental Statement contains no species-specific assessment of the consequences of:

- prolonged construction noise;
- repeated vibration;
- pile installation;
- heavy vehicle movements;
- road widening adjacent to woodland;
- construction compounds close to known commuting routes;
- or simultaneous disturbance occurring across multiple colony home ranges.

The Applicant instead relies upon generic construction controls applicable to many development types.

That approach might be appropriate where ecological receptors comprise widespread generalist species occupying relatively robust habitats.

It is not appropriate where the Applicant's own surveys establish a nationally important bat assemblage containing widespread barbastelle activity within overlapping maternity colony landscapes.

The issue is not whether construction noise exceeds a particular decibel threshold.

The issue is whether repeated disturbance alters bat behaviour sufficiently to reduce use of established commuting routes, feeding areas, maternity support habitat or hibernation sites.

The Environmental Statement contains no assessment capable of answering that question.

Spring Wood and the converted WWII bat hibernacula

The failure is particularly evident around Spring Wood.

As discussed in Section 8.5, the woodland lies adjacent to former Second World War bomb shelters that were deliberately converted into bat hibernacula. Those structures support multiple bat species and form part of a wider woodland network used by barbastelles and other woodland bats.

The Applicant has not assessed construction disturbance in relation to those hibernacula.

There is no assessment of:

- vibration transmission through the surrounding geology;
- disturbance during hibernation;
- repeated heavy vehicle movements immediately adjacent to the woodland;
- effects of construction compounds;
- interactions between lighting, vibration and traffic;
- or cumulative impacts arising from prolonged activity beside a known bat refuge.

The significance of this omission is reinforced by the findings of Tinsley et al. (2023).

The peer-reviewed study found that several of the bat taxa associated with the Spring Wood landscape—including Myotis species, brown long-eared bats (Plecotus), serotine and soprano pipistrelle—showed reduced activity at ground-mounted solar developments.

The Spring Wood landscape therefore contains precisely those taxa for which the published evidence already indicates sensitivity to solar development.

Rather than responding to that evidence through avoidance, the Applicant proposes prolonged construction immediately adjoining this important bat resource.

Pile driving and vibration

Construction vibration has received remarkably little ecological consideration despite its obvious relevance.

The Environmental Statement continues to allow pile installation within the construction envelope. Although alternative installation methods may be used in some locations, the application does not remove percussive piling from the authorised development.

The ecological implications have not been properly assessed.

Percussive piling can generate repeated impulsive vibration transmitted through the ground, with the extent of propagation depending upon the installation method, ground conditions, distance and receptor characteristics. Unlike continuous background noise, impulsive vibration has the potential to disturb roosting animals repeatedly throughout the construction period.

The Applicant provides no analysis of:

- vibration reaching woodland roosts;
- disturbance of maternity colonies;
- disturbance of hibernacula;
- repeated vibration affecting tree-roost occupancy;
- behavioural avoidance;
- or cumulative vibration arising from simultaneous construction activities.

This omission is particularly important given the geology of the area. Large parts of the Scheme overlie chalk and permeable superficial deposits through which both groundwater and vibration may propagate differently from heavier clay soils.

No site-specific modelling has been presented to demonstrate that vibration associated with piling would not affect nearby woodland habitats or underground bat refuges. South Norfolk Council has itself recognised this issue. Its consultation response specifically recommends that percussive piling should not be used and that screw piles should be adopted wherever practicable because of the environmental effects associated with conventional piling. The Council's concern is not limited to human amenity. It reflects the wider ecological sensitivity of the landscape.

Despite that advice, the Applicant has not removed pile driving from the Scheme nor demonstrated that any remaining use would avoid significant ecological disturbance.

Construction traffic and repeated disturbance

The ecological assessment also underestimates the effects of construction traffic. The transport assessment focuses primarily upon highway capacity and residential amenity. It does not evaluate construction traffic as a sustained ecological disturbance occurring across a connected landscape.

Heavy goods vehicles, abnormal indivisible loads and construction traffic would repeatedly use:

- ancient lanes;
- woodland-edge roads;
- hedgerow corridors;
- rural crossings;
- access tracks;
- and temporary haul routes.

The ecological consequences include:

- repeated noise;
- repeated headlight illumination;
- vibration;
- dust;
- air turbulence;
- increased human presence;
- and interruption of nocturnal movement.

These effects occur not once but thousands of times throughout the construction programme. Many of the most important bat commuting routes identified by the Applicant follow the same hedgerows and rural lanes proposed for construction access. Yet the Environmental Statement contains no quantitative assessment of repeated disturbance to commuting bats arising from prolonged traffic.

Similarly, the assessment does not consider whether repeated traffic may alter the behaviour of breeding birds, mammals or other nocturnal wildlife occupying roadside habitats.

Simultaneous construction across the Scheme

The Applicant's approach also fails to recognise the cumulative nature of disturbance. Construction will not occur at a single isolated location. Multiple compounds, access routes, cable corridors, substations and working areas will operate simultaneously across the Order Limits.

Consequently, bats displaced from one construction area may encounter disturbance again at alternative routes elsewhere within the same landscape. This is particularly important given the overlapping Core Sustenance Zones associated with several barbastelle maternity colonies.

The cumulative consequence may be progressive reduction in the availability of undisturbed commuting and foraging habitat across the colony home ranges.

The Environmental Statement assesses construction activities largely on a parcel-by-parcel basis. It does not evaluate the effects of simultaneous disturbance across the entire ecological network.

Interaction with other impact pathways

Construction disturbance cannot properly be separated from the other ecological changes introduced by the Scheme.

Noise interacts with:

- artificial lighting;
- hedgerow severance;
- fencing;
- altered prey availability;
- construction traffic;
- and human activity.

Together these pressures may substantially alter the suitability of retained habitat even where direct habitat loss is limited.

For example:

- a retained hedgerow may remain physically intact but become less suitable because it is repeatedly illuminated by vehicles, bordered by construction traffic and crossed by temporary haul roads;
- a retained woodland edge may experience vibration, lighting and prolonged human activity while simultaneously losing adjoining feeding habitat;
- a hibernaculum may remain structurally undamaged but become functionally degraded through repeated disturbance during critical seasonal periods.

The Applicant has not assessed these interacting effects.

Instead, each impact pathway is considered separately.

This compartmentalised approach does not reflect how wildlife experiences disturbance.

Reliance upon future management plans

The Applicant relies heavily upon the Outline Construction Environmental Management Plan, Ecological Clerk of Works and future method statements to address construction impacts.

Those documents contain useful principles but they do not presently specify:

- exclusion distances from maternity colonies;
- vibration limits;
- species-specific noise thresholds;
- seasonal restrictions around hibernacula;
- colony-specific working methods;
- monitoring protocols;
- behavioural triggers;
- adaptive management measures;
- or enforceable contingency arrangements if disturbance proves greater than predicted.

Nor has the Applicant demonstrated that such measures would be capable of maintaining favourable conservation status for the nationally important bat assemblage identified in its own surveys.

Construction disturbance is therefore not simply being managed through detailed mitigation. It is being deferred.

The Examination is consequently being asked to conclude that impacts will be insignificant before the detailed measures needed to support that conclusion have been developed or tested.

Failure to apply the mitigation hierarchy

The shortcomings of the construction assessment again illustrate the failure to apply the mitigation hierarchy correctly.

Where nationally important bat habitat, known maternity colonies and converted hibernacula occur within the proposed development area, the first question should be whether construction can be avoided in those locations.

Instead, the Applicant has retained major construction activity adjacent to sensitive ecological receptors and seeks to control its effects through later management.

Norfolk Wildlife Trust reached the opposite conclusion. It expressly requested removal of the Spring Wood land parcel because of its ecological importance.

Although the Applicant subsequently reduced the area affected, approximately half of the original parcel remains within the Scheme.

The principal ecological conflict therefore remains unresolved.

Conclusion

The Applicant has not demonstrated that construction disturbance will avoid significant effects on the nationally important bat assemblage or the wider ecological network.

No species-specific assessment has been undertaken of prolonged construction noise, vibration, pile driving, heavy traffic or simultaneous disturbance across multiple maternity colony landscapes.

The Spring Wood hibernacula, known woodland roosts and connected commuting corridors receive no dedicated construction disturbance assessment despite representing one of the most sensitive bat resources within the Scheme.

The reliance upon outline management plans, future Ecological Clerk of Works supervision and later method statements does not satisfy the requirements of EN-1 for effective, secured mitigation. Nor does it demonstrate that the statutory tests relating to European Protected Species can ultimately be met.

BEPS therefore submits that the ecological effects of construction disturbance have been materially underestimated. In the absence of detailed, species-specific assessment demonstrating that construction noise, vibration, traffic and associated disturbance will not impair the functioning of the nationally important bat landscape throughout construction, the Applicant has failed to establish that these impacts can be avoided or adequately mitigated. This weighs strongly against the grant of development consent.

8.6.4 Solar infrastructure, prey availability and ecological function

The Applicant's assessment of ecological effects focuses predominantly on the direct footprint of infrastructure and the retention or creation of habitats. It gives insufficient consideration to the more subtle ecological processes through which large-scale solar developments alter habitat function, food availability and species behaviour. This is a significant omission because the East Pye landscape supports a nationally important bat assemblage whose ecological value depends not simply upon the presence of hedgerows and woodland, but upon the functioning of complex food webs across the wider agricultural landscape.

The Applicant assumes that because mature hedgerows, woodland blocks and many watercourses will remain physically present, their ecological function will also remain. However, ecological function depends upon the continued interaction between vegetation, invertebrates, aquatic systems, birds, mammals and wider ecosystem processes. Those interactions can be altered substantially without the physical removal of habitat.

The Applicant has not adequately assessed those functional changes.

Changes to insect abundance and prey availability

The Environmental Statement contains relatively little assessment of how solar infrastructure may alter the abundance, distribution and behaviour of invertebrates which form the primary prey base for bats and many farmland birds.

This omission is particularly important because the Applicant's own surveys demonstrate exceptionally high bat activity throughout the Scheme. Such activity necessarily reflects an abundant and spatially diverse prey resource. If prey distribution changes significantly, bat activity and habitat use may also change even where the structural habitat remains intact.

Ground-mounted solar developments modify the physical environment in numerous ways.

Large panel arrays alter:

- solar radiation reaching the ground;
- soil temperature;
- soil moisture;
- vegetation structure;
- wind movement;
- humidity;
- frost formation;

- and local microclimate.

These environmental changes influence both plant communities and the abundance and composition of invertebrate populations.

The Applicant has assumed that extensive grassland beneath panels will generally enhance biodiversity. That conclusion is not supported by detailed evidence specific to this landscape.

Grassland developing beneath closely spaced solar panels experiences substantially different environmental conditions from existing field margins and open grassland. Shading patterns, altered moisture regimes and maintenance practices influence plant composition and consequently affect the insects dependent upon those plants.

For insectivorous bats such as barbastelle, Myotis species, brown long-eared bats and Daubenton's bats, these changes have direct ecological consequences.

The Applicant has not modelled whether the prey resource supporting the nationally important bat assemblage would remain functionally equivalent following construction.

Peer-reviewed evidence concerning bat responses to solar development

This omission is particularly striking in light of the findings of Tinsley et al. (2023). That peer-reviewed study examined bat activity across paired solar developments and comparable control sites and found statistically significant reductions in bat activity for six of the eight species analysed.

Importantly, reduced activity was not confined to open areas beneath solar panels. Several species also exhibited reduced activity along retained field boundaries.

This finding is directly relevant to East Pye because the Applicant's principal mitigation strategy relies upon retaining existing hedgerows while introducing solar infrastructure into the adjoining fields.

If retained field boundaries experience reduced use despite remaining physically intact, then the Applicant's assumption that hedgerow retention preserves ecological function becomes substantially weaker.

The mechanisms responsible remain an active area of scientific research. The authors discuss possible explanations including:

- altered insect communities;
- changes in vegetation structure;
- modified microclimates;
- disruption of commuting behaviour;
- altered acoustic environments;
- avoidance of extensive reflective surfaces;
- and broader behavioural responses to industrialised landscapes.

The precise mechanism is less important than the consistent ecological outcome. Solar development changes how bats use landscapes.

The Applicant has not demonstrated why East Pye, despite supporting a nationally important bat assemblage and multiple maternity colonies, should be expected to behave differently.

Indeed, if anything, the ecological consequences are likely to be more significant because the baseline value is considerably higher than that of many ordinary agricultural sites.

Aquatic insects and food-web disruption

The interaction between solar infrastructure and aquatic ecology provides another important example of functional effects that have not been adequately assessed.

The Environment Agency has specifically identified concern regarding the attraction of aquatic insects to solar panels. Many aquatic insects navigate using polarised light reflected from water surfaces. Solar panels may produce optical characteristics capable of attracting emerging insects away from rivers, ponds and streams. Where this occurs, several ecological consequences may follow.

Adult insects may:

- waste energy attempting to oviposit on unsuitable surfaces;
- suffer increased mortality;
- fail to reproduce successfully;
- become concentrated in artificial locations;
- or become unavailable to predators occupying their normal feeding habitats.

The effects extend beyond the insects themselves.

Aquatic insects form an important food source for:

- Daubenton's bats;
- Myotis species;
- pipistrelles;
- birds;
- amphibians;
- fish;
- and many riparian predators.

Consequently, disruption of aquatic insect emergence has the potential to propagate through the wider food web.

The Environment Agency's representation expressly identifies this issue and requests wider riparian buffers while recognising that the interaction has not been fully assessed. The Applicant

does not provide a species-specific assessment of this pathway. Instead, it assumes that maintaining watercourse buffers will adequately protect aquatic ecology.

Buffer distances alone do not answer behavioural effects associated with reflected light or altered insect movement.

Watercourses as ecological corridors

The River Tas, Hempnall Beck, Starston Brook, Broome Beck and associated ditch systems provide much more than aquatic habitat.

They function simultaneously as:

- bat commuting routes;
- insect production systems;
- bird feeding habitat;
- mammal corridors;
- amphibian habitat;
- botanical corridors;
- and hydrological connections linking the wider landscape.

The Applicant's assessment frequently separates these functions into different technical chapters. Ecologically, they operate together.

- Changes affecting aquatic productivity may alter prey availability for bats.
- Changes affecting riparian vegetation may influence commuting routes.
- Changes affecting hydrology may alter invertebrate communities.

The Environmental Statement contains no integrated ecosystem assessment examining these interacting relationships. Instead, aquatic ecology, terrestrial ecology, hydrology and bats are considered largely independently. That compartmentalised approach underestimates ecological complexity.

Effects on woodland-edge ecology

Woodland edges are among the most productive ecological habitats within the South Norfolk Claylands.

They support:

- high insect abundance;
- flowering shrubs;
- sheltered microclimates;
- mature trees;
- deadwood;
- and structurally diverse vegetation.

The Applicant frequently proposes woodland-edge buffering as mitigation. However, woodland-edge ecology depends upon the gradual transition between woodland and surrounding land uses. Introducing extensive solar arrays immediately adjacent to woodland fundamentally alters that transition.

Potential consequences include:

- modified air movement;
- altered humidity;
- changes in edge vegetation;
- altered insect communities;
- increased disturbance;
- lighting;
- maintenance activity;
- and changed predator-prey interactions.

The Forestry Commission has recognised these wider edge effects by expressing concern about woodland isolation and recommending expanded woodland creation around vulnerable ancient woods.

The Applicant has not demonstrated that simple thirty-metre buffers preserve woodland-edge ecological function.

Field margins and ecological productivity

The South Norfolk Claylands are characterised by narrow field margins, species-rich hedgerows and remnant grassland strips. These features support disproportionately high ecological productivity compared with the surrounding arable fields. Many bat species forage intensively along these edges because insects concentrate there.

The Applicant assumes that retaining margins while converting adjoining fields into solar arrays will largely preserve ecological function. That assumption has not been demonstrated.

Solar arrays alter:

- wind patterns;
- vegetation management;
- grazing regimes;
- shading;
- maintenance access;
- and human disturbance.

Each of these changes may influence insect abundance within adjoining margins.

The Applicant has not assessed whether retained margins will continue to produce equivalent prey resources following construction.

Interaction with agricultural stewardship

This issue also relates directly to the existing Countryside Stewardship habitats.

Many of the habitats supporting the current prey base have been actively managed for biodiversity since 2013 under publicly funded stewardship agreements.

Those agreements have increased:

1. floral diversity;
2. seed resources;
3. invertebrate abundance;
4. habitat for ground-nesting birds: lapwing and skylarks
5. and habitat connectivity.

The Applicant proposes replacing functioning stewardship habitats with newly created grassland designed partly to generate Biodiversity Net Gain.

There is no evidence demonstrating that newly established habitat beneath solar panels will immediately replicate the ecological productivity developed through over a decade of conservation management.

The BNG calculations therefore cannot be assumed to represent equivalent prey availability for protected species.

Failure to assess ecosystem function

Perhaps the greatest weakness in the Applicant's assessment is that it considers receptors separately rather than examining ecosystem function.

The nationally important bat assemblage exists because of the interaction between:

- ancient hedgerows;
- woodland;
- ponds;
- chalk streams;
- aquatic insects;
- terrestrial invertebrates;
- flowering margins;
- mature trees;
- grazing land;
- and long-established agricultural management.

Each component supports the others.

Removing or altering one component may produce cascading effects across the wider ecological network. The Applicant has not attempted to evaluate these ecosystem-scale interactions. Instead, the assessment focuses largely upon whether individual habitats remain present after construction.

Ecological function cannot be reduced to habitat presence alone.

Relationship to Biodiversity Net Gain

This omission also exposes one of the principal weaknesses in the Applicant's Biodiversity Net Gain case. The statutory biodiversity metric measures habitat area, distinctiveness, condition and strategic significance.

It does not measure:

- prey availability;
- food-web resilience;
- insect productivity;
- ecological interactions;
- predator-prey relationships;
- or behavioural changes in highly mobile protected species.

Consequently, a positive biodiversity metric cannot demonstrate that the nationally important bat assemblage identified by the Applicant will continue to function at favourable conservation status. Nor can it confirm that the skylarks and lapwing breeding in these stewardship arable fields will continue to do so once they have been stripped during construction and converted to grassland beneath solar panels. Indeed, research by Gwent Wildlife Trust has demonstrated that lapwing have not adopted the mitigation area of the Gwent Levels solar farm and have not returned to the area post construction. They also record reduced insect numbers having an impact on their bat populations.

The Applicant has repeatedly relied upon predicted habitat gains while providing little evidence that existing ecological processes will remain intact.

Failure to apply the mitigation hierarchy

The ecological processes described above reinforce the importance of the mitigation hierarchy.

Where the functioning of a nationally important ecosystem depends upon interactions that are not fully understood and cannot readily be recreated, the appropriate response is avoidance.

Instead, the Applicant has selected a landscape whose ecological value derives from long-established ecosystem function and seeks to justify development through habitat retention, future habitat creation and Biodiversity Net Gain calculations.

That approach reverses the hierarchy required by EN-1.

Rather than demonstrating that ecological processes will remain intact, the Applicant assumes that replacement habitat will compensate for changes whose magnitude has not been quantified.

Conclusion

The Applicant has not demonstrated that the ecological functioning of the East Pye landscape will be maintained following construction of the Scheme.

It has not adequately assessed:

- changes to prey availability;
- changes to insect communities;
- aquatic insect attraction to solar panels;
- woodland-edge ecological processes;
- field-margin productivity;
- ecosystem interactions;
- or the implications of these changes for the nationally important bat assemblage.

The findings of Tinsley et al., the Environment Agency's concerns regarding aquatic insects, the Applicant's own nationally important bat surveys, and the wider evidence concerning ecosystem connectivity all indicate that ecological function may change substantially even where habitat is physically retained.

The Environmental Statement does not adequately address these processes. Consequently, the Applicant has failed to demonstrate that the Scheme will preserve the ecological function of the nationally important bat landscape or that these impacts can be effectively mitigated. In accordance with EN-1 and the mitigation hierarchy, the appropriate response is avoidance rather than reliance upon generic habitat creation and Biodiversity Net Gain metrics.

8.6.5 Landscape fragmentation by fencing, roads and operational infrastructure

The Environmental Statement consistently underestimates the ecological consequences of fragmentation because it treats most infrastructure elements as having only localised effects. In reality, East Pye Solar would introduce a continuous network of fencing, access roads, substations, BESS compounds, CCTV infrastructure, maintenance tracks, drainage works, cable corridors and security infrastructure across an existing connected ecological landscape. The ecological significance of these features lies not simply in their individual footprints, but in their cumulative effect on the permeability, resilience and long-term functioning of the landscape.

This is particularly important because the Applicant's own surveys demonstrate that the ecological value of the Scheme area is fundamentally landscape-scale. The nationally important bat assemblage, overlapping barbastelle maternity-colony Core Sustenance Zones, connected hedgerow network, chalk-stream tributaries, ancient woodland complexes and widespread priority habitats all indicate that ecological function depends upon the continued movement of species through the landscape. Fragmentation therefore becomes one of the principal ecological impact pathways.

The Applicant's assessment largely considers habitat loss in terms of hectares removed. That is not the correct ecological question. The relevant question is whether the landscape will continue to function as a connected ecological system following sixty years of industrial development. On the evidence before the Examination, that has not been demonstrated.

Fragmentation is recognised as a principal ecological threat

The importance of fragmentation is not merely a matter of professional opinion. It is consistently recognised throughout the evidence submitted to this Examination.

The Forestry Commission identifies fragmentation as one of the greatest threats to ancient woodland, particularly where small woodland blocks become isolated within the wider landscape. In relation to East Pye Solar, it expresses specific concern regarding Doyly's Grove and especially Ringers Grove, observing that Ringers Grove would become almost completely enclosed by the development, with Market Lane forming the only remaining undeveloped boundary. The Forestry Commission explains that woodland isolated within development becomes progressively less resilient over time and recommends increasing woodland connections rather than relying solely upon buffer strips.

That advice has wider significance than woodland management. Ancient woodland does not exist independently of its surrounding landscape. Its ecological value depends upon the exchange of species, genetic material and ecological processes with adjacent habitats. The same principle applies to bats, woodland birds, invertebrates, fungi, mammals and countless other species.

The Applicant's mitigation strategy retains woodland while fundamentally altering the surrounding landscape within which that woodland functions. The Forestry Commission's evidence therefore directly supports BEPS' contention that landscape connectivity, rather than simple woodland retention, is the critical ecological issue.

Security fencing and ecological permeability

One of the least adequately assessed elements of the Scheme is the cumulative effect of fencing. The development would require extensive lengths of permanent security fencing around:

- solar fields;
- BESS compounds;
- substations;
- customer substations;
- National Grid infrastructure;
- operational compounds;
- and associated infrastructure.

Although the fencing may be designed to allow passage for some small mammals, its cumulative ecological effects extend well beyond direct physical exclusion.

The Forestry Commission expressly raises concern regarding deer movement. It notes that large areas of farmland would be removed from existing deer ranges and warns that fencing may:

- isolate woodland;
- alter movement patterns;
- increase browsing pressure elsewhere;
- affect surrounding stewardship habitats;
- increase pressure on ancient woodland regeneration;
- and increase road collisions as displaced deer seek alternative routes.

These observations illustrate a wider ecological principle. Species move through landscapes using established behavioural pathways developed over many generations. Introducing extensive fencing changes those movement patterns. Where movement is constrained, ecological pressures are redistributed elsewhere.

The Environmental Statement assesses fencing largely as an engineering requirement. It does not provide a landscape-scale analysis of how fencing alters ecological permeability for the wider species assemblage. Nor does it adequately assess cumulative fragmentation resulting from fencing acting together with roads, compounds, lighting and other infrastructure.

Fragmentation of woodland landscapes

The consequences are particularly important around the ancient woodland network. The Applicant correctly proposes that direct loss of ancient woodland should be avoided. However, avoiding direct felling is not equivalent to avoiding ecological fragmentation. Woodland ecology depends upon:

- surrounding woodland edge;
- adjoining scrub;
- transitional habitats;
- connected hedgerows;
- adjacent grassland;
- insect-rich margins;
- and uninterrupted ecological links to the wider landscape.

These ecological relationships are particularly important for woodland bats. Barbastelles, brown long-eared bats, Myotis species and many woodland birds routinely move between woodland blocks using hedgerows, lanes, tree belts and riparian corridors. Where those connections become interrupted by:

- fencing;
- roads;
- compounds;
- substations;
- maintenance infrastructure;
- repeated vehicle movements;
- lighting;
- or security infrastructure,

the woodland itself may remain physically intact while its ecological function progressively declines. This concern is particularly acute for Spring Wood, Doyly's Grove, Ringers Grove and other woodland blocks located close to development parcels.

The Applicant has not undertaken a functional woodland connectivity assessment demonstrating that these ecological relationships will remain intact throughout construction, operation, replacement and decommissioning.

Roads, access tracks and operational infrastructure

The Scheme introduces a permanent network of operational infrastructure extending throughout the Order Limits. This includes:

- internal maintenance roads;
- permanent access tracks;
- junction improvements;
- widened rural lanes;
- substations;
- transformer compounds;
- BESS infrastructure;
- CCTV poles;
- security equipment;
- drainage infrastructure;
- and permanent operational compounds.

Each element occupies relatively little land individually. Collectively they transform the structure of the landscape. The Environmental Statement generally assesses these features separately. There is no integrated assessment examining how the combined infrastructure alters movement opportunities for wildlife across the entire Scheme. For example, a bat commuting along a hedgerow may encounter:

- a widened access road;
- security fencing;
- operational lighting;
- maintenance vehicles;
- CCTV columns;
- altered vegetation management;
- and increased human activity.

Each individual feature may be considered insignificant. Together they fundamentally alter the ecological character of that commuting corridor. The same applies to mammals, birds, reptiles and invertebrates moving through the landscape.

Long-term industrialisation of a historic landscape

The duration of fragmentation also requires greater attention. This is not a temporary construction project. The Scheme would industrialise the landscape for approximately sixty years, followed by a substantial period of decommissioning.

Throughout that time, ecological communities would experience:

- altered habitat configuration;
- altered movement opportunities;
- repeated maintenance;
- vegetation management;
- infrastructure replacement;
- security requirements;
- operational access;
- and periodic reconstruction.

The Applicant frequently describes habitat creation as if it will progressively offset these effects. However, fragmentation is not simply an issue of habitat quantity. It concerns the organisation of the landscape itself.

The historic South Norfolk Claylands developed over centuries as an interconnected ecological mosaic. Replacing that mosaic with compartmentalised solar fields enclosed by fencing and linked by infrastructure represents a fundamental change in landscape structure.

No amount of newly planted hedgerow can immediately recreate centuries of ecological connectivity.

Cumulative interaction with other ecological pressures

Fragmentation cannot be assessed independently of other impact pathways. It interacts continuously with:

- artificial lighting;
- construction disturbance;
- altered prey availability;
- hydrological change;
- tree decline;
- road widening;
- cable corridors;
- and changing land management.

For example:

A woodland enclosed by fencing may also experience:

- increased lighting;
- altered insect abundance;
- repeated maintenance activity;
- construction vibration;
- and modified groundwater conditions.

Each effect reinforces the others. The Applicant's assessment largely considers these impacts chapter by chapter. Wildlife experiences them simultaneously.

This cumulative interaction is especially important for barbastelles. The Applicant's own surveys establish that the nationally important bat assemblage depends upon movement throughout the Scheme. Fragmentation occurring simultaneously with lighting, disturbance and altered prey availability is considerably more significant than any one pressure considered in isolation.

The Environmental Statement does not evaluate these cumulative behavioural consequences.

Biodiversity Net Gain does not address fragmentation

The Applicant relies heavily upon Biodiversity Net Gain calculations to demonstrate ecological enhancement. However, the statutory biodiversity metric principally measures habitat area, distinctiveness and condition. It does not measure:

- landscape permeability;
- connectivity;
- fragmentation;
- commuting routes;
- woodland enclosure;
- behavioural avoidance;
- metapopulation function;
- or ecological resilience.

Consequently, positive habitat-unit calculations do not demonstrate that fragmentation has been avoided.

This distinction is recognised by the Forestry Commission. Its recommendation is not simply to plant more woodland. It recommends enlarging woodland blocks and strengthening ecological connectivity because habitat area alone does not resolve fragmentation.

Similarly, the South Norfolk Tree Warden Network identifies mature hedgerows and trees as ecological infrastructure whose function cannot be replicated through simple replacement planting.

The Applicant's reliance upon Biodiversity Net Gain therefore does not answer the principal ecological concern.

Failure to apply the mitigation hierarchy

The treatment of fragmentation again illustrates the Applicant's failure to apply the mitigation hierarchy correctly.

The first stage of the hierarchy is avoidance.

Where nationally important ecological networks exist, infrastructure should be located so as to avoid severing those networks wherever possible.

Instead, the Applicant has selected a layout extending across multiple connected ecological corridors and then proposes to mitigate fragmentation through:

- retained hedgerows;
- additional planting;
- biodiversity enhancement;
- ecological management;
- and future monitoring.

That approach assumes fragmentation can be repaired after it has occurred. The evidence before the Examination indicates otherwise.

The Forestry Commission, Norfolk Wildlife Trust, the South Norfolk Tree Warden Network, local ecological evidence and the Applicant's own bat surveys all demonstrate that the ecological value of this landscape derives from long-established connectivity. Once fragmented, that connectivity cannot simply be recreated through post-development habitat enhancement.

Conclusion

The Applicant has materially underestimated the effects of landscape fragmentation.

The ecological consequences of fencing, operational roads, substations, access infrastructure, woodland enclosure, security measures and long-term industrialisation have not been assessed as components of a single interacting landscape. Instead, they have been considered individually, leading to systematic underestimation of cumulative effects.

The evidence submitted by the Forestry Commission, Norfolk Wildlife Trust, the South Norfolk Tree Warden Network and other consultees consistently identifies fragmentation as one of the principal ecological risks associated with the Scheme. The Applicant's own bat surveys demonstrate why: the nationally important bat assemblage depends upon movement through an extensive, connected landscape rather than isolated habitat parcels.

The Applicant has not demonstrated that this landscape will remain functionally connected following construction, operation, replacement and decommissioning. Nor has it shown that the fragmentation created by fencing, infrastructure and operational management can be effectively mitigated or compensated through Biodiversity Net Gain or future ecological management.

BEPS therefore submits that the effects of landscape fragmentation have been substantially underestimated. The Scheme conflicts with the mitigation hierarchy because it fails to avoid fragmentation of a nationally important ecological network and instead relies upon generic enhancement measures that do not address the underlying loss of ecological connectivity. This represents a fundamental ecological objection to the Scheme and provides a further reason why development consent should be refused.

8.6.6. Mitigation and BNG insufficient

The applicant cannot mitigate:

- Loss of maternity roost functionality
- Landscape-scale connectivity
- CSZ integrity

BNG proposals cannot replace:

- Mature woodland roost features
- Established bat movement networks

Examination consequence

These are not matters which can now be characterised as acceptance-stage deficiencies. The relevant question is whether the outstanding ecological evidence is sufficiently complete for the ExA to reach a robust conclusion on likely significant effects, mitigation and protected-species implications before making its recommendation. Where information is still needed to determine whether development can be avoided, relocated or made environmentally acceptable, that information goes to the consentability of the authorised envelope rather than merely to post-consent implementation.

ExQ1 now places the adequacy of the bat baseline directly in issue. The ExA asks Natural England whether the Applicant has established an adequate bat baseline, including in relation to barbastelle and woodland adjoining the Order Limits. That question is significant because the remaining issue is not merely whether barbastelles are present; the Applicant's own evidence already establishes a nationally important assemblage and widespread barbastelle activity. The unresolved question is whether the survey evidence is sufficient to identify the functional maternity-colony landscape, roost network, principal commuting routes and foraging areas which need to be protected before the final layout is fixed.

Closing statement

The scheme is located within a confirmed, multi-colony barbastelle metapopulation, with overlapping Core Sustenance Zones across the entire site. In the absence of a complete baseline and lawful assessment, the environmental effects cannot be understood and lawful consent cannot be granted.

Natural England's definition of Favourable Conservation Status for barbastelle bats confirms that the species is highly light-averse and dependent on dark, connected landscapes for foraging and movement between colonies. Artificial lighting is identified as a growing national threat, fragmenting habitats, reducing prey availability, and disrupting connectivity between maternity colonies.

The East Pye Solar scheme introduces permanent sources of artificial lighting across the entirety of a confirmed barbastelle maternity landscape, within overlapping Core Sustenance Zones. This will result in fragmentation of dark corridors, disruption of commuting routes, and degradation of foraging habitat at a landscape scale.

Natural England further states that favourable conservation status requires protection of existing roosts, maintenance of connectivity, and an increase in suitable roosting habitat. The proposed development directly conflicts with these requirements by introducing long-term disturbance, habitat fragmentation, and lighting into a functionally connected woodland network supporting maternity colonies.

In these circumstances, the present evidence does not demonstrate with sufficient confidence that the Scheme would be compatible with maintaining the affected barbastelle population at favourable conservation status. That creates a material unresolved issue for any future EPS licensing process and for the weight which can safely be placed on the Applicant's present mitigation case.

8.7 Ancient Woodland

8.7.1 Six ancient woodlands directly adjoining the Scheme

The concentration of ancient woodland immediately adjoining East Pye Solar is exceptional and must be treated as a defining constraint upon the Scheme, not as a collection of peripheral features capable of being protected by standard buffers. The Forestry Commission identifies six ancient woodlands directly adjacent to the proposed development:

- Saxlingham Grove — Ancient Semi-Natural Woodland;
- Doyly's Grove — Ancient Semi-Natural Woodland;
- Popes Wood — Plantation on an Ancient Woodland Site;
- Spring Wood — Plantation on an Ancient Woodland Site;
- Little Wood — Ancient Semi-Natural Woodland; and
- Ringers Grove — Ancient Semi-Natural Woodland.

Both Ancient Semi-Natural Woodland and Plantations on Ancient Woodland Sites are ancient woodland and therefore irreplaceable habitat. PAWS may have been replanted with non-native or plantation species, but its soils, seedbanks, fungi, hydrology, archaeological features and continuity of woodland cover retain characteristics developed over centuries. Its policy protection is not reduced because the present canopy has been modified. The Forestry Commission's

scoping advice accordingly emphasised that ancient woodland has been continuously wooded since at least 1600 and that the protection applies equally to ASNW and PAWS.

The absence of ancient woodland within the proposed panel footprint does not resolve the objection. National policy protects ancient woodland against both loss and deterioration, and EN-1 requires the direct and indirect effects of development upon ancient woodland and other irreplaceable habitats to be addressed during construction and operation. The relevant assessment must therefore extend beyond felling or excavation within the mapped woodland boundary. It must consider whether the Scheme would degrade the woodlands through fragmentation, enclosure, altered hydrology, dust, lighting, noise, vibration, edge effects, soil compaction, pollution, increased traffic and the loss of their ecological relationship with surrounding hedgerows, watercourses, field margins and other woodland blocks.

The Planning Inspectorate's Scoping Opinion required the ES to assess impacts upon the six ancient-woodland parcels adjoining the Scheme and to consider avoidance, mitigation and enhancement. The consultation advice recorded Popes Wood beside Sub-Site 7C, Doyly's Grove beside Sub-Site 7C, Saxlingham Grove beside Sub-Sites 7F and 7G, Little Wood beside Sub-Site 7H, Ringers Grove beside Site 8A, and Spring Wood beside Sub-Sites 3A and 3B. It also stressed that the standard 15-metre woodland buffer is only a minimum and may need to be increased where indirect effects extend further. The Applicant's own early site description likewise acknowledged that Doyly's Grove adjoins Sub-Site 7C on three sides, Popes Wood adjoins its southern side, Saxlingham Grove adjoins the Site 7 development and Little Wood lies beside Sub-Site 7H.

This spatial relationship is not incidental. The six woods lie within the same historic Claylands matrix of old hedgerows, mature trees, lanes, ditches, ponds, wet corridors and small fields that supports the Applicant's nationally important bat assemblage. Their ecological importance is therefore both intrinsic and relational. Each woodland contributes roosting, breeding, shelter and foraging habitat, while the surrounding landscape allows species, genetic material and ecological processes to move between woods. Development immediately around those woods threatens not only their individual condition but the functioning of the woodland network.

Saxlingham Grove

Saxlingham Grove is particularly sensitive because it is both ancient woodland and part of the Shotesham–Woodton Hornbeam Woods SSSI. The Applicant's scoping material describes that SSSI as a group of ancient coppice-with-standards woods that may once have formed part of a continuous primary hornbeam forest. It identifies Saxlingham Grove, Shotesham Little Wood, Hempnall Little Wood and Winter's Grove as representative examples of the distinctive south Norfolk and north-east Suffolk hornbeam-woodland type.

The woodland also supports a documented barbastelle maternity colony. Records summarised in the Applicant's bat assessment include roosts in ash, oak and dead oak trees, emergence counts and a lactating female. The woodland directly adjoins development parcels and forms part of the landscape in which the Applicant recorded widespread barbastelle activity. The significance of Saxlingham Grove therefore cannot be reduced to whether panel foundations fall outside a 30-

metre line. Its condition and protected-species function depend upon dark, connected and sufficiently undisturbed habitat extending beyond the woodland boundary.

Natural England's Relevant Representation identifies Shotesham–Woodton Hornbeam Woods SSSI as hydrologically connected to the Order Limits and accepts that damage can only be ruled out if the water-quality, pollution-prevention and runoff controls relied upon are followed and secured. It also identifies Saxlingham Grove itself as an ancient woodland hydrologically linked to the Scheme. That conditional position confirms that the woodland is exposed to indirect pathways and that its protection cannot be assumed merely from the absence of direct land take.

Doyly's Grove and Popes Wood

Doyly's Grove and Popes Wood are closely associated with Sub-Site 7C. The Applicant's own scoping report records Doyly's Grove adjacent to the south, west and north of the sub-site and Popes Wood adjacent to its south. This configuration places the proposed development within the immediate ecological setting of both woods and creates a particular risk of enclosure and loss of connectivity.

The Forestry Commission has expressed concern about Doyly's Grove because it is a relatively small ancient woodland and therefore especially vulnerable to isolation and climate-related pressures. Small ancient woods depend heavily upon their surrounding habitats. Their resilience is reduced where hedgerows, scrub, grassland and other wooded links are replaced by fenced infrastructure or where edge conditions become hotter, drier, brighter or more disturbed.

Natural England also identifies Popes Wood and Doyly's Grove as hydrologically connected ancient woodland. This is important because indirect deterioration may occur through changes in groundwater flow, surface runoff, sediment movement and soil moisture, as well as through visible physical disturbance. A buffer measured only as a horizontal distance from the woodland edge does not establish that those processes will be unaffected.

Norfolk Wildlife Trust identified both Popes Wood and Doyly's Grove as sensitive ancient woodland beside Site 7C and required large buffers, ecotones of shrubs and rough grassland, construction controls and evidence that the development would not have negative effects. The Trust's request for an ecotone is materially different from leaving a narrow strip of otherwise ordinary land between panels and woodland. A functioning ecotone should provide a graduated, semi-natural transition capable of supporting woodland-edge plants, invertebrates, birds and bats and of reducing abrupt microclimatic and disturbance effects.

Spring Wood

Spring Wood is a PAWS directly adjoining the Site 3 landscape. Its sensitivity is heightened by its relationship with Hempnall CWS, a known barbastelle roost and foraging area, and the converted Second World War bomb shelters used as bat hibernacula. The woodland and shelters form a combined year-round bat resource linked to the surrounding hedgerows, mature trees and fields.

Norfolk Wildlife Trust expressly sought removal of the development parcel adjoining Spring Wood because of the impacts upon ancient woodland, the County Wildlife Site and bats. The Applicant

removed only part of that parcel. The remaining development therefore continues to occupy the ecological setting of the woodland and the associated bat resource.

The appropriate question is not whether part-removal has reduced the number of panels. It is whether the remaining Scheme has avoided deterioration of Spring Wood and impairment of its woodland, roosting, hibernation, foraging and commuting functions. No complete radio-tracking, hibernacula-specific disturbance assessment or functional connectivity assessment has been produced to demonstrate that it has.

Little Wood

Little Wood is ASNW directly adjacent to the Site 7 and Site 8 development landscape. Its importance is reinforced by the Norfolk Barbastelle Study Group's confirmation of a maternity colony there. The woodland therefore functions not merely as a mapped ancient-woodland parcel but as an active breeding resource for a rare Annex II and European Protected Species.

The Scheme lies within the Core Sustenance Zone of that colony, and the Applicant recorded barbastelle activity throughout the surrounding Order Limits. Development beside Little Wood must consequently be assessed in terms of the continuing function of the maternity colony, including access to dark commuting routes, prey-rich margins, wet habitats and alternative woodland roosts. A retained woodland boundary and a nominal buffer do not establish that those functions will continue.

Norfolk Wildlife Trust identified the proximity of Site 7H to Little Wood, sought at least a 30-metre buffer and required that the buffer comprise a suitable shrub and rough-grassland ecotone rather than an unstructured stand-off distance.

Ringers Grove

Ringers Grove is ASNW beside Site 8A and is especially vulnerable because the development would surround it on three sides. Norfolk Wildlife Trust expressly identified this configuration, noted the presence of veteran trees and the proximity of Shotesham–Woodton Hornbeam Woods SSSI, and required the ES to demonstrate how connectivity between the woodlands would be maintained.

The Forestry Commission's later representation goes further, warning that Ringers Grove would become almost completely enclosed by development, with Market Lane providing the principal remaining open boundary. It identifies enclosure and isolation as long-term threats, particularly for a small ancient wood facing climate pressure, and recommends expansion and connection to create a more resilient woodland block with graduated woodland edge and scrub habitat.

That advice exposes the inadequacy of assessing Ringers Grove only by reference to direct loss. The Scheme may leave every mapped woodland tree standing and still cause deterioration by converting the woodland from part of a permeable rural network into an ecological island surrounded by panel arrays, fencing, roads and operational activity.

The six woods form a network, not six separate constraints

The ES does not adequately recognise the cumulative importance of having six irreplaceable woodland sites directly adjoining one development. Each woodland is assessed largely against the nearest parcel and proposed buffer. That approach fails to consider whether the combined Scheme would:

- reduce movement among the woodland blocks;
- interrupt hedgerow and riparian connections;
- isolate bat maternity colonies and satellite roosts;
- alter the hydrological conditions upon which woodland soils and ground flora depend;
- impose repeated lighting, noise, dust and traffic effects across the network;
- or reduce the woodlands' collective resilience over the Scheme's proposed lifetime.

The ancient woods of the South Norfolk Claylands are surviving components of a formerly more extensive historic woodland and hedgerow system. Their small size increases, rather than reduces, their dependence upon the surrounding ecological matrix. Professor Tom Williamson's Claylands evidence explains that woodland in this landscape has historically been connected through hedges, farmland trees, ponds, margins and other semi-natural features. The proper policy objective is to restore and reinforce that connectivity, not to preserve the mapped woodlands as fragments while industrialising the land between them.

The Applicant proposes approximately 25 hectares of new woodland planting and other habitat creation. That may provide future ecological value, but it does not establish avoidance of deterioration to the six existing ancient woods. Newly planted woodland cannot reproduce ancient woodland soils, fungi, seedbanks, veteran structures or long-established species relationships. Nor does planting elsewhere necessarily repair the enclosure of a particular woodland or preserve an existing bat route.

Natural England presently treats ancient woodland as a 'green' issue, but its position is expressly dependent upon the 30-metre buffers and associated protections being consistently recorded and secured in the LEMP, CEMP and DEMP. It also requires full BS5837-compliant survey, strict root protection, arboricultural supervision, no-dig methods, compaction prevention, dust and runoff control and micrositing. Natural England's absence of an objection is therefore not a finding that proximity to six ancient woods is environmentally immaterial. It is a conditional position based upon mitigation that must still be made consistent, detailed and enforceable.

BEPS submits that the six directly adjoining ancient woodlands must be treated as a scheme-wide irreplaceable-habitat constraint. Their protection cannot be demonstrated through the absence of direct felling or by drawing standard buffers around individual polygons. The assessment must establish that their condition, setting, hydrology, edge habitats, protected-species functions and connectivity with the wider Claylands network will not deteriorate throughout construction, operation, equipment replacement and decommissioning.

The Applicant has not yet made that demonstration. The concentration of six ancient woods immediately beside the development, several supporting or associated with barbastelle maternity and year-round bat habitat, is a strong indication that the Scheme has been located in the wrong

ecological landscape. Under the mitigation hierarchy, the first response should have been avoidance through site selection and removal of conflicting development areas, rather than enclosure of irreplaceable habitats accompanied by buffers and compensatory planting.

8.7.2 Woodland fragmentation, enclosure and loss of ecological function

The principal threat to the ancient woodlands adjoining East Pye Solar is not confined to direct felling or physical encroachment within their mapped boundaries. It is the long-term fragmentation, enclosure and degradation of the ecological network within which those woods have survived and continue to function.

The Applicant's own scoping work identified 29 areas of Ancient Woodland Inventory woodland within two kilometres of the principal sites, with six ancient woodland parcels directly adjoining the development. It also recorded native hedgerows throughout the sites, numerous ponds, hundreds of parcels of deciduous woodland and adjoining lowland fen and floodplain grazing marsh. The ecological question is therefore not whether six individual woodland polygons can be retained. It is whether those woods will continue to function as parts of a permeable woodland–hedgerow–watercourse network after the intervening and surrounding landscape has been occupied for approximately sixty years by panel arrays, substations, BESS infrastructure, access tracks, fencing, compounds, lighting and maintenance activity.

The Applicant has not demonstrated that they will.

Ancient woodland depends upon its surrounding landscape

Ancient woodland is irreplaceable because of the continuity and complexity accumulated within its soils, seedbanks, fungi, veteran trees, deadwood communities, hydrology and species assemblages over centuries. Those characteristics do not stop at a cartographic boundary. The ecological condition and resilience of a small woodland are strongly influenced by its surrounding land use, woodland-edge habitats and connections to other woods, hedgerows, trees, ponds and watercourses.

This is particularly important in the South Norfolk Claylands. Professor Tom Williamson's landscape history evidence explains that the Claylands historically supported an intricate network of small fields, species-rich hedges, farmland trees, ponds, commons, wide grassy lanes and woodland. Those features produced not merely habitat parcels but 'a wealth of connections between them'. The same evidence explains that hedges acted as habitat corridors, that ponds and ditches formed a connected seasonal water network, and that grassland verges and field margins extended the ecological web through the farmed landscape.

The surviving ancient woods are therefore remnants of, and nodes within, a much larger historic ecological system. Their small scale makes those external relationships more important, not less important. Small woodlands have a high proportion of edge habitat relative to interior habitat and are correspondingly more vulnerable to altered temperature, humidity, wind exposure, pollution, disturbance and isolation. Where surrounding hedges and semi-natural land remain intact, those pressures can be moderated and species can move between habitat patches. Where the

surrounding landscape is industrialised and enclosed, the woodland becomes progressively more isolated.

The Applicant's own landscape characterisation recognises that woodland groups, tree belts and hedgerow networks create enclosed wooded horizons and give structure and intimacy to the Site 8 and Site 10 landscapes. Those features cannot simultaneously be treated as integral to landscape structure and ecological value, yet regarded as unaffected merely because the woodland canopy is not felled.

The Forestry Commission's warning on fragmentation and enclosure

The Forestry Commission expressly identifies fragmentation as one of the greatest threats to ancient woodland. Its concern is not theoretical. It identifies Doyly's Grove and Ringers Grove as particularly vulnerable because they are small ancient woods whose relationship with the wider landscape would be altered by the Scheme. In the case of Ringers Grove, the development would almost completely enclose the woodland, leaving Market Lane as the principal remaining undeveloped boundary.

The Forestry Commission's earlier scoping advice stated that woodland isolation is a particular concern where development surrounds woodland on several sides or completely encloses it. It advised that hedgerows, individual trees and woodland must be considered in terms of their overall connectivity and recommended the creation or expansion of connected woodland blocks of at least five hectares to improve resilience across the whole landscape rather than planting isolated areas merely for screening.

That advice is highly material. It confirms that a woodland buffer cannot be considered independently from the configuration of the surrounding development. A retained strip immediately outside the woodland boundary does not overcome enclosure where the land beyond the strip is occupied by fencing, panels, tracks and operational infrastructure.

Nor does the proposal to plant new woodland elsewhere resolve the effect. The Forestry Commission's recommendation is for planting that expands and connects vulnerable woods in the correct locations, with graduated woodland-edge and scrub habitat. It is not an endorsement of generalised planting totals as compensation for enclosing ancient habitat.

Ringers Grove

Ringers Grove is the clearest example of the difference between physical retention and ecological protection.

The Applicant's own scoping material recorded Ringers Grove directly adjacent to the west and north of Sub-Site 8A. Norfolk Wildlife Trust described Site 8 as surrounding Ringers Grove on three sides and expressly required the ES to demonstrate how connectivity between woodland sites would be maintained. It recommended a minimum 30-metre buffer comprising a genuine ecotone of shrubs and rough grassland, not merely a stand-off distance between woodland and infrastructure.

The Forestry Commission's subsequent representation confirms that concern remains despite the proposed buffers and planting. Ringers Grove is a small ancient woodland and would be especially vulnerable to landscape isolation and climate pressures. Its almost complete enclosure would alter the relationship between the woodland and the fields, hedges and wooded links around it.

The potential consequences include:

- reduced movement between Ringers Grove and nearby woodland;
- loss or degradation of bat flight routes;
- altered deer and mammal movement;
- increased browsing pressure within or around the wood;
- changes to edge microclimate;
- increased exposure to lighting, noise and human activity;
- loss of adjoining invertebrate and foraging habitat;
- and reduced capacity for species to respond to climate change by moving through the landscape.

The issue cannot be answered by stating that no ancient woodland trees will be removed. The woodland may remain physically present while becoming ecologically diminished and isolated.

Doyly's Grove and Popes Wood

The same issue arises at Doyly's Grove and Popes Wood. The Applicant records Doyly's Grove adjacent to Sub-Site 7C on its southern, western and northern sides, with Popes Wood adjoining the same sub-site to the south. The development would therefore occupy land within and between the immediate settings of two ancient woodland sites.

Norfolk Wildlife Trust identifies both woods as sensitive County Wildlife Sites and ancient woodland and requires large buffers, woodland-edge ecotones and evidence that no negative effects would occur. The Forestry Commission remains particularly concerned about Doyly's Grove because its small size makes it vulnerable to isolation and climate change.

The configuration matters. A woodland with development along one distant boundary presents a different ecological risk from one bordered on several sides by a major energy scheme. At Doyly's Grove and Popes Wood, the proximity and extent of the development would alter the surrounding habitat matrix and could reduce the effective connection between the woods and the wider hedgerow and tree network.

The Applicant has not produced a woodland-network analysis demonstrating:

- the existing routes connecting Doyly's Grove and Popes Wood to other woods;
- the species using those routes;
- the effects of fencing, tracks and lighting upon those movements;
- how any new planting would maintain or improve the same connections;
- or the length of time before new woodland-edge habitat would become functionally effective.

Without that analysis, the conclusion that a 30-metre buffer avoids deterioration is not established.

Saxlingham Grove and Little Wood

Saxlingham Grove and Little Wood illustrate the close relationship between ancient woodland fragmentation and protected-species function.

Saxlingham Grove is part of the Shotesham–Woodton Hornbeam Woods SSSI, a group of ancient coppice-with-standards woodlands believed to represent remnants of a formerly more continuous hornbeam forest. The Applicant's scoping material describes the site as a distinctive south Norfolk woodland type and records the SSSI immediately adjacent to parts of Site 7. Saxlingham Grove also supports a documented barbastelle maternity colony.

Little Wood is ancient semi-natural woodland and supports a confirmed barbastelle maternity colony identified through Norfolk Barbastelle Study Group work. The Scheme lies within the colony's Core Sustenance Zone and within a wider landscape in which barbastelle activity was recorded throughout the Order Limits.

Fragmentation in these locations therefore has population-level implications. The woods are not simply static repositories of woodland habitat. They are active breeding sites within a connected maternity-colony landscape. Their continuing function depends upon access to:

- alternative tree roosts;
- dark hedgerows and treelines;
- riparian routes;
- prey-rich field margins;
- ponds and wetland;
- neighbouring woods;
- and sufficiently extensive foraging habitat.

A 30-metre strip around a maternity woodland does not preserve those functions where the landscape beyond it is fragmented or behaviourally avoided. For a light-averse and woodland-dependent species, a retained hedge interrupted by an access road or illuminated at a crossing may no longer provide an equivalent route.

The Applicant's own nationally important bat findings reinforce this point. The South Norfolk Tree Warden Network notes that 621 trees across the Order Limits have potential to support roosting bats and that the nationally important assemblage relies upon mature trees, tree lines, hedges and field margins. It accordingly describes those features as 'functional ecological infrastructure' and criticises the absence of a route-wide analysis of cumulative hedgerow severance, buffer disruption, lighting and the time required for replacement planting to become equivalent.

The protection of Saxlingham Grove and Little Wood therefore requires preservation of the network outside the woodland boundaries, not simply preservation of the trees within them.

Spring Wood

Spring Wood demonstrates the same issue in a year-round bat context. It is ancient woodland adjoining the remaining Site 3 development and is associated with a known barbastelle roost and foraging landscape. The converted Second World War bomb shelters immediately beside the woodland provide purpose-created bat hibernation habitat.

Norfolk Wildlife Trust sought removal of the relevant development parcel because of its relationship with Spring Wood, the County Wildlife Site and bats. Only part of the parcel was removed. The retained development therefore continues to fragment and industrialise the ecological setting of the woodland and hibernacula.

The woodland may remain standing, but its function can be reduced if bats encounter lighting, piling, vehicle activity, fencing or loss of foraging habitat when moving between the shelters, the woodland and the wider landscape. The Applicant has not shown that the remaining development preserves those year-round connections.

Physical and behavioural fragmentation

The ES appears to treat fragmentation principally as physical removal or severance of habitat. That is too narrow.

Woodland networks can be fragmented in at least two ways.

The first is physical fragmentation, caused by removal of trees or hedges, road and cable crossings, fencing and the replacement of permeable land with infrastructure.

The second is behavioural or functional fragmentation, where the physical feature remains but species cease or reduce their use because of:

- artificial lighting;
- noise and vibration;
- regular vehicle movement;
- human activity;
- altered prey availability;
- changed vegetation structure;
- increased exposure;
- or the cumulative perception of the surrounding land as unsuitable.

This distinction is especially important for bats. Tinsley et al. found reduced bat activity at ground-mounted solar sites, including reduced activity along retained field boundaries for some taxa. That evidence demonstrates that retaining the physical boundary does not necessarily retain its ecological use.

The same principle applies to woodland. A woodland buffered by grass but enclosed by arrays and fencing may remain mapped as ancient woodland and yet become less accessible, less productive or less suitable to the species that previously used it.

Edge effects and altered microclimate

Enclosure also changes the quality of woodland edges.

Woodland edges are dynamic transition zones. Their condition depends upon surrounding vegetation, shelter, humidity, light, soil moisture and management. The replacement of an open or semi-natural agricultural edge with panel arrays and infrastructure may alter:

- wind flow;
- shading;
- reflected heat;
- humidity;
- soil moisture;
- dust deposition;
- runoff;
- and the composition of edge vegetation and invertebrates.

These changes are especially significant for small woods, where a greater proportion of the habitat lies close to an edge.

The Applicant proposes 30-metre buffers to ancient woodland, but there is no site-specific evidence showing that 30 metres is sufficient to address every indirect pathway. Natural England and Forestry Commission standing advice treats 15 metres as a minimum and expressly recognises that larger buffers may be needed where effects extend farther, including traffic-related air pollution and construction dust.

A fixed buffer cannot substitute for assessment of the actual Zone of Influence. The necessary distance depends upon:

- the size and vulnerability of the woodland;
- topography and prevailing wind;
- the type and duration of construction activity;
- drainage and groundwater pathways;
- lighting design;
- the location of access tracks and compounds;
- and the ecological functions occurring beyond the woodland boundary.

Hydrological fragmentation

Woodland isolation is not only terrestrial. Natural England identifies several ancient woodlands as hydrologically connected to the Scheme and relies upon pollution-prevention, water-quality and runoff controls when reaching its present ‘green’ conclusion.

Changes to drainage, groundwater recharge, soil compaction, cable trenches and preferential flow paths may affect woodland soils and wet features even where excavation remains outside the

buffer. Ancient woodland ground flora, fungi and tree health may be sensitive to relatively small or gradual changes in water availability.

The Applicant has not provided a single integrated assessment showing how surface-water, groundwater and ecological connectivity will be protected for each of the adjoining ancient woods throughout construction, operation and decommissioning.

Deer fencing and redistributed ecological pressure

The Forestry Commission also identifies an indirect fragmentation pathway arising from extensive fencing. By excluding deer from large areas of existing farmland or constraining their customary routes, fencing may concentrate browsing and grazing pressure in surrounding woodlands, hedges and stewardship areas. It may also alter road-crossing patterns and increase collision risk.

This is a useful illustration of why effects cannot be confined to the land inside each solar field. The Scheme changes the movement of species across the wider area and may transfer ecological pressure into the very ancient woods the Applicant claims to protect.

The Applicant's ecology assessment does not contain a sufficiently detailed landscape-scale assessment of those displacement effects.

New planting does not remove the time lag or location problem

The Applicant relies in part upon approximately 25 hectares of proposed woodland planting, together with tree belts and scrub, to improve habitat connectivity.

BEPS does not dispute that well-designed and properly managed native planting could provide future ecological benefit. The problem is that the existence of new planting does not prove that deterioration of existing ancient woods has been avoided.

There are three reasons:

First, location matters. Planting used for visual screening may not reconnect the woodland blocks or maternity-colony routes most at risk. The Forestry Commission specifically advises that planting should connect existing woodland and create resilient blocks rather than be distributed as isolated screening features.

Secondly, time matters. Newly planted trees and scrub will take decades to develop woodland structure, sheltered edge conditions, deadwood, cavities, fungal relationships and an associated invertebrate community. Harm arising from enclosure begins at construction and cannot be cancelled by habitat that may become effective later.

Thirdly, ancient woodland is not reproducible. New planting cannot replace ancient woodland soils, seedbanks, archaeology, veteran structures and continuous ecological history. It may supplement the network but cannot compensate for deterioration of the ancient habitat itself.

Absence of a scheme-wide woodland connectivity assessment

The Applicant has not supplied an adequate scheme-wide assessment of woodland connectivity.

Such an assessment should identify:

- all ancient, priority and other woodland within the Zone of Influence;
- existing hedgerow, tree-line, riparian and grassland links;
- the species and ecological functions dependent upon each connection;
- physical and behavioural barriers introduced by the Scheme;
- the combined effects of arrays, roads, cables, fencing, lighting and construction;
- the effects of other plans and projects;
- the ecological purpose and maturity timetable of every proposed connection;
- measurable standards by which continued connectivity would be judged;
- and remedial action if monitoring identifies reduced use or woodland decline.

Instead, the ES relies upon mapped buffers, broad statements that hedges will largely be retained and future planting delivered under outline plans.

That is insufficient for a scheme directly adjoining six ancient woods and affecting a landscape of national importance for bats.

Natural England's position is conditional, not determinative

Natural England currently categorises ancient woodland and ancient or veteran trees as a green issue. However, that position is expressly conditional upon the 30-metre buffers being recorded consistently in the LEMP, CEMP and DEMP and upon strict protection measures being secured, including full BS5837-compliant survey, root-protection controls, no-dig methods, arboricultural supervision, soil-compaction prevention, runoff and dust control and micrositing.

That position does not establish that every wider fragmentation effect has been resolved. Natural England's representation focuses principally upon buffers and direct working controls. It does not displace the distinct concerns of the Forestry Commission regarding landscape isolation, Ringers Grove and Doyly's Grove, or Norfolk Wildlife Trust's requirement that woodland connectivity be demonstrated.

Nor does a consultee's green classification determine the statutory question. The Examining Authority must assess the whole evidence and determine whether loss or deterioration of irreplaceable habitat has been avoided.

Conclusion

The Scheme would not merely sit beside six separate ancient woods. It would alter the matrix connecting and supporting those woods for approximately sixty years. Ringers Grove would be substantially enclosed; Doyly's Grove and Popes Wood would be closely bordered by

development; Saxlingham Grove and Little Wood form part of an active barbastelle maternity-colony network; and Spring Wood is connected to known roosting and hibernation resources.

The proposed buffers may reduce some direct effects, but they do not by themselves prevent:

- landscape isolation;
- behavioural fragmentation;
- woodland-edge deterioration;
- loss of connectivity;
- hydrological change;
- displaced browsing pressure;
- or the cumulative effects of fencing, lighting, traffic and infrastructure.

The Forestry Commission, Norfolk Wildlife Trust and South Norfolk Tree Warden Network all identify connectivity as a central ecological issue. Their evidence is consistent with the Applicant's own findings that mature trees, hedgerows and woodland relationships support a nationally important bat assemblage.

BEPS therefore submits that the Applicant has not demonstrated that the six adjoining ancient woods will retain their ecological function, resilience and connectivity throughout the life of the Scheme. Physical retention of the woodland polygons is not sufficient. In the absence of a fixed and evidence-based woodland connectivity strategy, supported by a final scheme-wide arboricultural and ecological assessment, the risk of deterioration of irreplaceable habitat remains unresolved.

The mitigation hierarchy required the Applicant first to avoid enclosing and fragmenting these ancient woods. The Scheme instead places development around them and relies upon buffers and future planting to manage the resulting harm. That is not avoidance and does not establish compliance with EN-1 or the NPPF protection afforded to irreplaceable habitats.

8.7.3 Woodland buffers do not mitigate all indirect effects

The Applicant places substantial reliance on buffer zones as the principal means of protecting ancient woodland and other sensitive woodland habitats. The Environmental Statement states that the Outline Operational Environmental Management Plan adopts a minimum 30-metre buffer around ancient woodland, within which operational maintenance would be avoided apart from habitat-management activities. Natural England has welcomed that commitment in principle but has required it to be recorded consistently and secured through the Landscape and Ecological Management Plan, Construction Environmental Management Plan and Decommissioning Environmental Management Plan.

A properly designed and enforced buffer can reduce some risks. It can help protect roots from direct excavation, keep machinery away from woodland edges, provide space for transitional vegetation and reduce some forms of immediate disturbance. It does not follow, however, that a uniform 30-metre stand-off automatically prevents deterioration of ancient woodland.

The correct question is not whether a numerical buffer has been drawn on a plan. It is whether the Applicant has demonstrated, for each woodland and each relevant impact pathway, that the proposed buffer will prevent loss or deterioration throughout construction, operation, equipment replacement and decommissioning.

That demonstration has not been made.

Fifteen metres is a minimum, not a safe distance for every effect

Natural England and Forestry Commission standing advice identifies 15 metres from the boundary of ancient woodland as a minimum buffer intended principally to avoid root damage. The Forestry Commission expressly advised at scoping that, where impacts are likely to extend beyond that distance, a larger buffer will be required. It gave air pollution arising from significant traffic increases and construction dust as examples of effects that may extend beyond 15 metres. It also advised that buffers should form part of wider ecological networks and should consist of semi-natural habitat such as woodland, scrub, heathland or wetland rather than simply retained agricultural land.

Natural England likewise advised at scoping that 15 metres is a minimum and that the standing advice should be used to determine when a larger distance is necessary. It specifically required the ES to assess impacts upon the six ancient woodland parcels directly adjoining the Scheme and drew attention to construction dust as a potentially relevant pathway notwithstanding the Applicant's proposal at that stage to scope out air-quality effects.

The Applicant's subsequent adoption of 30 metres is therefore an improvement upon the minimum position, but it does not remove the need for assessment. Thirty metres is not a universally protective distance prescribed by national policy. It remains necessary to establish whether effects from a particular activity, in a particular location, extend beyond it.

For example, the appropriate stand-off from:

- a lightly used solar field;
- a major substation;
- a BESS compound;
- a construction haul road;
- an HDD entry or exit compound;
- a piling operation;
- an abnormal-load route;
- or a drainage outfall

cannot safely be assumed to be identical.

Each presents different risks, durations and zones of influence. A fixed buffer cannot replace a receptor-specific assessment.

Inconsistency between construction, operation and decommissioning controls

The available documents do not yet establish a single, unambiguous buffer regime applying to every relevant phase and document.

Natural England records that the Environmental Statement refers to a 30-metre ancient-woodland buffer through the Outline OEMP, but it has asked for the same commitment to be expressly carried into the LEMP, CEMP and DEMP. Natural England also requires a full BS5837:2012-compliant arboricultural survey, strict Root Protection Area protection, arboricultural supervision, no-dig methods, soil-compaction prevention, dust and runoff controls and micrositing.

That request is important. It indicates that a statement in the Outline OEMP is not, by itself, sufficient to secure woodland protection during the other phases of the development. Ancient woodland may be most exposed during construction and decommissioning, when the principal activities include excavation, cable installation, vehicle movements, storage, piling, compounds and removal of infrastructure. A buffer expressed clearly for operational maintenance cannot be assumed to control those materially different activities.

Norfolk Wildlife Trust similarly records concern that the Scheme relies in relevant locations on a 15-metre construction buffer and a 30-metre operational buffer. It considers that those distances may not be adequate for particularly sensitive habitats, including ancient woodland and lowland fen, and requests larger precautionary buffers, prohibition of compounds, lighting and storage within them, and resolution of HDD entry and exit locations before the close of examination.

The DCO must not leave different buffer distances, exclusions or exceptions scattered across outline documents. Unless the protective distance, permitted activities and prohibited activities are consistent and legally secured for every phase, the claimed mitigation cannot safely be treated as certain.

A buffer must be defined by the effect, not by convenience

The Applicant appears to treat 30 metres as a standard solution applicable across the Scheme. That is not an adequate application of the mitigation hierarchy.

The necessary buffer should be derived from:

- the sensitivity and condition of the particular woodland;
- the nature of the adjoining works;
- local topography;
- soils and geology;
- prevailing wind direction;
- surface-water and groundwater pathways;
- the location of veteran and boundary trees;
- the protected species using the woodland edge;
- the duration and timing of disturbance;
- and the cumulative effects of other adjoining development.

A small ancient wood surrounded on several sides by solar infrastructure may require a materially different protective arrangement from a larger woodland with extensive undeveloped land beyond it. Likewise, a woodland supporting a barbastelle maternity colony or connected hibernation habitat presents additional functional requirements that cannot be resolved by root protection alone.

The Applicant has not provided a woodland-by-woodland buffer justification demonstrating why 30 metres is sufficient at:

- Saxlingham Grove;
- Doyly's Grove;
- Popes Wood;
- Spring Wood;
- Little Wood;
- and Ringers Grove.

Nor is there a transparent assessment showing how the chosen distance relates to the identified zones of influence for dust, hydrology, lighting, noise, vibration, traffic, prey availability or protected-species movement.

The buffer therefore appears to operate as a general design rule rather than the result of a completed effects assessment.

Root protection and soil compaction

Avoiding direct root severance is one of the principal purposes of an ancient-woodland buffer, but even this function depends upon accurate baseline information and strict construction controls.

Tree roots frequently extend beyond the apparent canopy and may extend beyond mapped woodland boundaries. Boundary trees may have root systems extending into the adjoining development area. Soil compaction from vehicle movements, storage, temporary surfacing and construction plant may reduce soil porosity, water availability and oxygen exchange without visibly damaging the tree at the time of construction. Decline may only become apparent years later.

The Forestry Commission advised that Root Protection Areas must be identified and protected wherever land within or adjoining woodland is required for temporary use or utility works. It identified root cutting, trenching, vehicle compaction, heavy-equipment storage, chemical contamination and unintended construction incursions as risks requiring specific controls.

Natural England accordingly requires a full BS5837-compliant survey before construction and strict controls over Root Protection Areas, no-dig working, compaction and micrositing.

The South Norfolk Tree Warden Network remains concerned that the arboricultural position is preliminary and dependent upon later surveys and method statements. It identifies unresolved clashes between indicative access routes and ancient or veteran-tree buffers and requests final Tree Protection Plans showing exclusion zones, no-dig areas, ground protection, haul-road stand-

offs, storage exclusions, manoeuvring areas, lighting exclusions and fuel or chemical exclusion zones.

A nominal 30-metre line does not answer those concerns where:

- access routes remain flexible;
- compounds have not been fixed;
- visibility splays may change;
- Root Protection Areas are not finally mapped;
- or micrositing remains available after consent.

The protective function of the buffer depends upon those matters being resolved before authorisation, not after construction design has begun.

Construction dust and air pollution

Dust is capable of affecting woodland vegetation beyond the immediate works footprint. Deposition on leaves may interfere with photosynthesis and transpiration, alter leaf-surface chemistry and affect lichens, bryophytes and other sensitive organisms. Dust may also alter soil chemistry when washed from foliage or deposited directly upon woodland soils.

The Applicant originally proposed to scope air-quality effects upon ecological receptors out. However, the Forestry Commission and Natural England expressly identified construction dust and traffic-related pollution as pathways requiring consideration in determining buffer width. The Scoping Opinion recorded that ancient woodland within one kilometre should remain scoped into the assessment because of possible pollutants and disturbance.

The issue is particularly important where woodland borders:

- haul roads;
- construction accesses;
- earthworks;
- stockpiles;
- cable trenches;
- substations;
- or other prolonged working areas.

A general commitment to dust suppression does not demonstrate that deposition at each woodland will remain below a level capable of causing deterioration. The assessment should identify the works nearest each woodland, their duration, prevailing wind direction, soil type, likely dust generation and the measures necessary to avoid deposition.

Nor should the Applicant assume that effects are temporary merely because construction eventually ends. Damage to sensitive woodland ground flora, tree health, fungal communities or soils may persist beyond the period of dust generation.

Surface-water runoff and hydrological change

A buffer measured horizontally from a woodland boundary does not sever hydrological pathways.

Natural England records that Saxlingham Grove, Popes Wood and Doyly's Grove are hydrologically connected to the Order Limits through watercourses or groundwater flow. It considers effects capable of being ruled out only if the relevant pollution-prevention, water-quality and surface-water controls in the outline CEMP are followed and secured.

That is a conditional conclusion. It confirms that the woods remain exposed to indirect effects notwithstanding the proposed physical stand-off.

Ancient woodland may be affected by:

- altered surface-water flow;
- increased or reduced groundwater recharge;
- concentrated runoff from tracks or compounds;
- sediment-laden water;
- preferential flow along cable trenches;
- dewatering;
- changes to soil moisture;
- chemical spills;
- and contamination associated with construction or firewater.

Some of those processes may originate well beyond 30 metres. Cable trenches and access tracks can redirect flows across a wider catchment. Substation and BESS drainage systems may concentrate water into new discharge locations. Soil compaction may reduce infiltration and increase runoff towards woodland edges.

The Applicant has not provided a site-specific woodland hydrology assessment for each of the six adjoining ancient woods. Nor has it demonstrated through monitoring data or modelling that construction, operation and decommissioning will maintain the existing water regime upon which each woodland depends.

A buffer may provide physical space for a swale or vegetated strip. It does not, by itself, prove that the existing hydrological regime will be preserved.

Lighting and loss of dark woodland edges

Artificial lighting is another impact that cannot be controlled solely by distance.

Ancient woodland edges provide commuting and foraging habitat for bats and other nocturnal species. The Applicant's own evidence identifies a nationally important bat assemblage, widespread barbastelle use and multiple maternity-colony Core Sustenance Zones across the Scheme. Saxlingham Grove, Little Wood and Spring Wood are directly associated with known or

likely barbastelle colonies, while Spring Wood is also connected to converted wartime structures used as bat hibernacula.

The ecological function of these woods therefore depends upon retaining dark emergence routes, woodland edges and connections to the wider landscape.

A 30-metre buffer does not necessarily prevent light spill from:

- construction compounds;
- HDD operations;
- security lighting;
- substations;
- vehicle headlights;
- emergency work;
- maintenance operations;
- or temporary night-time activity.

Norfolk Wildlife Trust specifically requests that no lighting spill be permitted onto woodland edges, hedgerows, watercourses or designated sites, that enforceable lux limits be secured and that monitoring occur near known barbastelle roosts. It also notes that temporary continuous lighting may be required during HDD operations lasting one or two days and that the locations of associated compounds are not yet fully defined.

The appropriate control is therefore not merely a buffer distance. It requires:

1. mapped dark corridors;
2. fixed lighting exclusion zones;
3. maximum illuminance limits;
4. horizontal and vertical spill controls;
5. restrictions on vehicle orientation and compound location;
6. seasonal controls;
7. monitoring;
8. and enforceable remedial action.

None of those protections can be inferred from the existence of a 30-metre strip.

Noise, vibration and piling

Construction noise and vibration may also extend beyond a standard woodland buffer. Pile driving, trenching, HDD, heavy vehicle movements and construction plant can disturb fauna using woodland edges, tree roosts and hibernation sites.

This is particularly relevant at Spring Wood because of the known or reported combination of barbastelle roosting, commuting and hibernation resources. Norfolk Wildlife Trust previously asked for Site 3 to be removed because of its effects upon the County Wildlife Site, ancient woodland and bats. Although part of the parcel was removed, NWT remains concerned about

development immediately west of Spring Wood and states that an even wider buffer may be required between the woodland and the substation.

There is no evidence that a uniform 30-metre stand-off has been derived from vibration modelling or species-specific disturbance assessment. In particular, the Applicant has not demonstrated that:

- percussive piling would be imperceptible within the woodland;
- vibration would not reach tree roosts or the converted bomb shelters;
- repeated HGV movements would not disturb woodland fauna;
- or the combined effect of noise, lighting and vegetation change would remain insignificant.

A buffer may attenuate some noise and vibration, but its effectiveness depends upon source level, soil and geological conditions, duration, topography, woodland structure and receptor sensitivity. Those matters require assessment, not assumption.

Woodland-edge microclimate and ecological transition

A woodland buffer should protect and enhance the ecological transition between woodland and the surrounding landscape. A simple strip of grass does not necessarily perform that function.

Ancient woodland edges are influenced by:

1. temperature;
2. humidity;
3. wind;
4. shading;
5. soil moisture;
6. adjoining vegetation;
7. pollution;
8. and surrounding land management.

Panel arrays and associated infrastructure may alter those conditions by changing wind movement, shade, reflected heat, drainage and management. These changes may affect woodland-edge vegetation, insects, bats, birds and other fauna.

Norfolk Wildlife Trust has repeatedly advised that 30-metre woodland buffers should comprise genuine ecotones of shrubs and rough grassland. It recommends such treatment around Spring Wood and the woodland adjoining Sites 4 and 5, and around sensitive woods and County Wildlife Sites at Site 7. It further states that wider buffers may be necessary in particular locations, including between the substation and Spring Wood.

That evidence shows that the quality and design of the buffer are as important as its width.

A satisfactory woodland-edge buffer would need to provide:

- a graduated transition from woodland canopy to scrub and rough grassland;

- locally appropriate native species;
- structural diversity;
- long-term management;
- protection from lighting and disturbance;
- hydrological compatibility;
- and continuity with adjoining hedgerows and other woodland.

The Applicant has not demonstrated that every proposed ancient-woodland buffer will meet those requirements. Nor is it clear that planting intended principally for visual screening has been designed around woodland ecology.

Buffers do not preserve wider connectivity

Even a well-designed 30-metre ecotone cannot preserve a woodland's wider ecological function if the landscape beyond it becomes fragmented.

The six adjoining ancient woods form part of a network connected through hedgerows, mature trees, field margins, ponds, lanes and watercourses. The Applicant's own scoping report identified ancient woodland within one kilometre as requiring assessment for indirect effects and acknowledged that the surrounding farmed landscape contains priority hedgerows, ponds and extensive deciduous woodland.

The Forestry Commission advised that woodland buffers should contribute to wider ecological networks and that woodland and hedgerow planting should connect existing woods rather than be confined to isolated screening areas. It recommended connected woodland blocks of at least five hectares where feasible.

A 30-metre strip around Ringers Grove does not answer the enclosure of that woodland where panel arrays and fencing remain beyond the strip on several sides. A buffer around Little Wood does not preserve the maternity colony's functional landscape unless dark flight routes to surrounding foraging habitat remain intact. A buffer around Saxlingham Grove does not protect the colony if adjoining hedgerows are interrupted or illuminated.

The Applicant's buffer case therefore confuses local separation with landscape connectivity. Both are necessary, but they are not interchangeable.

Buffers must remain free from incompatible uses

The protective value of a buffer depends upon what is permitted within it. A buffer cannot perform its intended function if it accommodates:

- access roads;
- drainage structures;
- cable trenches;
- fencing;
- security equipment;

- lighting;
- storage;
- compounds;
- temporary working areas;
- turning heads;
- crane oversail or manoeuvring;
- or intensive maintenance.

Natural England states that operational maintenance, other than habitat management, should be avoided within the ancient-woodland buffer. It has asked for that commitment to be carried into all relevant management plans. NWT similarly seeks a prohibition on construction compounds, lighting and storage within precautionary buffer zones.

Those exclusions must be secured in the DCO itself or through requirements with clear approval criteria. They should not depend upon later contractor discretion.

The protective plan must also distinguish between the Order Limits and the actual construction exclusion zone. Inclusion of woodland buffers within broad works envelopes may permit later micrositing or temporary use that undermines the mitigation relied upon in the ES.

Long-term management and monitoring are unresolved

The Scheme would operate for approximately sixty years. A woodland buffer cannot be treated as successful merely because it is planted or fenced at the start of operation.

Its continued effectiveness will depend upon:

- establishment success;
- replacement of failed planting;
- control of invasive species;
- maintenance of structural diversity;
- appropriate grazing or cutting;
- protection from compaction;
- retention of darkness;
- avoidance of chemical use;
- continued hydrological function;
- and prevention of gradual operational encroachment.

Natural England has advised that the LEMP should explicitly secure management, monitoring and maintenance of ecological measures for the full operational lifetime, with performance indicators and remedial actions. It treats that aspect of the draft DCO as outstanding.

The same concern applies to decommissioning. Removal of panels, fencing, piles, tracks and cables may require extensive plant and renewed access close to woodlands. Unless the DEMP carries the same or stronger buffer controls, woodlands protected during operation may be exposed to significant disturbance at the end of the project.

The Applicant has not yet demonstrated how woodland buffers will be protected, funded, monitored and enforced across the full project life, including against successor owners or operators.

Natural England's 'green' classification is conditional

Natural England presently categorises ancient woodland and ancient or veteran trees as a green issue. That should be represented accurately but not overstated.

Natural England's classification is expressly conditional upon the mitigation being adequately secured. It asks for the 30-metre commitment to be incorporated consistently into the LEMP, CEMP and DEMP and for standing-advice protections to be followed. It also requires strict Root Protection Area controls, an arboricultural survey, no-dig methods, dust and runoff controls and micrositing.

Natural England's position therefore does not establish that a 30-metre buffer, by itself, eliminates all indirect effects. It confirms the opposite: additional construction, arboricultural, hydrological and long-term management measures are required.

Nor does its green classification displace the concerns of the Forestry Commission, Norfolk Wildlife Trust or the Tree Warden Network concerning:

- woodland isolation;
- ecotone quality;
- buffer clashes;
- construction disturbance;
- lighting;
- hydrology;
- incomplete arboricultural information;
- and the need for wider buffers in particular locations.

The Examining Authority must assess the evidence as a whole and determine whether deterioration has been avoided, rather than treating a consultee colour classification as determinative.

Buffers are mitigation, not avoidance

The Applicant's reliance on buffers also exposes a fundamental mitigation-hierarchy issue.

Leaving a strip between development and ancient woodland is a form of mitigation. It is not avoidance of the wider conflict where the development continues to surround, enclose or disturb the woodland.

True avoidance would involve:

- removing development parcels adjoining the most sensitive woods;
- relocating substations and compounds;

- keeping major construction routes away from woodland;
- preserving broad undeveloped connections between woodland blocks;
- and selecting a less constrained landscape in the first place.

At Spring Wood, NWT expressly recommended removal of Site 3 because of impacts on the County Wildlife Site, ancient woodland and bats. Partial removal of the parcel combined with a buffer does not represent full avoidance where development remains beside the same sensitive receptor.

At Ringers Grove, a buffer does not avoid enclosure. At Doyly's Grove and Popes Wood, it does not avoid the development occupying the surrounding ecological matrix. At Saxlingham Grove and Little Wood, it does not avoid development within the support landscape of barbastelle maternity colonies.

The Applicant cannot therefore use the existence of buffers to claim that the first stage of the mitigation hierarchy has been satisfied.

Conclusion

Buffer zones are a necessary component of ancient-woodland protection, but they are not a complete answer to the indirect effects of East Pye Solar.

The Applicant's proposed 30-metre buffer may reduce some direct risks, but it has not been demonstrated to prevent:

- construction dust and traffic-related pollution;
- hydrological change;
- soil compaction and root damage;
- lighting and loss of dark woodland edges;
- noise and vibration;
- disturbance to maternity and hibernation habitat;
- altered woodland-edge microclimate;
- loss of prey and foraging function;
- enclosure and landscape fragmentation;
- displaced animal movement;
- or impacts arising during replacement and decommissioning.

The Forestry Commission's advice establishes that 15 metres is only a minimum and that larger buffers are required where effects extend farther. Norfolk Wildlife Trust requests at least 30 metres, genuine shrub and rough-grassland ecotones and, in sensitive locations such as Spring Wood, potentially greater separation. Natural England's present position is conditional upon the 30-metre commitment and detailed protective measures being made consistent and enforceable across every project phase. The Tree Warden Network identifies unresolved buffer clashes and deficiencies in the final arboricultural evidence.

BEPS therefore submits that the Applicant has not demonstrated that a standard 30-metre buffer will prevent deterioration of the six adjoining ancient woodlands. Each woodland requires a site-

specific Zone of Influence assessment and a buffer designed around the actual sources and pathways of harm. Where that assessment cannot establish that indirect effects will be avoided, the adjoining development must be removed or relocated.

The policy test concerns loss or deterioration of irreplaceable habitat, not compliance with a nominal distance. Unless the Applicant can demonstrate that the woodlands' soils, hydrology, edge conditions, protected-species functions and landscape connectivity will remain intact throughout the whole life of the Scheme, reliance on buffers does not establish compliance with EN-1, the NPPF or the mitigation hierarchy.

8.7.4 Ancient trees, veteran trees and the wider tree network

The ancient and veteran tree resource affected by East Pye Solar is not confined to the six adjoining ancient woodlands. Individual ancient and veteran trees, mature boundary trees, tree lines and hedgerow trees occur throughout the Order Limits and the surrounding landscape. Together, they form an irreplaceable ecological and historic network that provides continuity between woodland blocks, watercourses, ponds, old lanes and field boundaries.

The Applicant's own evidence confirms that this is an extensive resource. Appendix 8.1 records 49 trees with veteran features within the Order Limits and a further 21 within 30 metres of the site boundary, distributed across Sites 3, 4, 5, 7, 9 and 10 and Cable Route Corridor section 6. Native hedgerows occur throughout the sub-sites, alongside ponds, watercourses and arable field margins. These veteran-feature trees are therefore not isolated specimens. They form part of the ecological structure through which wildlife moves across the Scheme landscape.

The same evidence base identifies a still larger tree resource relevant to protected bats. Chapter 8 records 621 trees assessed as having potential to support roosting bats, comprising 577 trees within Sites 1–10 and the BESS Site and 44 within the Cable Route Corridor and Highway Improvement Works boundaries. The Applicant recognises that the loss of trees capable of supporting roosting bats could cause direct harm, population fragmentation and habitat degradation. It also concludes that the Order Limits and surrounding landscape support a nationally important assemblage of foraging and commuting bats, including barbastelle, within the Core Sustenance Zones of several maternity colonies.

Those figures show that the affected tree resource is not peripheral to the Scheme. Ancient, veteran and mature trees are present across the development landscape, including along the access, cable and highway corridors through which the most disruptive works would occur.

Ancient and veteran trees are irreplaceable habitat

An ancient tree is one that has reached a great age in comparison with others of the same species and has developed exceptional ecological, cultural and historic value. A veteran tree need not yet be ancient, but displays important features associated with age, damage or natural decay, such as:

- cavities and hollowing;
- rot holes;
- loose or fissured bark;

- dead limbs and exposed heartwood;
- water pockets;
- fungal fruiting bodies;
- sap runs;
- and complex deadwood habitat.

Those features support highly specialised communities of fungi, lichens, bryophytes, invertebrates, birds and bats. They are the product of biological processes operating over many decades or centuries. They cannot be recreated by planting a young tree elsewhere.

National policy accordingly treats ancient and veteran trees as irreplaceable habitats, whether they occur within woodland, within a hedgerow or as individual field trees. The Forestry Commission's scoping response quoted EN-1 paragraph 5.4.53, under which development consent should not be granted for development resulting in the loss or deterioration of irreplaceable habitats, including ancient woodland and ancient or veteran trees, unless there are wholly exceptional reasons and a suitable compensation strategy exists. It also referred to EN-1 paragraph 5.4.32, which requires applicants to mitigate fully the direct and indirect effects of development on ancient woodland and ancient and veteran trees during construction and operation.

The policy test is therefore not limited to whether a tree is felled. It includes deterioration. A retained veteran tree may deteriorate through root severance, compaction, excessive pruning, altered hydrology, pollution, bark damage, fungal infection, loss of surrounding habitat or isolation from the wider ecological network.

The Applicant must therefore demonstrate not only that veteran trees will remain standing, but that the conditions necessary for their continued survival and ecological function will be preserved throughout construction, operation, replacement and decommissioning.

The wider tree network is part of the ecological infrastructure of the Claylands

The ecological importance of individual trees cannot be understood by treating them as separate arboricultural objects. In the South Norfolk Claylands, mature oaks, ash, hornbeam and other field and hedgerow trees operate collectively with old hedges, copses, ponds, ditches and ancient woodland.

The South Norfolk Tree Warden Network describes those features as functional ecological infrastructure. Its representation explains that the landscape is structured by mature hedgerows, field trees, woodlands and veteran features and that these features provide roosting, foraging and commuting habitat. It criticises the absence of a route-wide analysis of cumulative hedgerow severance, gap creation, veteran-tree buffer disruption, access widening, visibility splays, construction lighting and haul-road disturbance.

This is especially relevant to barbastelle bats. Barbastelles frequently use trees with splits, loose bark and other veteran features and may change roosts repeatedly within a woodland or wider tree network. The protection of one known roost tree is therefore not sufficient. The surrounding

resource of potential alternative roosts and the dark routes connecting them must also be retained.

The Applicant's own finding that barbastelle activity occurred across the Scheme and that mature trees, hedgerows and tree lines contribute to a nationally important bat landscape reinforces the point. Damage to mature and veteran trees may affect not only the tree itself but the functioning of maternity-colony landscapes extending across several development parcels.

Individual veteran trees may also operate as ecological 'stepping stones' between ancient woodland blocks. Their loss or deterioration can increase the distance between suitable roosting or refuge habitats, reduce landscape permeability and weaken the resilience of species populations. That function is not captured by a simple count of trees retained and removed.

The arboricultural assessment remains preliminary

The Applicant has submitted a Preliminary Arboricultural Impact Assessment, but the evidence does not establish a final, construction-ready understanding of the effects upon every tree, group, woodland and hedgerow.

The Tree Warden Network notes that the Applicant itself describes Appendix 7.10 as a Preliminary AIA based upon targeted surveys within the sites and wider surveys along the Cable Route Corridor. It is not a final tree-by-tree and hedgerow-by-hedgerow assessment of:

- all permanent and temporary accesses;
- all visibility splays;
- all highway works;
- all AIL routes and manoeuvring requirements;
- all construction compounds;
- all haul roads;
- all cable trenches and HDD compounds;
- all drainage works;
- all crane and delivery movements;
- or all decommissioning works.

The Applicant proposes a further pre-construction survey to re-establish the baseline and inform Tree Protection Plans, construction exclusion zones and an Arboricultural Method Statement. Those later controls may be necessary, but they are not a substitute for a complete impact assessment during Examination.

The purpose of the Environmental Statement is to identify the likely significant effects of the authorised development before consent is granted. A future survey cannot lawfully be used to postpone the central question of whether the Scheme can be constructed within the proposed limits without unacceptable harm to irreplaceable trees.

There is also an obvious risk in relying upon a future survey to 're-establish' the baseline. Trees may decline, branches may fail, ownership or management may change, and development pressure may increase between consent and commencement. The examination baseline should be fixed,

comprehensive and auditable so that subsequent changes can be identified rather than incorporated silently into a revised pre-construction position.

Four unresolved clashes with ancient and veteran tree buffers

The Applicant's own assessment has identified four clashes between indicative access routes and buffer zones applied to ancient and veteran trees within the Order Limits. Chapter 7 states that these clashes can be addressed at detailed design because the access routes are indicative and may be moved within the flexible envelope of Work No. 4.

That is not an adequate response.

An identified conflict with the buffer of an irreplaceable tree is an environmental constraint requiring redesign before consent. It is not simply a construction detail. The Examining Authority should know:

- which trees are affected;
- the location and purpose of each proposed access;
- whether an alternative route exists;
- the necessary road width and loading;
- whether visibility splays or turning movements require crown pruning;
- whether excavation or surfacing enters the Root Protection Area;
- whether ground protection or no-dig construction is practicable;
- and whether large vehicles can pass without branch, stem or root damage.

The use of a flexible works envelope creates a particular risk. While flexibility may assist engineering design, it must not permit an access route or haul road to be shifted after consent into the protected area of an ancient or veteran tree. A commitment to resolve the conflict during detailed design does not establish that a feasible avoidance solution exists.

The four clashes should therefore be resolved through fixed plans before the end of the Examination. Where an access cannot be delivered without intrusion into an ancient or veteran tree buffer, the access or the development it serves should be redesigned or removed.

Buffer requirements for individual ancient and veteran trees

The Forestry Commission's scoping advice states that the buffer around an ancient or veteran tree should be at least 15 times the tree's stem diameter, or extend five metres beyond the edge of the canopy where that produces a larger area. This is intended to establish a minimum Root Protection Area. The advice also makes clear that a larger buffer may be necessary where indirect effects extend farther.

A uniform distance is therefore not necessarily sufficient for every tree. The appropriate protection must account for:

- tree dimensions and rooting pattern;

- species and physiological condition;
- existing damage or decay;
- surrounding soil conditions;
- topography and drainage;
- the location of adjoining hedges and other trees;
- construction loading;
- vehicle turning and oversail;
- lighting;
- storage and compound use;
- and the nature and duration of nearby works.

Natural England records that the Applicant proposes a 30-metre buffer around veteran trees and states that veteran trees will not be removed and pruning will be avoided. Natural England welcomes that position but requires the 30-metre commitment to be recorded consistently in the LEMP, CEMP and DEMP. It also requires a full BS5837:2012-compliant arboricultural survey, strict Root Protection Area protection, arboricultural supervision, no-dig methods, soil-compaction prevention, dust and runoff control and micrositing.

Natural England's 'green' classification is therefore conditional. It depends upon the identified measures being made consistent, detailed and enforceable. It does not cure the unresolved access clashes or establish that every works component can remain outside the relevant protection areas.

Accesses, visibility splays and abnormal-load movements

The greatest risks to mature and veteran trees may arise not from the solar panels themselves but from the road and access works required to construct the Scheme.

The project requires articulated HGV access, abnormal indivisible load deliveries, cable-drum movements and the movement of transformers and other large electrical equipment. Existing agricultural accesses will be used where practicable, but new accesses and visibility splays will be required in some locations.

These activities may cause:

- removal of hedgerow sections and associated trees;
- crown lifting or lateral pruning;
- branch damage from high or wide loads;
- bark strikes;
- excavation within Root Protection Areas;
- soil compaction from repeated vehicle loading;
- installation of kerbs, drainage or hard surfacing;
- and changes in water movement around tree roots.

Visibility splays create a particular risk because they may require repeated management rather than a single intervention. A tree initially retained may later be subjected to continued pruning to preserve highway visibility throughout construction or operation.

AIL movements present another distinct risk. The swept path of a transformer or cable-drum vehicle includes not only the wheel track but vehicle overhang, turning space and vertical clearance. The Applicant must demonstrate that every such movement is feasible without damage to veteran trees, mature roadside trees and old hedgerows.

An assurance that trees will be retained 'wherever possible' is insufficient. Irreplaceable habitat should be a fixed design constraint, not an interest to be balanced against later contractor convenience.

Cable routes, trenching and Root Protection Areas

The extensive Cable Route Corridor creates a second major risk. Cable installation involves excavation, temporary working widths, haul roads, compounds, soil storage, jointing bays and potentially HDD entry and exit areas.

Tree roots do not follow mapped boundaries and may extend well beyond the visible canopy. Trenching can sever structural and absorbing roots, while repeated plant movement can compact soils and reduce air and water availability. Damage may occur even where the trunk and canopy remain untouched.

The Applicant's reliance upon reduced working widths, micrositing and future arboricultural supervision does not establish that harm will be avoided. The final route should identify:

- every Root Protection Area crossed or approached;
- the exact working width;
- the excavation method;
- whether trenchless installation is required;
- the position of soil storage;
- vehicle routes;
- temporary surfacing;
- and the method of reinstatement.

Where a cable route cannot avoid the Root Protection Area of an ancient or veteran tree, an alternatives assessment should be required. Convenience, cost saving or the desire to retain route flexibility cannot amount to wholly exceptional reasons for deterioration of irreplaceable habitat.

Soil compaction and delayed decline

Tree damage is not always immediate or visually obvious. A veteran tree may survive the construction period yet enter decline years later because of root injury, compaction, altered drainage, fungal infection or physiological stress.

The Tree Warden Network expressly identifies the risk of delayed harm from:

- soil compaction;
- root severance;
- excessive pruning;
- bark damage;
- fungal infection;
- altered drainage;
- pathogens;
- soil contamination;
- branch failure;
- and long-term decay.

Compaction is particularly significant. Heavy machinery compresses soil pores, restricting oxygen, water infiltration and root growth. The effect may persist long after temporary tracks or compounds have been removed. Simply loosening or reinstating the upper soil horizon may not restore the original structure of deeper compacted ground.

Changes to drainage may have similar delayed consequences. Cable trenches, new tracks and compacted surfaces can redirect water, creating either waterlogging or drought stress. A veteran tree already containing extensive heartwood decay may have limited capacity to respond to those changes.

The assessment must therefore address both immediate physical damage and delayed physiological deterioration. Success cannot be measured simply by whether a tree remains standing at the end of construction.

Operational pressure from shading, leaf fall and tree growth

The risk continues during operation.

Trees adjoining solar arrays, substations and access roads will continue to grow. Their crowns may shade panels, deposit leaves, seeds or sap, obstruct CCTV sightlines, encroach upon security fencing or affect operational access. Roots may extend beneath tracks or other infrastructure.

These ordinary biological processes can create pressure for future pruning or removal. The Tree Warden Network accordingly seeks express assurance that woodland and adjoining trees will not be cut back during the life of the Scheme to address shading, leaf fall, sap, seed deposition, root growth or other perceived operational inconvenience.

That protection should not depend upon an operator's general commitment to avoid pruning. It should be secured through the DCO and management plans, with any exceptional safety work subject to independent arboricultural assessment and approval.

The layout must be designed to accommodate the natural future growth of retained trees. A panel or access road placed so close to a mature tree that conflict becomes inevitable has not avoided the impact; it has merely postponed it.

Protected-species implications

The extensive potential-roost tree resource creates a separate legal issue under the Conservation of Habitats and Species Regulations 2017 and the Wildlife and Countryside Act 1981.

A tree may support a bat roost even if no bat was observed during an initial inspection. Roost features can be concealed, bats may use different trees seasonally, and occupancy may change between survey and construction. The Applicant's identification of 621 trees with roost potential confirms the scale of the issue.

Works capable of affecting those trees may include:

- felling;
- pruning;
- crown lifting;
- root damage leading to later failure;
- lighting of an emergence point;
- obstruction of a flight route;
- and vibration or disturbance close to a roost.

Pre-construction inspection is therefore necessary, but it cannot be the sole safeguard. The Scheme must first minimise the number of potentially affected trees through fixed avoidance. Where impacts cannot be excluded, the Applicant must establish what further surveys, licensing and mitigation are required and whether there is a realistic prospect of satisfying the relevant licensing tests.

Natural England continues to classify protected species as an amber matter and seeks clarification as to whether licences will be required for roosting bats and other species. That outstanding issue is directly relevant to any veteran or mature tree works.

Replacement planting and Biodiversity Net Gain are not equivalent compensation

The Applicant relies upon extensive proposed planting and Biodiversity Net Gain. New native trees and hedges may provide future benefits, but they cannot replace ancient or veteran trees.

A sapling does not contain:

- centuries-old heartwood decay;
- hollow trunks;
- loose bark;
- veteran cavities;
- long-established fungal communities;
- complex deadwood;
- or the same cultural and landscape presence.

Even well-designed planting may take many decades before developing limited veteran characteristics. Some specialist species may be unable to persist during that time. The loss is therefore not merely quantitative but temporal, structural and ecological.

Nor can habitat units elsewhere compensate automatically for the deterioration of an individual irreplaceable tree. The biodiversity metric is not a licence to trade ancient or veteran habitat for a greater area of younger planting.

The appropriate policy response is avoidance. Compensation arises only in the exceptional circumstances contemplated by national policy, after the decision-maker is satisfied that wholly exceptional reasons exist. No such reasons have been demonstrated for damaging trees to accommodate access geometry, temporary working space or route flexibility.

Required protection and monitoring

The South Norfolk Tree Warden Network requests a final AIA covering the whole Order Limits, Cable Route Corridor, highway works, AIL routes, visibility splays, compounds, accesses, haul routes, drainage works and decommissioning assumptions. It also seeks final Tree Protection Plans showing construction exclusion zones, no-dig areas, fencing, ground protection, haul-road stand-offs, storage exclusions, vehicle manoeuvring areas, lighting exclusions and fuel or chemical exclusion zones.

Those requirements are proportionate to the scale and sensitivity of the resource.

BEPS further submits that the DCO should secure:

- a presumption against removal or pruning of ancient, veteran and high-value mature trees;
- resolution of all access and buffer clashes before consent;
- fixed Root Protection Areas and construction exclusion zones;
- no-dig construction where any works are exceptionally permitted close to roots;
- prohibition of storage, compounds, drainage infrastructure, lighting and vehicle movements within protection areas;
- independent arboricultural and ecological clerks of works with authority to stop works;
- photographic and condition records before and after construction;
- and long-term monitoring for compaction, hydrological change, fungal infection, branch failure and delayed decline.

Monitoring must extend for a period sufficient to detect delayed effects. A short inspection immediately after construction would not establish that a veteran tree has avoided deterioration.

Conclusion

The Applicant's evidence establishes that East Pye Solar affects an extensive and highly valuable tree network. At least 49 trees with veteran features occur within the Order Limits, a further 21 occur within 30 metres, and 621 trees have been identified as having potential to support roosting bats. Those trees operate collectively with ancient woodland, hedgerows, ponds and watercourses as part of the functional ecological infrastructure of the South Norfolk Claylands.

Despite that importance, the arboricultural assessment remains preliminary. Four known clashes between indicative access routes and ancient or veteran tree buffers are deferred to detailed design, while important matters concerning AIL movements, visibility splays, cable routes, Root Protection Areas and future operational pressure remain dependent upon later surveys and method statements.

The Applicant's stated intention not to remove veteran trees and to avoid pruning is welcome, but it is not yet demonstrated by a fixed and deliverable design. Nor does retention alone exclude deterioration through root damage, compaction, altered drainage, excessive disturbance, lighting, isolation or delayed decline.

BEPS therefore submits that ancient and veteran trees must be treated as absolute design constraints throughout the Order Limits. Every known conflict must be resolved before development consent is granted. Where an access, cable route, visibility splay, compound or other works component cannot be delivered without risking loss or deterioration, that element of the Scheme must be redesigned or removed.

Replacement planting and Biodiversity Net Gain cannot make the loss or deterioration of centuries-old living habitat acceptable. In the absence of a final arboricultural assessment, fixed protection plans and enforceable whole-life safeguards, the Applicant has not demonstrated compliance with EN-1 or the national policy protection afforded to irreplaceable habitats.

8.7.5 The South Norfolk Tree Warden Network evidence

The Relevant Representation submitted by the South Norfolk Tree Warden Network provides important specialist and locally informed evidence concerning the Scheme's effects on trees, hedgerows, ancient woodland, veteran features and the wider ecological network. Its evidence should not be treated as a general objection to development or as a repetition of landscape concerns. It identifies specific deficiencies within the Applicant's Environmental Statement, including the preliminary nature of the arboricultural assessment, unresolved conflicts with ancient and veteran tree buffers, incomplete information about hedgerow removal, reliance on flexible access design and the absence of a final scheme-wide assessment of cumulative tree and hedgerow harm.

The Network's central conclusion is that the arboricultural effects of a project of this scale must be understood before development consent is granted, rather than being left to future surveys, detailed design and contractor method statements. That conclusion is supported by South Norfolk Council's own consultation evidence. The Council asked for tree surveys to inform the Scheme's detailed design and stated that, from its experience of other NSIPs, the arboricultural assessment should not be left until final design because it would otherwise be difficult to understand and weigh the implications of the proposals. It also expected a full arboricultural impact assessment for all elements of the Scheme to be available for Examination.

The Tree Warden Network's evidence demonstrates that this requirement has not yet been met.

A landscape structured by trees and hedgerows

The Network begins from the correct landscape and ecological characterisation. East Pye Solar is proposed within a landscape structured by mature hedgerows, hedgerow trees, field trees, woodland groups, veteran features, old lanes, ponds and watercourses. These features are not incidental obstructions within otherwise open agricultural land. They are among the defining components of the South Norfolk Claylands.

The Applicant's own scoping report describes several development areas as containing remnant hedgerow networks, isolated mature trees, established tree belts and woodland groups of high ecological and visual quality. At Site 8, for example, the Applicant described irregular small and medium-sized fields defined by a remnant hedgerow network and established tree belts and woodland groups, including ancient woodland, which create wooded horizons and landscape intimacy. Similar characteristics were recorded at Sites 9 and 10.

The Tree Warden Network therefore objects to the treatment of trees and hedgerows as individual landscape features capable of being removed in small sections and replaced by later planting. Its representation explains that they form functional ecological infrastructure. They connect woodland, roosting habitat, watercourses, ponds and feeding areas and provide the structure through which bats, birds, mammals and invertebrates move across the landscape.

That conclusion is strongly supported by the Applicant's ecological evidence. The Scheme contains native hedgerows throughout the sub-sites, at least 49 trees with veteran features within the Order Limits and a further 21 within 30 metres of the boundary. The trees are distributed across Sites 3, 4, 5, 7, 9 and 10 and part of the Cable Route Corridor. The affected resource is therefore extensive and dispersed, not confined to one or two isolated locations.

The ecological importance is further demonstrated by the Applicant's identification of 621 trees with potential to support roosting bats: 577 within Sites 1–10 and the BESS Site and 44 within the Cable Route Corridor and Highway Improvement Works boundaries. The Applicant also concludes that the Order Limits and surrounding landscape support a nationally important assemblage of foraging and commuting bats, including barbastelle, and that mature trees, tree lines, hedgerows and field margins provide supporting habitat within overlapping maternity-roost Core Sustenance Zones.

The Network is therefore correct that the arboricultural and ecological issues cannot be separated. Damage to a mature tree or hedgerow may simultaneously constitute:

- loss of a landscape feature;
- damage to historic landscape structure;
- interruption of a bat commuting route;
- loss or degradation of potential roosting habitat;
- fragmentation of woodland connectivity;
- loss of nesting or feeding habitat;
- and reduction in the resilience of the wider ecological network.

The Environmental Statement does not adequately assess those combined functions.

The Arboricultural Impact Assessment remains preliminary

A principal concern raised by the Tree Warden Network is that Appendix 7.10 is expressly described as a Preliminary Arboricultural Impact Assessment. It is based upon targeted surveys within the principal sites and wider survey work along the Cable Route Corridor. It is not a final, construction-ready assessment of every tree, hedgerow, access, compound, visibility splay, haul route and cable working area that may be affected by the authorised development.

This distinction is important. A preliminary assessment may identify broad constraints and inform early design, but it does not provide the certainty needed to determine the final environmental effects of a DCO containing extensive flexibility. The Network identifies unresolved matters including:

- temporary and permanent accesses;
- road widening and visibility splays;
- abnormal indivisible load routes;
- articulated HGV manoeuvring;
- haul roads;
- cable trenches;
- HDD compounds;
- construction compounds;
- soil and material storage;
- drainage works;
- lighting;
- and decommissioning access.

Each of those elements may affect trees and hedgerows beyond the footprint of the solar arrays. Several are also subject to later design or micrositing.

The Applicant proposes a further pre-construction survey to re-establish the baseline and inform Tree Protection Plans, construction exclusion zones and an Arboricultural Method Statement. The Network accepts that those measures will be necessary, but correctly states that they cannot substitute for a complete assessment at Examination.

A pre-construction survey may confirm current tree condition and refine working methods. It should not be used to determine for the first time:

- whether a proposed access can be constructed;
- whether a visibility splay requires tree removal;
- whether an AIL can pass beneath a mature canopy;
- whether a cable route enters a Root Protection Area;
- or whether an ancient or veteran tree buffer can be maintained.

Those are consent-stage questions because they bear directly upon whether the Scheme is environmentally acceptable and physically deliverable.

South Norfolk Council made the same point during consultation. It expected a full arboricultural impact assessment for all elements of the Scheme at Examination and stated that any potential conflict caused by uncertain GPS positions should be confirmed on site before approval of the Scheme, not merely before commencement of works. The Council also noted that the absence of a Tree Preservation Order does not indicate that no trees worthy of formal protection are present.

The continuing reliance on later survey and design therefore conflicts with both the local authority's advice and the Tree Warden Network's specialist evidence.

Four unresolved conflicts with ancient and veteran tree buffers

The most direct evidence of inadequate design resolution is the Applicant's identification of four conflicts between indicative access routes and buffer zones associated with ancient or veteran trees. The Applicant proposes to resolve those conflicts during detailed design because the access routes are indicative and can move within the flexible envelope of Work No. 4.

The Tree Warden Network identifies this as a central defect, and BEPS agrees.

Ancient and veteran trees are irreplaceable habitats. A known conflict with an irreplaceable-habitat buffer is not a minor engineering matter. It is a design constraint that should be resolved before consent.

The Applicant has not yet established:

- which precise trees are involved;
- what access each route serves;
- the required road width and construction method;
- whether excavation or surfacing enters the Root Protection Area;
- whether crown lifting or branch removal would be required;
- whether articulated HGVs can pass safely;
- whether abnormal loads can negotiate the route;
- whether alternative access is available;
- or whether moving the access merely transfers harm to another tree or hedgerow.

The use of a flexible works envelope increases rather than removes the need for certainty. A wide envelope may enable a later contractor to choose between routes, but it does not demonstrate that a route free from unacceptable arboricultural harm exists.

The Network therefore asks that all four conflicts be resolved before consent and that any access, visibility splay, AIL manoeuvre or haul road that cannot be delivered without entering an ancient or veteran tree buffer should be redesigned.

That request is necessary to ensure that the Environmental Statement's conclusions are based upon a deliverable design rather than an assumption that avoidance will be possible later.

Repeated hedgerow removal and cumulative severance

The Tree Warden Network also challenges the Applicant's treatment of hedgerow removal. Chapter 8 accepts that temporary removal of hedgerow sections, generally up to approximately 10 metres at individual locations, will be required for cable works, haul routes and access requirements. The Applicant proposes reinstatement, new planting and management through the Outline LEMP and Outline CEMP.

The assessment treats each opening as localised and relatively minor. The Network's evidence demonstrates why that is misleading.

The Scheme requires repeated crossings and openings across:

- the Cable Route Corridor;
- construction haul routes;
- new and widened accesses;
- visibility splays;
- highway improvement works;
- AIL routes;
- and internal operational routes.

A single 10-metre gap may appear limited. Repeated gaps across a large connected landscape can produce substantial cumulative effects, including:

- severance of bat commuting routes;
- loss of nesting habitat;
- opening of previously sheltered woodland and field edges;
- increased light spill;
- changes in wind exposure and microclimate;
- interruption of historic field patterns;
- and gradual loss of the age and structural diversity of the hedgerow network.

Reinstatement does not immediately restore those functions. A newly planted hedge cannot replicate the height, density, root structure, woody biomass, invertebrate community or ecological continuity of an old established boundary. The time required to recover an equivalent landscape and ecological function may extend for decades.

The Applicant's landscape assessment itself recognises loss of trees and hedgerow sections along the Cable Route Corridor, effects upon Important Hedgerows and alteration of field patterns. In some locations the effects on landscape features are assessed as Major Adverse and Significant or Moderate Adverse and Significant. The Network therefore correctly observes that the Applicant cannot rely upon those same trees, hedges and woodland features to screen and assimilate the Scheme while simultaneously treating their removal, disturbance and later reinstatement as minor or readily compensable.

Important Hedgerows have not been fully resolved

The evidence also identifies uncertainty concerning the Hedgerows Regulations 1997. The Applicant's landscape baseline assumes that Important Hedgerows are present within the Order Limits where complete assessment has not been undertaken. South Norfolk Council expected a full assessment against all relevant importance criteria for any hedgerow proposed for removal, including off-site works necessary for construction access or transportation.

That work is material because an Important Hedgerow is not simply a generic habitat unit. It may have archaeological, historical, landscape and ecological significance arising from its age, species composition, relationship to historic boundaries or associated features.

The Network's evidence indicates that the Examination does not yet have a final schedule identifying:

- every hedgerow proposed for complete or partial removal;
- whether it qualifies as Important;
- the reason for removal;
- the length and age structure affected;
- associated mature or veteran trees;
- bat-roost and commuting potential;
- and the precise reinstatement or replacement proposed.

Without such a schedule, the cumulative significance of hedgerow loss cannot be properly assessed. BEPS has evidence that an important hedgerow has already been grubbed up in site 9 in anticipation of the DCO.

Accesses, visibility splays and AIL routes create particular risks

The Tree Warden Network places particular emphasis on access and transport works because these may cause some of the most serious tree damage.

The Applicant confirms that new accesses will be constructed where existing field accesses are unsuitable and that access points must accommodate articulated HGVs. Abnormal loads are expected to include transformers and cable drums, and HGVs may use internal access tracks as haul roads. Localised hedgerow removal may also be required for visibility splays.

Those activities may require more than removal of the vegetation directly within the road opening. They can generate:

- crown lifting to provide vertical clearance;
- lateral pruning for vehicle overhang;
- removal of boundary trees;
- excavation and surfacing within Root Protection Areas;
- drainage installation;
- soil compaction;

- repeated loading from heavy vehicles;
- bark and branch strikes;
- and the removal or continued cutting back of vegetation within visibility splays.

The impact area should therefore be based upon the complete swept path, manoeuvring envelope and construction method, not merely the width of the finished access.

The targeted consultation changes made this issue more significant. The Applicant consulted on alterations involving additional land, AIL routes, general construction traffic routes and changes around Site 1, the National Grid Substation Site and Site 7D. The Network states that, without a final arboricultural schedule and impact plan, consultees could not determine whether those changes would lead to additional removal, pruning, Root Protection Area incursion or compaction.

This is both a substantive and procedural deficiency. The environmental consequences of route changes cannot be dismissed as materially unchanged where the tree and hedgerow effects of the revised routes have not been definitively assessed.

Risks of delayed and indirect tree decline

The Network's evidence is also important because it explains that damage to mature and veteran trees may not be immediately apparent. Potential causes of delayed decline include:

- soil compaction;
- root severance;
- altered drainage;
- excessive or unbalanced pruning;
- branch and bark damage;
- introduction of pathogens;
- fungal infection;
- chemical or fuel contamination;
- and long-term physiological stress.

A tree may remain standing at the completion of construction while having suffered damage that leads to canopy decline, branch failure or death several years later. This is particularly serious for veteran trees, whose ecological value may depend upon a complex balance between living tissue, decay and structural defects.

The Network therefore requests post-construction monitoring of retained veteran and mature trees, hedgerows and affected woodland edges. Monitoring should expressly address compaction, root damage, bark damage, fungal infection, branch failure, soil contamination, hydrological change and delayed decline.

That is a necessary safeguard, but monitoring cannot replace avoidance. It may identify deterioration after it occurs; it cannot restore a veteran tree that has entered irreversible decline.

Operational pressure upon retained trees

The Tree Warden Network also raises a legitimate whole-life concern. Trees adjoining solar arrays and electrical infrastructure will continue to grow during the proposed operational period. Their normal growth may cause:

- panel shading;
- leaf, seed or sap deposition;
- root interaction with tracks or infrastructure;
- obstruction of CCTV sightlines;
- interference with security fencing;
- or operational access concerns.

Those effects may create continuing pressure for pruning or removal after consent.

The Network therefore seeks assurance that woodland trees and other retained trees will not be cut back during the life of the Scheme merely to prevent shading, leaf fall, sap fall, seed fall, root growth or other ordinary consequences of tree growth.

That concern should be addressed through enforceable requirements. A layout that places infrastructure so close to retained trees that ordinary future growth will create operational conflict has not genuinely avoided the impact. It has deferred it.

Any consent would therefore need to secure:

- sufficient stand-off for the anticipated mature dimensions of retained trees;
- a prohibition on pruning for solar-yield or ordinary maintenance convenience;
- independent arboricultural approval for exceptional safety works;
- retention of standing and fallen deadwood where safe;
- and replacement or remedial habitat provision where unavoidable safety work affects veteran features.

Protected bats reinforce the need for a precautionary approach

The Tree Warden Network's evidence has particular weight because of the relationship between the tree network and the Applicant's nationally important bat assemblage.

The identification of 621 trees with bat-roost potential means that tree works cannot be regarded as purely arboricultural. Roost occupancy can change over time, and many woodland bats use networks of alternative roosts rather than one permanent tree. Barbastelles in particular may change roost frequently and depend upon loose bark, splits, cavities and other features commonly associated with mature and veteran trees.

Accordingly, even where a particular tree is not confirmed as occupied at the time of the initial survey, it may form part of the functional roost resource supporting a maternity colony or wider local population.

The Network's request for a presumption of avoidance covering veteran trees, ancient trees, high-value mature trees, trees with potential roost features, ancient woodland edges and Important Hedgerows is therefore justified by both arboricultural and protected-species evidence.

Natural England's Relevant Representation does not displace that concern. Natural England welcomes the Applicant's statement that veteran trees will not be removed and that pruning will be avoided, but asks that the proposed 30-metre protection be recorded consistently in the LEMP, CEMP and DEMP. Natural England also retains an amber position in relation to protected species.

Natural England's position is therefore conditional upon the commitments being secured and upon protected-species issues being resolved. It does not establish that the current preliminary assessment is adequate or that the four identified access conflicts can safely be left to detailed design.

The consultation deficiency remains relevant

The Tree Warden Network also identifies a procedural problem. The full arboricultural position now revealed by the Environmental Statement—including the Preliminary AIA, the identified buffer conflicts, the number of veteran-feature trees, the scale of the potential bat-roost tree resource, the repeated hedgerow removals and the reliance on later surveys—was not available during the principal statutory consultation.

The subsequent targeted consultation did not provide a final arboricultural assessment of the revised land, AIL routes, access routes or general construction traffic routes. The Network therefore could not meaningfully determine the final effect of those changes upon trees and hedgerows.

This is relevant not simply as a historical complaint. It explains why important issues remain unresolved at Examination. The purpose of consultation was to allow specialist and local consultees to understand the likely significant effects and influence the design before the application was finalised. Where the necessary tree and hedgerow information was unavailable, the opportunity to secure genuine avoidance through consultation was materially reduced.

The result is an application that still proposes to resolve identified arboricultural conflicts after consent.

The Network's requested safeguards

The South Norfolk Tree Warden Network identifies seven principal measures necessary to address the deficiencies:

- A final Arboricultural Impact Assessment covering the entire Order Limits, Cable Route Corridor, highway works, AIL routes, visibility splays, compounds, accesses, haul routes, drainage and decommissioning assumptions.
- Final Tree Protection Plans and Root Protection Area plans showing construction exclusion zones, no-dig areas, fencing, ground protection, vehicle and haul-road stand-offs, storage exclusions, manoeuvring areas and lighting and chemical exclusion zones.

- Resolution of all four access conflicts with ancient and veteran tree buffers before consent.
- A presumption of avoidance for ancient, veteran and high-value mature trees, trees with potential roost features, ancient woodland edges and Important Hedgerows, supported by a specific alternatives assessment wherever harm is asserted to be unavoidable.
- Independent arboricultural and ecological clerks of works for vegetation works, accesses, AIL works, trenching, HDD compounds, haul routes and reinstatement, with authority to stop works.
- Long-term monitoring for delayed harm to retained trees, hedges and woodland edges.
- A prohibition on relevant works until the final AIA, Arboricultural Method Statement, Tree Protection Plans and hedgerow impact schedules have been approved following consultation with the local authority arboricultural officer and affected parish Tree Wardens.

These safeguards are proportionate to the scale of the Scheme and the value of the affected resource. They are not substitutes for removing unacceptable development, but they represent the minimum evidence and controls necessary before any residual impact could be evaluated.

Conclusion

The South Norfolk Tree Warden Network's evidence materially reinforces the objection to the Applicant's treatment of ancient woodland, veteran trees, mature trees and hedgerows.

It demonstrates that:

1. the affected resource forms the ecological and historic infrastructure of the Claylands landscape;
2. at least 70 veteran-feature trees occur within or close to the Order Limits;
3. 621 trees have potential to support roosting bats;
4. the arboricultural assessment remains preliminary;
5. four known conflicts with ancient or veteran tree buffers remain unresolved;
6. repeated hedgerow removals have not been assessed cumulatively;
7. the Important Hedgerow position is incomplete;
8. access, AIL and highway works remain capable of causing pruning, root damage and compaction;
9. delayed decline may not become apparent until years after construction;
10. and future tree growth may create pressure for operational pruning or removal.

The Network's conclusion is consistent with South Norfolk Council's earlier requirement that the tree surveys and full arboricultural impact assessment should inform design and be available for Examination. It is also consistent with Natural England's insistence that veteran-tree and ancient-woodland protection be recorded and secured across all project phases.

BEPS therefore submits that the Tree Warden evidence should be given substantial weight. The current application does not demonstrate that the Scheme can be constructed, operated, maintained and decommissioned without unacceptable harm to the mature tree, veteran tree, hedgerow and woodland network.

The appropriate response is not to defer the conflicts to detailed design. The Applicant should be required to produce a final, scheme-wide arboricultural assessment and fixed protection plans during the Examination and to remove or redesign every component that cannot be delivered without risking loss or deterioration of irreplaceable or high-value tree habitat. Until that work has been completed, the Examining Authority cannot safely conclude that the Applicant has complied with the mitigation hierarchy or the national policy protection afforded to ancient woodland and ancient and veteran trees.

8.7.6 Irreplaceable habitats, policy conflict and the mitigation hierarchy

The protection afforded to ancient woodland and ancient or veteran trees is materially stronger than the ordinary planning balance applicable to most ecological receptors. These habitats are not treated as interchangeable habitat units whose loss can be offset through planting elsewhere. They are classified as irreplaceable because their ecological characteristics arise from age, continuity, rarity, species assemblages, soils, fungi, deadwood and other processes that cannot realistically be recreated within a planning or project timescale.

This distinction is central to East Pye Solar. The Applicant cannot answer the proximity, enclosure or potential deterioration of ancient woodland and ancient or veteran trees by relying generally upon Biodiversity Net Gain, proposed woodland planting or future landscape management. The applicable policy requires the Applicant first to demonstrate avoidance and full mitigation of both direct and indirect effects. If loss or deterioration remains, development consent should not be granted unless the separate and demanding policy gateway of wholly exceptional reasons and a suitable compensation strategy is met.

The applicable EN-1 policy

The current Overarching National Policy Statement for Energy, EN-1 (2025), came into force on 6 January 2026. The Forestry Commission's February 2025 scoping response necessarily referred to the equivalent provisions of the then-current 2024 EN-1, at paragraphs 5.4.32 and 5.4.53. Those protections have been carried forward into the present EN-1 at paragraphs 5.4.33 and 5.4.55.

EN-1 paragraph 5.4.15 defines irreplaceable habitats as habitats that would be technically very difficult, or would take a very significant time, to restore, recreate or replace, having regard to their age, uniqueness, species diversity or rarity. Paragraph 5.4.16 expressly identifies ancient woodland and ancient and veteran trees as particularly valuable resources and records the Government's commitment to maintain and enhance them. Lowland fen is also expressly identified as an irreplaceable habitat.

Paragraph 5.4.33 requires applicants to include measures to mitigate fully the direct and indirect effects of development upon ancient woodland, ancient and veteran trees and other irreplaceable habitats during construction and operation. Paragraph 5.4.55 then directs that the Secretary of State should not grant development consent for development resulting in the loss or deterioration of an irreplaceable habitat unless there are wholly exceptional reasons and a suitable compensation strategy exists.

Those provisions create a sequential policy test:

1. the direct and indirect effects must be identified;
2. avoidance must be applied first;
3. effects that cannot be avoided must be fully mitigated;
4. the decision-maker must determine whether any loss or deterioration nevertheless remains; and
5. where it does, consent should not be granted unless wholly exceptional reasons and a suitable compensation strategy are both established.

The Applicant's approach does not yet satisfy that sequence. It begins from the proposition that the woodlands and veteran trees will remain physically present and then treats buffers, management plans and replacement planting as sufficient protection. That is not the same as demonstrating that loss or deterioration has been avoided.

Critical National Priority status does not disapply the protection

The Applicant may rely upon the Scheme's status as Critical National Priority infrastructure and upon the substantial national need for renewable generation. That status does not remove the requirement to apply the mitigation hierarchy.

EN-1 paragraph 4.2.23 expressly provides that applicants for CNP infrastructure must continue to demonstrate compliance with the relevant NPSs, the mitigation hierarchy and all applicable legal and regulatory requirements. Paragraph 4.2.24 requires an applicant to demonstrate that residual effects are genuinely effects that cannot be avoided, reduced or mitigated. Compensation does not reduce the underlying adverse effect and is addressed only after the avoidance and mitigation exercise has been completed.

EN-1 does establish a strong presumption in favour of CNP infrastructure where ordinary residual environmental effects remain after the mitigation hierarchy has been applied. However, paragraph 4.2.28 expressly excludes residual effects presenting an unacceptable risk to, or unacceptable interference with, irreplaceable habitats from that presumption. Irreplaceable habitats therefore occupy an exceptional position even within the CNP regime.

It follows that CNP status cannot be used to bypass the preliminary question of whether the Scheme creates an unacceptable risk of loss or deterioration. Nor does the general need for renewable energy establish that every proposed parcel, access, cable route, compound or infrastructure location is necessary in its present form.

The policy requires a project-specific demonstration that avoidable conflicts have been removed. Otherwise, the CNP presumption would deprive the express irreplaceable-habitat exception in paragraph 4.2.28 and the decision-making rule in paragraph 5.4.55 of practical effect.

EN-1 also recognises that a limited reduction in generation capacity may exceptionally be justified where mitigation would produce a significant environmental benefit outweighing the marginal loss of function. The Applicant cannot therefore assume that every panel parcel must be retained merely because its removal would reduce generating capacity. It must identify the actual capacity consequence and weigh it against the benefit of avoiding harm to an irreplaceable habitat.

The NPPF establishes the same policy sequence

The National Planning Policy Framework reinforces this approach. Paragraph 193(a) states that, where significant biodiversity harm cannot be avoided through locating development on an alternative site with less harmful impacts, adequately mitigated or, as a last resort, compensated, permission should be refused.

Paragraph 193(c) separately states that development resulting in the loss or deterioration of irreplaceable habitats, including ancient woodland and ancient or veteran trees, should be refused unless wholly exceptional reasons and a suitable compensation strategy exist. Footnote 70 gives infrastructure projects as a possible example only where the public benefit would clearly outweigh the loss or deterioration. NSIP status is therefore capable of forming part of the exceptional-reasons case, but it does not automatically establish it.

Natural England and the Forestry Commission's standing advice is equally clear. It requires decision-makers to assess both direct and indirect effects during construction and operation and identifies alternative siting and redesign as methods of avoiding harm. It also states that compensation must not form part of the assessment of whether wholly exceptional reasons exist and must not be used to improve the perceived merits of the development proposal.

That separation is important. The correct approach is not:

the Scheme provides renewable energy and proposes extensive new planting, therefore some deterioration of ancient woodland is acceptable.

The proper sequence is:

has the Applicant first demonstrated that all loss and deterioration have been avoided or fully mitigated; if not, are there wholly exceptional reasons for the remaining harm; and, separately, is there a suitable compensation strategy?

The Applicant's BNG and landscape planting case cannot answer the first or second questions.

'Deterioration' includes indirect and functional harm

The policy is engaged not only where ancient woodland is felled or a veteran tree is removed, but also where the habitat deteriorates.

Natural England and Forestry Commission standing advice identifies direct and indirect pathways capable of causing deterioration. These include root damage, soil compaction, damage to understorey and fungi, fragmentation of functional habitat, air and light pollution, noise and vibration, altered drainage and water tables, woodland-edge removal, reduced semi-natural habitat around woodland, interruption of connections between woods and veteran trees, disturbance from traffic and reduced resilience to environmental change.

Those are the same pathways identified in relation to East Pye Solar:

- woodland enclosure by panel arrays and fencing;
- interruption of hedgerow and tree-line links;
- construction dust;
- lighting;
- noise and vibration;
- pile installation;
- HGV and abnormal-load movements;
- access widening;
- cable trenching;
- Root Protection Area incursion;
- soil compaction;
- altered surface-water and groundwater movement;
- loss or degradation of woodland-edge foraging habitat;
- and the displacement of deer and other animals into retained woodland.

The absence of direct felling therefore does not establish policy compliance. The relevant question is whether the physical condition, ecological resilience and functional relationships of the habitat will be maintained.

The East Pye evidence demonstrates an unusually high level of exposure

The Applicant's scoping evidence identified 29 Ancient Woodland Inventory areas comprising 53 woodland parcels within two kilometres of the principal sites. Six ancient woodland parcels were identified as directly adjoining the Scheme: Popes Wood, Doyly's Grove, Saxlingham Grove, Little Wood, Ringers Grove and Spring Wood. The same baseline identified lowland fen, another irreplaceable habitat, beside Site 7B.

The Planning Inspectorate's Scoping Opinion accordingly required assessment of those six adjoining woods, including direct and indirect effects, avoidance, mitigation and opportunities for enhancement. The Forestry Commission advised that the minimum buffer is not necessarily sufficient where impacts extend further and expressly raised woodland isolation, dust, Root Protection Areas and the need to maintain connections between woodland blocks.

The exposure is not uniform but includes particularly serious configurations:

- Ringers Grove is surrounded by the proposed Site 8 development on three sides;
- Doyly's Grove adjoins Site 7C to the south, west and north;
- Popes Wood adjoins the same development area;
- Saxlingham Grove and Little Wood are connected with known barbastelle maternity-colony landscapes;
- Spring Wood lies between the Site 3 parcels and is associated with both roosting habitat and converted wartime bat hibernacula.

Norfolk Wildlife Trust expressly identified Ringers Grove's three-sided enclosure and required the Applicant to demonstrate how connectivity between woodlands would be maintained. It sought

substantial buffers comprising genuine shrub and rough-grassland ecotones, rather than simple undeveloped strips.

Natural England has also confirmed that Saxlingham Grove and the Popes Wood–Doyly's Grove complex are hydrologically connected to the Order Limits through watercourse or groundwater pathways. Its conclusion that effects can be ruled out is expressly conditional upon the relevant pollution, runoff and water-quality measures being followed and legally secured.

These facts demonstrate that potential deterioration is not hypothetical. The Scheme is immediately adjacent to multiple irreplaceable habitats and introduces recognised impact pathways into their settings.

The Applicant has not demonstrated avoidance

The first stage of the mitigation hierarchy is avoidance. Natural England and Forestry Commission standing advice gives alternative siting and scheme redesign as examples of avoidance.

At East Pye, the evidence indicates that the Applicant has instead treated proximity to ancient woodland as a constraint to be managed largely by buffers. That is mitigation, not avoidance.

Avoidance would have required the design process to consider, among other matters:

- removing development that encloses Ringers Grove;
- withdrawing Site 7C development from the immediate setting of Doyly's Grove and Popes Wood;
- removing the remaining Site 3 development beside Spring Wood and the bat hibernacula;
- keeping substations, compounds and major accesses well beyond woodland influence zones;
- fixing cable routes outside Root Protection Areas;
- preserving broad, undeveloped connections between woodland blocks;
- and resolving every ancient or veteran tree conflict before submission.

There is evidence that these alternatives were available for consideration. Norfolk Wildlife Trust had previously recommended removal of Site 3 because of likely effects upon Spring Wood County Wildlife Site and the adjoining woodland. Although the Applicant reduced the parcel, it did not remove it in full, and concern remained regarding infrastructure in the field immediately west of the ancient woodland.

Partial reduction may reduce the scale of an impact, but it does not establish avoidance where the retained development continues to affect the same receptor through the same pathways. The Applicant has not produced an assessment demonstrating that the retained half of the parcel is outside the woodland's functional zone or is unused by the bats associated with Spring Wood and the adjoining hibernacula.

Likewise, the Applicant has retained development around Ringers Grove rather than avoiding its enclosure. A 30-metre strip around the woodland does not alter the fundamental fact that solar infrastructure would occupy the surrounding landscape on several sides.

Buffers are mitigation and must not be mischaracterised as avoidance

The Applicant's proposed 30-metre buffers may provide useful mitigation if correctly designed, protected and managed. Natural England welcomes them in principle but has required the commitment to be incorporated consistently into the LEMP, CEMP and DEMP. It also requires full BS5837-compliant survey work, strict Root Protection Area protection, arboricultural oversight, no-dig construction, compaction prevention, runoff and dust controls and micrositing.

Natural England's position therefore confirms that buffers do not operate alone. Their effectiveness depends upon several additional controls, some of which remain to be developed or secured.

The standing advice states that buffer size and type must respond to the scale and nature of the development and the character of the surrounding area. Fifteen metres is only a minimum root-protection distance, and a larger buffer is required where other effects extend farther. Buffers should contribute to the wider ecological network and should comprise semi-natural habitat.

The Applicant has not demonstrated on a woodland-by-woodland basis that 30 metres is sufficient to address:

- the near-enclosure of Ringers Grove;
- the multi-sided relationship between Site 7C, Doyly's Grove and Popes Wood;
- the barbastelle maternity-colony functions of Saxlingham Grove and Little Wood;
- the roosting and hibernation functions associated with Spring Wood;
- hydrological pathways to Saxlingham Grove, Popes Wood and Doyly's Grove;
- or construction dust, vibration, lighting and traffic associated with works close to those habitats.

Drawing the same numerical distance around each woodland is not evidence that the actual zone of influence has been avoided.

Deferred design is incompatible with the required certainty

The mitigation hierarchy cannot be demonstrated while known conflicts remain dependent upon post-consent design.

The South Norfolk Tree Warden Network records that the Applicant's arboricultural assessment remains preliminary and identifies four specific clashes between indicative access routes and ancient or veteran tree buffer zones. It requests that those conflicts be resolved before consent and that any access, visibility splay, AIL manoeuvre or haul road incapable of avoiding the buffer be redesigned.

That is the correct policy approach. A conflict with an irreplaceable-habitat buffer is not an ordinary detailed-design matter. Unless the Applicant identifies the final route, swept path, working width, excavation method and Root Protection Area implications, the Examining Authority cannot know whether deterioration will occur.

The Tree Warden evidence also records 621 trees with potential to support roosting bats and explains that the Applicant has not provided a route-wide assessment of cumulative hedgerow severance, lighting, access widening, haul-road disturbance and loss of tree-buffer integrity.

South Norfolk Council had already advised that a full arboricultural impact assessment should be available for Examination and that tree surveys should inform detailed design rather than being deferred until later. It also required possible positional conflicts to be confirmed before approval of the Scheme, not merely before commencement.

Where the design remains flexible, EN-1 requires the ES to assess the likely worst-case effects. The Applicant cannot rely upon the possibility that micrositing may later avoid a conflict without also demonstrating that a feasible, environmentally acceptable location exists within the authorised envelope.

Biodiversity Net Gain does not resolve irreplaceable-habitat harm

The Applicant's claimed BNG is not evidence that the policy test for ancient woodland or veteran trees has been met.

The statutory Biodiversity Gain Hierarchy is distinct from the ordinary ecological mitigation hierarchy and does not apply to irreplaceable habitats in the same way as ordinary metric habitats. Government guidance confirms that BNG does not replace the requirement first to avoid significant biodiversity harm and that irreplaceable habitats are subject to separate arrangements.

This is necessary because a metric cannot reproduce the defining characteristics of ancient woodland or an ancient tree. New woodland planting may eventually create valuable habitat, but it cannot reproduce:

- ancient soils and undisturbed soil profiles;
- long-established fungal and microbial communities;
- veteran decay structures;
- centuries of ecological continuity;
- the existing genetic resource;
- or current relationships between the woodland, protected species and the surrounding habitat network.

Natural England and Forestry Commission standing advice expressly states that new woodland is not a direct replacement for lost or damaged ancient woodland and that compensation can only ever partially compensate for the damage. It also states that ancient woodland cannot be relocated because the same ecological conditions cannot be recreated elsewhere.

Accordingly, the Applicant cannot place proposed woodland creation, hedgerow planting or habitat units on the positive side of the planning balance and treat them as cancelling deterioration of an irreplaceable habitat. Those measures may constitute enhancement or, in exceptional circumstances, part of a compensation strategy. They do not turn deterioration into no deterioration.

No suitable irreplaceable-habitat compensation case has been presented

The Applicant's case appears to be that no ancient woodland or ancient or veteran tree will be lost or deteriorated. It has therefore not advanced a distinct compensation strategy addressing such loss or deterioration under EN-1 paragraph 5.4.55.

That creates a clear consequence for the Examination.

If the Examining Authority concludes that deterioration cannot presently be excluded—for example through enclosure, loss of connectivity, hydrological change, Root Protection Area conflict, lighting, dust, vibration or delayed tree decline—the Applicant cannot fall back upon its general BNG proposals. A suitable compensation strategy directed specifically to the nature, scale and location of the irreplaceable-habitat harm would be required.

Such a strategy would need to be additional to ordinary mitigation and BNG and would require, among other matters:

- identification of the exact habitat and function lost or deteriorated;
- evidence that avoidance and full mitigation had first been exhausted;
- restoration and management of relevant existing ancient woodland;
- reconnection of affected woodland and veteran-tree networks;
- long-term monitoring and remedial measures;
- secure land, funding and governance;
- and evidence that the measures were proportionate to the harm while acknowledging that full replacement is impossible.

No such case has been presented because the Applicant assumes the policy gateway will not be engaged. That assumption is unsafe while the arboricultural assessment remains preliminary and the indirect effects described above remain unresolved.

Wholly exceptional reasons have not been demonstrated for avoidable harm

The Scheme provides nationally important renewable-energy benefits and falls within the CNP policy. Those matters attract significant weight. They do not demonstrate that deterioration of each affected woodland or tree is unavoidable.

A wholly exceptional reasons case would need to address why the public benefit requires the particular harmful element in the particular location. It is not enough to establish that solar generation is needed nationally. The Applicant would need to show, for example, why:

- panels must surround Ringers Grove on three sides;
- development must remain beside Spring Wood despite NWT's avoidance request;
- Site 7C must occupy the immediate setting of Doyly's Grove and Popes Wood;
- an access must conflict with an ancient or veteran tree buffer;
- or a cable, compound or road cannot be moved outside the relevant zone of influence.

The policy test would otherwise be satisfied by every renewable-energy NSIP irrespective of its design, making the express protection for irreplaceable habitats ineffective.

BEPS does not submit that renewable infrastructure could never meet the wholly exceptional reasons test. The submission is narrower: that the Applicant has not demonstrated wholly exceptional reasons for avoidable deterioration created by the present site selection, layout and retained design flexibility.

Natural England's 'green' position does not determine policy compliance

Natural England presently categorises ancient woodland and ancient or veteran trees as a green issue. That position should be recorded accurately, but its basis must also be understood.

Natural England's green classification is expressly subject to the proposed mitigation being secured. It requires the 30-metre buffer to be incorporated into the LEMP, CEMP and DEMP and requires strict Root Protection Area controls, an updated arboricultural survey, no-dig methods, arboricultural supervision, prevention of compaction, dust and runoff control and micrositing.

It is therefore a conditional consultation position, not a determination that all direct and indirect effects have been fully assessed or that the statutory decision-making test has been satisfied.

It also does not answer the separate evidence from:

- the Forestry Commission concerning woodland isolation and connectivity;
- Norfolk Wildlife Trust concerning Ringers Grove, Spring Wood and woodland ecotones;
- the Tree Warden Network concerning the preliminary AIA and unresolved access conflicts;
- South Norfolk Council concerning the need for a full arboricultural assessment;
- or Natural England's own acknowledgement of hydrological connectivity.

The Secretary of State remains responsible for applying EN-1 paragraph 5.4.55 on the complete evidence.

Conclusion

The policy protection for irreplaceable habitats is not satisfied merely because the Applicant does not propose to fell ancient woodland. The relevant test includes deterioration through indirect, functional and cumulative effects.

East Pye Solar directly adjoins six ancient woods, surrounds Ringers Grove on three sides, borders the Spring Wood maternity and hibernation landscape, lies beside barbastelle maternity woodland at Saxlingham Grove and Little Wood, and affects a wider network of veteran and mature trees, hedgerows and hydrologically connected habitats. The arboricultural assessment remains preliminary, known access-buffer conflicts remain unresolved and the Applicant relies upon buffers and later detailed design to demonstrate acceptability.

The applicable policy sequence has not been completed. In particular, the Applicant has not demonstrated that:

- all reasonable avoidance has been applied;
- each woodland's actual zone of influence has been identified;
- the 30-metre buffer fully mitigates every direct and indirect pathway;
- the remaining development will not cause woodland enclosure or functional fragmentation;
- all ancient and veteran tree conflicts can be resolved within the authorised envelope;
- hydrological and construction effects will not cause deterioration;
- or any residual deterioration is supported by wholly exceptional reasons and a suitable, habitat-specific compensation strategy.

BEPS therefore submits that the Scheme remains in conflict with EN-1 paragraphs 4.2.23–4.2.28, 5.4.33 and 5.4.55 and with NPPF paragraph 193. CNP status does not remove that conflict and BNG cannot compensate for it.

The development parcels and infrastructure that enclose, fragment or create unresolved risks to ancient woodland and ancient or veteran trees should be removed or relocated. If the Applicant cannot demonstrate before the close of Examination that loss and deterioration will be avoided, the irreplaceable-habitat policy gateway is engaged. In the absence of a demonstrated wholly exceptional reasons case and a suitable compensation strategy, development consent should not be granted.

8.7.7 Conclusions and remedies sought

The evidence considered in Sections 8.7.1–8.7.6 demonstrates that ancient woodland, ancient and veteran trees, mature hedgerows and the wider tree network are not peripheral constraints capable of being addressed by standard stand-off distances and post-consent management. They are defining features of the ecological structure of the East Pye landscape.

The Planning Inspectorate's Scoping Opinion identified six ancient woodland parcels directly adjoining the proposed development: Popes Wood, Doyly's Grove, Saxlingham Grove, Little Wood, Ringers Grove and Spring Wood. It required the Environmental Statement to assess the effects upon those woods and upon ancient and veteran trees, including the scope to avoid and mitigate harm. It also expressly identified construction dust as a potential impact pathway and confirmed that 15 metres is only a minimum buffer, to be increased where the nature or extent of the effects requires it.

The significance of that concentration cannot be reduced to the absence of development inside the mapped ancient-woodland polygons. The Scheme would introduce solar arrays, fencing, access roads, cable works, substations, construction compounds, lighting, drainage infrastructure and prolonged operational activity into the immediate setting of six irreplaceable woodland sites. In several cases, development would border the woods on more than one side or occupy land forming part of their wider ecological setting.

The Applicant's own scoping evidence records Doyly's Grove adjoining Sub-Site 7C to the south, west and north, with Popes Wood also adjoining that sub-site; Saxlingham Grove adjoining Sub-Sites 7F and 7G; Little Wood adjoining Sub-Site 7H; Spring Wood immediately between Sub-Sites 3A and 3B; and Ringers Grove immediately adjacent to Site 8A.

Those relationships engage the policy protection against both loss and deterioration of irreplaceable habitat. The evidence does not establish that deterioration has been avoided.

The woodland resource must be assessed as a connected network

The ancient woods do not function as six isolated receptors. They form part of the historic South Norfolk Claylands network of woodlands, hedgerows, mature field trees, ponds, watercourses, lanes, verges and field margins.

The Forestry Commission's advice expressly warns that isolation is a particular concern where woodland is surrounded by development on several sides. It requires consideration of the connectivity between woodland, individual trees and hedgerows and recommends that new planting should link existing woods and form meaningful connected woodland blocks rather than isolated screening belts. It also identifies root damage, trenching, soil compaction, chemical contamination and dust as indirect effects requiring protection beyond the woodland boundary.

The Norfolk Wildlife Trust's Claylands evidence similarly emphasises that ecological benefit depends upon restoring and strengthening connections between habitats. Linking existing hedges, grassland and other semi-natural features multiplies their ecological value, whereas isolated habitat creation does not provide the same function.

The Applicant has not provided a final, scheme-wide woodland-connectivity assessment establishing:

- the existing connections between the six ancient woods and the wider woodland network;
- the species and ecological functions dependent upon each connection;
- the routes used by bats and other woodland species;
- the effects of fencing, access roads, cable crossings, lighting and maintenance activity;
- the extent to which woodland-edge habitat will be altered;
- or the time required for proposed planting to become functionally effective.

Instead, the assessment relies largely upon retention of woodland, standard buffer distances and future habitat creation. That approach does not establish that the woods will retain their ecological resilience or their functional relationship with the surrounding landscape.

The ancient woods perform protected-species functions

The woodland issue cannot be separated from the Applicant's own bat findings.

Saxlingham Grove, Little Wood and Spring Wood are associated with known or reported barbastelle maternity or roosting resources. Spring Wood also adjoins the converted former Second World War shelters used as bat hibernacula. The Applicant identifies the wider Order Limits as supporting a nationally important bat assemblage and records mature trees, hedgerows and tree lines as important commuting, foraging and potential roosting habitat.

Norfolk Wildlife Trust considers bats to be one of the most significant ecological issues arising from the application. It records the Applicant's conclusion that the landscape supports a nationally

important assemblage and challenges the proposition that temporary hedgerow gaps, lighting and construction disturbance will not materially affect habitat functionality. NWT also warns that habitat creation cannot automatically replace established commuting routes and mature landscape features that may take decades to develop equivalent function.

This materially increases the sensitivity of the ancient-woodland setting. Protection cannot be confined to roots and woodland canopy. It must also maintain:

- dark woodland edges;
- maternity-roost support habitat;
- hibernation access;
- alternative tree-roost resources;
- prey-rich margins;
- connected hedgerows;
- and unobstructed movement between woodland blocks.

The Applicant has not demonstrated that the proposed layout and outline mitigation will preserve all of those functions.

Spring Wood demonstrates the failure to achieve avoidance

Spring Wood provides the clearest example of the difference between reducing a development parcel and avoiding an ecological conflict.

The Applicant's scoping report records Spring Wood as ancient replanted woodland and priority deciduous woodland immediately between Sites 3A and 3B. Norfolk Wildlife Trust expressly advised during consultation that Site 3 should be dropped from the site-selection process because of potential effects upon Spring Wood County Wildlife Site. Although the Applicant removed the field south of Spring Wood from the panel area, NWT remained concerned about works in the area, particularly the substation proposed immediately west of the woodland, and advised that an even wider buffer might be required.

NWT's Relevant Representation maintains that position. It states that Site 3 had previously been recommended for removal because of effects upon the County Wildlife Site, ancient woodland and bats; welcomes the changes made; but remains concerned and ideally recommends that the site be removed from the overall Scheme.

The Applicant has therefore not followed the avoidance advice in full. Only part of the affected parcel has been removed, while infrastructure remains beside the same ancient woodland, known bat habitat and hibernation resource.

A partial reduction may reduce the extent of development, but it does not demonstrate that the remaining land is ecologically unimportant or that the same impact pathways have been eliminated. No complete tracking, hibernacula-specific disturbance assessment or woodland-function assessment has been provided to show that the retained part of Site 3 falls outside the functional landscape of Spring Wood.

The mitigation hierarchy has consequently not been exhausted at this location.

Buffers have not been shown to prevent deterioration

The proposed 30-metre ancient-woodland buffer is a useful improvement upon the minimum 15-metre root-protection distance. It is not evidence that every indirect effect has been avoided.

The Forestry Commission's advice is explicit that the minimum distance must be increased where effects extend farther, including construction dust and traffic-related pollution. It also states that buffers should contribute to ecological networks and consist of appropriate semi-natural habitat.

Norfolk Wildlife Trust likewise seeks buffers comprising genuine ecotones of rough grassland and shrubs and advises that greater distances may be necessary in sensitive locations. Its Relevant Representation raises concern that the Applicant's construction and operational buffers may be insufficient for ancient woodland and other irreplaceable habitats, particularly where the locations of HDD compounds, construction lighting and temporary works remain unresolved.

Natural England presently identifies ancient woodland and ancient or veteran trees as a green matter, but that position is conditional. Natural England requires the 30-metre commitment to be recorded consistently and secured through the LEMP, CEMP and DEMP. It also notes that veteran trees are not to be removed and pruning is to be avoided.

Natural England's position does not establish that a uniform 30-metre buffer addresses:

- enclosure and loss of landscape connectivity;
- hydrological change;
- construction dust;
- lighting;
- noise and vibration;
- piling;
- disturbance of bat roosts or hibernacula;
- altered woodland-edge microclimate;
- Root Protection Area conflicts;
- displaced deer browsing;
- or operational pressure arising from future tree growth.

Natural England also confirms that Saxlingham Grove and the Popes Wood–Doyly's Grove complex are hydrologically connected to the Order Limits. Its conclusion that damage can be ruled out is expressly dependent upon water-quality, pollution-prevention and surface-water measures being followed and legally secured.

The proposed buffers are therefore part of a package of conditional mitigation. They are not a finding of no effect and should not be treated as a substitute for site-specific assessment of the actual zone of influence around each woodland.

The arboricultural baseline and design remain unresolved

The evidence concerning individual trees and hedgerows reinforces the woodland objection.

The South Norfolk Tree Warden Network records that the Applicant's baseline includes:

- 49 trees with veteran features within the Order Limits;
- a further 21 veteran-feature trees within 30 metres of the boundary;
- native hedgerows throughout the sub-sites;
- and 621 trees assessed as having potential to support roosting bats.

It also records that Appendix 7.10 remains a Preliminary Arboricultural Impact Assessment, rather than a final, construction-ready assessment of all access routes, visibility splays, AIL routes, compounds, haul roads, cable works and Root Protection Area incursions.

Most significantly, the Applicant has already identified four clashes between indicative access routes and buffers applied to ancient or veteran trees. The Applicant proposes to resolve those clashes at detailed design because the routes are indicative and flexible within Work No. 4. The Tree Warden Network objects to that approach and requests that every conflict be resolved before consent.

That objection is well founded. A known conflict with the protection area of an irreplaceable tree cannot properly be treated as a routine construction detail. Until the final route, working width, vehicle swept path, surfacing method and Root Protection Area implications are known, the Examining Authority cannot determine whether deterioration will occur.

The same uncertainty affects repeated hedgerow gaps, visibility splays, cable crossings and highway works. Although each individual removal may be described as localised, the cumulative effect across the Order Limits may include loss of mature structure, fragmentation of bat corridors and permanent alteration of the historic field network. The Tree Warden Network expressly states that the ES does not contain a clear route-wide analysis of cumulative hedgerow severance, veteran-tree buffer disruption, construction lighting, access widening or the time needed for replacement planting to become functionally equivalent.

The Applicant's conclusion of no unacceptable arboricultural or woodland effect is therefore premature.

Biodiversity Net Gain does not answer the irreplaceable-habitat objection

The Applicant's proposed woodland, hedgerow and grassland creation may produce ecological benefits. It does not demonstrate that deterioration of ancient woodland or ancient and veteran trees has been avoided.

Ancient woodland and veteran trees derive their value from continuity over centuries. New planting cannot reproduce ancient soils, fungal networks, veteran decay features, hollowing, deadwood assemblages or established relationships with protected species within the operational life of the Scheme.

Norfolk Wildlife Trust warns that biodiversity metrics do not fully account for temporal losses of ecological function, particularly for bats and species dependent upon mature hedgerows and connected habitat networks. It therefore seeks early habitat establishment, meaningful success criteria, long-term monitoring and adaptive management.

Natural England similarly welcomes the proposed net gain but asks for clearer success criteria, remedial triggers and long-term management responsibilities.

BNG should therefore be treated as a separate enhancement obligation. It cannot be used to convert a risk of deterioration to irreplaceable habitat into a neutral or beneficial effect.

Natural England's consultation position is not determinative

BEPS recognises that Natural England currently records no amber or red issue specifically for ancient woodland and veteran trees. That position must be represented accurately.

It is, however, expressly subject to the appropriate requirements being adequately secured. Natural England seeks consistent 30-metre protection in the LEMP, CEMP and DEMP and relies upon construction pollution and runoff controls when reaching its conclusions concerning hydrologically connected sites. It also retains an amber position concerning protected species and advises that licences may be required for roosting bats and other species.

The green classification therefore does not determine:

- whether the six woods will become ecologically isolated;
- whether Spring Wood has been adequately avoided;
- whether the four known tree-buffer clashes can be resolved;
- whether the preliminary AIA is sufficient;
- whether the woodland-dependent bat functions will be retained;
- or whether the proposed buffers address the full zone of influence.

Those matters remain for the Examining Authority and ultimately the Secretary of State on the whole of the evidence.

Overall conclusion

The Applicant has not demonstrated that East Pye Solar will avoid loss or deterioration of ancient woodland, ancient or veteran trees and the wider mature tree and hedgerow network.

The principal unresolved matters are cumulative and mutually reinforcing:

1. six ancient woodland parcels directly adjoin the Scheme;
2. development borders some woods on multiple sides;
3. several woods support or are associated with nationally important bat functions;
4. Spring Wood is linked to maternity, commuting and hibernation habitat;
5. the Forestry Commission identifies woodland isolation, root damage, compaction and wider connectivity as material concerns;

6. NWT continues to seek removal of Site 3 and wider, ecologically functioning buffers;
7. Natural England's conclusions depend upon mitigation being secured and consistently applied;
8. at least 70 veteran-feature trees occur within or close to the Order Limits;
9. 621 trees have bat-roost potential;
10. the AIA remains preliminary;
11. and four known access conflicts with ancient or veteran tree buffers remain unresolved.

This is not an evidential basis upon which the Examining Authority can safely conclude that deterioration will not occur.

The Applicant's case depends upon the proposition that the woods and veteran trees will remain physically present and that future plans, buffers and planting will control the indirect effects. Physical retention is not the relevant policy test. The issue is whether the habitats will retain their condition, resilience, ecological setting, protected-species functions and connectivity throughout construction, operation, equipment replacement and decommissioning.

That has not been established.

Remedies sought

BEPS submits that the following remedies are required before any conclusion of acceptability could be reached.

First, the remaining development at Site 3 adjoining Spring Wood, including infrastructure within its functional ecological setting, should be removed. This is the only response consistent with NWT's express avoidance advice and the combined ancient-woodland, maternity-roost and hibernation evidence.

Secondly, development enclosing or closely surrounding Ringers Grove, Doyly's Grove, Popes Wood, Saxlingham Grove and Little Wood should be redesigned to retain broad, undeveloped and dark ecological connections between the woods and the wider hedgerow and woodland network. A standard buffer around the woodland boundary is not sufficient where the wider landscape remains enclosed.

Thirdly, the Applicant should submit during the Examination:

- a final, scheme-wide Arboricultural Impact Assessment;
- final Tree Protection Plans;
- fixed Root Protection Areas;
- a complete schedule of tree and hedgerow retention, removal and pruning;
- all access, AIL, highway and cable-route impacts;
- and a woodland-by-woodland assessment of hydrology, dust, lighting, noise, vibration, edge effects and connectivity.

Fourthly, all four identified conflicts between access routes and ancient or veteran tree buffers must be resolved through fixed design before consent. The DCO should not permit those conflicts to be transferred to detailed design within a flexible works envelope.

Fifthly, every ancient-woodland and veteran-tree buffer should be based upon the site-specific zone of influence rather than a uniform numerical distance. Buffers should comprise functioning ecotones of native scrub, rough grassland and other appropriate semi-natural habitat and should remain free from compounds, roads, storage, cables, drainage infrastructure, fencing, lighting and ordinary operational activity.

Sixthly, the DCO should prohibit removal or pruning of ancient and veteran trees and prohibit later pruning of retained trees for panel efficiency, shading, leaf fall, CCTV visibility or ordinary operational convenience.

Seventhly, the final CEMP, LEMP, OEMP and DEMP should secure consistent woodland and tree protections for the entire project life, supported by independent arboricultural and ecological supervision, measurable success criteria, long-term monitoring and enforceable remedial action.

If the Applicant cannot provide that evidence and redesign before the close of Examination, the risk of deterioration to irreplaceable habitat remains unresolved. In that event, the Applicant has not demonstrated compliance with the mitigation hierarchy or the policy protection afforded to ancient woodland and ancient or veteran trees.

BEPS therefore submits that the ancient-woodland and tree evidence weighs strongly against the grant of development consent in the Scheme's present form. The affected parcels and infrastructure should be removed or relocated. Failing that, the Secretary of State should refuse consent because the Applicant has not demonstrated that loss or deterioration of irreplaceable habitat will be avoided.

8.8 Hydrologically connected ecology and chalk streams

The aquatic ecology affected by East Pye Solar cannot be assessed as a series of isolated ditches, crossings and watercourse buffers. The Applicant's own evidence identifies a connected network of rivers, becks, tributaries, field drains, ponds and seasonally flowing ditches extending across the Order Limits and into the River Tas and River Waveney catchments. Water, sediment, pollutants, aquatic organisms and ecological effects can move through that network beyond the immediate footprint of an individual construction activity.

This section should be read alongside Chapter 9 of this Written Representation, which addresses the adequacy of the Applicant's hydrological, hydrogeological, flood-risk, water-quality and Water Framework Directive assessments. The matter must nevertheless remain within Chapter 8 because hydrological connectivity is not merely a water-engineering issue. It is the mechanism by which aquatic and riparian habitats function, fish and invertebrates disperse, chalk-stream characteristics are maintained and pollution or sediment effects may reach downstream ecological receptors.

The Applicant's Aquatic Habitat Assessment identifies 21 waterbodies within or adjacent to the Order Limits. These include connected reaches and tributaries of Hempnall Beck and the River Tas, Pulham Beck and Starston Brook, Broome Beck and extensive field-ditch systems. The assessment uses hydrological connectivity, including Environment Agency information from downstream monitoring locations, to infer the likely fish and aquatic-invertebrate assemblages within the Scheme. That approach confirms that the affected watercourses are parts of wider catchment systems rather than independent local drains.

The central deficiency is that the Applicant relies upon connectivity when determining which species may be present, but does not assess the same connectivity adequately when determining how construction sediment, pollutants, altered runoff, drilling-fluid releases or changes to flow may propagate downstream. There is no equivalent catchment-scale analysis of the geographical extent, concentration, timing and ecological consequence of those effects.

8.8.1 River Tas, Hempnall Beck and connected tributaries

The River Tas system is the most ecologically sensitive aquatic network affected by the Scheme. The Applicant's Scoping Report identifies Hempnall Beck as a main river flowing between Site 7 and Sites 4–6. It identifies the River Tas itself as a main river running along the boundaries between Sub-Sites 8A and 8B, together with ordinary tributaries of the River Tas along or adjacent to other development parcels.

The Environment Agency has expressly identified the River Tas as a chalk-stream priority habitat and a focus of its ecological activity. At scoping, the Agency recorded that the River Tas was within the red-line boundary, was ecologically classified as Poor, and required a Water Framework Directive assessment because inadequately controlled works could cause prohibited deterioration. The Agency also sought watercourse and wetland Biodiversity Net Gain aligned with River Basin Management Plans, WFD objectives, catchment plans and the emerging Local Nature Recovery Strategy.

That priority status is important. Chalk streams are groundwater-influenced systems whose ecological character depends upon the interaction of the chalk aquifer, spring and seepage flows, stable water chemistry, relatively consistent temperatures, clean gravels, marginal vegetation and connected tributaries. Their value cannot be protected merely by avoiding direct excavation within the main river channel. Activities throughout the contributing catchment may affect the watercourse by changing runoff, sediment supply, groundwater movement or water quality.

The ecological function of the River Tas must therefore be understood at catchment scale. The main channel receives water and material from Hempnall Beck, smaller tributaries, roadside drains, field ditches and seasonally active headwaters. Some of those features may appear dry during summer or early autumn but carry significant flow during wetter periods. They may provide seasonal habitat, dispersal routes and pathways through which pollutants and fine sediment enter the main watercourse.

The Applicant recognised that ditch networks and watercourses are ecological features from the beginning of the project. Its Scoping Report states that the design would seek to avoid ditch networks and watercourses and acknowledges that ditches provide habitat for protected

mammals and foraging or commuting bats. It also proposed targeted otter and water-vole surveys where construction or habitat-clearance works could not be kept at least 10 metres from watercourse banks.

That approach is too narrow for aquatic ecology. A ten-metre construction distance may reduce immediate bank disturbance, but it does not define the hydrological zone of influence. Runoff generated farther upslope, drainage changes, cable trenches, access roads, piling, soil compaction or contamination may all reach a watercourse through topography, field drains or groundwater pathways.

The relationship between groundwater and surface water is particularly material. The Scoping Report identifies Principal and Secondary Aquifers beneath parts of the Scheme. The Environment Agency advised that the Applicant had not adequately demonstrated the relationship between groundwater and surface-water bodies and required further evaluation of that relationship. It also required hydrogeological risk assessment where HDD or other trenchless works could interact with aquifers, watercourses or sensitive ecological receptors.

The relevant pathways include:

- direct runoff from disturbed soil into ditches and streams;
- mobilisation of fine sediment from haul roads, access works and cable trenches;
- contaminated runoff containing fuels, oils, cementitious material or other construction substances;
- altered infiltration and groundwater recharge caused by compaction and new surfaces;
- preferential flow along cable trenches;
- temporary dewatering or interception of shallow groundwater;
- drilling-fluid escape during HDD;
- changes to bank structure or channel form at crossings;
- obstruction or delay of fish movement;
- and changes to the volume, timing or direction of surface-water flow.

Those are ecological pathways because they affect habitat quality, spawning gravels, dissolved oxygen, aquatic plants, macroinvertebrates and fish. Fine sediment may fill gravel interstices, smother eggs and reduce the availability of refuge habitat. Pollution can cause acute mortality or chronic ecological stress. Flow alteration can affect water depth, velocity, temperature, oxygenation and the seasonal accessibility of tributaries.

The Applicant's aquatic evidence itself records sediment release, increased turbidity, accidental pollution, temporary alteration of drainage or flow pathways and physical effects at crossings as relevant construction risks. It also records failing fish and dissolved-oxygen or phosphate elements within parts of the connected River Tas waterbody and recognises the need to avoid WFD deterioration.

These existing pressures increase the sensitivity of the receptor. A waterbody already failing particular ecological or chemical elements has less capacity to absorb additional disturbance. A temporary effect cannot be dismissed simply because the construction activity eventually ceases.

Loss of a spawning season, deposition of fine sediment or a pollution incident may affect fish or invertebrate populations beyond the duration of the works.

The Environment Agency has expressly challenged the Applicant's definition of short-term ecological effects. Chapter 8 defines short-term or temporary effects as lasting up to two years. The Agency states that this is too long for fish because two consecutive years of disturbance may affect two spawning or juvenile year classes and could significantly affect populations or contribute to WFD deterioration. It requires activities or effects lasting more than six months to be assessed as if they were permanent.

That criticism is directly relevant to the dispersed construction programme. Watercourse crossings, cable works, haul roads and reinstatement may not all affect one location continuously for two years, but repeated works across the same catchment can expose different tributaries and alternative habitats over successive seasons. A catchment-wide fish population may therefore experience a sequence of disturbances rather than one isolated temporary event.

The River Tas network is also known to support notable fish and protected aquatic species. At scoping, the Environment Agency identified records within Hempnall Beck of brown or sea trout, bullhead, European eel and brook lamprey. It required fish to be included in the desk study and required the effects of continuous HDD noise, sediment runoff and pollution to be assessed.

The ecological sensitivity is further reinforced by the white-clawed crayfish evidence. The Environment Agency's scoping response recorded the species in the River Tas and required a commitment to undertake surveys at relevant locations when the works affecting watercourses were known. Subsequent evidence submitted by a local resident records repeated Norfolk Rivers Trust surveys confirming a breeding white-clawed crayfish population at Saxlingham Thorpe, together with other notable species including river lamprey and brown trout.

That submission also identifies the pathways by which East Pye works could affect the population: connected ditches, drains, culverts, streams, groundwater runoff, sediment changes, contamination and potential bentonite releases associated with trenchless cable installation. The precise distribution of white-clawed crayfish is addressed elsewhere in this Chapter, but its confirmed presence within the receiving chalk-stream system is material here because it demonstrates the ecological consequences of getting the hydrological assessment wrong.

The Examining Authority has already determined that the aquatic baseline requires further attention. Its Rule 6 letter quotes Appendix 8.9's acknowledgement that the surveys were undertaken during unusually dry conditions and may under-represent the typical wetted extent and habitat availability of ephemeral headwaters and field ditches. Having regard to the survey timing and representations from BEPS, South Norfolk Council and Norfolk Wildlife Trust, the Examining Authority requested further information and survey proposals concerning white-clawed crayfish.

The River Tas and Hempnall Beck should therefore be assessed as a connected chalk-stream ecological system. The question is not limited to whether direct works within the main river are undertaken by HDD. It is whether all construction and operational activities within the hydrologically connected catchment have been assessed sufficiently to demonstrate that they will not:

- add fine sediment;
- mobilise contaminants;
- alter groundwater or surface-water flow;
- degrade spawning and refuge habitat;
- obstruct fish movement;
- spread invasive species or crayfish disease;
- or reduce the ecological status and resilience of the chalk-stream system.

The Applicant has not supplied a catchment-scale ecological model capable of answering those questions. The use of general pollution-prevention measures and outline water-management plans may reduce risk, but it does not establish the spatial extent or ecological significance of the effects being mitigated.

8.8.2 River Waveney-linked systems

The ecological connectivity issue is not confined to the River Tas catchment. The eastern and southern parts of the Scheme interact with watercourses and ditch networks draining towards the River Waveney system.

The Applicant's Scoping Report identifies Broome Beck as an ordinary watercourse adjoining the southern boundaries of Sub-Sites 10A and 10C before becoming a main river shortly downstream. It also identifies ordinary tributaries of Starston Brook along or adjacent to the south-western part of Sub-Site 4A. The Aquatic Habitat Assessment includes Starston Brook, Broome Beck and associated field ditches within the wider connected aquatic baseline.

These features should not be treated as low-value drainage channels simply because parts are classified as ordinary watercourses or are seasonally dry. Their ecological functions include:

- conveying water and sediment to downstream brooks;
- providing habitat for aquatic and semi-aquatic invertebrates;
- offering seasonal access and refuge for fish and amphibians;
- connecting ponds, wet field margins and riparian habitats;
- providing foraging routes for bats and birds;
- and acting as pathways for the spread of both native organisms and invasive species.

The distinction between a main river and an ordinary watercourse is principally regulatory. It does not determine ecological value. A small tributary may be critical to the quality of a downstream waterbody because it contributes clean flow, spawning habitat, refuge from high flows or connectivity between otherwise isolated habitats.

The Scheme introduces several potential impact mechanisms within these Waveney-linked systems.

Cable installation may require crossings of watercourses and ditches by trenchless or open-cut techniques. Even where HDD is used, launch and reception compounds, access routes, drilling-fluid management, dewatering and working areas remain necessary. An HDD bore may also

interact with shallow groundwater, mobilise existing contamination or produce a drilling-fluid breakout into the channel or adjoining ground.

At scoping, the Environment Agency stated that the final cable and haul-road routes had not been fixed and that their watercourse effects could not be determined if the Water Environment were scoped out. It required a WFD assessment, MoRPh or River Corridor surveys, information on crossing methods and environmental control documents including a drilling-fluid breakout plan.

Access works create separate effects. Temporary or permanent crossings may require culverts, bridges, bank works, vegetation clearance and repeated HGV movements. These activities may compact banks, damage marginal vegetation, introduce sediment, interrupt channel continuity and alter flow.

The Environment Agency's application-stage representation confirms that the Flood Risk Assessment continues to refer to the possible use of culverts. The Agency objects to new culverts and recommends clear-span bridges in accordance with its anti-culverting policy because culverts may increase flood risk and damage watercourse function. It also requires the locations and set-backs of main-river crossing works and HDD pits to be confirmed.

The ecological objection to culverting is additional to the flood-risk objection. A culvert may:

- remove natural bed and bank habitat;
- reduce light and vegetation;
- change velocity and sediment deposition;
- form a barrier to fish and invertebrate movement;
- trap debris;
- and reduce the continuity of the riparian corridor.

A temporary culvert may still affect a breeding season or leave compacted and altered banks after removal. The assumption that a structure is temporary does not determine that its ecological effect is insignificant.

Surface runoff is another important pathway. Solar fields, tracks, compounds, cable works and access roads may alter the distribution and velocity of runoff. Chapter 9 addresses whether the drainage strategy adequately predicts and controls those changes. Within Chapter 8, the relevant issue is the effect on downstream habitat and species.

Runoff from disturbed clay soils may carry fine sediment into ordinary ditches that subsequently discharge into Starston Brook or Broome Beck. Runoff from substations, compounds or construction areas may carry oils, fuels, concrete washout or other pollutants. Where several Scheme parcels drain into the same brook system, individually small releases may combine or occur repeatedly over the construction programme.

The Applicant has not provided a sufficiently integrated assessment showing:

- the catchment draining to each Waveney-linked watercourse;
- every Scheme parcel, access, compound and cable section within that catchment;

- the final location and method of each crossing;
- the direction and travel time of runoff;
- the location of sensitive downstream habitats;
- the interaction with groundwater;
- or the cumulative consequence of multiple works within the same system.

This absence is important because Broome Beck changes regulatory status shortly downstream of the Scheme. An impact originating beside an ordinary-watercourse reach may therefore be transmitted into a main river. The regulatory classification at the point of construction does not limit the downstream ecological zone of influence.

The field-ditch network also requires a seasonal assessment. The Applicant's surveys encountered many dry or partly dry features, but that does not mean those ditches are hydrologically disconnected. During wetter periods they may carry runoff rapidly into Starston Brook, Broome Beck and the wider Waveney system. They may also provide temporary habitat and dispersal pathways.

The proposed reliance on later construction planning is therefore insufficient. Before consent, the Applicant should identify all crossings and working areas within the Waveney-linked system and demonstrate, through a source–pathway–receptor assessment, that effects will not propagate beyond the immediate works.

At minimum, the assessment should distinguish:

- direct channel and bank effects;
- sediment and contaminant pathways;
- altered surface flow;
- groundwater interaction;
- barrier and fragmentation effects;
- effects upon fish, invertebrates and riparian species;
- and cumulative effects across all crossings within each connected catchment.

The present assessment does not provide that level of certainty.

8.8.3 Incomplete aquatic baseline

The reliability of the Applicant's conclusions depends upon the adequacy of the aquatic baseline. Appendix 8.9 is not a comprehensive aquatic-species survey. It is described as a proportionate, habitat-led appraisal. No direct macroinvertebrate sampling was undertaken, and the appraisal uses habitat characteristics, desk-study information and data from connected off-site or downstream monitoring locations to infer the likely ecological assemblages.

A habitat-led appraisal can be useful for identifying potential value and determining where more detailed work is required. It is less capable of supporting a confident no-significant-effect conclusion where:

- the catchments are complex and connected;
- protected or priority species are known downstream;
- crossing and compound locations remain flexible;
- direct biological sampling is absent;
- and the survey conditions under-represent normal hydrology.

The dry-condition limitation is not speculative. Appendix 8.9 expressly states that surveys were completed during unusually dry conditions and that many smaller drainage features were dry or partly dry. It accepts that the observed wetted extent, depth and in-channel habitat may under-represent typical conditions, particularly in ephemeral headwaters and field ditches. The surveys were undertaken in September and October 2025.

That timing matters because seasonal ditches and headwaters may perform their greatest hydrological and ecological role during winter, spring or periods of sustained rainfall. A feature that was dry in September may:

- carry substantial runoff in winter;
- connect otherwise isolated ponds and channels;
- provide temporary fish or amphibian habitat;
- transport macroinvertebrates;
- convey sediment and pollutants;
- or recharge wetland and riparian soils.

The dry survey therefore risks understating both habitat availability and impact pathways.

The limitation is especially significant because the Applicant's own methodology relies upon hydrological connectivity. Downstream Environment Agency fish and invertebrate data are used to infer what may occur within or close to the Order Limits. The Ecology Chapter recognises that Hempnall Beck could support diverse aquatic macroinvertebrate communities and that sensitive taxa are likely within flowing sections and principal tributaries.

That inference supports a precautionary conclusion that ecologically important assemblages may be present. It does not support a conclusion that the effect of the Scheme will be insignificant. To reach the latter conclusion, the Applicant must assess how impacts move through the same network.

There is presently an asymmetry in the assessment:

- downstream connectivity is used to infer ecological presence;
- but downstream connectivity is not modelled adequately when assessing impact propagation.

For example, downstream data may establish that eel, lamprey, salmonids or sensitive invertebrates are likely to use the connected system. The assessment does not then quantify how sediment released at an upstream cable crossing would travel, where it would deposit, how long elevated turbidity would persist or which downstream habitat could be affected.

Similarly, the existence of connected ditches is recognised when describing the aquatic network, but there is no wet-season survey or integrated model showing which ditches become active during rainfall and how they connect solar parcels, substations, roads and cable works to the main rivers.

No direct macroinvertebrate sampling means that the Applicant has not established the actual composition, abundance or seasonal use of the affected reaches. That matters because different assemblages have different sensitivities to:

- sediment deposition;
- altered flow;
- oxygen depletion;
- temperature change;
- pollution;
- channel shading;
- bank disturbance;
- and polarised light from solar panels.

A habitat appraisal may identify that a reach could support diverse invertebrates. It does not establish which taxa are present, whether breeding occurs there, or whether a particular season is critical.

The absence of direct sampling is particularly relevant to the Environment Agency's concern about the attraction of aquatic insects to panels. Without an adequate baseline, it is difficult to determine:

- which emerging aquatic insects occur;
- their source reaches;
- their normal dispersal direction;
- the distance over which they may respond to reflected polarised light;
- and whether panel arrays lie within that behavioural zone of influence.

The white-clawed crayfish evidence demonstrates the practical consequence of relying too heavily on desk-study radii and walkover signs. Appendix 8.9 stated that the environmental search had not returned records within the two-kilometre search area. The separate River Tas evidence submitted to the Examination records a professionally confirmed breeding population at Saxlingham Thorpe and argues that it lies within the relevant connected system and within two kilometres of affected parts of the Scheme.

Whether every detail of the local evidence is ultimately accepted is a matter for Examination. It is already sufficient to show that absence of a record from one data search is not equivalent to ecological absence. The Examining Authority has accordingly required the Applicant to explain further survey work or provide robust justification if additional survey is not undertaken.

The baseline is also incomplete in temporal terms. Fish and aquatic invertebrates use different reaches at different life stages and seasons. Salmonids may depend upon clean gravel for spawning, juveniles upon shallow marginal habitat and adults upon deeper cover. Eels migrate through connected systems. Aquatic insects emerge seasonally and may disperse from

watercourses into adjoining land. A one-off autumn habitat inspection cannot characterise all of those functions.

The Environment Agency's application-stage response also identifies errors and omissions in the Applicant's treatment of fish habitat. It notes that Appendix 8.9 refers to coarse fish, eel and lamprey but does not specifically describe salmonid habitat use, including spawning gravels, marginal cover and woody material. The Agency considers that salmonids should be identified expressly even where some of the relevant habitat features overlap with those used by other species.

A robust aquatic baseline should therefore include, proportionately to the final works:

- wet-season and appropriate seasonal habitat surveys;
- direct macroinvertebrate sampling at sensitive reaches;
- current fish data and, where necessary, targeted fish surveys;
- crayfish survey or eDNA work at relevant connected locations;
- mapping of permanent, intermittent and ephemeral connectivity;
- channel-form and riparian-condition surveys;
- baseline water-quality and sediment data;
- groundwater–surface-water conceptual models;
- and upstream and downstream monitoring locations at each major crossing.

The need for that evidence does not mean that every small ditch requires the same survey effort. It means that survey scope must be determined by ecological function and hydrological connectivity rather than by whether a feature happened to contain water during a dry autumn visit.

Until the baseline is completed, the Applicant cannot confidently determine receptor value, impact magnitude or mitigation effectiveness. Outline pollution controls cannot correct an under-valued receptor, and post-consent monitoring cannot retrospectively establish what ecological conditions existed before construction.

8.8.4 Environment Agency's unresolved ecology concerns

The Environment Agency's Relevant Representation is particularly important because it assesses the final application documents rather than the earlier PEIR alone. Its position is not that all aquatic-ecology matters have been resolved through Chapter 8, Appendix 8.9 and the outline management plans. It identifies continuing disagreement and further work concerning fish valuation, temporary effects, electromagnetic fields, aquatic invertebrates and the security of riparian enhancement.

European eel has been undervalued

The Applicant's Table 8.14 classifies freshwater fish as being of Local ecological importance. The Environment Agency expressly disagrees with that valuation because it fails to account for European eel.

The Agency identifies European eel as a critically endangered species and a priority species under section 41 of the Natural Environment and Rural Communities Act 2006. It states that retaining fish at Local value may lead to the significance of effects on protected fish being underestimated and requires freshwater fish to be categorised as being of County importance under the Applicant's own geographical scale.

Receptor value is one of the inputs used to determine effect significance. If the receptor is assigned too low a value, the same magnitude of effect produces a lower significance conclusion.

The error therefore affects the Applicant's assessment of:

- construction noise;
- sediment and pollution;
- temporary obstruction;
- bank disturbance;
- HDD effects;
- operational EMF;
- and cumulative effects across connected watercourses.

The Applicant should revise the receptor valuation and reassess every relevant effect using County importance. The existing conclusions cannot simply be retained unless the Applicant demonstrates that the corrected valuation makes no difference to the significance assessment.

The Environment Agency also disputes the Applicant's treatment of temporary effects. The Applicant's two-year definition may encompass two fish breeding cycles. The Agency requires effects lasting longer than six months to be assessed as permanent for fish and WFD purposes.

Taken together, these points indicate a systematic risk of under-assessment: the fish receptor is valued too low, while effects lasting long enough to affect multiple year classes are labelled temporary.

EMF and the 12-microtesla precautionary threshold

The Environment Agency expressly states that it does not agree with the conclusion at paragraph 8.9.481 of Chapter 8 that operational electromagnetic fields are not expected to cause ecologically significant effects on freshwater fish.

The Agency identifies a risk that residual magnetic fields from buried cables may affect European eel behaviour. It refers to evidence that anguillid species can detect magnetic fields as low as 12 microtesla and requires the Applicant to demonstrate that cable burial depth will reduce the magnetic field to below that level at the bed of the watercourse.

This requirement is especially material at the 400 kV cable crossing of Hempnall Beck. The Agency had raised the issue at scoping and required evidence that the cables would be buried sufficiently deeply for fields at the watercourse to remain below levels detectable by fish.

The application-stage representation records that the Applicant has indicated a field strength of approximately 95 microtesla at one metre above ground, while recognising that the field attenuates rapidly with distance. The Agency does not accept attenuation in principle as sufficient. It requires a calculated or modelled result at the ecological receptor: the bed of the watercourse.

The relevant assessment should therefore specify:

- the number, voltage and configuration of cables;
- conductor spacing and phasing;
- normal and maximum load;
- the depth below the watercourse bed;
- the thickness and magnetic characteristics of surrounding material;
- the predicted field at the bed and within the water column;
- the position of the maximum field relative to likely eel movement;
- and the effect of any cable-depth variation or scour during the operational lifetime.

A general statement that fields decline with distance does not demonstrate compliance with the precautionary threshold. Nor should the question be deferred entirely to detailed design, because the feasibility of achieving the necessary burial depth and field strength is part of the ecological acceptability of the crossing.

The Applicant must either demonstrate that the field at the watercourse bed will remain below 12 microtesla under the reasonable worst-case operating configuration or redesign the cable arrangement, burial depth or crossing location accordingly.

Aquatic-invertebrate attraction to solar panels

The Environment Agency also identifies a separate operational effect omitted from Chapter 8: the potential attraction of aquatic invertebrates to solar panels.

Certain aquatic insects use reflected polarised light as a cue for locating water. Solar panels may imitate aspects of that signal, causing insects to approach panels or attempt to lay eggs upon them. The result may be wasted reproductive effort and interruption of the aquatic-invertebrate life cycle.

The Agency raised this matter at scoping, noting that aquatic invertebrates had not been considered adequately and that Norfolk hawker records existed within the scoping area. It requested assessment and mitigation of polarised-light effects, including measures that break up reflected polarisation where necessary.

The final application has still not resolved the issue. In its Relevant Representation, the Agency states that the potential attraction of aquatic invertebrates to panels has not been addressed and identifies the impact as interruption of their life cycle.

This matters beyond the insects themselves. Aquatic invertebrates form part of the food resource for:

- fish;
- bats;
- birds;
- amphibians;
- and riparian predators.

A change in emergence, dispersal or reproductive success may therefore alter wider ecological function. The effect is especially relevant to Hempnall Beck because Appendix 8.9 identifies the Beck as capable of supporting a diverse aquatic-invertebrate community.

The Applicant should assess not simply the distance between the nearest panel and the watercourse, but the likely behavioural zone of influence. That requires consideration of:

- the aquatic-invertebrate assemblage;
- panel orientation and tracking;
- surface treatment and reflected polarisation;
- the extent and density of panel arrays;
- topography and visibility from the watercourse;
- intervening vegetation;
- seasonal emergence periods;
- and cumulative effects where arrays lie on more than one side of a connected riparian corridor.

The omission is directly relevant to the Applicant's reliance on retained riparian habitat and watercourse BNG. A watercourse may remain physically intact while its invertebrate community is affected by infrastructure beyond the nominal bank buffer.

Wider watercourse buffers are not secured

The Environment Agency acknowledges that the outline masterplan does not appear to place solar modules immediately beside the relevant watercourses. It nevertheless states that the wider distances shown on that plan are not secured. The Design Principles, Parameters and Commitments document appears to commit only to a 10-metre stand-off from watercourses.

The Agency requires wider buffers to be secured around watercourses capable of supporting diverse aquatic-invertebrate communities, including through both the OLEMP and the Design Principles document.

This distinction between indicative design and secured mitigation is important. An outline masterplan may show a wider gap, but unless the DCO and certified documents impose that gap, later detailed design may move panels or infrastructure closer while remaining within the Order Limits and parameters.

The appropriate buffer cannot be determined by applying one standard distance to every feature. It should reflect:

- ecological value;
- channel width and morphology;
- floodplain and riparian habitat;
- fish and invertebrate use;
- groundwater dependence;
- topography;
- the nature of adjoining development;
- lighting and reflected-polarisation effects;
- and the location of compounds, roads and drainage infrastructure.

A ten-metre stand-off may be a minimum control for certain construction activities. It is not evidence that solar panels beyond that distance cannot affect emerging invertebrates or that runoff, lighting and disturbance are adequately controlled.

The EA's water-quality comments reinforce the need for clear and consistent distances. It notes that some application documents merely require storage to be 'away from' watercourses, while others specify ten metres. It asks for consistent wording measured from the top of bank and for compounds and materials to be kept at least ten metres away, with greater separation where practicable in areas of high groundwater vulnerability.

Those minimum pollution controls should not be confused with an ecologically sufficient operational buffer. The latter may need to be materially wider where required to maintain riparian habitat, aquatic-insect life cycles, dark corridors and protected-species movement.

Riparian enhancement is not secured consistently

The Environment Agency identifies a material inconsistency between the Biodiversity Net Gain Report and the Outline Landscape and Ecology Management Plan.

Section 4.3 of the BNG Report apparently relies upon riparian enhancement and reduced encroachment. The OLEMP does not contain the corresponding commitments. The Agency warns that riparian management and enhancement opportunities may therefore be overlooked and identifies the management of Himalayan balsam, acknowledged to contribute to the poor condition of Hempnall Brook, as an example. It requires the riparian enhancements relied upon in the BNG Report to be secured in the OLEMP and requires explicit measures for checking and managing invasive species.

The inconsistency has several consequences.

First, it undermines the deliverability of the claimed watercourse BNG. The Applicant's BNG Report predicts a 16.08% gain in watercourse units, but the practical management document does not secure all of the riparian measures on which that calculation relies.

Secondly, it weakens the ecological mitigation case. If enhanced riparian habitat is relied upon to offset disturbance, improve connectivity or increase ecological resilience, the measures must be specified, funded, managed and monitored.

Thirdly, it creates uncertainty about invasive-species management. Himalayan balsam can dominate riverbanks and, following winter dieback, leave exposed soil vulnerable to erosion. Disturbance by construction machinery may also spread seed along the catchment. A general future commitment is not equivalent to a mapped and funded catchment-management programme.

The final LEMP should therefore identify:

- every riparian reach to be enhanced;
- the baseline habitat condition;
- the width and type of buffer;
- planting or natural-regeneration measures;
- invasive-species survey and treatment;
- bank and channel management;
- livestock and machinery exclusion;
- monitoring indicators;
- timescales;
- remedial triggers;
- and responsibility for delivery throughout the operational period.

The BNG metric should then be recalculated against measures that are actually secured. Unsecured or inconsistent commitments should not be credited.

The Environment Agency's overall position remains unresolved

The Agency's Relevant Representation summarises its ecology and fisheries concerns as requiring further consideration. These include:

- short-term and temporary effects on fish;
- the ecological status and valuation of European eel;
- EMF effects on eel;
- the effect of panels on macroinvertebrate life cycles;
- and the securing of BNG and riparian recommendations.

The Applicant therefore cannot state that the statutory regulator has accepted the Chapter 8 conclusions on aquatic ecology. The Agency does not agree with the EMF conclusion and considers the fish valuation and duration methodology inadequate. It also identifies an unassessed operational effect and a mismatch between the mitigation claimed in the BNG Report and that secured by the OLEMP.

These matters are not capable of being dismissed as minor drafting points. They affect:

- receptor valuation;
- impact magnitude and duration;
- the existence of an operational effect;
- the adequacy of cable design;

- the necessary width of ecological buffers;
- and the deliverability of mitigation and BNG.

BEPS submits that the Applicant has not demonstrated that the River Tas, Hempnall Beck, Starston Brook, Broome Beck and their tributary and ditch networks will retain their ecological function throughout the Scheme.

Before any conclusion of acceptability can be reached, the Applicant should be required to provide:

- a catchment-scale ecological assessment of the Tas and Waveney-linked systems;
- wet-season mapping of permanent, intermittent and ephemeral connectivity;
- direct aquatic-invertebrate sampling at sensitive reaches;
- updated fish and protected-species evidence;
- completion of the white-clawed crayfish work requested by the Examining Authority;
- a final schedule and method for every watercourse and ditch crossing;
- groundwater–surface-water conceptual models for sensitive crossings;
- sediment and pollutant-pathway assessment extending to downstream receptors;
- EMF modelling demonstrating less than 12 microtesla at the watercourse bed;
- assessment and mitigation of aquatic-invertebrate attraction to panels;
- site-specific and legally secured riparian buffers;
- and reconciliation of the BNG Report, OLEMP and DCO commitments.

Until those matters are resolved, the Applicant's conclusion of no significant adverse aquatic-ecology effect is not supported by a complete baseline or by agreement with the Environment Agency. The hydrologically connected ecology of the Scheme should therefore attract substantial adverse weight.

8.9 White-clawed crayfish

White-clawed crayfish are a distinct and potentially decisive ecological constraint for East Pye Solar. The issue cannot be absorbed into a general discussion of aquatic habitats because there is specific evidence of a breeding population within the River Tas catchment, a material conflict between that evidence and the Applicant's baseline, multiple credible pathways by which the Scheme could affect the population or connected habitat, and a protected-species and Water Framework Directive framework requiring precautionary assessment.

The Applicant's Aquatic Habitat Assessment states that its environmental data search returned no records of white-clawed crayfish within a two-kilometre search area. It also relies upon the absence of field signs during habitat walkovers when reaching its conclusions. However, the same assessment acknowledges that the absence of signs during a walkover does not establish absence, that white-clawed crayfish are legally protected and vulnerable to habitat modification and sedimentation, and that biosecurity, pollution prevention and sediment controls are required because of the wider River Tas catchment context. The Ecology Chapter separately records an Environment Agency record approximately six kilometres downstream and historical occurrence within the wider catchment.

More importantly, evidence submitted to the Examination records a professionally confirmed breeding population at Saxlingham Thorpe, within the River Tas chalk-stream system and stated to be within two kilometres of part of the Scheme. That evidence also states that the Applicant was given the relevant Norfolk Rivers Trust information in December 2025, before submission of the DCO application.

The evidential effect is not merely that another record should be added to a desk-study table. The existence of a breeding population materially changes the assessment of receptor value, likely presence, survey requirements, the geographical Zone of Influence and the adequacy of generic construction controls. It requires the downstream and hydrologically connected River Tas system to be treated as a known protected-species catchment, rather than as a landscape in which absence can be inferred from incomplete records and dry-condition walkovers.

8.9.1 Evidence of a breeding River Tas population

The River Tas white-clawed crayfish evidence submitted to the Examination provides a chronology of discovery, professional confirmation and repeat Norfolk Rivers Trust survey.

The chronology begins with the discovery of a dead white-clawed crayfish in the River Tas at Saxlingham Thorpe during summer 2020. The specimen was retained and supplied to the Environment Agency in October 2020. According to the submitted report, the Environment Agency confirmed the identification, referred to the rarity of the species and to historical records near Newton Flotman, and arranged for Norfolk Rivers Trust to undertake further survey work.

Norfolk Rivers Trust subsequently surveyed the Saxlingham Thorpe reach on 10 October 2020. The submitted evidence records that the survey found two juvenile white-clawed crayfish. Juveniles are important evidence because they demonstrate recent successful reproduction rather than the incidental presence of one ageing or displaced adult. The report consequently characterises the finding as confirmation of a healthy breeding population and states that the location was then one of only six known native-crayfish sites in Norfolk. The results were reported through the Norfolk Crayfish Group's summary of conservation work undertaken during 2020.

The population was not based upon a single survey or isolated specimen.

On 9 August 2021, Norfolk Rivers Trust worked with a Bristol University doctoral researcher to undertake hand-searching and environmental DNA work for native and non-native crayfish in several Norfolk rivers, including the River Tas at Saxlingham Thorpe. The submitted evidence records that three white-clawed crayfish were found and that photographic evidence is available.

Norfolk Rivers Trust surveyed the location again on 28 September 2022 and reconfirmed the species' presence. The evidence also records that Banham Zoo volunteers installed two short brash-bundle habitat-enhancement areas close to the known concentration. This intervention is consistent with the location being treated by those involved as an identified conservation site rather than an unverified anecdotal record.

The chronology therefore comprises:

- Environment Agency confirmation of a specimen in 2020;
- two juveniles found by Norfolk Rivers Trust in October 2020;
- three animals found during further Norfolk Rivers Trust and university-associated survey work in August 2021;
- reconfirmation by Norfolk Rivers Trust in September 2022;
- and subsequent habitat enhancement close to the recorded concentration.

That is materially stronger evidence than an uncorroborated public sighting. The presence of juveniles, combined with repeated findings over several survey seasons, supports the conclusion that Saxlingham Thorpe holds, or at the relevant survey dates held, a reproducing River Tas population.

The submitted report also records other notable aquatic species in the same reach or system, including river lamprey and brown trout. While those species are addressed separately, their presence reinforces the ecological quality and sensitivity of the receiving watercourse.

Proximity to East Pye Solar

The River Tas evidence submission places the Saxlingham Thorpe population within two kilometres of part of the East Pye Scheme and within the hydrologically connected River Tas system. Precise coordinates are stated to be available for the physical evidence, although they are appropriately withheld from the public version because of the sensitivity of the species record.

The exact distance from every individual Scheme component is not the decisive issue. A radial distance from a panel field or cable route is not an ecological Zone of Influence where watercourses are connected.

The relevant questions are:

- which Scheme parcels, access routes, compounds and cable works drain into the River Tas or its tributaries;
- whether the population lies upstream or downstream of individual works;
- whether affected ditches, field drains, culverts, becks or groundwater pathways connect the works to occupied or potentially occupied reaches;
- how sediment, contaminants, altered flows or disease could travel through that system;
- and whether construction activity could affect other, as yet unrecorded populations between the Scheme and the known Saxlingham Thorpe site.

The Applicant itself relies upon hydrological connectivity when using downstream Environment Agency information to infer likely aquatic assemblages in reaches closer to the Scheme. It cannot logically treat the same connectivity as irrelevant when a protected-species record demonstrates risk elsewhere in the connected catchment.

The evidence was supplied before the application

The timing is also material.

The River Tas evidence submission states that professionally confirmed information concerning the Saxlingham Thorpe population was provided to East Pye Solar Limited in December 2025. BEPS' full Relevant Representation likewise records that the Applicant was supplied pre-application with Norfolk Rivers Trust evidence identifying a repeatedly surveyed breeding population within two kilometres in the connected chalk-stream system.

The DCO application was subsequently submitted with an Aquatic Habitat Assessment stating that the environmental search had returned no records within two kilometres.

BEPS does not suggest that the Applicant was necessarily required to accept every item of locally submitted evidence without verification. The proper response to credible, specific and professionally attributable protected-species evidence was to investigate it. That should have included obtaining the relevant Norfolk Rivers Trust and Environment Agency records, confirming the location and survey methodology, consulting the Norfolk Crayfish Group or county records service, and undertaking properly licensed survey work within potentially affected reaches.

The evidence should not have been omitted while the application continued to rely upon a conclusion of no records within two kilometres.

Even if the Applicant disputed the precise distance or current status of the Saxlingham Thorpe population, the repeat survey evidence was sufficient to defeat an assumption of absence and to trigger a precautionary catchment-scale assessment.

Natural England's current standing advice confirms that a survey should be required where distribution or historical records suggest that white-clawed crayfish may be present. It expressly warns that absence of a record does not demonstrate absence because it may simply reflect a lack of survey data, and it identifies July to September as the appropriate survey period.

The Planning Inspectorate has treated the evidence gap as material

The Examining Authority's Rule 6 letter confirms that the matter remains unresolved.

The ExA records concerns raised by South Norfolk Council, Norfolk Wildlife Trust and BEPS. It quotes Appendix 8.9's admission that surveys were undertaken during unusually dry conditions, that many smaller drainage features were dry or only partly wet, and that observed habitat availability may under-represent normal conditions, particularly in ephemeral headwaters and field ditches. The ExA also records that the relevant site visits took place in September and October 2025.

Having regard to those limitations and the representations received, the ExA has required further information. It requested an update by Procedural Deadline A on any additional survey undertaken or proposed, or robust justification and further evidence where no further survey is undertaken. The request was made early to allow work during the July-to-September survey period and expressly directs the Applicant to Natural England's white-clawed crayfish standing advice.

The ExA's procedural decision does not determine that the Scheme will harm the population. It does establish that the application evidence is not presently sufficient for the ExA to complete its assessment without further information.

BEPS therefore submits that the breeding-population evidence must be treated as part of the environmental baseline unless and until competent, current and appropriately licensed evidence demonstrates otherwise.

8.9.2 Defective Applicant baseline

The principal baseline defect is the conflict between the Applicant's statement that no white-clawed crayfish records were returned within two kilometres and the specific River Tas evidence described above.

That conflict is compounded by four further deficiencies:

- the use of an arbitrary radial search distance in a connected catchment;
- reliance upon the absence of walkover signs;
- the absence of direct species survey;
- and the lack of a sufficient catchment-scale impact assessment.

The two-kilometre desk-study search is not the Zone of Influence

A two-kilometre data-search radius may be a useful starting point for obtaining records. It is not a lawful or ecological boundary beyond which effects can be disregarded.

The EIA must assess the likely significant effects of the Scheme throughout the area in which those effects may occur. For an aquatic species, that area is determined by:

- catchment boundaries;
- surface-water flow;
- groundwater movement;
- ditch and culvert connections;
- locations of crossings and discharge points;
- the mobility of sediment and contaminants;
- and the potential movement of animals, disease and invasive species.

The River Tas evidence submission correctly identifies the distinction between a conventional desktop search radius and the actual Zone of Influence. It states that, where construction land drains into a watercourse, the relevant area may extend along the downstream pathway, irrespective of whether the receiving receptor lies outside an arbitrary two-kilometre circle.

The defect is apparent even on the Applicant's own evidence. Chapter 8 records an Environment Agency white-clawed crayfish record approximately six kilometres downstream and historical presence in the wider River Tas catchment. It then accepts that biosecurity, pollution prevention and sediment control are needed to safeguard downstream habitat.

That means the Applicant itself recognises both a protected-species record beyond two kilometres and a pathway by which effects could extend beyond the immediate works. The two-kilometre record search cannot therefore define the ecological assessment boundary.

Absence of walkover signs does not establish absence

The Applicant's field work did not comprise a direct white-clawed crayfish survey. The Aquatic Habitat Assessment was a habitat-led appraisal. No licensed hand search, hand-netting, refuge search, night search, trapping programme or targeted eDNA survey was undertaken to establish presence or absence at the potentially affected reaches.

The assessment nevertheless refers to the absence of field signs.

That evidence carries little weight in determining actual absence. White-clawed crayfish can remain concealed beneath stones, roots, undercut banks, woody debris and other submerged refuges. Their detectability varies with water depth, clarity, flow, season, survey method and population density. Absence of obvious remains, burrows or animals during a general aquatic walkover is not equivalent to a competent species survey.

The Applicant itself accepts that absence of signs during a walkover does not confirm absence. Natural England's standing advice makes the same point more generally: absence of a record may simply indicate absence of survey data. It identifies direct survey methods including hand searching, hand-netting, night searching, licensed refuge trapping and eDNA.

The Applicant's conclusion therefore relies upon a form of evidence that its own appendix acknowledges cannot establish the proposition for which it is being used.

Surveys were undertaken in unusually dry conditions

The baseline was further compromised by hydrological conditions.

Appendix 8.9 accepts that its inspections took place during unusually dry conditions, with many smaller drainage features dry or only partly wet. It states that observed wetted extent, depth and in-channel habitat availability may under-represent typical conditions, especially in ephemeral headwaters and field ditches. The Rule 6 letter records those admissions and the September–October 2025 survey dates.

Those limitations are directly relevant to crayfish assessment.

A dry ditch may not provide permanent occupied habitat, but during wetter periods it may:

- connect occupied and potentially occupied reaches;
- convey sediment and pollutants;
- provide seasonal refuge or dispersal habitat;
- connect ponds, tributaries and the main river;
- or form part of the pathway by which disease or invasive organisms are transported.

The problem is therefore not limited to whether crayfish were visible in a dry feature. The dry conditions obscured the hydrological connections needed to determine the extent of the Scheme's impact pathways.

An assessment undertaken in dry conditions should have been supplemented by wet-season connectivity work before conclusions were reached. The Applicant has instead relied on acknowledged under-representation of the watercourse network while characterising residual effects as negligible or non-significant.

The Scoping Opinion had already required attention to the species

The omission is particularly serious because the Applicant was put on express notice at scoping.

The Environment Agency's scoping response stated that its records showed white-clawed crayfish on the River Tas and that the species had not been considered in the Scoping Report. It identified a risk of harm to a protected species and requested a commitment to survey at relevant locations once the watercourse works were known.

The Environment Agency also disagreed with scoping out the water environment and associated receptors, including white-clawed crayfish. It identified the River Tas as a chalk-stream priority habitat and required the effects of watercourse and haul-road crossings to be assessed.

By the time of the DCO application, the Applicant knew that the Scheme would require multiple cable and access interactions with watercourses and that HDD would be the default technique for many cable crossings. The works were therefore sufficiently developed to identify locations requiring species survey or, at minimum, to define precautionary survey zones.

The application does not contain the direct survey commitment sought by the Environment Agency translated into completed survey evidence.

The baseline omits known or readily obtainable evidence

The River Tas submission identifies several sources that, on its account, contradicted the no-record conclusion:

- the Environment Agency's confirmation of the 2020 specimen;
- Norfolk Rivers Trust surveys from 2020, 2021 and 2022;
- the Norfolk Crayfish Group's 2020 conservation summary;
- Norfolk Rivers Internal Drainage Board material;
- local information supplied to the Applicant;
- and the Planning Inspectorate's Scoping Opinion recording Environment Agency knowledge of the species on the River Tas.

The point does not depend on every one of those sources being independently conclusive. Collectively they provided more than sufficient reason to investigate.

A competent baseline should reconcile conflicting information. It should not state only that one search returned no records while omitting credible evidence supplied through consultation and other recognised sources.

No sufficient catchment-scale assessment

The Applicant has also failed to translate the known River Tas context into a catchment-scale impact assessment.

The Aquatic Habitat Assessment recognises hydrological connectivity when inferring likely fish and invertebrate assemblages. It identifies sediment release, turbidity, accidental pollution, changes to drainage and flow, and bank or barrier effects as relevant construction pathways. However, it does not model or map how those effects would move through the connected Tas system.

The assessment does not provide:

- a definitive map of all land draining towards occupied or potentially occupied reaches;
- a wet-season map of active ditch and tributary connections;
- the final location and method of every cable and access crossing;
- identification of every HDD launch and reception area;
- pollutant and sediment travel pathways;
- groundwater–surface-water interaction at sensitive crossings;
- the likely deposition points for mobilised sediment;
- or cumulative assessment of multiple works affecting the same connected system.

The River Tas evidence submission identifies the same deficiencies, including the absence of definitive species surveys, pollutant-pathway modelling, population data, cumulative assessment and species-specific mitigation.

The baseline defect therefore extends beyond a missing dot on a records map. It affects the identification of the receptor, the geographical scope of assessment, the magnitude of effects and the design of mitigation.

The Applicant's present conclusion is premature

Natural England's standing advice says that survey should be sought where historical or distribution evidence suggests presence and that the developer should submit information with the application explaining how harm will be avoided or mitigated.

Here, the evidence indicates:

- a repeatedly surveyed breeding population;
- an Environment Agency record elsewhere in the connected River Tas system;
- a statutory scoping request for survey commitment;
- an application baseline developed under unusually dry conditions;
- no direct species survey;

- and an ExA request for further information.

In those circumstances, a conclusion of negligible or non-significant effect cannot safely be maintained until the evidence has been corrected and the assessment repeated.

8.9.3 Risk pathways

White-clawed crayfish are vulnerable not only to direct excavation of occupied habitat but to changes transmitted through the water environment. The absence of works at the precise Saxlingham Thorpe survey location does not remove risk where Scheme activities occur within the connected catchment.

Natural England identifies the principal development threats as introduction of non-native crayfish, spread of disease through poor biosecurity, habitat loss or modification, obstruction of movement, and reductions in water quality or quantity through altered flow, increased siltation, reduced oxygenation or pollution.

Each of those pathways is relevant to East Pye Solar.

Sedimentation

Construction of a dispersed solar NSIP requires extensive soil disturbance. Relevant activities include:

- cable trenching;
- HDD compounds and pit excavation;
- new and upgraded access tracks;
- highway and visibility works;
- temporary haul roads;
- piling and foundation works;
- drainage construction;
- stockpiling;
- vegetation clearance;
- and repeated HGV movement.

Fine sediment can be mobilised from disturbed ground and transported through field drains, ditches, tributaries and groundwater-fed channels into the River Tas system.

For crayfish, the relevant effect is not simply temporary visual turbidity. Deposited fine sediment may:

- fill spaces beneath cobbles and woody material used as refuge;
- reduce habitat complexity;
- alter the bed substrate;
- affect prey communities;
- increase oxygen demand;

- and compound existing water-quality stress.

Natural England's standing advice expressly identifies increased siltation and decreased oxygenation as threats and recommends reducing the amount of sediment released as a core mitigation measure.

The Applicant's own aquatic assessment recognises sediment release and increased turbidity as construction risks. The relevant question is therefore not whether the pathway exists, but whether it has been quantified and controlled for every part of the connected catchment.

Generic statements that good-practice silt controls will be used do not establish:

- the sediment yield from each works area;
- the performance of controls during intense rainfall;
- the consequence of simultaneous works;
- the route taken through seasonal ditches;
- or the sensitivity of occupied and potential crayfish habitat downstream.

Chemical pollution

Potential chemical pathways include:

- fuel and hydraulic-fluid spills;
- oils and lubricants;
- concrete or cementitious washout;
- contaminated soil;
- cleaning chemicals;
- drainage from compounds;
- drilling fluids;
- firewater or contaminated runoff from electrical infrastructure;
- and accidental damage to existing utilities or drainage systems.

The River Tas evidence submission records existing pressures upon the population, including diffuse agricultural pollution, persistent chemicals, water-industry discharges and low dissolved oxygen. It characterises the Saxlingham Thorpe population as small or isolated and therefore vulnerable to additional stress.

A population already exposed to poor water quality may have reduced resilience. The consequence of an additional pollution event must therefore be assessed against the existing condition of the waterbody, not against a hypothetical pristine baseline.

The Scheme's scale increases the importance of prevention. Numerous work fronts, vehicles, compounds and crossings create repeated opportunities for failure. Even where the probability of an incident at one location is low, the cumulative probability across the whole construction programme may be materially greater.

The Applicant has not produced a white-clawed crayfish-specific incident model or emergency plan explaining how a pollution event entering the Tas system would be detected, contained and remediated before reaching occupied habitat.

Crayfish plague, signal crayfish and biosecurity

Disease is one of the most serious pathways because its effects may be rapid and irreversible.

The River Tas evidence records Environment Agency information that signal crayfish are established within the wider Yare catchment and have been identified around the River Tas–River Yare junction. It also records more recent reports of signal crayfish elsewhere within the wider system.

The presence of signal crayfish in the wider catchment makes strict biosecurity essential. Machinery, boots, nets, pumps, hoses, vehicles and other equipment moving between watercourses may carry water, mud, animals or disease organisms.

Natural England's standing advice expressly identifies spread of disease through poor biosecurity as a development threat and requires use of the Check, Clean, Dry protocol. It also identifies the introduction of non-native crayfish through new hydrological connections as a risk.

The Applicant's management documents must therefore do more than contain a generic invasive-species clause. A crayfish-specific biosecurity plan should identify:

- every watercourse at which personnel, machinery or equipment may enter;
- the sequence in which catchments and reaches will be worked;
- designated cleaning and disinfection areas;
- the treatment and disposal of wash water;
- drying periods;
- restrictions on movement of pumps, hoses and plant between watercourses;
- staff training;
- ecological supervision;
- procedures following suspected signal-crayfish discovery;
- and immediate stop-work and notification requirements.

Particular care is required where equipment is brought from outside the Scheme or used by contractors on other river projects.

The risk is not resolved by saying that no crayfish were observed during the Applicant's walkover. The biosecurity requirement arises from known presence within the connected catchment and from the potentially catastrophic consequence of disease introduction.

Altered flows and hydrological conditions

White-clawed crayfish require water of sufficient quality, quantity and oxygenation, together with stable submerged refuges. Changes to flow may affect water depth, velocity, wetted habitat, oxygen levels, temperature, substrate stability and the availability of refuges.

Scheme activities capable of altering those conditions include:

- soil compaction;
- panel and track drainage;
- cable trenches acting as preferential pathways;
- temporary dewatering;
- interception of shallow groundwater;
- new culverts or crossings;
- drainage outfalls;
- changes to field drains;
- and altered infiltration around substations and compounds.

Natural England identifies changes to water flow, water quantity, siltation and oxygenation as development threats to white-clawed crayfish.

The Environment Agency had already objected at scoping to the Applicant's incomplete understanding of groundwater–surface-water connectivity. It required hydrogeological risk assessment for HDD and other deep works potentially affecting shallow groundwater.

A hydrological change does not have to dry the whole river to be ecologically significant. Localised reduction in water depth may expose refuges, reduce connectivity or increase temperature and oxygen stress. Increased peak runoff may mobilise sediment, destabilise substrate or displace animals. Changes may also occur seasonally and therefore be missed by annual-average modelling.

The assessment must address these biological consequences rather than treating flow solely as a flood-risk or drainage-design issue.

HDD and cable crossings

The Applicant proposes trenchless methods, principally HDD, as the default for many main-river and ordinary-watercourse cable crossings, while retaining the possibility that other techniques may be used for some ordinary watercourses and ditches.

HDD may avoid open excavation of a riverbed, but it is not ecologically risk-free.

Relevant risks include:

- release of drilling fluid through a frac-out or inadvertent return;
- excavation and drainage effects at launch and reception pits;

- interception of groundwater;
- vibration;
- contamination from plant or stored materials;
- sediment runoff from compounds;
- and creation of preferential subsurface pathways.

The submitted River Tas evidence specifically identifies potential bentonite use and the hydrological connection between solar fields, substations, ditches, drains, culverts, streams and groundwater runoff.

Where the crossing passes beneath or near chalk-stream habitat, the hydrogeology requires particular care. Fissured and permeable chalk can provide pathways different from those assumed in a simple surface-drainage model. An inadvertent drilling-fluid return may emerge at the channel, in the hyporheic zone, through a spring or at another point away from the bore alignment.

The assessment should therefore specify for every Tas-connected HDD:

- final entry and exit locations;
- bore depth and profile;
- geology and groundwater level;
- estimated fracture risk;
- drilling-fluid type and volume;
- monitoring pressures;
- surface and subsurface monitoring points;
- containment equipment;
- emergency shutdown criteria;
- access for response;
- and measures for removing material without causing further habitat damage.

A generic frac-out plan does not demonstrate that a particular crossing is acceptable where the species baseline and subsurface pathway remain uncertain.

Open-cut crossings of smaller ditches may create still greater direct risks through bed disturbance, sediment release, flow interruption and movement of contaminated equipment. The Applicant should not assume that an ordinary or seasonally dry ditch is ecologically insignificant where it connects to the River Tas during wetter conditions.

Construction access and culverts

Construction access may affect crayfish habitat even where no electrical cable crosses the watercourse.

Temporary and permanent access works may require:

- culverts;
- temporary bridges;

- bank grading;
- bed protection;
- vegetation removal;
- drainage installation;
- and repeated HGV passage.

Natural England identifies obstruction of movement, including through new culverts, as a threat to white-clawed crayfish. Culverts may also alter light, substrate, velocity and sediment deposition and can create barriers or unsuitable uniform habitat.

Heavy vehicles increase the risks of bank collapse, compaction, fuel spills and sediment mobilisation. Access construction may also bring equipment into direct contact with wet channels, increasing disease-transfer risk.

All Tas-connected access crossings should therefore be fixed and assessed before consent. Clear-span structures should be preferred where a crossing cannot be avoided, with supports and working areas outside the channel and riparian protection zone.

Groundwater and chalk-fissure pathways

The Applicant's early water-environment evidence did not adequately characterise groundwater–surface-water relationships. The Environment Agency expressly identified failures to recognise evidence of connectivity and required hydrogeological risk assessment for HDD and deep foundation works.

This matters because the River Tas is a groundwater-influenced chalk-stream system. Effects may reach aquatic habitat through:

- direct surface runoff;
- shallow groundwater;
- springs and seepages;
- fissures in chalk;
- permeable superficial deposits;
- and cable trenches intersecting or redirecting subsurface flow.

The conventional assumption that soil, a nominal buffer or distance from the bank will contain a pollutant may be unsafe where subsurface pathways exist.

A robust assessment should provide a catchment conceptual model linking:

- the chalk and superficial geology;
- groundwater bodies;
- springs and seepages;
- field drains and ditches;
- the River Tas and Hempnall Beck;
- the Saxlingham Thorpe population;

- and every relevant cable, substation, compound and access location.

Without that model, the Applicant cannot demonstrate that sediment, pollution, altered flow or drilling fluid will remain outside occupied or potentially occupied crayfish habitat.

8.9.4 Legal and policy consequences

The white-clawed crayfish issue engages several overlapping legal and policy duties. Those duties must be stated accurately.

Protected-species status

White-clawed crayfish are protected under the Wildlife and Countryside Act 1981. Natural England's current standing advice states that intentional taking is an offence and that intentional or reckless possession, transport and sale-related activities are also prohibited. The species' present Schedule 5 protection is therefore not identical to the full killing, injury and habitat protections applying to some other Schedule 5 species. It nevertheless remains a legally protected species, and activities affecting animals or requiring their capture or relocation may require a Natural England licence and Environment Agency permission.

That distinction does not reduce the planning importance of the population.

Natural England advises that developers should submit information with the application showing how harm will be avoided or mitigated. It states that a survey should be requested where historical or distribution evidence suggests presence and that the absence of a record does not establish absence.

Where works may affect white-clawed crayfish, the decision-maker must therefore have enough information to determine:

- whether the species is present;
- which works may affect it;
- whether avoidance is possible;
- what mitigation or compensation is required;
- whether capture or relocation may be necessary;
- and whether there is a realistic and lawful licensing route.

Natural England's guidance states that it will confirm whether a white-clawed crayfish licence is needed for an NSIP. It also requires a mitigation plan where a licence is necessary.

The Applicant cannot defer the basic presence, impact and avoidance questions to a later licence application. A licence is not a substitute for an adequate EIA or for designing the Scheme to avoid the protected population.

Species of principal importance

White-clawed crayfish are also included on the list of species of principal importance in England under section 41 of the Natural Environment and Rural Communities Act 2006. Natural England's standing advice states expressly that their conservation must be considered as part of the planning decision.

The section 41 list exists to identify priority species of conservation concern and to inform public bodies' biodiversity responsibilities.

This means the planning assessment is not confined to avoiding the specific criminal offences created by the Wildlife and Countryside Act. It must consider the conservation of the population and the ecological network supporting it.

For East Pye, that requires attention to:

- population viability;
- breeding success;
- maintenance of occupied and potential habitat;
- water quality and flow;
- catchment connectivity;
- disease exclusion;
- recovery opportunities;
- and avoidance of further fragmentation or decline.

A conclusion that no individual will intentionally be taken does not answer those broader conservation obligations.

Water Framework Directive no-deterioration obligations

The River Tas system is also subject to the Water Environment (Water Framework Directive) (England and Wales) Regulations 2017.

The environmental objectives include preventing deterioration of the status of surface-water bodies. The Planning Inspectorate's current NSIP advice explains that the WFD protects surface water and groundwater, requires the Secretary of State to consider implications for WFD objectives and requires the ExA to ensure that sufficient information is available for that decision.

The WFD assessment must be comprehensive and identify waterbodies directly or indirectly affected, their baseline characteristics, the methods used to quantify impacts, the risk of deterioration, and the mitigation required and how it will be secured.

White-clawed crayfish are not necessarily a separate formal classification element in every River Tas WFD assessment. However, the pathways capable of affecting the population are directly relevant to WFD quality elements, including:

- aquatic invertebrate communities;

- fish;
- physicochemical conditions;
- specific pollutants;
- hydromorphology;
- flow;
- and habitat continuity.

The loss or deterioration of crayfish habitat could therefore coincide with, evidence or result from deterioration in one or more WFD elements.

Planning Inspectorate guidance states that deterioration occurs where the status of at least one quality element falls by one class, even if the waterbody's overall classification does not change. Where an element is already in the lowest class, any further deterioration is treated as deterioration. A project risking deterioration cannot be authorised unless the applicable derogation requirements are met.

The Applicant must therefore demonstrate, on a comprehensive evidence base, that:

- sedimentation will not worsen biological or hydromorphological elements;
- pollution will not worsen chemical or physicochemical status;
- flow alteration will not degrade habitat or ecological function;
- crossings will not create barriers or morphological deterioration;
- and cumulative Scheme effects will not prevent achievement of the waterbody's objectives.

The existence of a breeding priority-species population materially increases the need for that assessment to be precautionary and receptor-specific.

Precautionary assessment

The precautionary requirement arises from the combination of credible presence evidence, potentially severe consequences and incomplete baseline information.

Natural England's standing advice does not permit absence to be inferred merely because a data search returned no record. It requires survey where distribution or historical information suggests presence.

The evidence before the Examination includes:

- Environment Agency knowledge of white-clawed crayfish on the River Tas recorded at scoping;
- a submitted chronology of repeat Norfolk Rivers Trust surveys;
- juvenile evidence indicating breeding;
- an Applicant-acknowledged downstream record and wider catchment history;
- unusually dry survey conditions;
- no direct Applicant species survey;
- and an ExA request for further information and survey proposals.

That is not an evidential position in which absence can safely be assumed.

The Applicant must assess a reasonable worst case until adequate survey demonstrates the distribution and status of the species. The reasonable worst case is not that crayfish occur in every ditch within the Order Limits. It is that occupied or functionally important habitat may occur within the hydrologically connected Tas system and that Scheme effects may reach it through surface-water or groundwater pathways.

Avoidance must precede mitigation

Natural England's advice identifies avoidance as the first response. It states that development should, where possible, be redesigned to avoid work in or near the relevant waterbody. Only where avoidance is not possible should mitigation or, as a last resort, compensation be considered.

For East Pye, avoidance should include:

- rerouting cables away from occupied and potential crayfish reaches;
- avoiding haul-road and construction-access crossings of the River Tas and its connected tributaries;
- excluding open-cut working from hydrologically connected channels;
- keeping HDD pits, compounds and storage areas outside species-specific riparian and hydrogeological protection zones;
- avoiding new culverts;
- retaining natural banks, beds and riparian vegetation;
- and avoiding works where chalk-fissure or groundwater pathways create an unacceptable frac-out or pollution risk.

Mitigation cannot be relied upon before the Applicant demonstrates that the relevant works are genuinely unavoidable.

Nor can translocation be treated as a routine solution. Natural England describes movement of crayfish as a last-resort compensation measure and emphasises the need to minimise disease spread. Moving animals may itself require capture, handling, licensing and identification of a suitable disease-free receptor site.

Irreversible harm

The Saxlingham Thorpe evidence describes a small and isolated breeding population within a catchment where signal crayfish and other existing pressures are already present.

That context increases the potential severity of harm. A major pollution incident, persistent sediment deposition or disease introduction could cause population collapse that would not be repaired by later habitat planting or biodiversity-unit delivery. Monitoring after construction would record the loss; it would not reverse it.

The mitigation hierarchy must therefore be applied before works are authorised, with a strong presumption against activities capable of introducing disease, drilling fluid, significant sediment or uncontrolled hydrological change into the connected catchment.

Required outcome

BEPS submits that the current Environmental Statement does not provide a sufficient evidential basis for concluding that effects upon white-clawed crayfish will be negligible or non-significant.

Before the Examination can reach a lawful and reliable conclusion, the Applicant should be required to provide:

- verification and full incorporation of the Norfolk Rivers Trust and Environment Agency evidence;
- direct, appropriately licensed survey between July and September at all potentially affected and hydrologically connected reaches;
- targeted eDNA and physical survey using competent white-clawed crayfish ecologists;
- wet-season mapping of ditch, tributary and groundwater connectivity;
- a catchment-scale distribution and impact assessment;
- a definitive plan of every cable, HDD, access, culvert and drainage interaction within the River Tas system;
- a hydrogeological risk assessment for every relevant HDD and deep excavation;
- sediment and pollutant-pathway modelling extending to occupied and potential habitat;
- a white-clawed crayfish-specific biosecurity plan;
- a drilling-fluid breakout and emergency pollution plan;
- WFD assessment of the corrected baseline and all relevant biological, chemical and hydromorphological elements;
- and fixed avoidance, buffer, monitoring and stop-work measures secured through the DCO and final management plans.

Where survey confirms occupied or functionally connected habitat, works capable of causing material sedimentation, pollution, disease transfer, obstruction or hydrological alteration should be removed or rerouted unless the Applicant demonstrates, on species-specific evidence, that harm can be avoided.

The ExA has already recognised that further evidence is required. Until that evidence is supplied, assessed and incorporated into a revised ecological and WFD assessment, the white-clawed crayfish issue remains unresolved.

BEPS therefore submits that the present baseline is materially defective and that the Scheme has not demonstrated compliance with protected-species requirements, the conservation duties associated with a section 41 priority species, the ecological mitigation hierarchy or the WFD no-deterioration objective. Development consent should not authorise works within the River Tas catchment that may cause irreversible harm while the distribution, pathways and mitigation remain uncertain.

8.10 Botany, lowland meadow, roadside verges and field margins

The botanical effects of East Pye Solar require assessment as a distinct ecological impact rather than merely as a deficiency in the Applicant's baseline. The Scheme would not affect only the interiors of intensively cultivated fields. Its access works, visibility splays, haul routes, cable corridors, compounds and construction movements would be concentrated along roadside verges, hedgerow banks, ditch edges, grassland strips and field margins. Those are the parts of an agricultural landscape most likely to have escaped repeated cultivation and chemical improvement and, consequently, the places most capable of retaining locally important plant assemblages.

The Applicant's own habitat evidence demonstrates that these habitats are widespread. Its surveys record species-rich native hedgerows, other neutral grassland, modified grassland margins, wet and dry ditches, ponds, scrub, floodplain grazing marsh, lowland fen and arable margins across the Scheme. Some margins are several metres wide and are expressly described as floristically diverse. The application mapping also identifies lowland meadow, arable field margin and other grassland priority habitats within and around the Order Limits.

That evidence is important, but it is not a substitute for a proper botanical survey. The Applicant's extended habitat survey expressly disclaims being a full botanical survey. Records of dominant or notable plants were incidental to broad UK Habitat Classification mapping, and the survey also disclaims providing complete mapping of invasive plants or a definitive protected-species baseline. BEPS' evidence from a botanist described as holding Level 6 botanical expertise identifies the need for a full-season survey because important and potentially rare plant assemblages may occur in the very verges, field margins, ditch edges and semi-natural strips threatened by the development.

Norfolk Wildlife Trust reaches substantially the same conclusion. Its Relevant Representation describes the East Pye landscape as containing miles of species-rich hedgerows, semi-natural road verges, Roadside Nature Reserves and rare threatened flora dispersed through a landscape that is 'dense with nature'. It states that the application lacks a comprehensive assessment of roadside verge impacts and strongly recommends botanical surveys in all areas potentially affected by transport, haul roads and road widening.

The Applicant therefore cannot treat botanical effects as minor simply because most of the Scheme is mapped broadly as arable land or modified grassland. The ecological value in this landscape is concentrated disproportionately within its edges, boundaries, surviving meadow fragments and less intensively managed linear habitats. Those features are also the locations through which much of the Scheme's engineering and construction activity is proposed.

8.10.1 Rare and locally important plant assemblages

BEPS relies upon evidence from a Level 6 botanist that the East Pye area has the potential to support important and potentially rare botanical assemblages, particularly within field margins, roadside verges, ditch edges and other semi-natural strips. The expert recommendation is for a proper full-season botanical survey rather than reliance on incidental plant recording undertaken while assigning broad UKHab categories. That distinction is fundamental.

A habitat may be classified as modified grassland, other neutral grassland or an arable margin without the survey having established its complete floristic composition. Broad habitat classification is useful for mapping land cover and calculating habitat units, but it does not necessarily identify:

- plants visible only during a limited flowering period;
- species whose identification depends upon flowers, fruits or mature vegetative features;
- annual arable plants whose appearance varies according to cultivation;
- small populations occurring in hedge bottoms, banks or disturbed ground;
- assemblages whose importance derives from the combination of species present rather than the rarity of one plant;
- or species surviving in a narrow strip that may not influence the classification assigned to the wider habitat polygon.

The Applicant's own disclaimer is therefore material. If the survey was not designed to be a full botanical inventory, the absence of a recorded rare plant cannot properly be treated as evidence that no rare or locally important assemblage is present.

The potential importance of these habitats is reinforced by the ecological and historical character of the Norfolk Claylands. Norfolk Wildlife Trust's Restoring the Claylands, written by Professor Tom Williamson of the University of East Anglia, describes an historically intricate landscape of small fields, pasture, hedges, trees, commons, greens and wide roadside corridors. It explains that many of the landscape's roads, woods and field boundaries have medieval origins; that small fields were commonly enclosed by hedges planted on banks accompanied by ditches and trees; and that historic land use created not only varied habitats but extensive connections between them.

The same evidence describes the severe simplification of that landscape during the twentieth century. Hedges were removed, fields amalgamated, pastures and meadows ploughed, ponds lost and mature trees reduced. Permanent grassland was also lost through post-war agricultural intensification. The surviving grassland strips, pockets, field margins and roadside habitats are therefore remnants of a much more extensive ecological network rather than interchangeable pieces of low-value vegetation. Norfolk Wildlife Trust explains that even narrow grassland strips can be valuable and that connecting existing grasslands by unploughed field margins significantly multiplies their ecological benefit.

This historical context matters to the evaluation of significance. A narrow verge or meadow fragment may appear small when assessed in isolation, but its scarcity is partly the product of extensive historic loss. Remaining examples can hold plant communities, seed banks and ecological relationships that have disappeared from the surrounding cultivated land. Their importance cannot be assessed simply by measuring their area.

Norfolk Wildlife Trust's consultation evidence similarly identifies the Claylands as a focus for the conservation and reconnection of hedges, woods, meadows and ponds, including a 'suite of localised meadow flora'. Its objective is to restore connectivity between those features rather than treat them as isolated habitat parcels.

The Applicant's own survey descriptions support the conclusion that potentially valuable edge habitats are widespread:

- Sub-Site 1A is bounded by two-to-three-metre grassland margins, species-rich native hedgerows with trees, veteran-feature oaks, a ditch and a pond.
- Sub-Site 3A contains three-to-four-metre margins expressly described as floristically diverse other neutral grassland, together with a pond and scrub.
- Sub-Site 5A is surrounded by margins of up to four metres and mostly continuous unmanaged species-rich native hedgerows, associated ditches, a wet ditch, pond and woodland.
- Sub-Site 5B has grassland margins, species-rich hedgerows and ditches.
- Site 6 has field margins ranging up to five metres, with species-rich native hedgerows.
- Site 7 includes other neutral grassland margins, floodplain grazing marsh, lowland fen and reedbed habitat associated with Fritton Grange Meadows.
- Site 10 includes tussocky grass margins, temporary grass and clover leys, neutral grassland, hedgerows and ditches.

Other application mapping records arable margins sown with wildflowers or pollen and nectar mixes. Such features are not ecologically equivalent to the cropped field interiors surrounding them. They may have been deliberately established or retained to provide flowering resources, cover and ecological connectivity.

The Applicant also identifies arable field margins as priority habitat present within the Scheme. Its own desk study records Roadside Nature Reserves as designated road verges with notable botanical diversity. These admissions are inconsistent with any general assumption that the verges and margins affected by engineering works are of negligible value.

The correct survey question is not merely whether a broad habitat category has been mapped. It is whether the species composition, condition, seasonal variation and ecological relationships of each potentially affected verge, margin, meadow, ditch bank and hedgerow bank have been established with sufficient confidence to inform avoidance.

That work should have included appropriately timed botanical surveys across the growing season, with repeat visits where required; species lists and abundance information; identification of locally or nationally notable species and assemblages; condition assessment of lowland meadow and other grassland priority habitat; identification of important seed-bank areas; and integration with hedgerow, ditch and invertebrate evidence. Surveys should have covered not only land beneath the proposed arrays but the complete construction footprint, including every access, visibility splay, passing place, highway intervention, cable working width, HDD compound, haul road and storage area.

Until that work is undertaken, the Applicant cannot reliably distinguish between vegetation that is genuinely of limited botanical value and habitat which has been undervalued because it was visited at the wrong season, assessed only to broad habitat level or excluded from the principal survey area.

8.10.2 Road widening and highway works

The botanical risk is particularly acute along the construction and abnormal-load routes.

South Norfolk Council's targeted-consultation response records that additional land was added to the Scheme for highway visibility splays and to accommodate abnormal indivisible loads, with potential highway works, removal of street furniture and vegetation removal. The targeted-consultation material also identified boundary enlargements and vegetation removal at Fairstead Lane and the A140, further vegetation removal associated with an internal access between Sites 7B and 7C, and comparable interventions at Broaden Lane, Church Hill and other junctions.

The final extent of intervention remains important because the Applicant's transport documents retain flexibility for passing places, visibility improvements, local highway alterations and temporary management along constrained rural roads. The CTMP also identifies Parker's Lane and numerous other rural roads as potentially subject to closures or restrictions while acknowledging that the precise affected sections and distances remain subject to detailed design.

That degree of flexibility prevents a reliable botanical assessment unless the maximum potential footprint of the highway works has itself been surveyed.

Verge stripping

Verge stripping would remove not only visible vegetation but also the upper soil horizons and seed bank upon which recovery depends. Where a species-rich verge has developed over decades, removing the turf and soil can eliminate both established plants and dormant propagules. Reinstatement using generic topsoil or a standard seed mix would not recreate the previous assemblage.

The effect can be permanent even if the engineering work is described as temporary. A verge reconstructed with compacted subsoil, imported material or nutrient-rich topsoil may support coarse grasses, ruderal vegetation or invasive plants rather than the original community. Changes in soil depth and chemistry may make restoration of the former flora impossible within the construction period or even the operational life of the Scheme.

Visibility splays

Visibility splays can require more than a single episode of cutting. They may create a continuing requirement to suppress regrowth for the operational use of an access. Their impacts may include removal or repeated reduction of verge vegetation, hedgerows, scrub and young trees, together with the loss of shaded hedge-bottom or bank conditions.

The ecological effect is not confined to the triangular area shown on a highway drawing. Opening a splay can expose previously sheltered vegetation to increased sunlight, wind, dust and road spray. It can alter the humid microclimate at the base of a hedge and interrupt the continuity between verge, bank, hedge and ditch.

Where a splay is said to be temporary, the application must establish when it will cease to be needed and how its former vegetation will be restored. Where the access is retained for operation, panel replacement or decommissioning, the effect may continue for decades.

Hedgerow and bank removal

Many Claylands hedges are established on historic banks with associated ditches. Their botanical interest may lie not only in woody hedge species but in the ground flora of the bank, base and adjoining verge. Removal of a short hedge section can therefore affect several habitat components simultaneously.

Norfolk Wildlife Trust records that the Environmental Statement identifies partial removal of 32 hedgerows, removal of five trees and temporary removal of hedge sections for cable installation and access. It requests confirmation that no ancient or species-rich hedgerows will be removed, even temporarily, and seeks detailed restoration and monitoring for any removal.

The repeated creation of access gaps across a dispersed Scheme cannot be treated as one small effect. Each gap may remove woody vegetation, bank flora and soil; interrupt a linear habitat; expose adjacent vegetation to edge effects; and create an area subject to repeated vehicle movement. The cumulative botanical effect must be assessed across all sites, accesses, haul routes and cable crossings.

Soil disturbance and mixing

Highway construction commonly involves excavation, grading, temporary storage and replacement of soil. Unless the existing soil profile is carefully characterised and separately handled, valuable surface soil and seed banks may be mixed with subsoil or imported aggregates.

This can alter:

- soil fertility and pH;
- soil depth and moisture retention;
- the distribution of dormant seeds;
- mycorrhizal and microbial communities;
- and the suitability of the substrate for the former vegetation.

Species-rich grassland and long-established verge communities often depend upon relatively low soil fertility. Nutrient enrichment from imported topsoil, construction mud, straw, fertilisers or inappropriate reinstatement material may favour a small number of vigorous grasses and weeds, displacing less competitive plants.

The application has not demonstrated, for every affected verge, that soils will be stripped, stored and replaced in a manner appropriate to that particular botanical community.

Compaction

Norfolk Wildlife Trust expressly identifies soil compaction from repeated vehicle movements as a threat to roadside verge habitat, including damage from HGVs and abnormal loads overrunning the carriageway edge. It warns that direct removal is not necessary for ecological degradation to occur.

Compaction reduces pore space, impedes root growth, changes infiltration and aeration, and can alter the balance between species adapted to drier, wetter or less disturbed conditions. Damage may extend beyond the visible wheel rut because heavy vehicle loading affects the soil profile beneath and beside the point of contact.

This pathway is particularly credible on narrow lanes where large vehicles may need to mount or overrun soft verges, pass opposing traffic, negotiate bends or wait for escorts. Temporary protective matting does not necessarily prevent deeper compaction, particularly under repeated HGV loading or in wet conditions.

The Applicant must therefore identify the maximum vehicle tracking envelope, not merely the nominal carriageway width, and survey all verge habitat within that envelope.

Drainage alteration

Verges, hedge banks and ditches form an integrated drainage system. Road widening, culvert works, new kerbing, hardstanding, grips, drainage channels and changes in road camber may redirect water or alter seasonal soil moisture.

This matters botanically because the distribution of plants along a rural verge may reflect fine-scale hydrological variation. A short section may support damp grassland, ditch-edge or seepage vegetation, while an adjoining raised bank supports a drier community. Altering the drainage regime can damage a plant assemblage without physically removing it.

The same applies to lowland meadow habitat. Meadows may depend upon a particular combination of groundwater, surface-water movement, periodic saturation and low nutrient inputs. Drainage intended to protect an access or working area can dry one part of the habitat while concentrating runoff, sediment or pollutants in another.

Construction access and indirect disturbance

Roadside habitats may also be affected by:

- storage of materials and spoil;
- placement of traffic signs, barriers and temporary lighting;
- installation of fencing;
- refuelling or plant maintenance;
- deposition of dust and mud;
- accidental fuel or hydraulic-fluid releases;
- road-salt or contaminated runoff;

- repeated cutting to maintain clearance;
- and colonisation by invasive plants carried on machinery.

These effects can extend outside the permanently acquired highway footprint. A narrow construction boundary on a plan does not demonstrate that adjoining vegetation will remain unaffected.

Norfolk Wildlife Trust's conclusion is therefore important. It states that many rare plants persist on road verges precisely because those areas have escaped agricultural improvement and that temporary works can cause disproportionate ecological damage. It asks the Examination to establish the full extent of verge loss, compaction, disturbance and vegetation clearance and to secure avoidance, protection, reinstatement and monitoring through the DCO.

BEPS agrees. A commitment to use existing accesses 'where practicable', retain vegetation 'wherever possible' or determine final works after contractor appointment is not sufficient. The full maximum highway footprint must be surveyed and assessed before the works are authorised.

8.10.3 Roadside Nature Reserves and Parker's Lane

Roadside Nature Reserves require separate consideration because they are not ordinary pieces of highway verge. Their designation records recognised local ecological importance, often based upon botanical interest that has survived within the road corridor despite extensive loss from the surrounding countryside.

The Applicant's own desk study includes Roadside Nature Reserves within its non-statutory designated-sites baseline and describes individual reserves as road verges with notable botanical diversity. Norfolk Wildlife Trust confirms that the Order Limits include or adjoin several Roadside Nature Reserves, expressly including Bussey's Loke, Market Lane and Parker's Lane.

The fact that these are non-statutory designations does not deprive them of planning significance. Their designation is evidence that a competent conservation body or local authority has identified ecological value warranting recognition and management. The decision-maker must consider both direct effects upon the designated verge and indirect effects upon the conditions which sustain it.

The Applicant's position that no activities other than limited vegetation management are proposed within certain Roadside Nature Reserve boundaries does not answer the issue. Norfolk Wildlife Trust expressly states that the ES acknowledges potential temporary reductions to overgrown hedgerows and tree canopies beside access roads but does not comprehensively assess verge impacts throughout the transport network. Nor does a commitment confined to the mapped RNR boundary address:

- HGV or abnormal-load overrun;
- compaction beside the carriageway;
- temporary signs, barriers or lighting;
- changes to drainage;
- removal of adjacent hedge sections;
- dust and sediment deposition;

- altered verge management;
- works immediately outside the designation;
- or effects upon an adjoining meadow or connected habitat.

Parker's Lane

Parker's Lane is specifically identified by Norfolk Wildlife Trust as one of the Roadside Nature Reserves included within or adjoining the Order Limits. The transport evidence also places Parker's Lane within the Scheme's wider access and traffic-management network.

The Wood Green representation is important in this context because it identifies the risk as direct and site-specific rather than merely a general concern about rural verges. It raises the relationship between the designated roadside habitat, the associated lowland meadow resource and the works that may be required to make the construction and cable strategy function.

That relationship must be assessed as an ecological unit. A roadside verge may provide the surviving connection between a meadow, hedgerow, ditch and nearby woodland or grassland. Damage to the verge can therefore isolate the meadow or reduce its effective size even where the principal meadow polygon is not directly excavated.

The Applicant should not be permitted to draw a narrow line around the formal RNR and conclude that everything outside that line is ordinary highway land. The relevant receptor includes:

- the designated verge;
- any supporting bank, ditch and hedgerow;
- adjoining species-rich or lowland meadow vegetation;
- the soil and hydrology sustaining those habitats;
- and the ecological connection to Wood Green and the wider habitat network.

Lowland meadow and historic habitat loss

Lowland meadow is a priority habitat whose value depends upon more than the presence of grass cover. Its significance arises from the plant community, soil conditions, management history and associated invertebrate and animal assemblages.

The historical evidence makes remaining meadow habitat particularly important. Restoring the Claylands records that pasture and grassland once formed a much greater part of the South Norfolk landscape but declined through enclosure, agricultural change and especially post-war ploughing and intensification. The surviving areas are remnants of a formerly connected landscape.

The relevant baseline is therefore not that a small meadow remains among extensive arable fields and can be balanced against a larger area of proposed new grassland. The correct baseline recognises that:

- a substantial proportion of the historic meadow resource has already been lost;
- surviving examples may retain long-established soils and seed banks;

- small and linear remnants may be essential to ecological connectivity;
- the condition and species composition cannot be inferred from aerial mapping;
- and newly sown grassland is not immediately equivalent to an established lowland meadow.

The Applicant's priority-habitat mapping itself identifies lowland meadow among the habitat types occurring through the wider Scheme landscape. That should have prompted a precautionary survey of every meadow and grassland fragment potentially exposed to highway or cable works.

Survey must precede authorisation

The Wood Green and Parker's Lane evidence demonstrates why botanical and hedgerow surveys cannot be deferred until after consent.

Before any highway work, access construction, cable installation, visibility clearance or vegetation removal is authorised in this area, the Applicant should be required to provide:

1. a full botanical survey of the Roadside Nature Reserve and all adjoining verge and meadow habitat;
2. repeat visits at appropriate seasons;
3. a National Vegetation Classification or equivalent detailed community assessment where potentially species-rich or priority grassland is present;
4. a hedgerow survey identifying woody species, ground flora, bank, ditch, age and historical importance;
5. mapping of the precise RNR and lowland meadow boundaries;
6. soil and hydrological assessment;
7. fixed maximum construction and vehicle-tracking envelopes;
8. final visibility-splay and passing-place drawings;
9. and an impact assessment addressing direct loss, compaction, drainage, dust, pollution, fragmentation and management change.

The outcome must inform the design. Survey undertaken only after the DCO has authorised the works would reverse the mitigation hierarchy: it would discover the receptor after the location and principle of the potentially harmful intervention had already been approved.

Where survey identifies species-rich verge, important hedgerow, lowland meadow or an ecologically necessary connection, the work should be removed or rerouted. Later reinstatement should not be accepted as a substitute for avoiding the loss of an established community.

8.10.4 Field margins and cable corridors

The same principle applies to field margins throughout the Scheme. They cannot be treated as spare engineering land simply because their use would avoid trenching through the centre of a crop.

The Applicant's own habitat evidence records field margins throughout the Order Limits. These include modified grassland margins, other neutral grassland, floristically diverse strips, tussocky

grass margins and areas sown with wildflowers or pollen and nectar mixtures. Arable field margin is itself identified as priority habitat present within the Scheme.

The Cable Route Corridor is likely to encounter these features repeatedly because field margins provide apparently convenient linear routes between sites. But engineering convenience is not evidence of ecological acceptability.

Norfolk Wildlife Trust stated during consultation that no detailed habitat mapping had been provided for the Cable Route Corridor. It emphasised that underground cable works can adversely affect biodiversity, that routes must be designed to avoid important habitat, that hedgerow removal should be minimised, and that retained boundaries are important for landscape connectivity.

The Applicant's later assessment must therefore be tested against whether it now provides a route-wide, species-level botanical baseline for the complete cable working area. Mapping the broad habitat crossed by the centre line is insufficient where the actual construction footprint may include:

- one or more cable trenches;
- haul and access tracks;
- working strips;
- topsoil and subsoil storage;
- drainage and pumping;
- jointing bays;
- compounds;
- HDD launch and reception areas;
- security fencing;
- and turning or parking areas for plant.

Each of those elements may extend into a margin that the final cable itself does not occupy.

Botanical assemblages

Field margins may contain plants excluded from the cultivated field by herbicide use, ploughing or crop competition. They may also retain remnants of earlier grassland, hedge-bank or wet-ditch communities. Their flora can vary substantially over short distances according to management, aspect, shading, soil type and moisture.

Trenching can destroy established plants and mix their seed bank through the soil profile. Heavy plant can compact adjoining vegetation. Stockpiling can smother the margin and enrich it with nutrients. Reinstatement can introduce a uniform seed mix unrelated to the previous flora.

The Applicant has not established that the relevant margins are botanically interchangeable or that every affected community can be recreated after construction. Where important assemblages are found, the proper response is route avoidance or a crossing method that retains the habitat and its soils undisturbed.

Invertebrates

Botanically diverse field margins provide flowering resources, foliage, stems, litter and overwintering habitat for invertebrates. Even where a specific invertebrate assemblage has not been fully surveyed, the ecological pathway is evident: reducing plant diversity and structural variation is likely to reduce the range of niches and food resources available.

This function extends beyond the margin itself. Invertebrates emerging or dispersing from grassland, hedgerows, ditches and woodland edges provide prey for birds and bats. Loss or degradation of a narrow margin may therefore affect other receptors without producing a large area of direct habitat loss.

A metric calculation based on the number of hectares temporarily disturbed does not capture those food-web and connectivity functions.

Farmland birds

The Applicant's ecological material recognises that fields, hedgerows and grassland margins provide nesting and foraging opportunities for red- and amber-listed farmland birds, including skylark, turtle dove, corn bunting and reed bunting.

Different species use margins in different ways. They may provide seed, invertebrate prey, nesting cover, shelter or a transition between crop, hedge and ditch. Margins managed through stewardship or pollen-and-nectar prescriptions may have been deliberately created to support those functions.

Construction can affect them through vegetation clearance, repeated disturbance, trenching, lighting, noise, loss of cover and changes in future management. Restoring a strip after the cable is installed does not eliminate the temporary loss during construction, and there is no assurance that the restored strip will regain its previous plant composition or bird use.

The Applicant must therefore assess margins as part of the farmland-bird habitat mosaic, not merely as a botanical polygon.

Bat prey and commuting habitat

The Applicant itself states that hedgerows, tree lines, woodland and ditches provide suitable bat foraging and commuting habitat and that areas near riverine habitats and woodland are likely to support higher activity. Norfolk Wildlife Trust likewise stresses that the Scheme's nationally important bat assemblage depends upon connected networks of hedges, woodland edges, tree lines and watercourse corridors.

Field margins contribute to that system in two related ways.

First, flowering and structurally varied vegetation supports invertebrates forming bat prey. A margin beside a hedge or ditch can therefore increase the foraging value of the linear feature.

Second, the combined hedge–margin–ditch structure provides a wider and more sheltered corridor than the hedge alone. Trenching or stripping the margin may reduce habitat quality even where the woody hedge is retained. The Applicant's repeated reliance on hedge retention therefore does not demonstrate that corridor function will be maintained if the associated margin is compacted, cleared, lit or used as a haul route.

This is particularly important within a landscape the Applicant has assessed as nationally important for foraging and commuting bats. The effect of numerous small margin losses and working corridors must be assessed cumulatively across the multiple sites and maternity-colony sustenance zones.

Ecological connectivity

Field margins connect ponds, woods, hedgerows, ditches, grassland fragments and road verges. Their significance therefore depends partly on position rather than area. A narrow strip connecting two larger habitats may have greater functional importance than a larger isolated grassland parcel.

Norfolk Wildlife Trust's Claylands evidence expressly states that connecting grassland areas by unploughed margins significantly multiplies environmental benefit. The reverse is also true: removing, narrowing or repeatedly disturbing such a margin can disproportionately reduce connectivity.

Cable construction may create several forms of severance:

- removal of hedge sections at field boundaries;
- stripping of the margin parallel to a hedge;
- crossing of ditches;
- temporary lighting at compounds;
- movement of heavy machinery;
- and establishment of long working corridors through previously continuous habitat.

The Applicant must therefore identify ecological bottlenecks and connected margin systems before fixing the cable route. It is not enough to reinstate a line after construction without showing that its interim loss, altered soils and future management will not reduce ecological function.

Reinstatement is not equivalent to avoidance

The Applicant may argue that cable impacts are temporary because trenches will be backfilled and the ground reseeded. That conclusion is not justified without receptor-specific evidence.

Successful restoration depends upon:

- preserving the correct soil horizons;
- retaining an appropriate seed bank;
- avoiding compaction;
- preventing nutrient enrichment and contamination;
- using suitable locally derived material;

- matching previous hydrological conditions;
- controlling invasive species;
- and maintaining the area for long enough to restore the former community.

Even then, the result may not be equivalent to an established margin or lowland meadow. Where the original habitat contains a locally important assemblage or has a strategic connecting function, the mitigation hierarchy requires avoidance before restoration is considered.

The same objection applies to Biodiversity Net Gain. Proposed wildflower areas elsewhere cannot compensate automatically for the loss of a particular established margin, verge or meadow whose value lies in its species composition, soils, history and position within the ecological network. Habitat units do not demonstrate continuity of ecological function.

Conclusion and remedies sought

The botanical issue is not a minor matter capable of being left to a pre-construction walkover. The evidence presently available shows:

- a Claylands landscape in which much historic meadow, pasture, hedgerow and pond habitat has already been lost;
- surviving species-rich hedgerows, grassland strips, Roadside Nature Reserves and locally important meadow flora;
- priority arable margins, lowland meadow and other grassland habitats within the Scheme's ecological network;
- a Level 6 botanist's recommendation for full-season survey;
- an Applicant survey that expressly does not constitute a full botanical assessment;
- highway and access proposals involving visibility splays, vegetation removal and potential verge intervention;
- designated roadside habitat at locations including Parker's Lane;
- and cable and construction works concentrated within the margins and boundaries most likely to retain botanical value.

On that evidence, the Applicant has not demonstrated that the likely botanical effects have been identified, avoided or adequately mitigated. It has also not shown that proposed road, cable and access works can be delivered without unacceptable harm to Roadside Nature Reserves, lowland meadow, species-rich verges, important hedgerows and ecologically functional field margins.

BEPS requests that no highway improvement, visibility splay, passing place, access, cable working area or vegetation-removal power be authorised unless the complete maximum footprint has first been subject to full-season botanical and hedgerow survey and the results have been incorporated into a revised impact assessment and fixed design.

At minimum, the Applicant should be required to provide:

- full-season botanical surveys by suitably qualified botanists across all affected verges, Roadside Nature Reserves, lowland meadow, field margins, ditch edges, cable corridors and access works;

- detailed surveys of Parker's Lane and the Wood Green verge–meadow network;
- route-wide hedgerow assessment, including banks, ditches and ground flora;
- final visibility-splay, passing-place, access and vehicle-tracking plans;
- mapping of every area at risk of overrun, compaction, storage or drainage alteration;
- avoidance of all Roadside Nature Reserves, priority lowland meadow, important botanical assemblages and ancient or species-rich hedgerows;
- fixed exclusion zones preventing plant, compounds, lighting and storage from encroaching upon retained habitat;
- receptor-specific soil handling, reinstatement and invasive-species controls;
- and long-term botanical monitoring with measurable restoration criteria and remedial obligations.

Where those surveys identify important assemblages or ecological connections that cannot be protected, the affected works must be removed or rerouted. The discovery of such habitats after consent should not be managed merely through later mitigation because, by that stage, the Applicant would already possess powers to undertake the works.

BEPS therefore submits that the current botanical evidence is insufficient to support the Applicant's conclusion of no significant residual ecological effect. Development consent should not be granted on the assumption that unsurveyed verges, meadows and field margins can be disturbed and later recreated. The mitigation hierarchy requires the Applicant first to establish what is present and then to avoid the harm. It has not yet done so.

8.11 Breeding and wintering birds

The East Pye landscape supports a substantial assemblage of breeding and wintering farmland birds. Its ecological value arises from the combination of large open arable fields, grazing pasture, winter stubbles, game-bird and wildflower strips, field margins, species-rich hedgerows, mature trees, scrub, ponds, reedbeds, ditches, watercourses and woodland edges. Those habitats perform different but complementary functions: open fields provide breeding territories for ground-nesting birds; hedgerows and scrub provide nesting cover; margins and low-input crops provide seed and invertebrate food; and ponds, ditches and reedbeds support wetland-edge species.

The Applicant's final breeding-bird survey recorded 85 species between May 2024 and July 2025. It confirmed linnet, skylark and yellowhammer—all Birds of Conservation Concern Red List species—as breeding within the survey area. Dunnock, moorhen and whitethroat were confirmed as breeding Amber List species. Barn owl, greenfinch, kestrel, mallard, song thrush, woodpigeon and wren were assessed as probable breeders.

The Applicant's Planning Statement separately acknowledges that some fields are subject to Countryside Stewardship and that priority birds confirmed as breeding within the Order Limits include linnet, skylark and yellowhammer. It records that many territories are associated with mature boundary hedgerows, trees and field margins, while skylark territories occur within the arable fields themselves.

That evidence is incompatible with any general characterisation of the affected land as ecologically neutral or as merely low-value intensive arable land. The Applicant's own results demonstrate that the fields and boundaries currently perform active breeding functions for declining farmland birds.

The Applicant nevertheless values the breeding-bird assemblage at only Local importance and assesses most arable fields as being of negligible nesting value, apart from their use by skylark. It then limits its assessment of all breeding birds other than skylark to construction and decommissioning, because operational effects were scoped out. That approach understates three important matters.

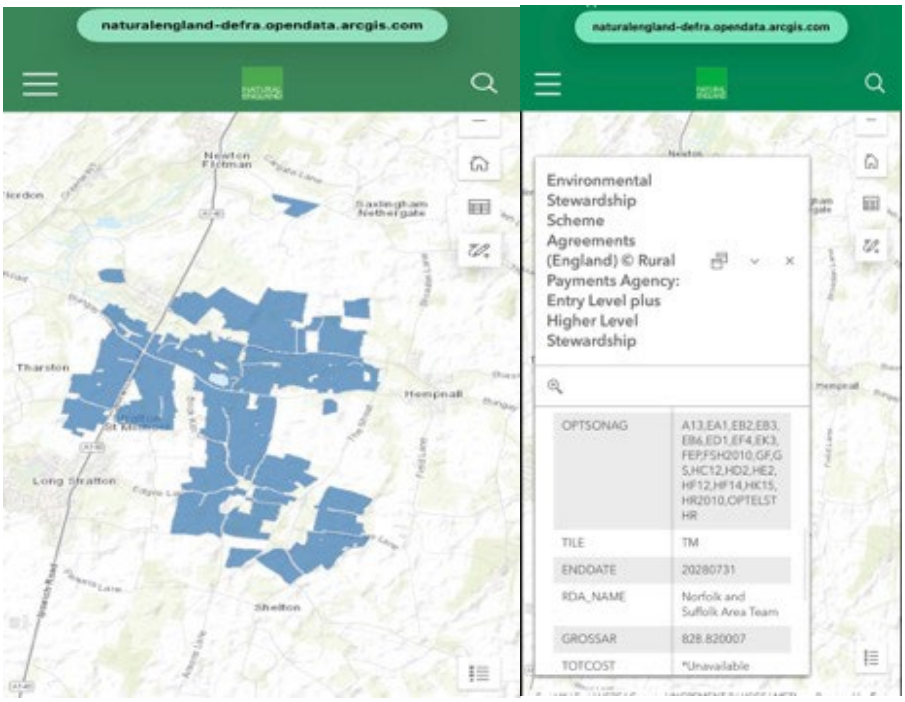
First, the value of the landscape is not confined to nests physically located within hedgerows. Open cropland, field margins, stewardship features and adjoining boundary habitats operate together as a breeding and feeding system. Secondly, the change from open farmland to arrays of panels, fencing, tracks, substations, inverters and maintenance infrastructure is an operational land-use change, not merely a temporary construction effect. Thirdly, the Applicant's own species-specific skylark assessment accepts that the solar arrays will render substantial areas unsuitable for nesting. The same operational layout may affect the availability, accessibility and functional relationship of nesting and foraging habitats used by other species, even where nests are concentrated in retained boundaries.

Norfolk Wildlife Trust raised precisely this point during consultation. It advised that priority species unlikely to be accommodated within the solar footprint, expressly including skylark and lapwing, required a separate mitigation strategy if present. It also advised that operational effects should be assessed and monitored rather than being scoped out and expressed concern that hedgerow, tree and scrub removal could affect breeding birds.

The wintering-bird position is still weaker. The Applicant proposed to scope out wintering and passage birds in all phases. Its reasoning focused primarily on the perceived unlikelihood that whooper swan and Bewick's swan associated with the Broadland SPA and Ramsar site would regularly use the Scheme. It then assumed that future habitat management would benefit wintering buntings, larks, finches and partridges by increasing food and shelter.

The Planning Inspectorate accepted that scope-out at scoping stage on the evidence and assumptions then presented. It did not make a finding, based upon winter survey data, that no locally important wintering assemblage existed. The final Environmental Statement confirms that wintering and passage birds were not assessed because PINS and Natural England had agreed to the scope-out.

That distinction matters. A decision to scope out effects based upon an assumed future benefit is not evidence that the existing wintering function of the land has been identified or that the assumed benefit will occur. The Applicant has not provided a wintering-bird survey capable of establishing:



- which fields are used by winter flocks;
- the importance of winter stubbles, stewardship plots and seed-rich margins;
- the locations and sizes of regular aggregations;
- movement between feeding and roosting areas;

- the relationship between local flocks and the Scheme's woodland, reedbed and settlement-edge roosts;
- or how concurrent construction across multiple parcels would affect the availability of alternative feeding areas.

BEPS therefore submits that the effects on breeding and wintering birds have been materially understated. The issue is not confined to avoiding destruction of active nests. It includes permanent displacement from open breeding habitat, interruption of established stewardship management, loss of winter feeding resources, degradation of hedgerow and margin habitat, disturbance, fragmentation and the absence of demonstrated replacement habitat capable of performing the same species-specific functions.

8.11.1 Countryside Stewardship Scheme

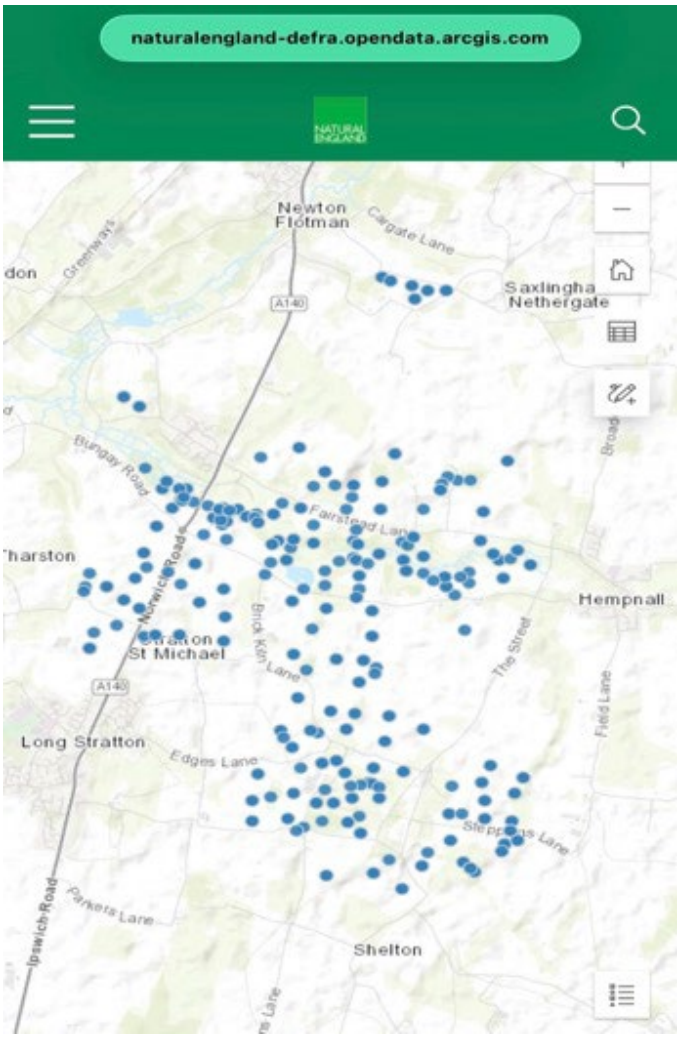
The proposed East Pye Solar development is not situated on ecologically neutral or ordinary agricultural land. Evidence from Natural England's Environmental Stewardship spatial data confirms that substantial parts of the Order Limits – including land parcels 4, 5 and 7 – are subject to active agri-environment agreements, comprising Entry Level Plus and Higher Level Stewardship extending to at least 2028. These agreements are not incidental; they are structured, publicly funded interventions designed to restore and maintain declining farmland biodiversity, particularly ground-nesting and arable-associated bird species.

The option codes recorded for these agreements (including A, EB, EF and related prescriptions) are characteristic of measures such as low-input cropping, overwinter stubbles, field margins, and habitat mosaics specifically intended to support farmland bird assemblages. This aligns directly with field evidence across the Site, where multiple Birds of Conservation Concern (BoCC Red and Amber List species) are recorded, including skylark, lapwing, yellowhammer, linnet, starling and others. Several parcels are explicitly identified within Countryside Stewardship targeting frameworks for priority farmland bird species, and the ecological conditions present – large, open arable fields with low disturbance and managed margins – are those required for successful skylark and lapwing breeding.

Accordingly, the Site currently functions as **active conservation land**, delivering ecological outcomes funded through public money. It is not baseline farmland awaiting enhancement. This distinction is critical and has not been properly reflected in the Applicant's assessment.

The industrialisation of this landscape through the introduction of extensive solar infrastructure, security fencing, lighting, inverter stations and construction disturbance would result in the direct displacement and functional loss of this managed habitat. Ground-nesting birds such as skylark and lapwing are particularly sensitive to enclosure, fragmentation and disturbance; the transformation of open arable systems into enclosed, engineered parcels would render large areas unsuitable for breeding. These impacts are not speculative but well established in ecological literature and reflected in the targeting rationale of the stewardship schemes themselves.

This has three significant implications.



First, in **Biodiversity Net Gain (BNG)** terms, the Applicant's position is fundamentally undermined. BNG calculations premised on a low ecological baseline are invalid where land is already delivering enhanced biodiversity under stewardship. The Scheme would not be creating biodiversity value from a neutral baseline, but replacing an existing, functioning ecological system with one of uncertain and likely reduced value. There is no evidence that the specialised habitat requirements of farmland bird assemblages – particularly open, disturbance-free breeding territories – can be recreated within a solar array layout.

Second, the Scheme would result in the **loss of publicly funded environmental goods**. Countryside Stewardship agreements represent targeted investment by the state to reverse long-term declines in farmland birds. Their displacement by private energy infrastructure raises a clear issue of policy conflict: land currently subsidised to deliver biodiversity recovery would be removed from that function without any demonstrated equivalence in replacement. This is not merely habitat loss, but the loss of an ongoing, funded conservation programme.

Third, the **ecological damage is cumulative and structural**, not minor or mitigable. The Site forms part of a wider farmed landscape supporting interconnected populations of declining bird species.

The removal and fragmentation of stewardship-managed land across multiple parcels risks undermining the integrity of that network, reducing breeding success, and contributing to further regional decline of already threatened species.

In this context, the Birds of Conservation Concern recorded within the Site are not incidental occurrences. They are indicators of a landscape that is currently functioning, by design and by public investment, as a recovery area for declining farmland biodiversity. The failure to recognise and assess this baseline condition represents a fundamental flaw in the ecological assessment of the Scheme.

The consequences of development in this context are immediate and irreversible. The stewardship options identified are not passive designations but active management prescriptions that require continuity over time to deliver ecological outcomes, particularly for ground-nesting and overwintering farmland birds. The Environmental Stewardship data confirms that these

agreements commenced in approximately 2013 and are secured until at least 2028, meaning that the Site has been subject to sustained ecological management for over a decade. This duration is significant: it reflects the gradual establishment and maturation of habitat conditions required by declining farmland bird species, including the development of suitable breeding territories, foraging resources and landscape-scale ecological coherence.

The timing of the proposed development is therefore directly conflicting. Construction of the Scheme is anticipated to begin at or around the point at which these agreements are still active, resulting in their premature termination or effective nullification. This would lead to the abrupt cessation of long-established ecological management and the immediate loss of habitats that have taken years to develop. This is not a gradual transition but a step-change: land that has been deliberately managed for biodiversity recovery over an extended period would be converted into an industrialised landscape of panels, fencing and infrastructure, rendering it unsuitable for those species from the outset of construction.

The implications are twofold. First, there is a clear and immediate loss of ecological function at the point of construction, including breeding and foraging habitat for Birds of Conservation Concern, which cannot be maintained during construction and cannot be meaningfully replicated within the operational layout of a solar array. Second, there is a loss of continuity, which is fundamental to the success of stewardship schemes. Many farmland bird populations depend on stable, long-term habitat management; interrupting that management after more than a decade of delivery risks undermining breeding success, disrupting established territories, and contributing to further population decline. The Scheme therefore conflicts directly with the objectives and temporal logic of the stewardship agreements themselves, resulting in the displacement of a long-standing, publicly funded conservation regime without any demonstrated equivalence in replacement

Skylarks

The application area includes land that has been **specifically targeted and actively managed for skylark conservation under Countryside Stewardship agreements**, including **Land Parcels 4, 5 and 7**, where field-level stewardship options are in place to support breeding territories. These agreements, many of which commenced in 2013 and run until 2028, have been publicly funded to create and maintain suitable nesting habitat for skylarks (open arable fields with low disturbance and appropriate sward structure). The proposed introduction of industrial-scale solar infrastructure into these parcels would result in the **immediate and irreversible loss of this purpose-built habitat at the point construction is due to begin**, directly undermining over a decade of ecological investment. There is a substantial and well-established evidence base demonstrating that skylarks are **highly sensitive to vertical structures, enclosure and disturbance**, with studies consistently showing **reduced territory density, displacement, and in some cases complete abandonment of solar sites** where panel arrays, fencing and associated infrastructure fragment open farmland. The effect is not mitigable through Biodiversity Net Gain measures, as skylarks require large, uninterrupted expanses of open ground and do not adapt to

the presence of panel rows or enclosed layouts. The conversion of these stewardship-managed fields therefore represents not only a significant ecological impact on a species of principal conservation concern, but also a **misuse and nullification of public environmental funding**, with direct conflict between agri-environment policy objectives and the proposed development.

The Applicant recorded 81 skylark breeding territories, of which 70 occur within areas subject to permanent development. It confirms that skylark was the only open-habitat ground-nesting species proven to be breeding within the Order Limits during its survey and recognises the species as both Red Listed and a species of principal importance under section 41 of the Natural Environment and Rural Communities Act 2006.

Seventy affected territories is not a theoretical habitat-suitability calculation. It is direct evidence that the land proposed for permanent development currently supports an extensive breeding population.

The Applicant also makes a significant admission regarding the effect of the Scheme. It accepts that nesting within solar arrays is rare or non-existent and that the shaded, fragmented and enclosed conditions beneath panels reduce visibility and appear to increase predation risk. It consequently assumes that skylarks will be deterred from nesting in fields containing solar arrays, the BESS and associated infrastructure.
